	Adding Tools to a Tool Catalog	143
	Copying and Moving Tool Palettes and Tool Packages	143
	Copying and Moving Tools	144
	Customizing a Tool	145
	Deleting Tool Catalog Items	146

Using Tool Catalog Items in AutoCAD Architecture 2009	146
Linked and Unlinked Tool Catalog Items	146
Using a Tool in the AutoCAD Architecture Workspace	147
Copying a Tool Palette to the AutoCAD Architecture Workspace	148
Copying a Tool Package to the AutoCAD Architecture Workspace	149
Refreshing Linked Tools	150
Refreshing Linked Tool Palettes	150
Specifying Refresh Options for Linked Tool Palettes	150
Working with Multiple Content Browser Windows	150
Opening a Tool Catalog in a New Content Browser Window	151
Opening Catalog Items in a New Content Browser Window	151
Dragging Catalog Items Between Content Browser Windows	151
Starting the Content Browser from a Windows Command Prompt	152
Chapter 4 Creating and Saving Drawings	155
About Templates	155
Creating a Drawing from a Template	156
Creating a Drawing Without a Template	156
Opening Legacy Drawings	157
Setting Up a Drawing	158
Specifying the Drawing Units	158
Specifying the Drawing Scale	160
Specifying a Layer Standard and a Layer Key Style	162
Specifying the Default Display Representations	164
Specifying AEC Options	165
Changing the AEC Editor Settings	166
Changing the AEC Content Settings	168
Specifying AEC Object Settings	169
Specifying the Display Resolution of Objects with Facets	169
Changing the AEC Project Defaults	170
Sharing Drawings with AutoCAD Users	171
Comparing Methods of Sharing Drawings	172
Generating Proxy Graphics	173
Exporting a Drawing to AutoCAD	173
Exporting a Drawing to a DXF File	175
Viewport Layer Mapping	176
Chapter 5 Interoperability with Other Applications	177
Importing and Exporting IFC Files	177
How Drawing Files Are Exported to IFC	178
How IFC Files Are Imported	188
Importing LandXML	193
Schema Version	193
Supported Data Types	193
File Validation	196
Importing LandXML Data	196
Selecting Layer Keys for LandXML Data	198
Publishing Drawing Files to Autodesk MapGuide	199
Prerequisites	199
Published Data Types	199
Generating a MWX File	200
An Overview of the Published Data Structure	200
An Overview of the Database Structure	201
Publishing Data to Autodesk MapGuide	202
Exporting Property Set Data to an MDB	204
Publishing Drawings to DWF and DWFX	204
Conditions and Limitations to Publishing Drawings to 3D DWF or DWFX	205
Exporting Property Set Data to a DWF or DWFX File	206

Publishing Property Set Data from External References	207
Property Set Data Structure	207
Publishing a 3D DWF or 3D DWFX File with Automatic Property Set Data	208
Publishing a 3D DWF or 3D DWFX file with User-Defined Property Set Data	210
Publishing a 2D or 3D DWF or DWFX file with Property Set Data	212
Creating a New Published Property List (PPL)	215

Chapter 6 Drawing Management	217
Process Overview: Working in a Project Environment	217
Concepts of Drawing Management	218
The Project Structure	225
Before You Begin: External References	226
Before You Begin: Working in a Network Environment	227
Project Support Files	228
Specifying the Default Project Options	229
Working with Design Teams Located Remotely	231
Opening a Project From a Mapped Drive	231
The Project Browser	231
Opening the Project Browser	231
Using the Project Browser	232
Setting a Project Current	235
Creating a New Project	235
Working with Project Properties	239
Moving a Project	250
Renaming a Project	250
Closing All Project Files	251
Electronically Transmitting a Project	252
Deleting a Project	255
Closing the Project Browser	255
Removing the Project Context	256
Opening a Project from Windows Explorer	257
The Project Navigator	257
Opening the Project Navigator	258
The Tabs of the Project Navigator	258
Using the Project Navigator	262
The Drawing Status Bar	269
Displaying the Project Tool Palette Group	269
Displaying the Project Content Browser Library	270
Levels	271
Creating a New Level	272
Copying a Level with Assigned Constructs	273
Changing the Properties of a Level	274
Deleting a Level	275
Changing Levels: Interactions with the Project	276
Divisions	276
Creating a New Division	277
Changing a Division	277
Deleting a Division	278
Changing Divisions: Interactions with the Project	278
Categories	279
Creating a Category in the Drawing Explorer	281
Creating a Category from Windows Explorer	282
Specifying the Location of Top-Level Categories	283
Changing the Subcategory of a Project File	285
Deleting a Category	286
Constructs	287
When To Start with Constructs	288
The Role of Constructs in the Building Project	289
The Content of Constructs	289

Creating a New Construct	290
Copying Constructs to Levels	291
Converting a Drawing to a Construct	292
Opening and Closing a Construct	294
Dragging Objects into a Construct	295
Referencing Elements into Constructs	296
Displaying External References of a Construct	298
Changing the Properties of a Construct	300
Electronically Transmitting a Construct	301
Deleting a Construct	302
Converting a Construct to an Element	302
Changing Constructs: Interactions with the Project	304
Elements	304
When to Start with Elements	305
Processing Elements in the Building Project	306
Creating an Element	306
Converting a Drawing to an Element	308
Opening and Closing an Element	311
Dragging Objects into an Element	312
Changing the Properties of an Element	312
Electronically Transmitting an Element	313
Deleting an Element	314
Referencing an Element into Another Element	314
Displaying External References Attached to an Element	316
Converting an Element to a Construct	317
Changing Elements: Interactions with the Project	318
Views	318
When to Start with Views	322
Process Overview: Creating a View Drawing	323
Creating a New View Drawing	323
Displaying External References of a View Drawing	327
Opening and Closing a View Drawing	329
Creating a Model Space View Drawing from a Callout	329
Changing the Properties of a View Drawing	330
Regenerating the View Drawings in a Project	331
Placing a View Drawing onto a Sheet	331
Electronically Transmitting a View Drawing	332
Deleting a View Drawing	333
Creating a Model Space View	334
Placing a Model Space View onto a Sheet	335
Changing the Properties of a Model Space View	337
Deleting Model Space Views	338
Synchronizing View Drawing Layers with Sheet View Layers	338
Changing Views: Interactions with the Project	341
Sheets	342
When to Start with Sheets	344
Creating a Sheet	345
Setting the Properties of the Project Sheet Set	347
Creating a Sheet Subset	348
Setting the Properties of a Sheet Subset	349
Removing a Sheet Subset	350
Importing Sheets into the Sheet Set	350
Importing the Current Layout as a Sheet	351
Opening and Closing a Sheet	352
Changing the Properties of a Sheet	352
Removing a Sheet	352
Deleting a Sheet Drawing	353
Creating a Sheet View	353
Opening a Sheet View	354
Numbering Sheet Views	354

Deleting a Sheet View	354
Displaying External References of a Sheet Drawing	355
Inserting a Sheet List	356
Changing the Sheet List Properties	358
Updating the Sheet List	358
Refreshing the Sheet Set	359
Creating a Sheet Selection	359
Activating a Sheet Selection	360
Removing a Sheet Selection	360
Electronically Transmitting Sheets and Sheet Sets	360
Publishing Sheet Sets	362
Changing Sheets: Interactions with the Project	362
Creating a Sheet Set Template	363
Creating a Sheet Set Template	363
Creating a Template from Existing Drawings	368
Repath the Project	372
Refreshing the Project Navigator	373
Object Display in External References	374
Annotating a Project	374
Generating Spaces	375
Tagging in a Project	375
Property Set Data and Schedule Tables in Projects	375
Creating a Title Block for a Project	382
Dimensioning a Project	386
Working with Cut Planes in a Project	387
Global Cut Planes	388
Object-Specific Cut Planes	394
Drawing Management Commands	396
Command Line: Opening the Project Browser	396
Command Line: Opening the Project Navigator	397
Command Line: Refreshing the Project	397
Command Line: Regenerating Views	397
Command Line: Selecting a New Project Environment	397
Command Line: Closing the Project Navigator	398
Frequently Asked Questions about Drawing Management	398
Appendix 1: Template Projects	400
Levels and Divisions	401
Project File Naming	402
Constructs Included in the Commercial Template Project	404
The Element File Included in the Commercial Template Project	406
Views Included in the Template Project	406
Sheets Included in the Template Project	407
Project Standards	408
Chapter 7 Project Standards	409
Project Standards Terminology	409
Project Standards Overview	410
AEC Standards	411
AutoCAD Standards	412
Standard Tools	413
Synchronizing the Project	413
Process Overview: Using Standards in a Project	413
Using Project Standards	414
Prerequisites for Working with Project Standards	414
Setting up Standards in a Project	415
Creating a New Project with Predefined Standards	415
Configuring Project Standards	416
Setting up Standard Tools in a Project	425
Creating a Tool Catalog for a Project	427

Adding a Project Catalog to a Content Browser Library	431
Adding a Project Library and Tool Palette Group	431
Displaying the Project Tool Palette Group	434
Building the Tool Palette Group	435
Copying the Project Tool Palettes to the Tool Palette File Location	436
Adding the Project Profile to the Tool Palette File Location	437
Adding Standards to a Project Drawing	437
Project Tool Palette Group	438
Adding Standard Styles from Content Browser	438
Adding Standard Styles from Style Manager	439
Adding Standard Display Settings from Display Manager	440
Synchronizing a Project with the Standards	440
Synchronization Status	443
Synchronizing a Project with AEC Standards	444
Synchronization Exceptions	446
Synchronizing a Project Drawing with AEC Standards	446
Synchronizing Selected Styles and Display Settings with AEC Standards	448
Generating a Synchronization Report	452
Synchronizing a Project with AutoCAD Standards	452
Synchronizing a Project Drawing with AutoCAD Standards	453
Auditing a Project or a Drawing	454
Showing Display Overrides in Project Drawings	455
Editing Project Drawings Outside the Project	456
Creating a New Project Standards Drawing	456
Updating Project Standards Drawings	458
Process Overview: Updating AEC Standards in a Project	458
Versioning Standards	459
Change Types in Project Standards Drawings	460
Updating Standard Objects in a Project Standards Drawing	461
Updating Standard Objects in a Project Standards Drawing from a Project Drawing	463
Adding Standard Objects from a Project Drawing to a Project Standards Drawing	464
Editing the Version History of a Standard Object	466
Versioning a Project Standards Drawing	466
Purging the Version History from a Project Standards Drawing	467
Purging the Version Information from a Project Standards Drawing	467
Synchronizing Project Standards with Each Other	468
Editing Project Standards Drawings Outside the Project	469
Scripting Project Standards Commands	469
Chapter 8 Drawing Compare	471
Overview of Drawing Compare	471
Starting a Drawing Compare Session	474
Reviewing the Results of a Drawing Compare Session	478
Creating a Visual Filter	482
Drawing Compare Commands	482
Frequently Asked Questions about Drawing Compare	483
Chapter 9 Layer Management	485
Layer Management	485
Managing Drawing Layers	488
Opening the Layer Manager	489
Making a Layer Current	489
Creating a Layer with a Layer Standard	490
Creating a Nonstandard Layer	491
Renaming a Layer	491
Deleting a Layer	492
Changing the Layer Standard of a Layer	492
Defining the Properties of a Layer	492

Overriding Layer Properties in Layout Viewports	494
Identifying Viewport Layer Overrides	495
Removing Viewport Layer Overrides	496
Working with Layer Groups	497
Types of Layer Filters	498
Creating a Group Filter	499
Creating a Property Filter	499
Creating a Layer Standards Filter	503
Adding Layers to Layer Groups	503
Changing the Properties of a Layer Group	504
Renaming and Deleting Layer Groups	505
Converting a Property Filter to a Group Filter	505
New Layer Notification	505
Setting up the Notification for New Layers	505
Identifying New Layers in the Drawing	507
Reconciling New Layers in the Drawing	507
Working with Layer States	508
Creating a Saved Layer State	508
Editing a Saved Layer State	511
Restoring a Layer State	512
Deleting a Layer State	513
Importing Layer States to the Current Drawing	513
Exporting a Layer State from the Current Drawing	514
Working with Layer Keys	514
Default Layer Keys	516
Default Layer Key Values	520
Creating a Layer Key Style	521
Creating a Layer Key Style from an LY File	521
Editing Layer Key Styles	522
Attaching Notes and Files to a Layer Key Style	523
Layer Key Overrides	524
Creating and Editing Layer Standards	526
Component Fields in Layer Standards	527
Creating a Layer Standard	532
Editing Component Fields	532
Editing Descriptive Fields	533
Editing Descriptions	534
Editing Description Specifications	534
Purging Layer Standards	535
Importing Layer Standards	535
Exporting Layer Standards	536
Appendix: LISP Changes for Layer Snapshots and Layer States	536

Chapter 10 Display System	537
Introduction to the Display System	537
Using the Properties Palette to Change Display Properties	538
Display System Structure	543
Display Representations	544
Display Sets	548
Display Configurations	549
The Display Manager	552
Opening the Display Manager	553
Viewing Display Configurations	554
Viewing Display Sets	555
Viewing Display Representations	556
Viewing an Object in a Display Representation	557
Viewing the Display Representation of an Object in a Display Set	558
Accessing the Default Display Properties of an Object	559
Creating and Editing Display Configurations	559

Process Overview: Creating a Display Configuration	559
Tips for Working with Display Configurations, Sets, and Representations	560
Creating a Display Configuration	560
Creating a Display Set	561
Creating a Display Representation for an Object	562
Editing a Display Representation	562
Assigning a Display Representation to a Display Set	563
Comparing Display Representations Between Display Sets	565
Assigning a Display Set to a View Direction	566
Assigning a Display Configuration to a Viewport	566
Specifying a Display Set as a Default Display Set	567
Specifying the Default Display Configuration	567
Specifying the Display Configurations Used in Xref Overlays	568
Changing the Display Configuration Used in Xref Drawings	569
Displaying Objects by Classification	570
Specifying Settings for Live Sections and Materials	570
Managing Display Configurations	571
Renaming a Display Configuration or a Display Set	572
Renaming a Display Representation	572
Deleting a Display Configuration or a Display Set	572
Deleting a Display Representation	573
Adding Notes and Reference Files to a Display Configuration or a Display Set	573
Using Display Settings in Multiple Drawings	574
Purging a Display Configuration	576
Purging a Display Set	576
Purging a Display Representation	576
Working with Standard Display Settings	577
Synchronizing Individual Display Settings with AEC Standards	579
Excluding Display Settings from Synchronization	579
Updating Standard Display Settings in a Project Standards Drawing	579
Updating Standard Display Settings in the Project Standards Drawing from a Project Drawing	581
Adding Standard Display Settings from a Project Drawing to a Project Standards Drawing	583
Editing the Version History of a Standard Display Setting	584
Purging the Version History from a Project Standards Drawing	584
Purging the Version Information from a Project Standards Drawing	585
Synchronizing Project Standards with Each Other	585
Troubleshooting the Display System	586
Object Not Displayed in a Viewport	586
Viewport Not Updating Properly	586
Objects Copied from Another Drawing Display Differently	586
Verifying the Existence of Objects Not Displayed in a Drawing	587
Object Linetype Displayed Incorrectly	587
Chapter 11 Style Manager	589
Style Manager	589
Getting Started with the Style Manager	590
Sorting Styles in the Style Manager	592
Viewing Styles in the Style Manager	593
Viewing Styles Across Multiple Drawings	594
Working with Drawings and Templates in the Style Manager	594
Creating a Style	596
Copying and Assigning a Style to an Object	597
Creating a Tool from a Style	597
Renaming a Style	597
Copying Styles Between Drawings	598
Sending Styles to Other Users	599
Purging Styles	599

Chapter 12	Materials	601
	Materials	601
	Objects That Support Materials	603
	Working with Material Tools	605
	Using the Material Tool to Add Materials to Objects	605
	Creating Custom Material Tools	606
	Applying Material Tool Properties	610
	Material Components and Display Properties	610
	Linework Material Component	611
	Plan Hatch Material Component	611
	3D Body Material Component	611
	Surface Hatch Material Component	612
	2D Section/Elevation Linework	613
	Section Hatch Material Component	613
	Sectioned Body and Sectioned Boundary	614

	Adding Custom Railing Blocks and Profiles to a Railing Style	1574
	Adding a Custom Block to a Railing Style	1574
	Adding a Custom Profile to a Railing Style	1577
	Turning Off a Custom Block or Custom Profile in a Railing Style	1580
	Removing a Custom Block from a Railing Style	1581
Chapter 27	Roofs	1583
	Roofs	1583
	Using Roof Tools to Create Roofs	1584
	Creating a Slope Roof	1585
	Creating a Gable Roof	1586
	Creating Dormers	1586
	Creating a Slope Roof with User-Specified Settings	1586
	Creating a Gable Roof with User-Specified Settings	1587
	Creating a Roof from Walls	1588
	Creating a Roof from Polylines	1589
	Creating a Roof Tool	1590
	Editing Roofs	1591
	Using Grips to Edit Roofs	1591
	Applying Tool Properties to an Existing Roof	1592
	Changing the Dimensions of a Roof	1592
	Changing the Edges and Faces of a Roof	1593
	Converting a Roof to Roof Slabs	1594
	Specifying the Material of a Roof	1594
	Specifying the Display Properties of a Roof	1595
	Specifying the Hatching of a Roof	1596
	Changing the Location of a Roof	1597
	Attaching Hyperlinks, Notes, or Files to a Roof	1597
Chapter 28	Slabs and Roof Slabs	1599
	Overview of Slabs and Roof Slabs	1599
	Using Tools to Create Slabs and Roof Slabs	1602
	Creating a Slab or a Roof Slab	1603
	Creating a Slab/Roof Slab with User-Specified Settings	1604
	Creating a Slab or Roof Slab from Walls	1606
	Creating a Roof Slab from a Roof	1608
	Creating a Slab or Roof Slab from a Polyline	1608
	Creating a Slab from a Space	1611
	Creating a Slab or Roof Slab Tool	1611
	Editing Slabs and Roof Slabs	1613
	Using Grips to Edit Slabs/Roof Slabs	1614
	Applying Tool Properties to an Existing Slab/Roof Slab	1629
	Changing the Properties of Slabs or Roof Slabs	1629
	Using Slab and Roof Slab Context Menu Tools	1632
	Creating a Clipped Gable Roof	1650
	Creating a Dormer in a Roof Slab	1651
	Slab and Roof Slab Styles	1652
	Creating a Slab or Roof Slab Style	1653
	Specifying the Components of a Slab or Roof Slab Style	1654
	Specifying the Materials of a Slab or Roof Slab Style	1659
	Specifying the Display Properties of a Slab or Roof Slab Style	1661
	Adding Classifications to a Slab or Roof Slab Style	1664

Defining a Slab/Roof Slab Style as Bounding for Associative Spaces	1665
Attaching Notes and Files to a Slab or Roof Slab Style	1665
Slab and Roof Slab Edge Styles	1666
Creating a Slab or Roof Slab Edge Style	1667
Specifying the Overhang, Edge Cut, and Angle of a Slab/Roof Slab Edge Style	1668
Creating Profiles for the Fascia and Soffit	1669
Controlling Profile Edges and Extrusion	1670
Specifying a Fascia and a Soffit for a Slab/Roof Slab Edge Style	1671
Editing the Geometry of Fascia and Soffits	1672
Assigning Materials to a Slab/Roof Slab Edge Style	1674
Turning on Materials for a Slab/Roof Slab Edge Style	1674
Attaching Notes and Files to a Slab/Roof Slab Edge Style	1675

Chapter 29 Structural Members 1677

Structural Members	1677
Process Overview: Creating Structural Members with the Structural Member Catalog or Structural Member Style Wizard	1680
Creating Structural Member Styles in the Structural Member Catalog	1681
Opening the Structural Member Catalog	1682
Creating a Style from a Shape in the Structural Member Catalog	1682
Locating a Shape in the Structural Member Catalog from a Structural Member in a Drawing	1684
Opening a Catalog File in the Structural Member Catalog	1684
Creating a Structural Member Style with the Structural Member Style Wizard	1684
Creating Structural Member Tools	1686
Creating a Beam Tool	1686
Creating a Brace Tool	1690
Creating a Column Tool	1693
Using Structural Member Tools to Create Structural Members	1695
Creating a Beam	1696
Creating Beams with User-Specified Settings	1697
Creating a Brace	1703
Creating a Brace with User-Specified Settings	1704
Creating a Freestanding Column	1707
Creating a Freestanding Column with User-Specified Settings	1707
Creating Grid-Anchored Columns	1710
Creating Grid-Anchored Columns with User-Specified Settings	1711
Creating a Structural Member from Linework	1714
Editing Structural Members	1715
Using Grips To Edit Structural Members	1715
Changing the Structural Member Length	1720
Changing the Structural Member Start and End Offsets	1721
Changing the Structural Member Start Point and Endpoint	1722
Changing the Structural Member Roll	1723
Changing the Radius of a Curved Structural Member	1724
About Curved Structural Members	1725
Changing the Structural Member Justification	1726
Changing the Structural Member Type	1727
Trimming Structural Members	1727
Changing the Style of a Structural Member	1734
Applying Tool Properties to a Structural Member	1734
Specifying the Cut Plane Display of a Structural Member	1734
Specifying the Display of Custom Block Components of a Structural Member	1735
Specifying the Offsets for a Structural Member in Plan Low Detail	1736
Attaching Hyperlinks, Notes, and Files to a Structural Member	1737
Working with Structural Member Body Modifiers	1738
Adding a Body Modifier to a Structural Member	1738
Subtracting a Body Modifier from a Structural Member	1739
Replacing a Structural Member with a Body Modifier	1740

Editing the Geometry of a Body Modifier	1741
Managing Body Modifiers	1742
Restoring a Body Modifier to a Mass Element	1743
Working with Structural Member Interference Conditions	1743
Creating Structural Member Interference Conditions	1744
Removing Structural Member Interference Conditions	1745
Editing Structural Member Interference Conditions	1745
Structural Member Styles	1746
Creating a Structural Member Style in the Style Manager	1746
Specifying the Materials of a Structural Member Style	1747
Specifying the Display Properties of a Structural Member Style	1749
Specifying Classifications for a Structural Member Style	1756
Defining a Structural Member Style as Bounding for Associative Spaces	1756
Attaching Notes and Files to a Structural Member Style	1757
Creating Custom Structural Members	1757
Understanding the Design Rules of a Structural Member	1759
Changing the Shape in the Style of a Structural Member	1761
Adding a Shape to a Structural Member	1761
Process Overview: Creating a Single-Component Structural Member (Tapered Column)	1762
Process Overview: Creating a Multi-Component Structural Member (Composite Column)	1764
Process Overview: Creating a Multi-Component Structural Member Using Multiple Segments (Rigid Frame)	1766
Creating Custom Shapes for Structural Members	1771

Design Utilities 1775

Chapter 30 Anchors 1777

Anchors	1777
Working with Object Anchors	1778
Adding Object Anchors	1778
Releasing Object Anchors	1779
Working with Curve Anchors	1780
Adding Curve Anchors	1780
Changing the Position of Objects Anchored to Curves	1781
Anchoring Objects to New Curves	1784
Working with Leader Anchors	1785
Adding Leader Anchors	1785
Changing the Position of Objects Anchored to Layout Nodes with Leader Anchors	1785
Grip-Editing Leaders	1786
Extending Leaders	1787
Copying Objects to All Layout Nodes	1787
Working with Node Anchors	1788
Adding Node Anchors	1788
Changing the Position of Objects Anchored to Layout Nodes with Node Anchors	1789
Anchoring Objects to Different Nodes	1789
Copying Objects to All Layout Nodes	1790
Working with Cell Anchors	1791
Adding Cell Anchors	1791
Changing the Position and Size of Objects Anchored to Layout Cells	1792
Anchoring Objects to a Different Cell	1792
Copying Objects to All Layout Cells	1793
Working with Volume Anchors	1793
Adding Volume Anchors	1794
Changing the Position and Size of Objects Anchored to Volumes	1794
Anchoring Objects to a Different Volume	1795
Copying Objects to All Layout Volumes	1796
Releasing and Positioning Anchored Objects	1796
Releasing Anchored Objects	1796

	Positioning Anchored Objects	1796
	Creating an Anchor Tool	1797
Chapter 31	Layout Curves and Grids	1799
	Layout Curves and Grids	1799
	Using Layout Curves	1800
	Creating a Layout Curve Tool	1800
	Adding Layout Curves	1801
	Adding Nodes to Layout Curves	1804
	Removing Nodes from Layout Curves	1804
	Changing the Offsets of Layout Curves	1805
	Changing the Node Spacing of a Layout Curve	1806
	Changing the Node Positions on a Layout Curve	1806
	Changing the Spacing Mode of Layout Curves	1807
	Switching Layout Curves	1808
	Changing the Display Properties of Layout Curves	1808
	Changing the Node Radius for a Layout Curve	1809
	Attaching Hyperlinks, Notes, or Files to a Layout Curve	1810
	Using Layout Grids	1810
	Creating a Layout Grid Tool	1811
	Adding Radial Layout Grids	1811
	Changing Radial Layout Grids	1813
	Adding Rectangular Layout Grids	1813
	Changing Rectangular Layout Grids	1814
	Adding Grid Lines to Layout Grids	1814
	Removing Grid Lines from Layout Grids	1815
	Changing the Spacing Mode of Layout Grids	1815
	Changing the Display Properties of Layout Grids	1816
	Changing the Node Radius for a Layout Grid	1817
	Creating and Removing Boundaries for Layout Grids	1817
	Creating Holes in Layout Grids	1818
	Removing Holes from Layout Grids	1818
	Changing the Location of Layout Grids	1818
	Attaching Hyperlinks, Notes, or Files to a Layout Grid	1819
	Using Layout Volumes	1819
	Creating a Layout Volume Tool	1819
	Adding Layout Volumes	1821
	Changing Layout Volumes	1822
	Adding Grid Lines to Layout Volumes	1822
	Removing Grid Lines from Layout Volumes	1822
	Changing the Spacing Mode of Layout Volumes	1823
	Changing the Display Properties of Layout Volumes	1824
	Changing the Node Radius for a Layout Volume	1824
	Changing the Location of Layout Volumes	1825
	Attaching Hyperlinks, Notes, or Files to a Layout Volume	1826
Chapter 32	Grids	1827
	Grids	1827
	Using Column Grid Tools to Create Column Grids	1828
	Creating a Column Grid	1829
	Creating a Column Grid with User-Specified Settings	1829
	Creating a Column Grid from a Layout Grid	1831
	Creating a Column Grid from Linework	1832
	Creating a Column Grid Dynamically	1832
	Creating a Structural Column Grid Tool	1833
	Working with Column Grids	1833
	Labeling Column Grids	1833
	Extending Column Grid Lines Beyond the Grid Boundary or Limits	1835

Dimensioning Column Grids	1835
Editing Column Grids	1836
Changing the Dimensions of a Column Grid	1836
Changing the Lines of a Column Grid	1836
Attaching Clipping Profiles to Column Grids	1841
Attaching Hyperlinks, Notes, or Files to a Column Grid	1842
Changing the Location of Column Grids	1842
Changing the Display of Column Grids	1843
Changing the Node Radius for a Column Grid	1844
Using Ceiling Grid Tools to Create Ceiling Grids	1844
Creating a Ceiling Grid	1845
Creating a Ceiling Grid with User-Specified Settings	1845
Creating a Ceiling Grid from a Layout Grid	1847
Creating a Ceiling Grid from Linework	1847
Creating a Ceiling Grid Dynamically	1847
Creating a Ceiling Grid with a Clipping Boundary	1848
Creating a Ceiling Grid Tool	1849
Editing Ceiling Grids	1850
Changing the Dimensions of a Ceiling Grid	1850
Changing the Lines of a Ceiling Grid	1850
Attaching Clipping Profiles to Ceiling Grids	1855
Attaching Hyperlinks, Notes, or Files to a Ceiling Grid	1856
Changing the Location of Ceiling Grids	1857
Changing the Display of Ceiling Grids	1858
Changing the Node Radius for a Ceiling Grid	1858
Chapter 33 Detail Drafting Tools	1861
Construction Lines	1861
Creating Construction Lines From Existing Objects/Linework	1861
Creating Construction Lines Independently	1863
Hatch Productivity Tools	1863
Repositioning a Hatch	1864
Generating a Hatch Boundary	1864
Redefining a Hatch Boundary	1865
AEC Modify Tools	1868
Trimming Linework or Profile-Based Objects	1868
Trimming Linework or Profile-Based Objects to an Edge	1869
Extending Linework to an Edge	1870
Dividing Linework and Profile-Based Objects	1871
Subtracting from Linework and Profile-Based Objects	1872
Obscuring Regions of Linework	1873
Merging Linework or Profile-Based Objects	1874
Cropping Linework or Profile-Based Objects	1875
Shrinkwrapping Linework	1875
Creating Arrays	1876
Repositioning from a Reference Point	1877
Evenly Spacing Linework or Objects	1877
Centering Linework or Objects	1877
Chapter 34 Mask Blocks	1879
Mask Blocks	1879
Creating Mask Block Definitions	1880
Creating a Mask Block Definition from a Polyline	1880
Creating a Mask Block Definition from an Existing Mask Block Definition	1880
Importing Mask Block Definitions	1881
Exporting Mask Block Definitions to a New Drawing	1881
Exporting Mask Block Definitions to an Existing Drawing	1882
Editing a Mask Block Definition	1882

Adding Classifications to a Mask Block Definition	1883
Purging Mask Block Definitions	1884
Using Mask Block Tools to Create Mask Blocks	1884
Adding a Mask Block	1885
Adding a Mask Block with User-Specified Settings	1885
Creating a Mask Block from Polylines	1886
Creating a Mask Block Tool	1886
Attaching Mask Blocks to Objects	1888
Detaching Mask Blocks from Objects	1889
Editing Mask Blocks	1889
Using Grips to Move Mask Blocks	1890
Changing the Location of a Mask Block	1890
Editing the Profile of a Mask Block	1891
Applying Tool Properties to an Existing Mask Block Reference	1892
Changing Display Properties of Mask Blocks	1892
Attaching Hyperlinks, Notes, and Files to a Mask Block	1893
Chapter 35 Multi-View Blocks	1895
Multi-View Blocks	1895
Creating Multi-View Block Definitions	1896
Process Overview: Creating Multi-View Block Definitions	1896
Creating View Blocks	1897
Creating a New Multi-View Block Definition	1898
Connecting View Blocks to View Directions	1899
Defining a Multi-View Block Definition as Bounding for Associative Spaces	1899
Attaching Notes and Files to a Multi-View Block Definition	1900
Adding Classifications to a Multi-View Block Definition	1900
Adding a Multi-View Block Definition to DesignCenter	1901
Creating a Multi-View Block Tool	1902
Adding Multi-View Blocks to a Drawing	1904
Inserting a Multi-View Block	1904
Modifying Multi-View Blocks	1905
Changing the Rotation of a Multi-View Block	1905
Changing the Associated Multi-View Block Definition	1906
Changing the Scale Factor of a Multi-View Block	1906
Changing the Offset of a Multi-View Block Using Grips	1906
Changing the Location of a Multi-View Block Using Grips	1907
Attaching Hyperlinks, Notes, or Files to a Multi-View Block	1908
Editing the Location and Rotation of Attributes in a Multi-View Block	1909
Updating Multi-View Block Attributes	1910
Documentation	1911
Chapter 36 Spaces	1913
New Features in Spaces for AutoCAD Architecture 2009	1913
Space Types	1914
Space Workflows	1916
Working with Associative Spaces - Overview	1916
Working with List Definitions - Overview	1916
Working with Space Boundaries - Overview	1917
Working with Zones - Overview	1919
Working with Calculation Modifiers - Overview	1920
Working with Calculation Cut Planes - Overview	1921
Working with Space Evaluations - Overview	1922
Moving Forward to AutoCAD Architecture 2009 from Autodesk Architectural Desktop 2006 and Earlier	1923
Auto-Converting Legacy Areas to Spaces	1925
Space Properties	1926

Using Space Tools to Create Spaces	1930
Generating Associative Spaces	1931
Boundary Objects for Associative Spaces	1931
Generating an Associative Space	1938
Generating Associative Spaces from Xrefs and Blocks	1941
Defining a Maximum Gap Size for Associative Spaces	1944
Updating Associative Spaces	1945
Activating and Deactivating Automatic Updates	1946
Manually Updating Associative Spaces	1947
Merging Associative Spaces	1948
Dividing an Associative Space	1950
Deducting Spaces from an Associative Space	1951
Making a Space Associative or Non-Associative	1952
Troubleshooting Associative Spaces	1953
Creating Non-Associative Spaces	1958
Drawing a Non-Associative 2D or Extruded 3D Space	1958
Converting Objects, Profiles, and Polylines to Non-Associative Spaces	1961
Creating a Space Tool	1964
Editing General Space Properties	1967
Renaming a Space	1967
Changing the Style of a Space	1968
Changing the Location of a Space	1968
Specifying the Decomposition Type for a Space	1969
Specifying the Decomposition Text Properties for a Space	1970
Specifying the Cut Plane Display of a Space	1972
Attaching Hyperlinks, Notes, or Files to a Space	1972
Working with Space Boundaries	1973
Working with Manual Boundaries	1974
Working with Style-Based Boundaries	1975
Working with Boundaries Based on an Area Calculation Standard	1975
Defining the Boundary Offset Type of a Space	1976
Specifying an Area Calculation Standard for a Drawing	1977
Classifying a Space According to an Area Calculation Standard	1978
Changing the Area Calculation Standard for Existing Spaces	1979
Working with Drawings with Different Area Calculation Standards	1979
User-Defined Area Calculation Standards	1980
Editing Space Boundaries	1980
Changing the Type of a Space	1989
Changing the Space Height	1991
Changing the Height of Extruded 3D Spaces	1992
Changing the Height of 3D Freeform Spaces	1992
Changing the Height of Space Surfaces (Extruded 3D Spaces)	1994
Boolean Operations for Extruded 3D Spaces	1995
Creating Interference Conditions for Spaces	1995
Removing Interference Conditions from Spaces	1996
Merging Extruded 3D Spaces	1996
Dividing Extruded 3D Spaces	1999
Creating Holes in Extruded 3D Spaces	2000
Creating Spaces from the Intersection of Other Spaces	2001
Trimming an Extruded 3D Space	2004
Removing Voids from Spaces	2005
Reversing Space Rings	2006
Reversing All Rings in a Space	2006
Boolean Operations for 3D Freeform Spaces	2006
Trimming 3D Freeform Spaces	2006
Splitting Surfaces of 3D Freeform Spaces	2007
Joining Surfaces of 3D Freeform Spaces	2008
Merging 3D Freeform Spaces with AEC Objects	2009
Subtracting AEC Objects from 3D Freeform Spaces	2010
Intersecting 3D Freeform Spaces with AEC Objects	2010

Grip-Editing the Surfaces of 3D Freeform Spaces	2011
Editing Space Surface Properties	2014
Opening the Space/Zone Manager	2014
Editing Surface Properties	2016
Editing Ceiling and Floor Surfaces	2017
Working with Surface Openings	2018
Setting Up Adjacency Relations between Space Surfaces	2037
Displaying Adjacency Relations between Space Surfaces	2038
Space Styles	2039
Creating a Space Style	2039
Specifying Target Dimensions for the Space	2040
Specifying Space Boundary Offsets in a Space Style	2041
Attaching a List Definition to a Space Style	2042
Specifying Classifications for a Space Style	2042
Specifying the Materials of a Space Style	2043
Specifying the Display Properties of a Space Style	2045
Specifying the Hatching for Components of a Space Style	2047
Setting the Object Cut Plane of a Space Style	2048
Attaching Notes and Files to a Space Style	2049
Converting Area Styles to Space Styles	2049
List Definitions	2051
Creating a List Definition	2052
Specifying the Application for a List Definition	2052
Editing a List Definition	2053
Attaching Notes and Files to a List Definition	2053
Zones	2054
Using Zone Tools to Create Zones	2055
Zone Properties	2055
Creating a Zone	2057
Creating Zones with User-Specified Settings	2058
Creating Zone Structures from a Zone Template	2059
Creating a Zone Tool	2060
Converting Area Groups to Zones	2061
Zones and Spaces	2063
Attaching Spaces and Zones to Zones	2063
Detaching Spaces and Zones from Zones	2064
Selecting Spaces and Zones Attached to a Zone	2064
Editing Zones	2064
Renaming a Zone	2064
Changing the Zone Style	2065
Changing the Zone Boundary Offset	2065
Changing the Content Rules of a Zone	2066
Changing the Calculation Type of a Zone	2066
Changing Calculation Modifiers for a Zone	2067
Ordering Zone Structures	2067
Creating Polylines from Zones	2068
Specifying Additional Display Properties for a Zone	2069
Attaching Hyperlinks, Notes, or Files to a Zone	2070
Zone Styles	2071
Creating a Zone Style	2071
Attaching a List Definition to a Zone Style	2072
Restricting the Content of a Zone Based on the Zone Style	2073
Specifying Classifications for a Zone Style	2073
Specifying the Display Properties of a Zone Style	2073
Attaching Notes or Files to a Zone Style	2077
Converting Area Group Styles to Zone Styles	2078
Zone Templates	2079
Creating a Zone Template	2080
Building the Structure of a Zone Template	2080
Attaching Notes and Files to a Zone Template	2082

Converting Area Group Templates to Zone Templates	2083
Working with Space Data	2083
Schedule Properties of Spaces	2084
Calculation Modifiers	2088
Setting Calculation Cut Planes for 3D Freeform Spaces	2092
Generating Output Data and Exporting Space Data	2092
Space Decomposition	2093
Space Evaluation	2097
Using Spaces for Load Analysis	2105
Conversion of Space Boundaries to Walls and Spaces	2110
Appendix 1: Command Changes for Spaces and Areas	2110
Area Commands	2110
Area Group Commands	2112
Space Boundary Commands	2113
Appendix 2: Predefined Area Calculation Standards	2114
Calculating Spaces Based on the Basic Area Calculation Standard	2114
Calculating Spaces Based on the DIN 277 Standard	2115
Calculating Spaces Based on the SIS Standard	2118
Calculating Spaces Based on the BOMA Standard	2122
Appendix 3: Implementing an Area Calculation Standard Plug-in with the AutoCAD Architecture .NET API	2126
Implementing an Area Calculation Standard	2126
Implementing Offset Rules	2131
Chapter 37 Sections	2147
Sections	2147
Process Overview: Creating a 2D or 3D Section	2151
Process Overview: Creating a Live Section View	2153
Drawing and Editing Section Lines	2153
Drawing a Section Line and Marks	2155
Changing the Height of a Section Using Grips	2156
Changing the Lower Extension of a Section Using Grips	2157
Changing the Length of a Section Using Grips	2157
Changing the Angle Dimensions of a Section	2159
Creating Graphic Subdivisions for 2D and 3D Sections	2159
Changing a Subdivision Using Grips	2160
Changing Section Mark Attributes	2160
Changing the Location of a Section Line	2160
Modifying a Section Line Using Grips	2161
Attaching Hyperlinks, Notes, and Files to a Section Line	2162
Creating a 2D or 3D Section	2162
Creating a Horizontal 2D Section	2164
Creating and Editing a Live Section View	2165
Creating a Live Section View	2166
Updating a Live Section View	2166
Displaying the Sectioned Body in a Live Section View	2167
Removing a Live Section View	2168
Editing a 2D or 3D Section	2168
Using Grips to Edit Linework in a 2D Section	2168
Changing the Display of Graphic Subdivisions in a 2D Section	2169
Changing the Display of Graphic Subdivisions in a 3D Section	2170
Reversing a 2D or 3D Section	2171
Changing the Style of a 2D Section	2171
Creating a Material Boundary in a 2D Section	2172
Editing a Material Boundary	2172
Editing and Merging Linework in a 2D Section	2175
Changing the Location of a 2D or 3D Section	2176
Attaching Hyperlinks, Notes, and Files to a 2D or 3D Section	2177
Updating a 2D or 3D Section	2177

Globally Updating 2D Sections	2178
Supported Project Drawing Types	2179
Globally Updating 2D Sections and Elevations in a Project or a Folder	2179
Updating Legacy Drawings	2181
2D Section Styles	2181
Creating a 2D Section Style	2182
Adding a Display Component to a 2D Section Style	2183
Removing a Display Component from a 2D Section Style	2184
About 2D and 3D Section Display Components and Materials	2184
Use Subdivision Properties and Materials in 2D Section Styles	2189
Use the 3D Body Component of a Material for the 2D Section Linework	2189
Adding a Design Rule to a 2D Section Style	2190
Changing a Design Rule in a 2D Section Style	2191
Removing a Design Rule from a 2D Section Style	2192
Adding Classifications to a 2D Section Style	2192
Changing the Layer, Color, and Linetype of a 2D Section Style	2192
Attaching Notes and Files to a 2D Section Style	2193
Chapter 38 Elevations	2195
Working With Elevations	2195
Process Overview: Creating a 2D or 3D Elevation	2199
Drawing and Editing Elevation Lines	2201
Drawing an Elevation Line and Mark	2203
Changing the Height of an Elevation Using Grips	2204
Changing the Lower Extension of an Elevation Using Grips	2205
Changing the Length of an Elevation Using Grips	2206
Changing the Angle Dimensions of an Elevation	2207
Creating Graphic Subdivisions for 2D and 3D Elevations	2207
Changing Elevation Mark Attributes	2208
Changing the Location of an Elevation Line	2208
Modifying an Elevation Line Using Grips	2209
Attaching Hyperlinks, Notes and Files to an Elevation Line	2210
Creating a 2D or 3D Elevation	2210
Creating a Horizontal 2D Elevation	2211
Editing a 2D or 3D Elevation	2212
Using Grips to Edit Linework in a 2D Elevation	2213
Changing the Display of Graphic Subdivisions in a 2D Elevation	2214
Changing the Display of Graphic Subdivisions in a 3D Elevation	2215
Reversing a 2D or 3D Elevation	2216
Changing the Style of a 2D Elevation	2216
Adding and Removing Custom Components for an Elevation	2216
Specifying the Display of Surface Hatching for an Elevation Subdivision	2217
Specifying the Display of 2D Linework for an Elevation	2219
Creating a Material Boundary in a 2D Elevation	2219
Editing a Material Boundary	2220
Editing and Merging Linework in a 2D Elevation	2223
Changing the Location of a 2D or 3D Elevation	2224
Attaching Hyperlinks, Notes, and Files to a 2D or 3D Elevation	2224
Updating a 2D or 3D Elevation	2225
Globally Updating 2D Elevations	2226
Supported Project Drawing Types	2227
Globally Updating 2D Sections and Elevations in a Project or a Folder	2227
Updating Legacy Drawings	2228
2D Elevation Styles	2229
Creating a 2D Elevation Style	2230
Adding a Display Component to a 2D Elevation Style	2231
Removing a Display Component from a 2D Elevation Style	2232
About 2D and 3D Elevation Display Components and Materials	2232

Workflow and User Interface

New Features and Introduction

Welcome to AutoCAD Architecture 2009! Built on the new AutoCAD® 2009 platform, this release is targeted at boosting efficiency with user interface enhancements that increase overall drafting productivity by decreasing the number of steps to reach a command. Performance acceleration further enhances the workflows of your building model. Newly designed features simplify working with your design whether you are currently using or new to AutoCAD Architecture.

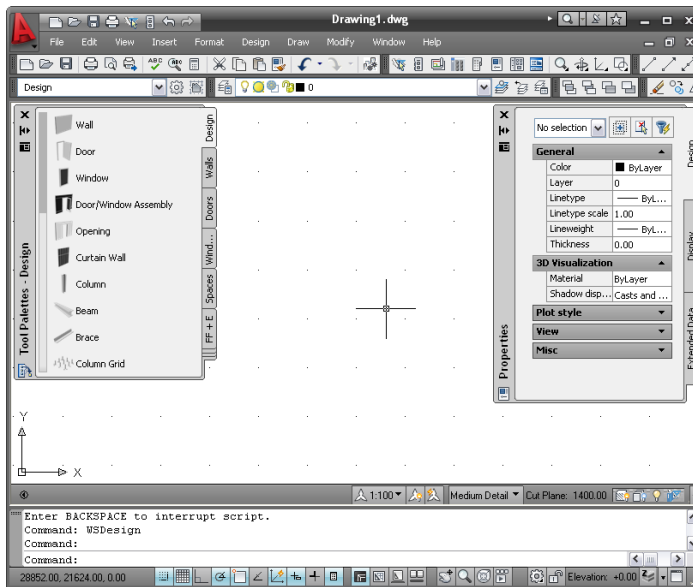

New Features in AutoCAD Architecture 2009

AutoCAD Architecture 2009 is oriented around 3 main themes:

- Draw more efficiently with tools that automate your most common drafting and documentation tasks
- Annotate your designs faster with streamlined tools that reduce the workload of drafting
- Collaborate with members of your extended project team as smoothly as possible

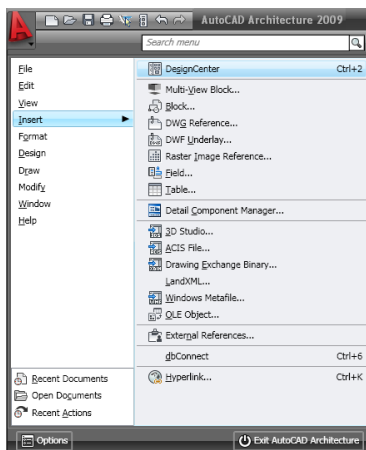

User Interface

The AutoCAD Architecture 2009 user interface offers a new look and feel. It provides you with easy access to the most commonly used tools while maximizing the drawing area. The default application window includes the Menu Browser, Quick Access toolbar, InfoCenter, and Status bar.

The main components in the application window are:

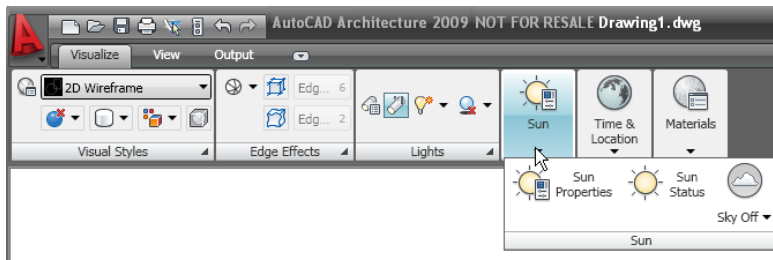

- **Menu Browser:** The new menu browser provides easy access to a variety of content, including commands and documents, from a single button in the upper left corner of the application window. Use the menu browser to preview and open documents, to search for commands and tags, and to display extended tooltips.

- **Quick Access Toolbar:** The Quick Access Toolbar is displayed at the top of the application window, next to the menu browser. By default, it includes the most common tools such as New, Open, Save, Plot, Project Navigator, Project Browser, Undo, and Redo. You can add and remove tools easily. Drag and drop commands from the Command list onto the Quick Access toolbar. The Quick Access tools can be reorganized or removed for each workspace.

- **Ribbon:** In AutoCAD Architecture 2009, the Ribbon is displayed with the Visualization workspace.

The Ribbon provides easy access to AutoCAD tools through a collection of tabs and panels. Each tab contains multiple panels and each panel contains multiple tools. Some panels can be expanded to access additional tools.

- **InfoCenter:** The InfoCenter has been enhanced to provide more flexibility when searching for help. You can collapse or expand the search field, saving space on the title bar. And when searching the help system for a topic, you can specify which document to search; decreasing the amount of time you spend trying to locate a topic.

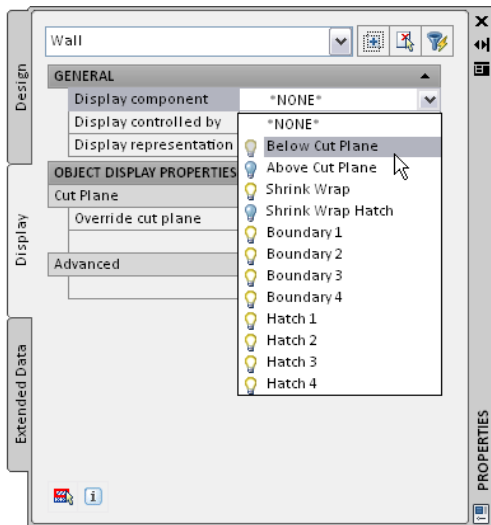

In addition, InfoCenter displays Did You Know balloons for selected feature areas. Did You Know balloons provide Knowledge Base information and general instructional messages such as tips. You can click on the text or the Expand icon to expand the balloon to view the detailed information.

For a detailed description of the new user interface, see [Workspace Components](#) on page 36.

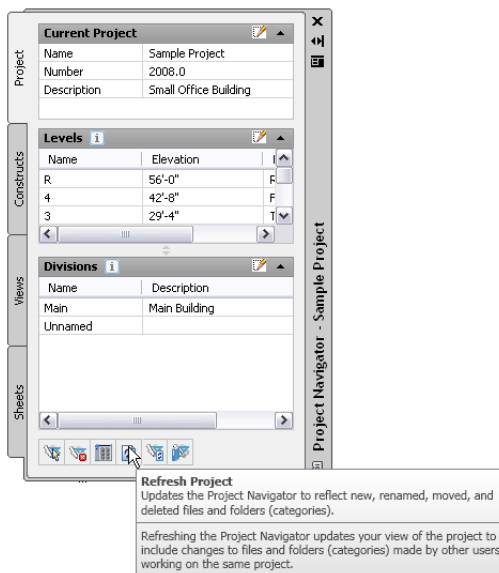

- **Properties Palette:** Object display properties formerly modifiable only through the Display Manager are now easily accessible from the Display Tab of the Properties Palette. From this tab you can quickly change visibility and other settings for individual display components in the current display representation. You specify whether your changes will apply to all objects of the selected type (drawing default), all objects of the same style as the one to which the component belongs (a style override), or only that object itself (an object override). You can also apply your changes to other display representations that use the same display component to draw the selected component.

The visibility of components can be controlled with the Light Bulb control.

For a detailed description, see [Using the Properties Palette to Change Display Properties](#) on page 538.

- **Enhanced Tooltips:** New tooltips have been added to the design environment, giving you helpful hints about how to use the tools within the program without leaving your project. With rollover functionality, multilevel support, and context-sensitive behavior embedded in the user interface, you'll find it easier to locate the tools you need in order to perform your work faster.

- **Solution Tips:** Warning symbols and defect markers used in previous versions of the program have been consolidated and standardized. The new solution tip icons display in the drawing area to alert you to problem conditions in AEC objects.

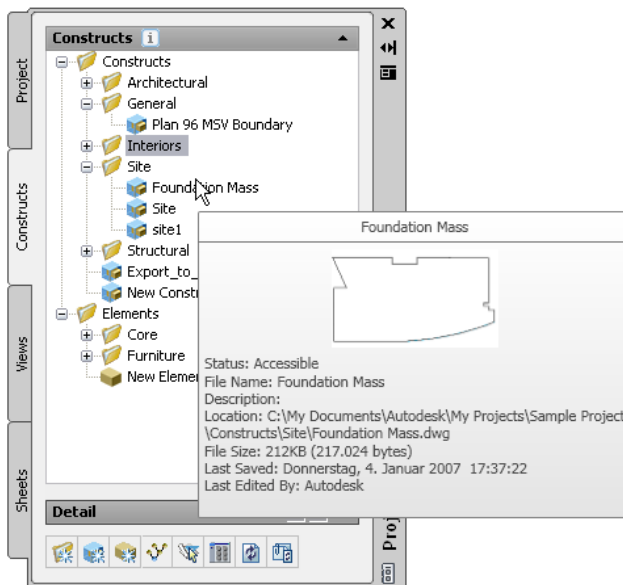

When you move the cursor over the icon, the solution tip displays, suggesting corrective action and providing a link to more detailed Help when applicable. You can specify whether to display the solution tip icons when drawing, or when publishing/plotting.

For more information, see [Solution Tips](#) on page 57.

Drawing Management Enhancements

Now you can get previews of each drawing that include a thumbnail of the design and the status of the drawing.

In addition to an indication of the drawings that are currently in use with the  lock icon, you can see who on your team has a drawing open in case you need to ask them to close it for editing purposes.

A number of additional improvements have been added to Drawing Management:

- You can now better control how drawings are pathed for storage and external references. If you do not want to repath a file immediately, the Repath queue is saved for later repathing. An Undo function has been added when deleting files from the repath queue.
- From Project Navigator you can close individual project files, or all files in a project at once by clicking the Close Current Project button.
- Commas, ampersands and semicolons allowed in titles of sheets.

For more information about these and more enhancements, see [Drawing Management](#) on page 217.

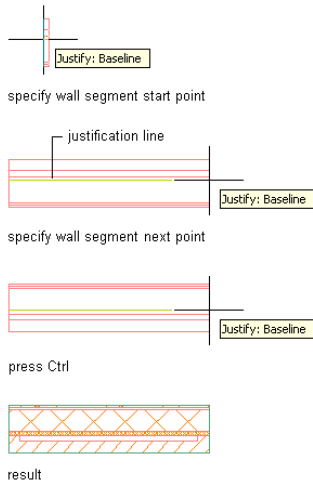

Wall Enhancements

In this release a number of key improvements have been made to the Walls feature in order to make them even more powerful and efficient to use.

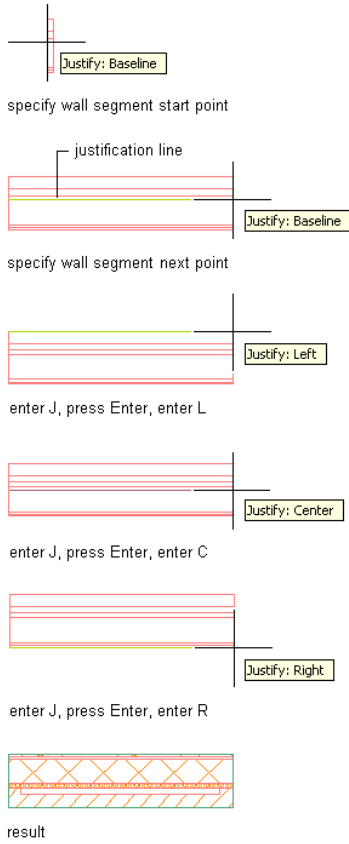

Drawing Walls

Enhancements to wall layout functionality give you the ability to quickly change a wall's justification, direction, and offset distance during insertion.

- Changing the orientation of a wall segment while drawing it: You can change the orientation of a wall segment about its justification line by first specifying the start point of the wall segment, then pressing CTRL to flip the wall segment about its justification line. End the command by specifying the wall segment endpoint.

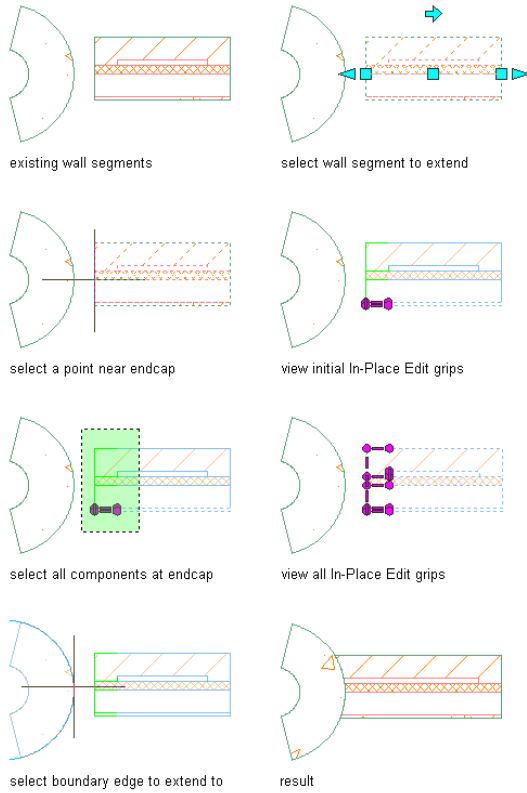

- Changing the justification of a wall segment while drawing it: You can change the justification of a wall segment about its justification line by first specifying the start point of the wall segment, entering **J** (for Justification) on the command line, and then entering **L** (for Left), **C** (for Center), **R** (for Right), or **B** (for Baseline) to specify the appropriate justification. End the command by specifying the wall segment endpoint.

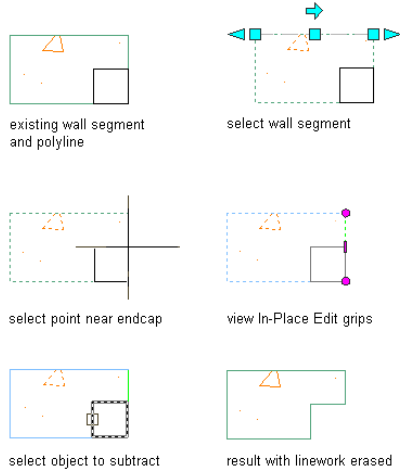

- Repositioning a wall segment while drawing it: You can reposition a wall segment as you are drawing it by specifying an offset based on a wall component's face or center, or the overall center of the wall. When you move your cursor over the wall segment, assistant lines with a tooltip display to indicate which part of the particular wall segment is selected. A solid line indicates a component face, a dashed line indicates a component center, and a center line indicates the overall center of the wall. Once you specify the wall segment start point and the offset from point, specify the offset distance to reposition the wall segment. End the command by specifying the wall segment endpoint.

Extending Wall Endcap Components

Subtracting from Wall Endcap Components

For more information, see [Modifying Wall Endcaps Using AEC Modify Tools](#) on page 906.

Space Enhancements

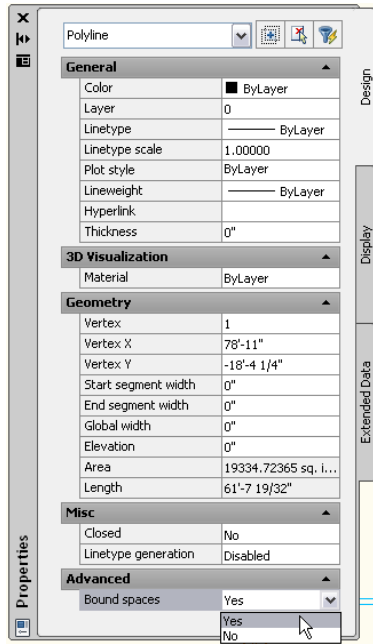

In this version of AutoCAD Architecture workflows around generating and evaluating spaces have been improved so space calculation is even more intuitive than before.

Improved Workflow for Associative Spaces

In AutoCAD Architecture 2009, the selection of objects that can serve as boundaries for associative spaces has been simplified and enhanced.

- The Bound Spaces property can be set on all boundary objects in the Properties palette, including linework like lines and polylines. This allows you to divide spaces that don't have objects such as walls bounding them, even across xrefs.

Make a linework object a space-bounding object

Use a linework object to generate spaces

- Objects on frozen and hidden layers participate in the generation of spaces.
- A visual filter allows you to quickly display all boundary objects in the drawing area, making space generation more transparent. For more information, see [Displaying all Boundary Objects in the Drawing Area](#) on page 1937.
- The following boundary objects have been enhanced: Ellipse, Spline, 3D polylines.
- Blocks and MV-blocks now have their own Bound Spaces property.

For more information, see [Generating Associative Spaces](#) on page 1931.

Surface Openings on Curved Surfaces

In previous versions, openings on curved surfaces were segmented according to the selected facet resolution. Now, you can create unsegmented openings on curved space surfaces. For more information, see [Adding Openings to 3D Freeform Space Surfaces](#) on page 2023.

Previous version (left) and current version (right)

Automatic Update of Associative Spaces through External References

Associative spaces that are bounded by objects in external references are now included in the automatic update of associative spaces. No manual updates are necessary anymore. For more information about working with xrefs and blocks, see [Generating Associative Spaces from Xrefs and Blocks](#) on page 1941.

Improved SIS Space Calculation Standard

The room height calculation under the SIS space calculation standard has been improved, and now takes into consideration that a space must have a room height of at least 1.90 meter with a width of at least 0.6 meter to be counted as measurable area. The SIS calculation standard delivered with this software is automatically checking the height of each space to make sure the space height conditions are met.

gbXML Support

When creating spaces and zones in AutoCAD Architecture, you can assign engineering data necessary for calculating loads and airflows. This data can be exported to the engineering and building information in Green Building XML (gbXML) format. You can use gbXML files in external analysis tools. After you analyze the calculated loads and airflows for the spaces and zones, you can design your duct systems accordingly.

For more information, see [Using Spaces for Load Analysis](#) on page 2105.

Match Properties for AEC Objects

The AutoCAD Match Properties functionality has been extended to AEC objects, allowing you to quickly copy both style and object properties from a source AEC object to one or more other destination AEC objects of the same type. Any style or object overrides in effect for the source object will be applied to the destination object; any style/object overrides in effect for the destination object will be removed.

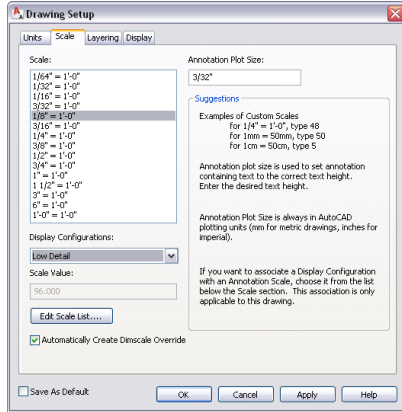

Matching properties from left door to right door

For more information, see [Matching Object Properties](#) on page 111.

Improved Annotation Scaling

AutoCAD Architecture 2009 streamlines steps around construction documentation by allowing you to link display configurations to the annotation scale. Once you select the Scale you can now also select a Display Configuration to match. This give you more control of the graphics that are displayed when you change scales, such as from the drawing status bar.

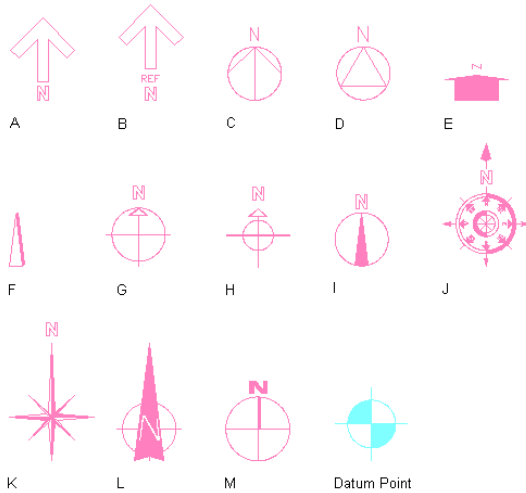

For more information, see [Annotation Scaling](#) on page 2441.

New Annotation Tools

A number of annotations tools formerly available only as content blocks in DesignCenter are now available through tools on the tool palettes and in Content Browser, allowing you more options and greater flexibility when annotating drawings. The following tools can be accessed from the Annotation tool palette and Content Browser:

North arrow and datum point symbols

Fire rating line tools

Match line tools

Revision cloud tools

Bar scale tool

Column grid bubble tool

For more information about working with these tools, see [Annotation and Keynoting Tools](#) on page 2381.

Multiline Tags

You now have the ability to create multiline annotations quickly and efficiently. The multiline tag support also includes the ability to specify text orientation, alignment, and wrapping through intuitive grips. Using new multiline abilities you can simply stretch the grip and watch the annotation change.

101

view attribute justification grips

For more information, see [The Basic Annotation Tool](#) on page 2381

Multiline Leaders

New multiline leaders make annotation faster and easier. You can efficiently annotate multiple objects with a single text reference.

Adding a leader line

The updated annotative tools are accessible via the Content Browser and include: Leader, Sheet Keynote, Reference Keynote, Reference Keynote (Straight Leader), Square (Straight Leader), Text (Straight Leader).

For more information, see [Adding and Removing Leader Lines from Leaders](#) on page 2392.

Material Tool

Material tools now let you apply a material directly to an AEC object component you select in the drawing. When the tool is active, object components highlight as you move the cursor over them, displaying a tooltip that identifies the component/object and the material to be applied. You specify whether to apply the material to the style or only to the object. The tools also support applying render materials to AutoCAD entities.

For more information, see [Using the Material Tool to Add Materials to Objects](#) on page 605.

Performance Improvements

The performance on these objects and workflows has been improved in order generate a faster and more efficient work environment for your building models:

Associative Spaces Performance

The performance for generating and updating associative spaces has been improved. Boundary objects are detected more quickly, and objects that do not form a boundary are filtered out more effectively. The interaction with boundary objects in external references is improved, so that an update especially across a large model will show significant acceleration.

Changing the properties of space surfaces and openings has been improved too, so that now when you change surface information of individual space surfaces, like changing the surface type or renaming a surface, you will experience a much better performance than before.

NOTE When you are converting drawings with xrefs and associative spaces from a previous version, the first time the main drawing is opened will be accompanied by a noticeable performance hit. This is however only a one-time effect; once the main drawing and its associated xref drawings have been opened and saved with the current version, the performance will be improved for all future sessions.

Drawing Compare Performance

The Drawing Compare feature has significantly improved in performance in the areas of file matching, drawing analysis, and object comparison. Also a change to the visual filters or the included objects in the comparison does no longer cause a full reload and re-comparison of the model.

For more information, see [Drawing Compare](#) on page 471.

Graphic System Performance

The performance of the graphic system during panning, zooming, and orbiting AEC objects in wireframe or shaded views has been significantly improved. This is especially visible for objects that have materials assigned to them.

Xref Performance

The performance of the OBJRELUPDATE command when used across xrefs has been improved. This is especially visible in drawings with many xrefs, and it will help you to improve your workflows on large projects and complex models.

Data Exchange

The following areas of data exchange have been added or improved for AutoCAD Architecture 2009:

- Windows Vista support for DWF files: AutoCAD Architecture 2009 provides native DWF support for users of Windows Vista. DWF files published to the XPS specification can be automatically opened and viewed using the XPS viewer built into Windows Vista, without the need for plug-ins or other downloads. For XP users, this same DWF support can be achieved via a download.
- IFC support: This release of AutoCAD Architecture natively imports and exports the most current Industry Foundation Classes (IFC). Improved import and export functionality gives you the ability to specify which objects are included during exchange. Additionally, style names can be preserved during import and IFC files can be converted to projects, complete with Project, Site, Building and Building Storey Information. For more information, see [Importing and Exporting IFC Files](#) on page 177.
- Enhanced Metadata for DWF or DWFX: Products such as Autodesk Quantity Takeoff (QTO) and Autodesk FMDesktop use property set data to extract rich information from AutoCAD Architecture models via DWF. Consuming DWF or DWFX data in these applications from an AutoCAD Architecture model has been improved. With a new option for “Automatic Property Set Data”, users do not have to create and

apply property set definitions to objects; all automatic properties, like the wall length or space area, are exported automatically when generating the DWF or DWFX file.
For more information, see [Publishing Drawings to DWF and DWFX](#) on page 204.

- **gbXML support:** When creating spaces and zones in AutoCAD Architecture, you can assign engineering data necessary for calculating loads and airflows. This data can be exported to the engineering and building information in Green Building XML (gbXML) format. You can use gbXML files in external analysis tools. After you analyze the calculated loads and airflows for the spaces and zones, you can design your duct systems accordingly.
For more information, see [Using Spaces for Load Analysis](#) on page 2105.

64-bit Support

AutoCAD Architecture 2009 now supports 64-bit computer architecture. You can install AutoCAD Architecture 2009 on a 64-bit computer and have access to all product and data import and export functionality, like importing database fields, exporting property set data, or exporting IFC.

The new 64-bit architecture lets you take advantage of the memory improvements provided by more powerful computers.

AutoCAD Highlights

AutoCAD Architecture 2009 is built on the design platform of AutoCAD 2009. In addition to the new features described, you can benefit from the exciting new feature set of AutoCAD 2009 too.

For a full listing of the new AutoCAD features, see the AutoCAD Help.

The following sections describe the new AutoCAD features that will be most likely to be useful for the architect, engineer, or construction professional.

DGN Support

AutoCAD 2009 has extended its support of the MicroStation™ DGN format by Bentley®. Now when you import a DGN file, you have better control of how properties, such as layers, linetypes, lineweights, and colors are mapped from DGN to DWG.

Additionally, export has been expanded beyond V8 DGN to also include V7 DGN, giving you more control of how you collaborate with other design professionals who may be referencing files of this format.

Lighting Tools

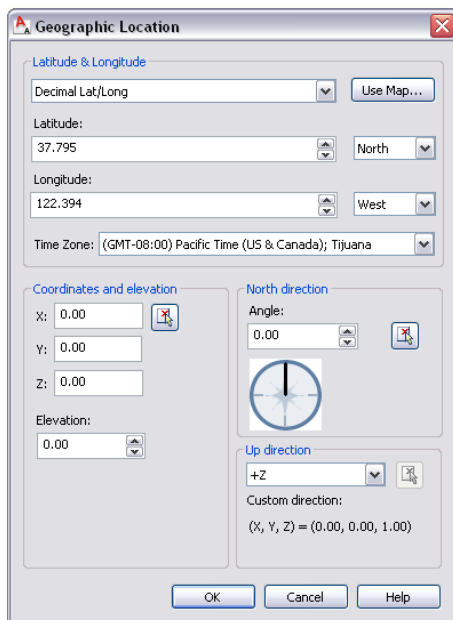

AutoCAD 2009 gives you more control over lighting, letting you create more realistic scenes, complete with shadows. The improvement of this feature, combined with the ability to leverage design material for visualization purposes, will allow you to create more realistic renderings with highly integrated visualization tools.

Geo-Enabled DWG Files

The new GEOGRAPHICLOCATION command (GEO alias) enables you to enter the location values for a geographic location or import them from various sources including XML or XMZ files as well as from Google Earth™ mapping service.

With this ability, imported data can be used to create sunlight based on the site location for design and visualization purposes.

View and Navigation Tools

There are a number of different ways to view the model in AutoCAD Architecture. For a complete description, see “Control the Drawing Views” in the AutoCAD help. The following sections highlight view and navigation tools new for this release of AutoCAD Architecture.

Quick View Layouts

Quick View layouts let you preview model space and all layouts in a drawing as a horizontal row of images from the application status bar.

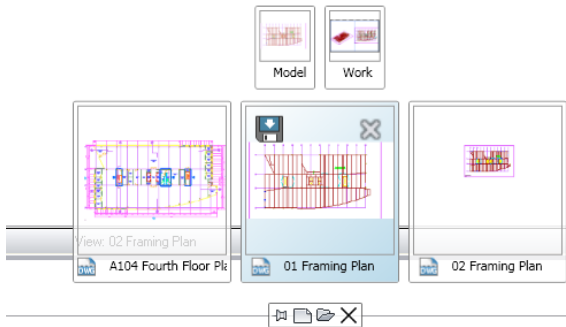

The model space and all the layouts within the drawing are displayed in a horizontal row above the status bar. The thumbnail is highlighted when the cursor is on it. Click on the thumbnail to navigate to the model space or layout.

You can also easily plot or publish with the plot and publish icons that appear at the top corners of the layout thumbnail when a cursor is on it.

For more information, see “Switch Between Layouts in the Current Drawing” in the AutoCAD Help.

Quick View Drawings

The Quick View Drawings functionality lets you preview and switch between currently open drawings from the application status bar.

A two-level row structure is displayed for Quick View drawings. The first level displays the thumbnail images of open drawings and the second level displays the thumbnail images for model space and all layouts in a drawing.

You can save and close a drawing with the icons located at the top corners of the thumbnail images when a cursor is placed upon it. You can also create and open a new drawing with the Quick View toolbar that appears when Quick View is displayed.

For more information, see “Switch Between Open Drawings” in the AutoCAD Help.

ViewCube

The ViewCube is a 3D navigation tool that appears when the 3D graphics system is enabled and allows you to switch between standard and isometric views.

Once the ViewCube is displayed, it appears in one of the corners of the drawing window over the model in an inactive state. When you position the cursor over the ViewCube, it becomes active. You can switch to one of the available preset views, roll the current view, or change to the Home view of the model.

The ViewCube can be displayed in the drawing area and in the Object Viewers provided with the program.

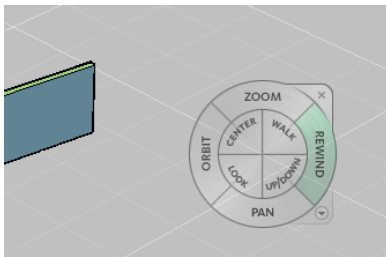

For detailed information about the ViewCube, see “View Cube” in the AutoCAD Help.

For information about Object Viewers, see [Object Viewer](#) on page 757.

SteeringWheels

SteeringWheels are tracking menus that are divided into different sections known as wedges. Each wedge on a wheel represents a single navigation tool. You can pan, zoom, or manipulate the current view of a model in different ways.

SteeringWheels can save you time and clicks by combining many of the common navigation tools into a single interface. A wheel is specific to the context that a model is being viewed in.

For detailed information, see “SteeringWheels” in the AutoCAD Help.

ShowMotion

The ShowMotion feature lets you add movement and transitions to captured camera positions called shots. You can create Still shots, Cinematic shots or a recorded walk that allows you to click and drag along the path of desired animation. Shots can be grouped together to form sequences called view categories.

For detailed information, see “ShowMotion” in the AutoCAD help.

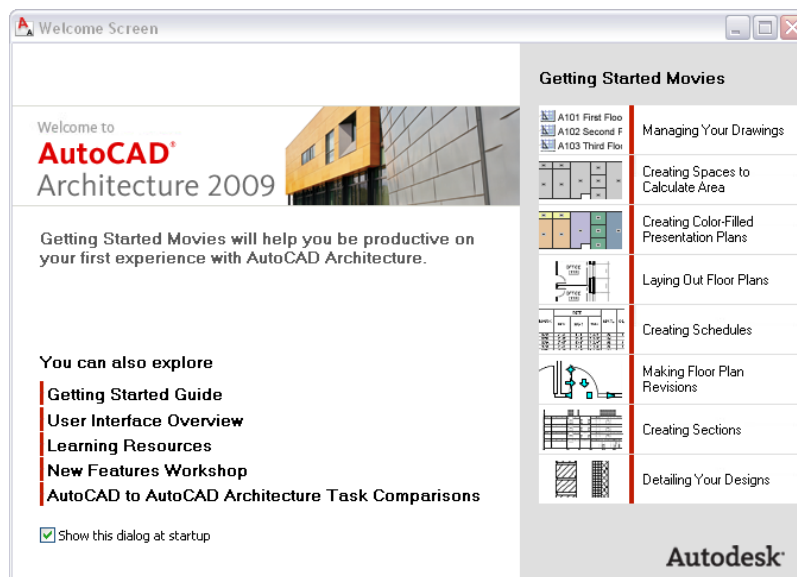

A Quick Start for Transitioning from AutoCAD to AutoCAD Architecture

If you have previously accomplished your architectural tasks with AutoCAD and want to transition to using AutoCAD Architecture, you will find that using tools specifically designed for architects provides additional productivity and benefits over the AutoCAD drafting methods you used before.

The help system is designed to simplify the transition from AutoCAD to AutoCAD Architecture. These help components will assist new users with previous AutoCAD experience to easily segue into working with AutoCAD Architecture:

- Getting Started movies
- Learning resources overview for different expertise levels
- User interface overview
- New Features Workshop
- Webcasts for typical architectural tasks
- Getting Started guides

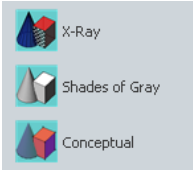

Welcome Screen

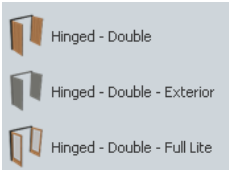

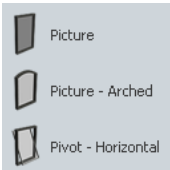

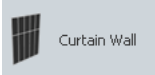

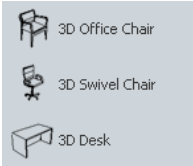

This quick overview of tasks and how to accomplish them in AutoCAD Architecture can help you get an easy start. For additional information, watch short movies which you can find on the Welcome to AutoCAD Architecture 2009 page, the Learning Resources page, or the main Help page.

- Click Help menu ► Welcome Screen, and then select a movie under Getting Started Movies on the right pane.
- Click Help menu ► Learning Resources, and then click Panel 2 - Getting Started Movies.

NOTE The software locations for tools, palettes, and catalogs listed below are the default locations for a standard US install. Customized installations, as well as localized versions may vary in the tools they supply and the structure of the tool palettes.

Starting AutoCAD Architecture

Use one of the following methods to start AutoCAD Architecture:

- Double-click the AutoCAD Architecture icon on your desktop. The icon is displayed on your desktop if you chose to create it when you installed the software.
- On the Start menu, click Programs ► Autodesk ► AutoCAD Architecture 2009 ► AutoCAD Architecture 2009.

NOTE AutoCAD Architecture 2009 can be run under Windows 2000, Windows XP, and Windows Vista.

Customizing Startup

You can use command-line switches in the properties of the desktop icon to specify AutoCAD Architecture startup options:

- Run a startup script when you start the software.
- Start the software with a specific template.
- Start the software with a specific profile (ARG file).
- Create several desktop icons, each with different startup options.

For more information, see “Customize Startup” in AutoCAD Help.

Default Content Paths for Microsoft Windows Vista

AutoCAD Architecture 2009 is running under Microsoft Windows Vista. The default content paths for style drawings, support files, and tool catalogs vary between Windows XP and Windows Vista:

Operating System	AutoCAD Architecture 2009 Content Path
Windows XP	C:\Documents and Settings\ <user>\My Documents</user>
Windows Vista	C:\Users\ <user>\Documents</user>

Finding Help

With AutoCAD Architecture 2009, you can move smoothly from 2D drafting to building information modeling in an AutoCAD-based environment. AutoCAD Architecture supports your current practices and helps you to take advantage of your knowledge of AutoCAD. Intelligent architectural objects and other powerful design and documentation features offered by AutoCAD Architecture will help you reap productivity benefits by minimizing tedious drafting and rework.

Autodesk provides many resources to ensure that you quickly become productive with AutoCAD Architecture and the many new features available in this release. Online and print documentation, real-world tutorials, and technical support channels are all available to answer your questions as you begin working with the software.

There are various available resources to help you learn about AutoCAD Architecture 2009 and AutoCAD® 2009.

Documentation	Description
<i>AutoCAD Architecture 2009 Installation Guide</i>	Explains how to install and configure AutoCAD Architecture 2009.
<i>AutoCAD Architecture 2009 Help</i>	Explains AutoCAD Architecture concepts and provides step-by-step procedures.
<i>AutoCAD Architecture 2009 Printed Getting Started Guide</i>	The printed Getting Started tutorial gives you a quick, but comprehensive introduction to the concepts of working with AutoCAD Architecture 2009.
<i>AutoCAD Architecture 2009 Online Tutorials</i>	A set of exercises designed to give you an overview of the capabilities and features of AutoCAD Architecture.
<i>AutoCAD Architecture 2009 New Features Workshop</i>	Gives an overview of the new features in AutoCAD Architecture 2009.
<i>AutoCAD Architecture 2009 Getting Started Movies</i>	View these movies to learn about typical and frequently used tasks.
<i>AutoCAD 2009 User's Guide</i>	Provides conceptual and overview material with step-by-step procedures for AutoCAD 2009.
<i>AutoCAD 2009 New Features Workshop</i>	Gives an overview over the new features in AutoCAD 2009.

The advantage of online manuals is that they present information quickly while you are in a drawing session. Although online Help topics provide some conceptual and overview material, their main purpose is to help you get a task done efficiently. Therefore, the AutoCAD Architecture online Help emphasizes step-by-step procedures relevant to command selection. It also incorporates visual examples and links to more information.

Online tutorials are also an excellent way to become familiar with AutoCAD Architecture. When you use the tutorials to learn program concepts, you can keep the tutorial window open in the drawing area while you perform the steps.

To access AutoCAD Architecture 2009 Help

- 1 Click Help menu ► Help.
- 2 When the Help window is displayed, click the AutoCAD Architecture 2009 Help book on the Contents tab, and then browse the contents to locate the information you need. Or use the Index or Search tabs to find specific topics. Icons with a red marker indicate topics that include information about new features.

about Autodesk Authorized Training Centers, contact atc.program@autodesk.com or visit the online ATC locator at <http://www.autodesk.com/atc>.

Autodesk Official Training Courseware

Autodesk publishes many courseware titles each year for users at all levels to improve their productivity with Autodesk software. The preferred training materials of Autodesk partners, these books are also well-suited for self-paced, standalone learning. All courseware simulates real-world projects with hands-on, job-related exercises. Autodesk Official Training Courseware (AOTC) is developed by Autodesk. Autodesk Authorized Training Courseware (AATC) is developed by Autodesk partners, including titles in a growing number of languages. Autodesk Official Certification Courseware (AOCC) teaches the knowledge and skills assessed on the Certification examinations. Visit <http://www.autodesk.com/aotc> to browse the Autodesk Courseware catalog.

Autodesk Certification

e-Learning

Autodesk e-Learning for Autodesk Subscription customers features interactive lessons organized into product catalogs. Each lesson is 20-40 minutes in length and features hands-on exercises, with an option to use a simulation or the software application. You can also use an online evaluation tool that identifies gaps in skills, determines what lessons will be most helpful, and gauges learning progress.

If you are a member of Autodesk subscription, you can access e-Learning and other subscription services from within your Autodesk product. For more information about Autodesk subscription resources, visit <http://www.autodesk.com/subscription>.

Contacting Autodesk

Autodesk, Inc.
111 McInnis Parkway
San Rafael, CA 94903 USA
Phone: 415-507-5000
Website: <http://www.autodesk.com>

Sales Information

To purchase additional Autodesk software, contact your local reseller. For the name of the authorized reseller nearest you, call 1-800-964-6432 or access the Resellers and Training Centers website, <http://www.autodesk.com/resellers/>.

Technical Support

If you have technical questions about the products, you should contact your local reseller or check the frequently asked questions (Technical Solutions & FAQs) section and Discussion Groups on the website for

AutoCAD Architecture at <http://www.autodesk.com/support>. News groups are another good source of information. You can look through the questions that have already been posted, or you can post your own questions.

Feedback

Please let us know what you think! Whether you have a suggestion for product enhancement, a compliment, or a complaint, or if you think you have found a bug, we would like to know about it.

To make comments and find additional information, visit our website at <http://www.autodesk.com/contact>.

The Workspace

2

The AutoCAD Architecture workspace is a highly customizable graphical user interface designed to accommodate the various workflows and work styles of architectural professionals. The topics in this section provide an overview of the available workspace components and describe how to access and configure them to meet your needs. For detailed instructions on using workspace components to create and edit architectural objects, refer to the relevant object-specific topics in Help (Walls, Doors, Windows, and so on).

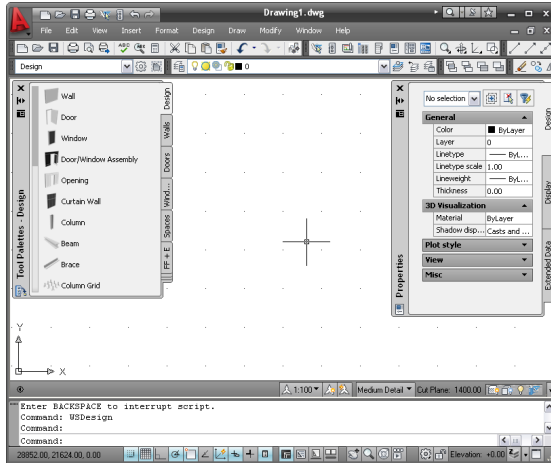

The Workspace Concept

In AutoCAD Architecture, a workspace is a task-based customization of the basic user interface that includes only those menus, toolbars, and palettes you need for a particular architectural process. When you first start AutoCAD Architecture, you are prompted to set the initial drawing environment and the default drawing template file by selecting one of the following workspaces:

Workspace	Description
Design	Provides all the basic tools for creating architectural objects in your drawings.
Document	Provides tools for adding schedule tables, annotations, callouts, and other documentation objects to your drawings.
Detailing	Provides tools for inserting a wide variety of predefined detail components, as well as tools for detail drafting.
Visualization	Includes all the tools available in the Design workspace as well as the Ribbon, which provides tools for 3D modeling, viewing, and rendering.

Whichever workspace you select, you can reconfigure it according to your preferences as you work. You can move or hide various components as needed, display additional toolbars, or add new tools and tool palettes. If desired, you can save your customizations as a new workspace that you can access for later drawing sessions. You can also switch from one workspace to another at any time by selecting a new one from the drop-down list on the Workspaces toolbar or from the Workspace Switching flyout menu on the application status bar. For more information, see [Changing Workspaces](#) on page 36 and “Create Task-Based Workspaces” in the AutoCAD help.

Default configuration of the Design workspace

Changing Workspaces

Use this procedure to change from one workspace to another.

- 1 Display the Workspaces toolbar in the drawing window.

Alternatively, you can click  (Workspace) on the application status bar.

- 2 Select the desired workspace option:

if you want to...

Then...

use an existing workspace

select it from the drop-down menu.

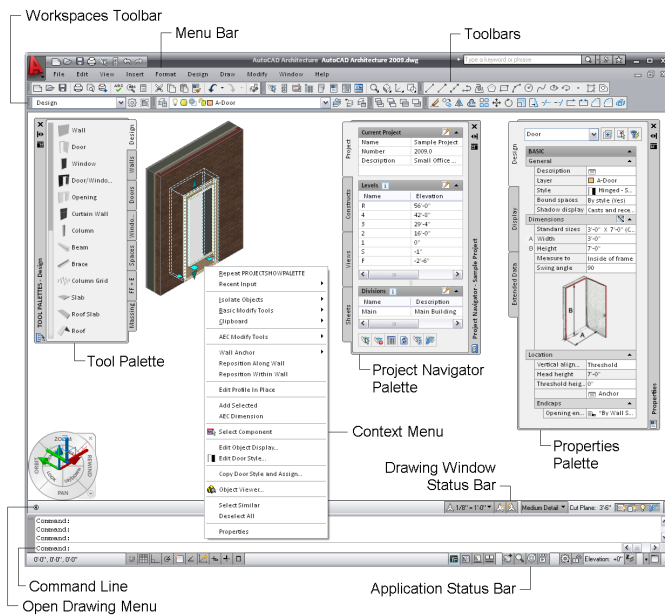

edit an existing workspace or create a new workspace

select Customize. For more information, see "Customize Workspaces" in the AutoCAD Customization Guide.

Workspace Components

The AutoCAD Architecture workspace consists of a drawing window with menus, toolbars, tool palettes, and other controls that you use to set up an architectural project, create your design, and generate construction documents. The default configuration of these components varies depending on which of the predefined workspaces you select (Design, Document, Detailing, or Visualization).

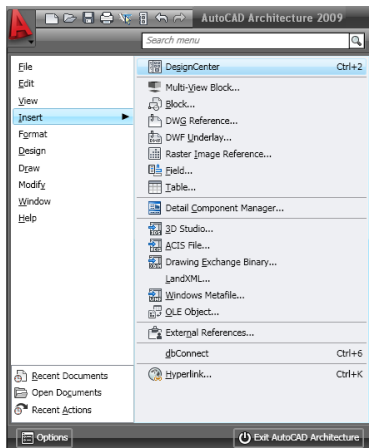

In the following sections, each component of the workspace is described in detail. Not every component is necessarily visible in each workspace configuration. Most components can be turned on and off according to user requirements.

For an interactive guide through the User Interface, select Help menu ► Welcome Screen ► User Interface Overview.

The Menu Browser

The menu browser lets you organize and display pull-down menu commands.

The menu browser can be displayed instead of the standard menu bar, or in addition to it.

NOTE The menu browser cannot be turned off. Menu browser, Quick Access toolbar, and the application status bar are one integrated user interface component.

The menu browser lets you perform the following operations:

- List recently opened documents, including APJ files

- Search for a command by name
- Add search tags to a command
- Display extended tooltips for each command

Accessing Commands from the Menu Browser

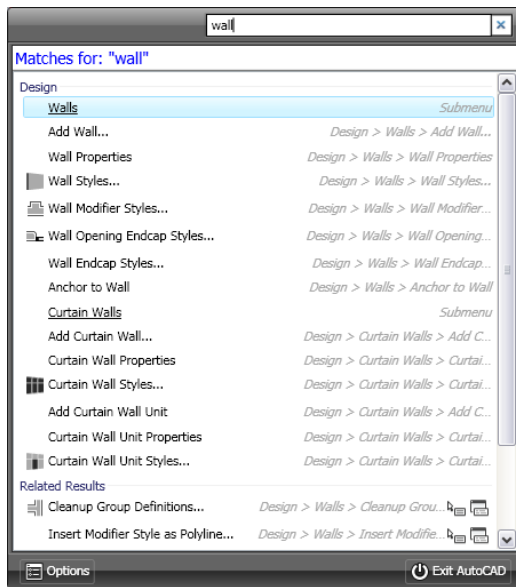

To access the menu browser click  at the upper-left corner of the workspace. Move the cursor over a menu or category on the left side of the browser, and then click the desired option on the right.

The menu browser remains open as long as the cursor is located inside the menu browser window. To close the menu browser, either activate a menu command, or click outside of the menu browser window.

Searching for Commands in the Menu Browser

As opposed to the traditional menu bar, where each command can be accessed only from a set location, in the menu browser you can search for a command and then select it from the list of matches.

NOTE In addition to instances of the search string, the results include the contents of the associated tooltip and any Search tags you have defined in the Customize User Interface editor (CUI). For information about search tags, see “Assign Search Tags” in the AutoCAD help.

- 1 Click  to open the menu browser.
- 2 In the Search field, enter the desired search term.
A list of found matches is displayed in the menu browser. To select one of the found commands, click it.
- 3 Click the desired command in the list of matches.

4 To return to the regular menu display in the menu browser, click  at the right side of the Search field.

Displaying Recently Opened Documents in the Menu Browser

Menu browser offers the following options for displaying recently opened documents in AutoCAD Architecture 2009:

- Group documents by file type (including DWG, DWT, APJ) or by last-saved date
- Show either icons that indicate the document type or actual preview images of drawings at the size you specify
- Flag documents you want displayed regardless of the last-saved date.

1 Click  to open the menu browser.

2 Click Recent Documents.

3 At the top left of the list of documents, specify how you want them grouped.

The default setting (Ordered List) displays documents alphabetically. Alternatively, you can group them by last-saved date or file type.

4 At the top right of the list of documents, click  (Preview) to specify whether to display file type icons, or small, medium, or large preview images next to the document names.

5 If you want to keep a document in the list, regardless of its last-saved date, click its pushpin so

that the image changes from  to . The document will remain in the list until you unpin it.

Displaying Recently Performed Commands in the Menu Browser

For quick access to frequently used commands in the menu browser, use the following instruction:

1 Click  to open the menu browser.

2 Click Recent Actions to display a list of commands recently selected in the menu browser.

(Commands run from the command line, context menus, or other mechanisms are not included.)

3 If you want to keep a command in the list, regardless of its last-performed date, click its pushpin so

that the image changes from  to . The command will remain in the list until you unpin it.

Changing the Number of Recent Files and Actions in the Menu Browser

Use this procedure to change the default number (9) of recent documents or recent actions displayed in the menu browser:

1 Click  to open the menu browser.

2 At the bottom of the menu browser click Options.

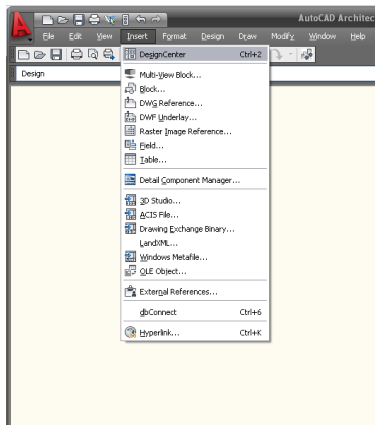

Alternatively you can click Format menu ► Options.

3 On the Open and Save tab of the Options dialog, under Menu Browser, change the values for Number of recently-used files and Number of recently-used actions.

4 Click OK.

The Menu Bar

The menu bar is located at the top of the application window and offers hierarchical access to commands.

The menu bar of the drawing window provides the following pulldown menus, each of which includes a group of commands that support a particular aspect of the architectural workflow. Where applicable, menu options show alternate access methods, such as a toolbar button or a keyboard shortcut.

Menu	Contents
File	<ul style="list-style-type: none">■ Drawing transmittal and publishing commands■ Access to the Project Browser■ Drawing utilities such as Audit, Recover, and Purge.
Edit	Standard Microsoft Windows editing commands, such as Copy and Paste
View	<ul style="list-style-type: none">■ Commands that change the working view■ Access to Keynote Display and Cameras

Menu	Contents
Insert	<ul style="list-style-type: none"> ■ General insertion commands for external files and file types ■ Access to DesignCenter and Detail Component Manager
Format	<ul style="list-style-type: none"> ■ Formatting commands for color, linetype, lineweight, and other graphic characteristics. ■ Access to tools for managing styles, layers, display system, structural members, schedule tags, blocks, and profiles. ■ Access to the Options dialog, where you can modify default settings for a wide range of system behaviors and characteristics
Design	<ul style="list-style-type: none"> ■ Access to architectural objects for the design phase of the project ■ Access to architectural objects for the conceptual modeling phase of the project
Draw	<ul style="list-style-type: none"> ■ Access to basic AutoCAD linework objects, like lines, polylines, and rectangles ■ Access to AutoCAD text and table tools
Modify	<ul style="list-style-type: none"> ■ Access to basic object manipulation tools, like stretch, mirror, and rotate
Window	<ul style="list-style-type: none"> ■ Standard window configuration tools such as Tile and Cascade ■ Access to Project Navigator, Markup Set Manager, Tool Palettes, and Properties Palette ■ Commands for adding other pulldown menus to the menu bar (see table below for descriptions)
Help	<p>Access to the online Help, tutorials, and other resources to help you learn and use AutoCAD Architecture</p>

NOTE In AutoCAD Architecture Help and tutorials, instructions for selecting a particular pulldown or context menu option use this symbol ► to indicate any submenus in the path to that option. For example, the instruction for selecting the Sheet Keynotes option on the Keynote Display submenu of the View pulldown menu would be: Select View menu ► Keynote Display ► Sheet Keynotes.

In addition to the standard pulldown menus described above, you can load any of the following pulldown menus by selecting them from the Window menu:

Menu	Contents
Document	Similar to the Documentation menu in previous versions of the software.
CAD Manager	Access to advanced features like AEC Project Standards, Tool Catalog Generator, Keynote Editor, VBA Manager, Visual Basic Editor, Visual LISP Editor, the Script command, and Visual Audit. When this menu is loaded, toolbars are available to provide quicker access to some of these features. To display them, right-click in the toolbar area (not on a toolbar), and click ADT_CAD_MANAGER ► AEC Project Standards or ADT_CAD_MANAGER ► CAD Manager.
3D Solids	Access to the Convert to Solids and Convert to 3D Solids commands plus suites of commands for creating and editing solids. When this menu is loaded, toolbars with the corresponding commands are also available. To display them, right-click in the toolbar area (not on a toolbar), and click ADT_3DSOLIDS ► Solids or ADT_3DSOLIDS ► Solids Editing.
Dimension	Access to AutoCAD dimensioning tools

Adding additional menus to the menu bar

- 1 Click Window menu ► Pulldowns.
- 2 Select the menus you want to add to the menu bar.

Turning the Menu Bar On and Off

You can turn the menu bar off completely if you want to work exclusively with the menu browser.

To turn the menu bar off, right-click anywhere on the menu bar, and click Display Menu Bar.

To turn the menu bar back on, click anywhere on the Quick Access toolbar (see [The Quick Access Toolbar](#) on page 42), and click Show Menu Bar.

The Quick Access Toolbar

The Quick Access toolbar is a customizable toolbar s located at the top of the application window, just to

the right of the  menu browser button. By default, this toolbar contains a set of frequently used commands for the currently selected workspace. You can add or remove commands as follows:

You can add and remove commands on the Quick Access toolbar.

Adding a command to the Quick Access toolbar

- 1 Click Window menu ► Pulldowns ► Customize.
- 2 In the Customize User Interface dialog, select the Customize tab.
- 3 In the Customization in All CUI files panel, expand Workspaces, and select the workspace for which you want to add a command.
- 4 In the Workspace Contents panel, select Quick Access Toolbar.
 - Expand Quick Access Toolbar in order to see which commands are currently contained in it.
- 5 In the Command List panel, select the command you want to add, and drag it over to the Workspace Contents panel onto the Quick Access Toolbar node.
- 6 Click OK.

Removing a command from the Quick Access toolbar

- 1 Click Window menu ► Pulldowns ► Customize.
- 2 In the Customize User Interface dialog, select the Customize tab.
- 3 In the Customization in All CUI files panel, expand Workspaces, and select the workspace from which you want to delete a command.
- 4 In the Workspace Contents panel, expand Quick Access Toolbar.
- 5 Select the command to remove, right-click, and click Remove from Workspace.
- 6 Click OK.

Toolbars

Toolbars in AutoCAD Architecture workspaces contain buttons that you click to initiate commands, change settings, or access other features that you might often need during a drawing session. The icon on a toolbar button indicates its function. To display a tooltip with the button name, you move the cursor over the button. In some cases, the tooltip extends after hovering for a longer period of time. For detailed information, see [Tooltips](#) on page 53.

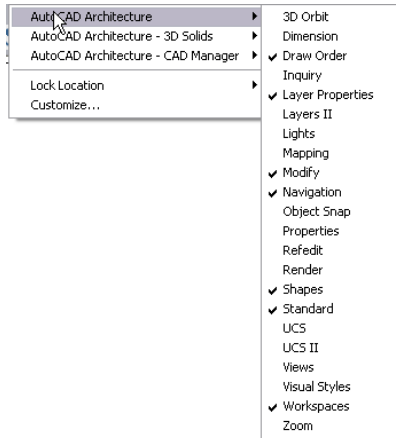

By default, toolbars are displayed in the toolbar area just below the menu bar, but you can drag them into the drawing area or completely out of the drawing window if desired. You can also dock toolbars to an edge in the drawing area, hide them, resize them, or create your own. For detailed instructions on customizing the display of toolbars, see “Toolbars” in the AutoCAD Help.

To display a toolbar that is currently not visible, right-click any visible toolbar, and click the name of the toolbar you want to see. Or you can right-click in the toolbar area (not on a toolbar), select a toolbar group, and then click a toolbar name.

NOTE Most of the toolbars are for AutoCAD functionality; AEC functionality is by default accessed from the tool palettes, the Properties palette, and the menus.

Accessing the list of toolbars

Context Menus

Context menus in AutoCAD Architecture function the same way as the shortcut menus described in the AutoCAD Help. Right-clicking in most areas of the workspace displays a context menu that contains commands appropriate to the cursor position at that time. For example, when you right-click in the toolbar area, the context menu lists all the available toolbars. When you right-click in the drawing area, the content of the context menu depends on the currently selected object(s). For example, if one or more wall objects are selected, a wall-specific context menu is displayed as shown.

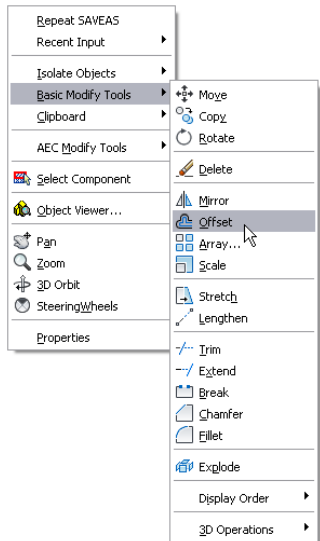

Wall context menu

If more than one type of object is selected, the context menu includes only those commands that can be applied to all the selected objects. If no objects are selected, the general context menu is displayed as shown

below. This menu contains non-object-specific commands, including the same commands available from the Modify toolbar.

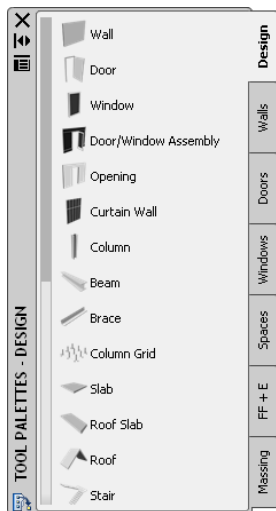

General drawing context menu

Tool Palettes

Tool palettes provide the main method for accessing tools to create objects in your model. You can have tools for standard objects as well as for objects with specific styles and properties. Tool palettes are organized by tool palette groups in a tool palettes set. You can create your own tool palettes, or you can copy existing tool palettes from the Content Browser.

Design tool palette with tools for standard design objects

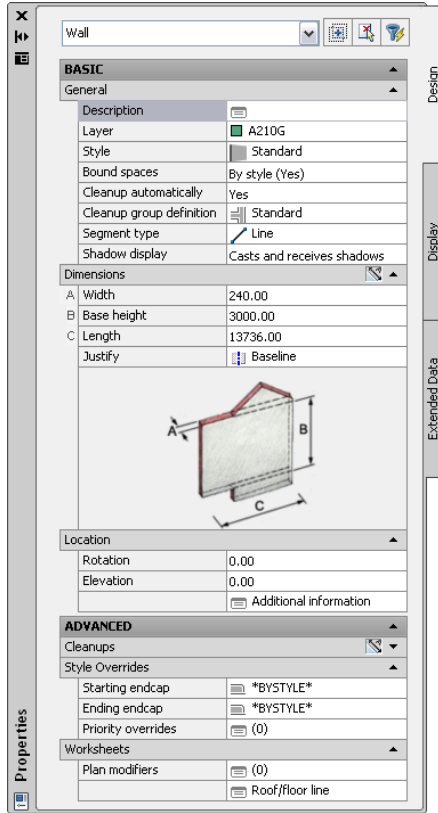

For more information, see [Working with Tool Palettes](#) on page 65.

Properties Palette

The Properties palette provides a central location to view and modify both the physical and graphical properties of an object. The object can be one you are about to draw, or one that is already selected in the drawing area. Using the Extended Data tab of the Properties palette, you can also attach other kinds of information to an object, such as classifications, notes, reference documents, hyperlinks, and property set data. You typically keep the Properties palette open during an AutoCAD Architecture session.

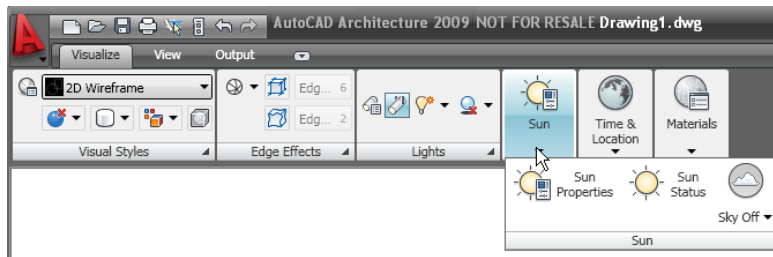

Wall Properties Palette

For more information, see [The Properties Palette](#) on page 92.

Ribbon

The ribbon is a palette that displays task-based buttons and controls in a workspace. For example, when you switch to the Visualization workspace, the necessary tools for setting up and creating a rendering are displayed on the ribbon. For more information, see “The Ribbon” in the AutoCAD help.

Drawing Window Status Bar

Located at the bottom of the drawing area, the drawing window status bar displays status information about the current drawing and provides access to various commands that can be applied to the drawing as described below.

- **Open Drawing Menu:** Click  at the far left of the drawing window status bar to display a context menu of frequently used commands. These commands are also available from the standard pull-down menus.

- **Project Information:** If the drawing is part of an AutoCAD Architecture project, this information includes the name of the project, and the type of file, (such as View or Construct). For more information, see [Drawing Management](#) on page 217.
- **Annotation Scale:** To change the annotation scale for the current viewport, click the current value and select a new one from the list. Changing the scale may also change the Level of Detail setting described below.

- **Annotation Visibility:** Click  to show annotative objects for all scales. Click  to automatically add scales to annotative objects when the annotation scale changes.
- **Level of Detail:** Shows the current display configuration of the active viewport and provides a drop-down list from which you can select another configuration.

- **Cut Plane:** Identifies the global cut plane height for the active display configuration and provides access to a dialog that lets you adjust the setting. For more information, see [Global Cut Planes](#) on page 388.

-  (Surface Hatch Toggle): Lets you switch the display of surface hatching on or off. For more information, see [Working with Surface Hatches](#) on page 615.
-  (Layer Key Overrides): Lets you switch layer key overrides on or off in the Layer Key Overrides dialog. For more information, see [Layer Key Overrides](#) on page 524.
-  (Isolate Objects): Lets you hide or display objects you have selected in the drawing. For more information, see [Isolating Objects](#) on page 112.
-  (AEC Project Standards): When a project is loaded, click here to synchronize or configure standards for the current project. For more information, see [Project Standards](#) on page 409.
-  (Autodesk Trusted DWG): This icon indicates that you have opened a DWG, DWT, or DWS file that is created using Autodesk applications or RealDWG™-based applications.
-  (Manage Xrefs): Click to open the External References palette, where you can reload xrefs that are associated with your current drawing.
- Missing Standards File(s): When applicable, this warning indicates that standards files are missing in the current drawing; you can then check settings for the standards and configure them as necessary. For more information, see [Configuring Project Standards](#) on page 416.
- Drawing Status Bar Menu: A drop-down list of the settings and commands available for display on the drawing window status bar.

Showing and Hiding Commands on the Drawing Window Status Bar

You can turn individual features on the Drawing Window Status Bar menu off, if you do not need them.

- 1 Click the Drawing Window Status Bar menu arrow at the right end of the Drawing Window Status Bar.

- 2 Select or deselect individual items.

Turning the Drawing Window Status Bar On and Off

The drawing window status bar can be turned on and off entirely from the Application Status Bar (see also [Application Status Bar](#) on page 49.) Turning the drawing window status bar off will increase the size of the drawing area.

- 1 At the far right of the Application Status Bar, click the Application Status Bar menu.
- 2 Select or deselect Drawing Status Bar to show or hide this status bar.

Command Window

You can directly enter commands using the command window located immediately below the drawing window status bar. To hide the command window, or to display it if it is currently hidden, click Window menu ► Command Line.

If you want to hide the command window except for its title bar when you are not using it, click . Moving the cursor over the title bar will redisplay the command window.

Application Status Bar

The application status bar contains settings valid for the whole drawing session in AutoCAD Architecture. Some settings, such as options for different elevations, only display if you are working within a project. For more information, see [The Drawing Status Bar](#) on page 269.

The group of commands on the left side of the application status bar can be displayed as icons or text labels.

Commands displayed as icons

Commands displayed as text labels

To change the display of these commands right-click any of them, and select or deselect Use Icons.

To activate or deactivate any of the commands in this group, click the icon or label. Blue indicates an active control; gray indicates an inactive control. To change the settings for one of these commands, right-click the icon or label, and click Settings.

For detailed information about these options, see “Use Precision Tools” in the AutoCAD help.

The following list describes all the commands and settings on the application status bar:

- Cursor coordinate values: Controls the coordinate format as either relative or absolute. For more information, see “Overview of Coordinate Entry” in the AutoCAD help.

-  (Snap): Lets you restrict the movement of the cursor to the drawing grid.

-  (Grid): Lets you display a rectangular grid as a drawing aid.

-  (Ortho): Lets you restrict cursor movement to horizontal and vertical directions when creating and modifying objects.
-  (Polar Tracking): Lets you restrict cursor movement to specified angles.
-  (Object Snap): Lets you restrict movement of the cursor to specified points on objects, such as the midpoint or an intersection point.
-  (Object Snap Tracking): Lets the cursor track along alignment paths based on other object snap points when specifying points in a command. This feature can be used only in conjunction with Object Snap.
-  (Dynamic UCS): Lets you temporarily and automatically align the XY plane of the UCS with a plane on a solid model while creating objects.
-  (Dynamic Input): Lets you enter values for objects directly onscreen near the cursor. Dynamic input can be turned on and off during creating or editing an object in the drawing area.
-  (Lineweight): In model space, lineweights are displayed in pixels and do not change when zoomed in or out. Displaying the lineweight could create some very heavy line display.
-  (Quick Properties): This feature is intended for AutoCAD objects and is turned off in AutoCAD Architecture.
-  (Model Space) or  (Paper Space): Switches between layouts.
-  (Quick View Layouts): Lets you preview model space and all layouts in a drawing as a horizontal row of images. Click on a preview image to display the layout. For more information, see [Quick View Tools](#) on page 62 and “Navigate within a Drawing (Model Space and Layouts)” in the AutoCAD Help.
-  (Quick View Drawings): Lets you preview all currently open drawings with their model space and layouts. Click on the preview image to display the drawing or layout. For more information, see [Quick View Tools](#) on page 62 and “Navigate Between Open Drawings” in the AutoCAD Help.
-  (ShowMotion): Provides an onscreen display that can be used to create, select, and play back cinematic camera animations called Shots. These animations can be used for presentation purposes or for navigation. For more information, see “ShowMotion” in the AutoCAD Help.
-  (Pan). Lets you move the view in the drawing area
-  (Zoom): lets you increase or decrease the apparent size of objects in the drawing area
-  (SteeringWheel): Lets you display a tracking menu for different navigation tools.
-  (Workspaces): Lets you switch between workspaces. For more information, see [The Workspace Concept](#) on page 35.

-  (Lock Toolbar and Window positions). Lets you switch between docked windows and toolbars and floating windows and toolbars.
- Elevation: Select a level for the calculation of the elevation offset.

NOTE This option is available only if your current drawing is a construct drawing from an AEC project.

- Elevation relative to construct's level: Lets you define the elevation of the construct relative to the level you have selected. This button points the Elevation Offset worksheet where you enter or pick the elevation offset.
-  (Replace Z value with current elevation): Switching on or off, replacing the existing Z value with the current elevation.
-  (Clean Screen): Click to switch between the standard screen and a full screen. In full-screen mode, all toolbars and palettes (except the Tool Palettes) are hidden. Hidden palettes retain their current state.

Showing and Hiding Commands on the Application Status Bar

You can show or hide individual commands on the Application Status Bar menu.

- 1 Click the Application Status Bar menu arrow at the right end of the application status bar.

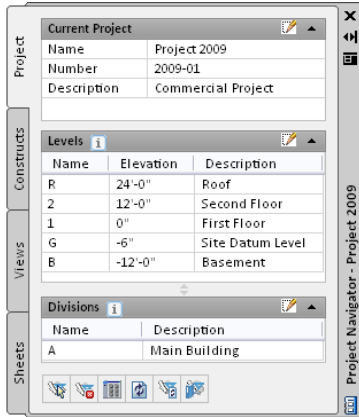

- 2 Select or deselect individual items.

Project Navigator Palette

The Project Navigator palette is the central location to create, modify, and access AutoCAD Architecture project files. You typically have the Project Navigator palette open in the workspace while you work on a project. For more information, see [Drawing Management](#) on page 217.

Project Navigator palette

Finding Information in AutoCAD Architecture

In addition to online help and tutorials, AutoCAD Architecture provides various ways to quickly access the information you need to be successful with new and existing features. Review the sections below to learn how you can get help quickly and with minimal disruption of your workflow.

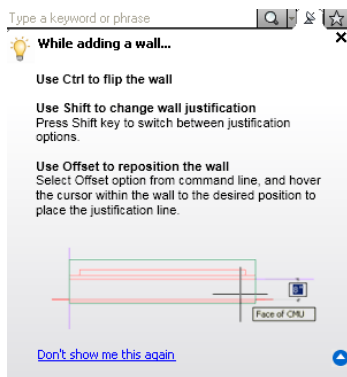

Info Center Toolbar

InfoCenter is a central location where you can search for product-related help and other information sources. You can search for information through keywords (or by typing a phrase), display the Communication Center panel for product updates and announcements, or display the Favorites panel to access saved topics.

When you enter keywords or type a phrase, and then press ENTER or click the Search button, you search multiple Help resources in addition to any files that have been specified in the InfoCenter Settings dialog. The results are displayed as links on a panel. You can click any of these links to display the Help topic, article, or document.

In addition, InfoCenter displays Did You Know balloons for selected feature areas. Did You Know balloons provide Knowledge Base information and general instructional messages such as tips. You can click on the text or the Expand icon to expand the balloon to view the detailed information.

For detailed information about InfoCenter, see “Search For and Receive Information” in the AutoCAD Help.

Communication Center

Communication Center is accessed from the InfoCenter toolbar. This resource displays links to information about product updates and product announcements, and may include links to Subscription Center, CAD Manager specified files, and RSS feeds.

F1 Context Help

For many commands and dialogs you can access a context-related Help topic using one of the following methods:

- Press F1 while a command is active or a dialog is open.
- Click the Help button in an open dialog.

Tooltips

In addition to interactive tooltips that help you to create and edit objects (see [Direct Editing with Grips and Dynamic Dimensions](#) on page 98), AutoCAD Architecture provides tooltips that display information about the command, option, or file over which you pause the cursor.

Command Tooltips

A short description displays whenever you pause the cursor over a command in any of the following locations:

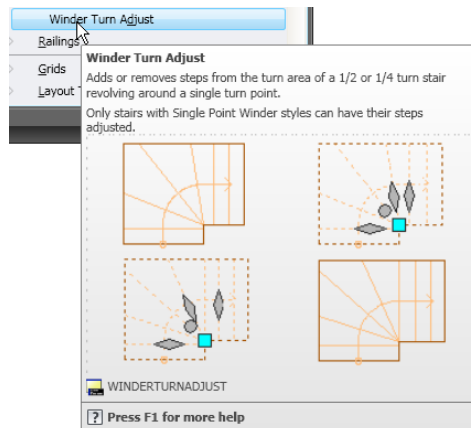

- In the menu browser
- On toolbars
- On the AutoCAD ribbon

For some commands, an extended tooltip displays after a user-specified time interval.

Standard tooltip for command

Extended tooltip for command

Controlling the Display of Command Tooltips

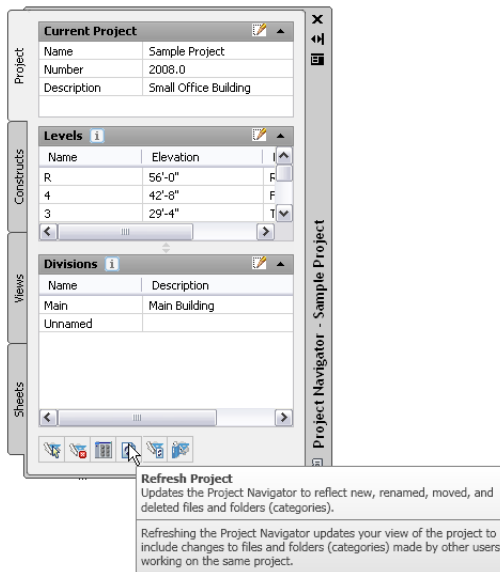

You can change the display of command tooltips. For extended tooltips you can define a time interval between the display of the basic tooltip and the extended tooltip.

- 1 Click Format menu ► Options.
- 2 Click the Display tab.
- 3 Under Window Elements, select or deselect Show Tooltips.
- 4 If you want to change the time interval between displaying the basic tooltip and the extended tooltip, select a different value for Number of seconds to delay. If you want to turn off the extended tooltip information completely, deselect Show extended Tooltips.
- 5 Click OK.

Dialog and Palette Tooltips

the following dialogs and palettes in AutoCAD Architecture support extended tooltips:

- Project Browser dialog
- Project Navigator palette
- Drawing Compare palette

Object Rollover Tooltips

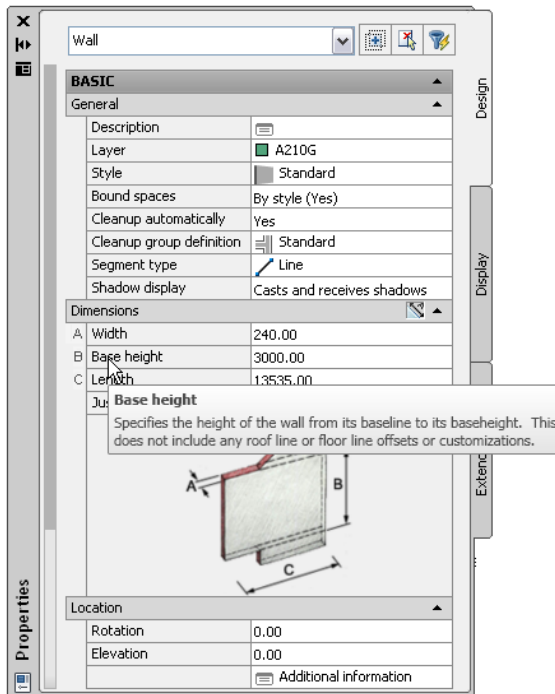

When you pause the cursor over an object in the drawing area, an informational tooltip displays basic information about the object.

Unlike the rollover tooltips provided for ACAD objects, such as lines or polylines, this information is standardized and cannot be changed. For information on how to configure rollover tooltips for AutoCAD objects, see “Customize Rollover Tooltips” in the AutoCAD Customization Guide.

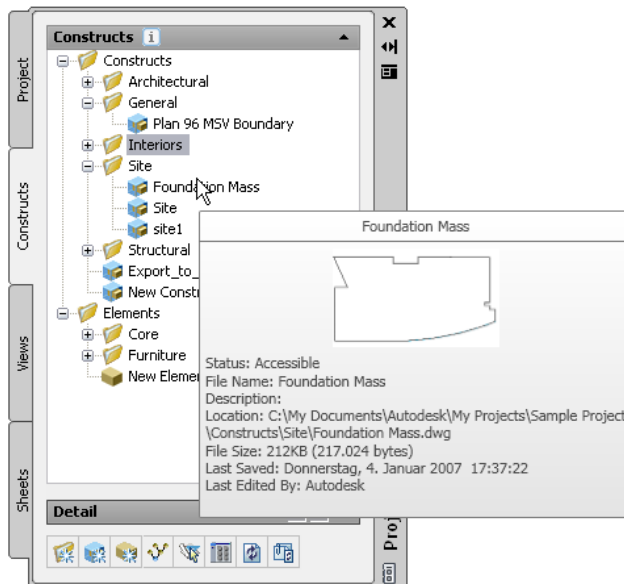

Property Palette Tooltips

The Properties palette and other property listings in AutoCAD Architecture display tooltips when you pause the cursor over a property in the list.

Thumbnail (Preview) Tooltips

In Project Navigator, you can display thumbnail previews of project drawings. The preview can be a graphic or a detail, or a combination of both. Displaying thumbnails can be helpful when you are navigating large projects with many drawings.

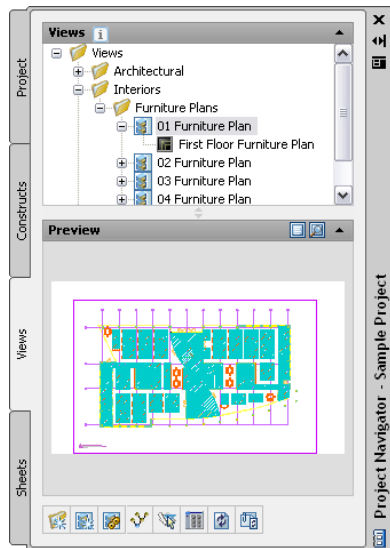

To activate preview tooltips in Project Navigator

- 1 In Project Navigator, open the Constructs, Views, or Sheets tab.
- 2 Right-click in the toolbar area at the bottom of the tab.

3 Click Tooltip style, and select one of these options:

Tooltip Style Option	Tooltip Display
Name	Displays only the name of the drawing file. Use this option if you want to maximize the file tree visibility.
Preview	Displays only a preview image of the file. You can specify the preview size (Small, Medium, or Large).
Details	Displays a text description of the file, identifying its location, size, last-saved date, and last editor.
Preview & Details	Displays a preview image and a text description. You can specify the preview size (Small, Medium, or Large).

4 If you want to display the information provided with the preview and detail tooltips, right-click, and click Preview/Details Pane. This option displays either a text description, or a preview of a selected graphic in an area below the file tree.

Solution Tips

The intended interaction among objects in an AutoCAD Architecture drawing depends on various rules about how objects are placed in relation to one another. Whenever the software identifies a problem with the placement of objects or their components, a solution tip icon is displayed to identify the location of the problem, as shown.

Move the cursor over the icon to display a message that describes the problem and provides one or more possible solutions. Some solution tips provide complete instructions for resolving the problem. Where more detailed instructions are required, you can press *F1* to access the relevant topic in Help.

Note that not all object configuration problems have an easily identifiable cause or a specific solution. This is often true in the case of boolean operations where an entity such as a body modifier is added to or subtracted from an object. In these cases, the solution tip identifies the kind of object or component involved and suggests corrective action. You may be advised to modify the location or the geometry of the object, but it is essentially a trial-and-error approach. The messages are tips rather than guaranteed solutions.

By default, solution tip icons are displayed when you are drafting, but not during plotting or publishing. You can change these settings in the Options dialog using the following procedure:

- 1 Click Format menu ► Options
- 2 In the Options dialog, click the AEC Editor tab.
- 3 In the Solution Tip panel, select or clear Drafting and Plotting/Publishing as desired.

Object Grip Tooltips

Objects in AutoCAD Architecture have grips to manipulate them. Each grip has a tooltip that displays the function of the grip.

Door dimension grips

When you use a grip to edit an object, in many cases additional information appears in a tooltip, helping you to perform the grip action.

Changing the standard size of a door with grips

For more information, see [Direct Editing with Grips and Dynamic Dimensions](#) on page 98.

Working with Objects in the Workspace

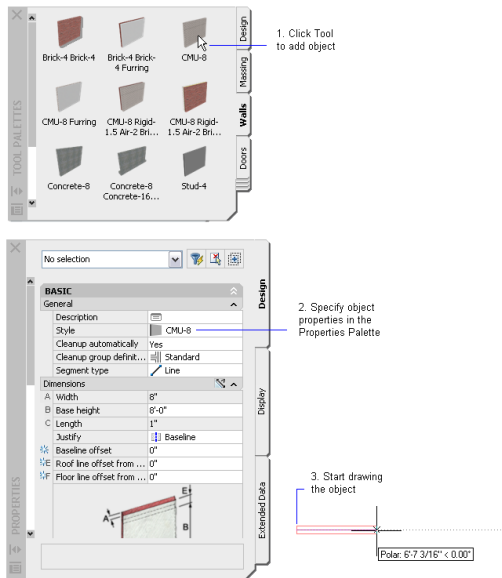

The AutoCAD Architecture workspace is where you add and manipulate the architectural objects that make up your drawings.

Adding Objects

You add objects to the drawing with tools.

Tools generally have preset creation parameters called properties. When you click an object tool to add an object in the drawing, the Properties palette opens so that you can change properties for the new object if desired. If not, you can go ahead and place the object in the drawing. For more information, see [Tools](#) on page 76.

Adding a wall to the drawing

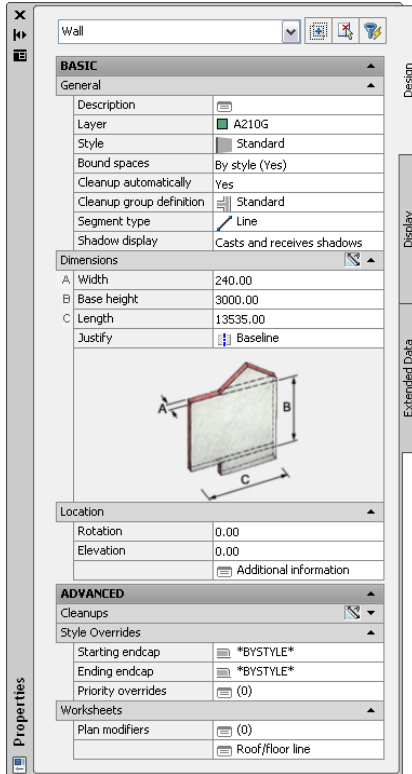

Tools are arranged on tool palettes for easy access. To open the tool palettes, click Tool Palettes on the Window menu.

Modifying Objects

You can modify an object using any of the following methods:

- Properties palette: The Properties palette is the central location for entering and changing information about an object. This palette has categories that correspond to the tabs in the Properties dialog boxes from earlier releases of the software.
For detailed information, see [The Properties Palette](#) on page 92.

Modifying a wall with the Properties palette

- Matching properties between objects: You can use the Match Properties command to copy the style and display properties of one AEC object and apply them to one or more other objects of the same type. For more information, see [Matching Object Properties](#) on page 111.
- Context menu: Right-click the object to display its available commands.

Wall context menu

- Direct editing with grips: Commands for modifying objects are accessible from the object's grips. Click an object in two-dimensional (2D) or three-dimensional (3D) view to display its grips. For detailed information about object grips, see [Direct Editing with Grips and Dynamic Dimensions](#) on page 98. Information about grip-editing is also covered in the individual object sections.

Window grips for direct editing

Selecting Similar Objects

Use this procedure to create a selection set of objects on the same layer and that have the same style.

You may want to select a number of objects that are on the same layer and that have the same style in order to perform a global change. The QSELECT command allows a single selection criterion, like layer or style. With the Select Similar command, you can select objects on the same layer that have the same style.

NOTE Block references are selected based on their layer and block definition.

- 1 Select the first object in the selection set.
- 2 Right-click, and click Select Similar.

NOTE Alternatively, you can click Edit ► Select Similar, and then select the first object. As a shortcut, you can select the first object, and then press *CTRL+SHIFT+A*.

View and Navigation Tools

There are a number of different ways to view the model in AutoCAD Architecture. For a complete description, see “Control the Drawing Views” in the AutoCAD help. The following sections highlight view and navigation tools new for this release of AutoCAD Architecture.

Quick View Tools

Quick View Tools make navigating and selecting drawings and layouts easier.

Quick View Layouts

Quick View layouts let you preview model space and all layouts in a drawing as a horizontal row of images.

Click  (Quick View Layouts) in the application status bar to display the Quick View layouts view:

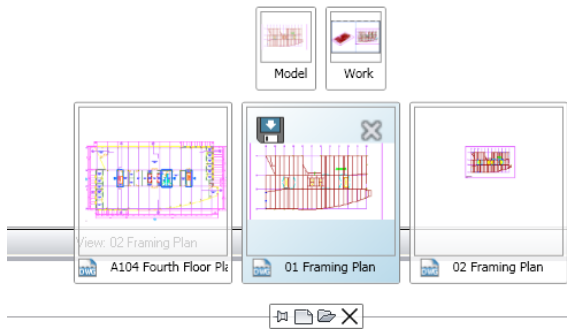

The model space and all the layouts within the drawing are displayed in a horizontal row above the status bar. The thumbnail is highlighted when the cursor is on it. Click on the thumbnail to navigate to the model space or layout.

You can also easily plot or publish with the plot and publish icons that appear at the top corners of the layout thumbnail when a cursor is on it.

For more information, see “Switch Between Layouts in the Current Drawing” in the AutoCAD Help.

Quick View Drawings

The Quick View Drawings functionality lets you preview and switch between currently open drawings from the application status bar. Click  (Quick View Drawings) to display the preview of open drawings:

A two-level row structure is displayed for Quick View drawings. The first level displays the thumbnail images of open drawings and the second level displays the thumbnail images for model space and all layouts in a drawing.

The thumbnail image of the current drawing is highlighted by default. The second level of the thumbnail image enlarges and the first level reduces when a cursor is placed over the button. At any time, you can click on a thumbnail image to navigate to a drawing or layout.

You can save and close a drawing with the icons located at the top corners of the thumbnail images when a cursor is placed upon it. You can also create and open a new drawing with the Quick View toolbar that appears when Quick View is displayed.

For more information, see “Switch Between Open Drawings” in the AutoCAD Help.

ViewCube

The ViewCube is a 3D navigation tool that appears when the 3D graphics system is enabled and allows you to switch between standard and isometric views.

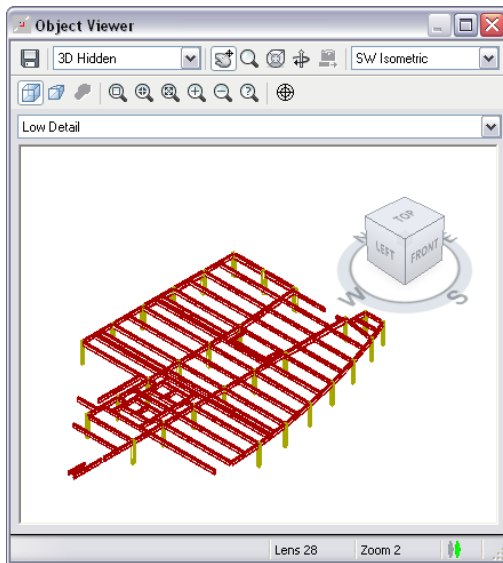

Once the ViewCube is displayed, it appears in one of the corners of the drawing window over the model in an inactive state. When you position the cursor over the ViewCube, it becomes active. You can switch to one of the available preset views, roll the current view, or change to the Home view of the model.

Displaying the ViewCube in the drawing area

- 1 Click View menu ➤ ViewCube ➤ On.

The ViewCube can be displayed in the drawing area and in the Object Viewers provided with the program.

NOTE In the ViewCube in the drawing area, you have access to a compass and can define a UCS. When you access the View Cube in an Object Viewer, no UCS option is available. When you access the View Cube in an Object Viewer for an object style, no UCS option and no compass are available.

The ViewCube is always turned on in Object Viewers.

For detailed information about the ViewCube, see “View Cube” in the AutoCAD Help.

For information about Object Viewer, see [Object Viewer](#) on page 757.

SteeringWheels

SteeringWheels are tracking menus that are divided into different sections known as wedges. Each wedge on a wheel represents a single navigation tool. You can pan, zoom, or manipulate the current view of a model in different ways.

SteeringWheels can save you time and clicks by combining many of the common navigation tools into a single interface. Wheels are specific to the context that a model is being viewed in.

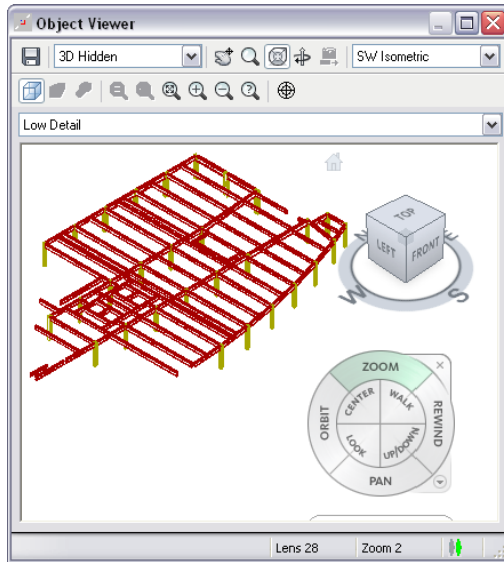

Displaying the SteeringWheel in the drawing area

- 1 Click View menu ► SteeringWheels.

Alternatively, you can right-click in the drawing area (with no objects selected), and click SteeringWheels.

You can choose from several different wheels. Each has its own drafting theme. Some wheels are designed for 2D navigation while other wheels are better suited for 3D navigation.

The SteeringWheels can be displayed in the drawing area and in the Object Viewers provided with the program.

Displaying the Steering Wheel in an Object Viewer

- 1 Open the Object Viewer from the context menu of an object or from Style Manager.
- 2 Right-click in the view area, and click SteeringWheel.

Alternatively, you can click  .

- 3 To close the SteeringWheel, right-click, and click Close Wheel, or click  again.

For detailed information, see “SteeringWheels” in the AutoCAD Help.

ShowMotion

The ShowMotion feature lets you add movement and transitions to captured camera position called shots. You can create Still shots, Cinematic shots or a recorded walk that allows you to click and drag along the path of desired animation. Shots can be grouped together to form sequences called view categories.

Starting ShowMotion

- 1 Click View menu ► ShowMotion.

Alternatively, you can click  on the Application Status Bar.

For detailed information, see “ShowMotion” in the AutoCAD help.

Working with Tool Palettes

Tool palettes provide instant access to a complete inventory of AutoCAD Architecture tools—such as walls, doors, and windows—in one consistent user interface. Highly visual, tool palettes include previews of styles. You can create custom tool palettes that address your specific design needs. For example, you can create a palette to store a list of commonly used curtain wall, stair, and window tools.

Tool palette components

Tool Palettes Set

Tool palettes sets contain groups of tool palettes. You can rename the default tool palettes set or create a custom tool palettes set. Additionally, you can add, remove, and rearrange palettes and groups in the set.

You can add tool palettes to the tool palettes set from a tool catalog. For example, you could create one tool palette set for imperial tools and another for metric tools. For more information, see [Specifying Different Tool Palettes for the Tool Palettes Set](#) on page 69.

Only one tool palettes set can be active during an AutoCAD Architecture session, although you can specify different tool palettes for different user profiles. When that profile is used, the collected tool palettes will be combined into one tool palettes set.

Tool Palettes Group

A tool palettes group is a collection of tool palettes. Three tool palettes groups are available when you start AutoCAD Architecture: Design, Document, and Detailing. You can add, rename, remove, export, import, and rearrange tool palettes groups. Tool palettes groups are contained in the tool palettes set. For more information, see "Organize Tool Palettes" and "Save and Share Tool Palettes" in the AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic referenced in AutoCAD Architecture Help is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

Tool Palettes

Tool palettes contain collections of tools and represent the individual tabs of a tool palettes group. A number of tool palettes are available from the AutoCAD Architecture Sample Palette catalog. You can create new tool palettes in AutoCAD Architecture or in the Content Browser. Usually you place tools on tool palettes according to tool type or design phase. For example, you could place your wall tools on a tool palette called "Walls" or your preliminary conceptual tools on a tool palette called "Massing Study." When you create a

tool palette in the Content Browser, you can link it to AutoCAD Architecture. Whenever the tool palette is updated in the Content Browser, the changes are updated in the tool palette in AutoCAD Architecture too. This is useful for large projects where consistency of styles and tools is necessary. For more information, see [Working with Tool Palettes from a Central Location](#) on page 74.

Tools

Tools represent the individual objects you can add to a drawing. A tool contains creation parameters for the object it creates. When you add an object with a specific tool, the object has the settings you defined in the tool. This eases the design process and enhances consistency across a project.

For example, you might define a wall tool that contains the style “CMU 8 Furring” and that has automatic cleanup and a baseline offset of 1". Whenever you add a wall with this tool, the wall has the style “CMU 8 Furring,” it cleans up automatically, and it has an offset of 1". For more information, see [Tools](#) on page 76.

Tool Palettes and the Content Browser

When multiple users are working on a large project, consistency of tools is especially important. Typically, the objects for the project and their styles and properties are set up by a CAD manager or system administrator, and then distributed to the team. The administrator can put tools and palettes in a central location in the Content Browser and link them to each user’s computer. Whenever the tools or palettes are updated in the Content Browser, they are updated on the users’ computers too. For more information, see [Understanding the Content Browser](#) on page 121 and [Working with Tools from a Central Location](#) on page 88.

Project Tool Palettes

When you are working with an AutoCAD Architecture project, you can design and associate a project tool palette group to the project. The project tool palettes contain the tools used in the project, and can be based on project standards. For detailed information about setting up project tool palettes, see [Setting up Standard Tools in a Project](#) on page 425.

Opening the Tool Palettes Set

Use this procedure to open the tool palettes set.

- Click Window menu ► Tool Palettes.

Alternatively, you can click  on the Navigation toolbar, or press **CTRL+3**.

Tool palettes set with tool palettes

Controlling the Appearance of the Tool Palettes Set

Typically, the tool palettes set remains open during the AutoCAD Architecture session. It is the central location from which you add objects to the drawing and start object-related commands. A number of user-definable display options let you optimally integrate the tool palettes with your workspace.

Docking the Tool Palettes Set

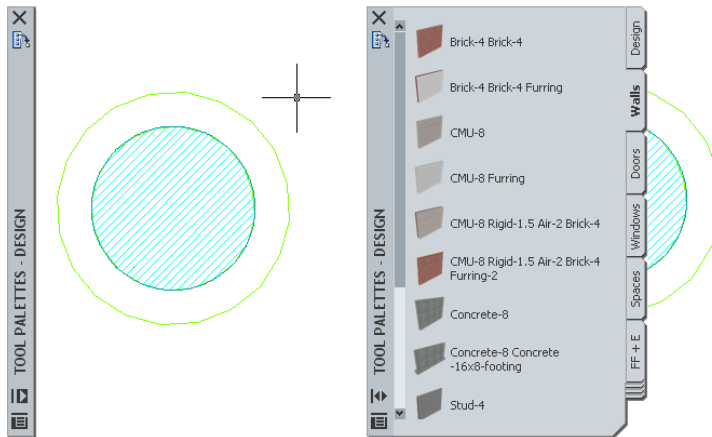

Use this procedure to dock the tool palettes set on the left or right side of your workspace.

- 1 In the title bar of the tool palettes set, click , and then click Allow Docking.
- 2 Position the cursor over the title bar, and drag the tool palettes set to one side of your workspace. A preview graphic shows the new position of the tool palettes set.
- 3 Release the tool palettes set when it is in the location you want.

Hiding the Tool Palettes Set

Use this procedure to hide the tool palettes set when it is not in use. The tool palettes set becomes hidden when you move the cursor away from it, leaving only the title bar visible. When you move the cursor over the title bar, the tool palettes set is re-displayed.

Tool palettes set hidden (left) and re-displayed (right)

- 1 In the title bar of the tool palettes set, click  (Auto-hide). The tool palettes set is hidden, except for the title bar.
- 2 To re-display the tool palettes set, move the cursor over the title bar.

Adjusting the Transparency of the Tool Palettes Set

Use this procedure to adjust the transparency of the tool palettes set. The more transparent the tool palettes set, the more easily you can see objects in your drawing underneath it.

NOTE Transparency is not available if hardware acceleration is enabled.

- 1 In the title bar of the tool palettes set, click , and then click Transparency.
- 2 To adjust the transparency of the tool palettes set, move the slider.
- 3 To turn off transparency, select Turn off window transparency.
- 4 Click OK.

Renaming the Tool Palettes Set

Use this procedure to rename the tool palettes set. You may want to name it with a project or company name.

- 1 In the title bar of the tool palettes set, click , and then click Rename Palette Set.
- 2 Enter a name for the tool palettes set, and press *ENTER*.

Specifying Different Tool Palettes for the Tool Palettes Set

Use this procedure to switch between different palette combinations in the tool palettes set.

Only one tool palettes set can be active during an AutoCAD Architecture session. You can, however, set different tool palettes for different user profiles. You do this by collecting tool palettes from several locations (paths) in a profile and letting the workspace combine them into one tool palettes set.

- 1 Click Format menu ► Options.
- 2 Define the tool palettes used for the current session:
 - If you have created a workspace profile containing a tool palettes path, click the Profiles tab, select the desired profile, and click Set Current.
 - If you have not created a workspace profile, click the Files tab, and click the Tool Palettes File Location entry. Then click Browse, and browse for a folder containing the desired tool palette.
Add paths to all additional tool palettes to be included in the tool palettes set of this profile.
- 3 Click OK.

Creating a New Tool Palettes Set

Use this procedure to create a new tool palettes set.

- 1 Create a folder in which you will create the new tool palettes set.
The default tool palettes set is in *\Documents and Settings\<Username>\Application Data\Autodesk\ACD-A 2009\enu\Support\WorkspaceCatalog (Imperial/Metric)*.
- 2 Click Format menu ► Options.
- 3 Click the Profiles tab.
- 4 Click Add to List, and create a profile to contain the new tool palettes set; for example, "Design - Metric Palette Set."
- 5 Select the new profile, and click Set Current.
- 6 Click the Files tab.
- 7 Under Tool Palettes File Locations, select the support path for the previously defined folder in which you will create the new tool palettes set.

NOTE If you point to a folder already containing a tool palettes set, a new tool palettes set is not created; instead, the existing tool palettes set is used in the profile.

8 Click OK.

In the AutoCAD Architecture workspace, an empty tool palettes set is displayed.

New tool palettes set

9 To rename the tool palettes set, click , and then click Rename Palette Set.

10 Add tool palettes and tools to the new set:

If you want to...

Then...

add a new empty tool palette

see [Creating a New Tool Palette](#) on page 71.

add a tool palette from the Content Browser

see [Adding a Tool Palette from a Tool Catalog in the Content Browser](#) on page 75.

add a tool to a palette

see [Creating a Tool from an Object in the Drawing](#) on page 82.

The changes you make are saved to the tool palettes set in the new profile you created.

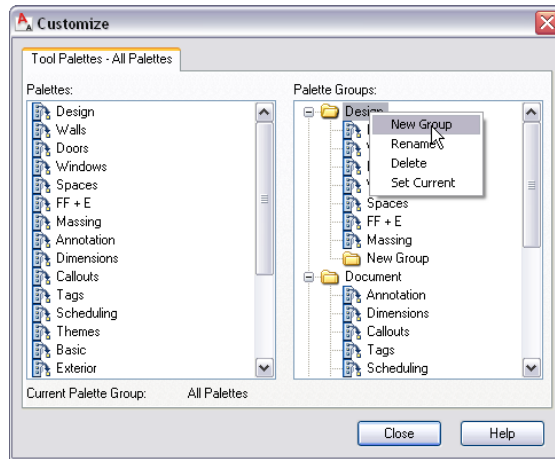

To revert back to your original tool palettes set, select your original profile in the Options dialog box.

Creating a New Tool Palettes Group

Use this procedure to create a new tool palettes group.

1 In the title bar of the tool palettes set, click , and then click Customize Palettes.

2 Select a palette group, right-click, and click New Group.

3 Enter a name for the new group, and press *ENTER*.

4 Drag the new group folder to the correct position in the tree structure.

5 Select a tool palette from the left pane for the new tool palettes group, and drag it into the new group folder.

6 Click Close.

TIP The Customize dialog can be very useful for adding palettes to project palette groups. For more information, see [Displaying the Project Tool Palette Group](#) on page 434.

Creating a New Tool Palette

Use this procedure to add an empty tool palette to your tool palettes set.

After creating the tool palette, you can add tools to it. For more information, see [Tools](#) on page 76.

1 In the title bar of the tool palettes set, click , and then click New Palette.

2 Enter a name for the new tool palette, and press *ENTER*.

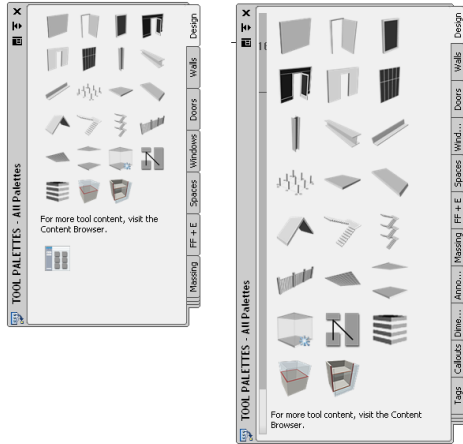

Defining the Appearance of Tool Palettes

Use this procedure to define the appearance of individual tool palettes.

The display of the tool palettes depends on the settings you specify for the overall tool palettes set, (as described in [Controlling the Appearance of the Tool Palettes Set](#) on page 68), and the settings you specify for individual tool palettes. In the tool palettes set, you specify the transparency, size, position, and auto-hide of the tool palettes set.

On the tool palette, you specify the size of tool images and their arrangement on the tool palette.

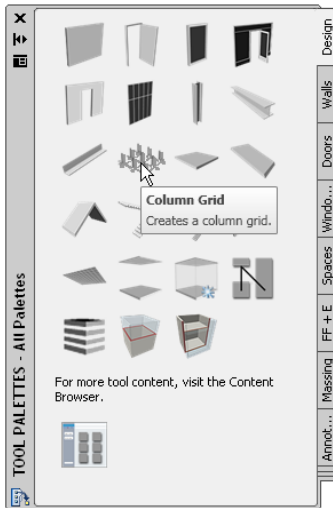

Tool palettes with different sized icons displayed

When you change tool images to a smaller size, you can display more tools on a tool palette. This might become important if you display different palettes at the same time, such as the Properties palette or the Project Navigator palette.

To save space, you can also display tool images without tool text below them. This method is best suited when the icons for your tools are easy to differentiate. If the icon alone proves insufficient to identify a tool, the tooltip for each icon provides additional guidance.

Icon-only display on the tool palette

You can also display tools in a single column on the tool palette. When you are using a single-column list, tool texts is always displayed.

Tool palette in list view

- 1 Open the tool palette that you want to change.
- 2 Right-click the palette, and click View Options.
- 3 In the View Options worksheet, select the desired View style:

If you want to...	Then...
view only tool icons	select Icon only for View style.
view tool icons and tool text	select Icon with text for View style.
view tool icons and tool text in a single column list	select List view for View style.

- 4 To apply these changes to all palettes in the tool palettes set, select All Palettes for Apply to.
- 5 Click OK.

Adding Text and Separator Lines to Tool Palettes

Use this procedure to add separator lines and text to a tool palette.

Separator lines can be useful if you want to create subdivisions on a tool palette containing many tools. To annotate a separator line, you can insert a text element.

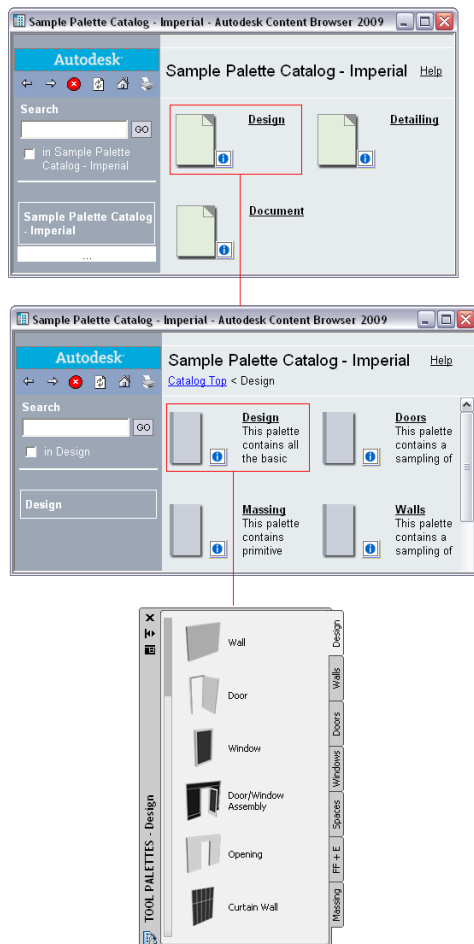

- 1 Open the tool palette to which you want to add separator lines and text.
- 2 Right-click in the palette between the tools where the separator should go, and click Add Separator.
A separator line is inserted between the tools.
- 3 To add text above the separator line, right-click either to the right of the last tool before the separator line, or to the left of the separator line itself, and click Add Text.
- 4 Enter the text you want to display above the separator line, and press *ENTER*.

- 5 To edit the text, select the text item, right-click, and click Rename. Then, edit the text as necessary.
- 6 To delete a separator line or a text annotation, select the separator line or text, right-click, and click Delete.

Working with Tool Palettes from a Central Location

When multiple users are working on a large project, consistency of tools is especially important. Typically, the objects for the project and their styles and properties are set up by a CAD manager or system administrator, and then distributed to the team. The administrator can put tools and palettes in a central location in the Content Browser and link them to each user's computer. Whenever the tools or palettes are updated in the Content Browser, they are updated on the users' computers too. For more information, see [Understanding the Content Browser](#) on page 121.

Using tool palettes from the Content Browser

TIP If you are working with an AutoCAD Architecture project, you can generate a tool catalog based on the standard styles of the project. For more information, see [Creating a Tool Catalog for a Project](#) on page 427.

Adding a Tool Palette from a Tool Catalog in the Content Browser

Use this procedure to link a tool palette from a tool catalog in the Content Browser to the tool palettes set in AutoCAD Architecture.

For information on creating tool palettes in the Content Browser, see [Adding Content to a Tool Catalog](#) on page 139.

- 1 Click Window menu ► Content Browser.

Alternatively, you can click  on the Navigation toolbar, or press *CTRL+4*.

- 2 Select the tool catalog containing the tool palette you want to copy, right-click, and click Properties.
- 3 Select Link items when added to workspace, and click OK.
- 4 Open the tool catalog, and navigate to the tool palette.
- 5 Move the pointer over the i-drop® icon next to the tool palette so that the pointer image changes

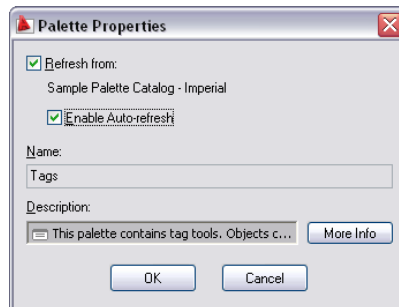

to an eyedropper ().

To copy multiple tool palettes, press and hold *CTRL* while clicking each palette; then position the eyedropper over any of the selected palettes.

- 6 Drag the palette to the tool palettes set in the AutoCAD Architecture workspace.

The tool palette is dropped into the tool palettes set.

- 7 Right-click on the palette, and click Properties.

The text below the check box displays the name of the catalog in the Content Browser from which the palette is updated.

If you click that name, it opens the catalog from which the tool palette was linked.

- 8 Select or clear Enable Auto-Refresh:

If you want to...	Then...
automatically update the linked tool palette from the Content Browser when starting AutoCAD Architecture	select Enable Auto-Refresh.
update the linked tool palette manually with one of the methods described in Updating a Tool Palette from a Tool Catalog in the Content Browser on page 76	clear Enable Auto-Refresh.

The name of the tool palette in the Content Browser (from which the selected tool palette is updated) is displayed under Name.

9 Click OK.

Updating a Tool Palette from a Tool Catalog in the Content Browser

Use this procedure to update a linked tool palette in the tool palettes set from its source tool catalog in the Content Browser.

1 Link a tool palette from a catalog in the Content Browser to the tool palettes set, as described in [Adding a Tool Palette from a Tool Catalog in the Content Browser](#) on page 75.

When a tool palette is linked to the tool palettes set from a catalog in the Content Browser, a Refresh button is displayed at the bottom of the palette.

2 Click the Refresh button to update your local tool palette with the latest changes from the catalog in the Content Browser.

Alternatively, you can right-click the palette, and click Refresh Palette.

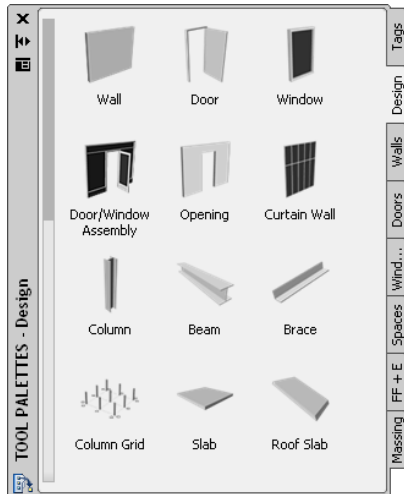

NOTE You can also update the whole palette set by clicking  in the tool palettes set, and then clicking Refresh Palette Set. This command updates all linked tool palettes in the tool palettes set.

Tools

Tools represent the individual objects you can add to a drawing. A tool contains creation parameters for the object it represents. When you add an object with a specific tool, the object has the settings you defined in the tool. This eases the design process and enhances consistency across a project.

For example, you might define a wall tool that contains the style “CMU 8 Furring” and has automatic cleanup and a baseline offset of 1”. Whenever you add a wall with this wall tool, the wall has the style “CMU 8 Furring,” it cleans up automatically, and it has an offset of 1”.

Standard object tools

Based on the tool type, some general properties you can define may include:

- Tool name
- Tool description (also used as the tooltip and as the tool description when the tool is copied to a tool catalog in the Content Browser)
- Description of objects inserted with this tool
- Layer key of objects inserted with this tool
- Layer overrides of objects inserted with this tool
- Object style
- Location of object style

In addition, you can define object-specific properties that apply to this tool type. For example, if you create a wall tool, you can set the wall cleanup, width, height, baseline settings, and the roof/floor lines of walls that are inserted with this tool.

Style Location

Object styles are now located in Styles drawings, rather than in templates as in earlier releases. To assign a style to an object tool, you can either point to a style in the current drawing or to a style in an external drawing. For more information, see [Styles and Support Files](#) on page 117.

Tool Types

Tools in AutoCAD Architecture fall into 3 categories.

Tool Category	Description
Object tools	An object tool inserts a design object—such as a wall or a window assembly—into a drawing. An object tool has a specific style and specific object properties: for example, a wall tool might have the style “Brick-4 Brick-4.”

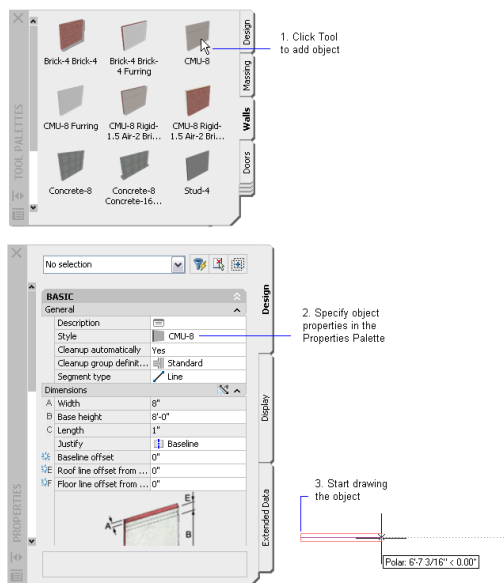

Tool Category	Description
Command tools	<p>Command tools are a graphical representation of an object-related command. For example, the Browse Property Data tool opens a dialog box for browsing the property data of all objects in a drawing; the Renumber Data tool rennumbers property data in selected property sets by increment or by a user-defined number. You can also create your own tools for each command. An AutoCAD general-purpose command tool lets you associate any command or macro. For commands that create an object, you can also assign basic AutoCAD object properties. For a list of available AutoCAD Architecture command tools, see Using Command Tools on page 84.</p>
AEC Content tools	<p>You can create tools for frequently used AEC Content items that were created with the AEC Content Wizard. For more information, see Creating a Tool from AEC Content in DesignCenter on page 83.</p>

Project Standard Tools

When you are working with an AutoCAD Architecture project, you can set up standard styles that are updated and synchronized throughout the project lifecycle. For more information, see [Setting up Standards in a Project](#) on page 415.

Creating an Object with a Tool

Use this procedure to create an object with a tool.

- 1 Click Window menu ► Tool Palettes.
- 2 Click the tool palette that contains the tool for the object you want to insert.

For example, if you want to insert a bifold double door, click the Doors palette, and navigate to the Bifold Double Door tool.

3 Click the tool.

4 On the Properties palette, enter any changes you want to make to the default.

NOTE Certain values can be set only when inserting the object; for example, the position of a door along the wall into which it is inserted can be defined only when inserting the door. You cannot change the position later for an existing door. Values that can be set only during insertion are marked

with this symbol  on the Properties palette.

5 Click in the drawing where you want to insert the object.

6 Follow any additional prompts as required to insert the objects in the drawing, and then press *ENTER*.

Changing the Tool Properties

Use this procedure to change the properties of a tool on a tool palette.

You can set these general properties for an object tool:

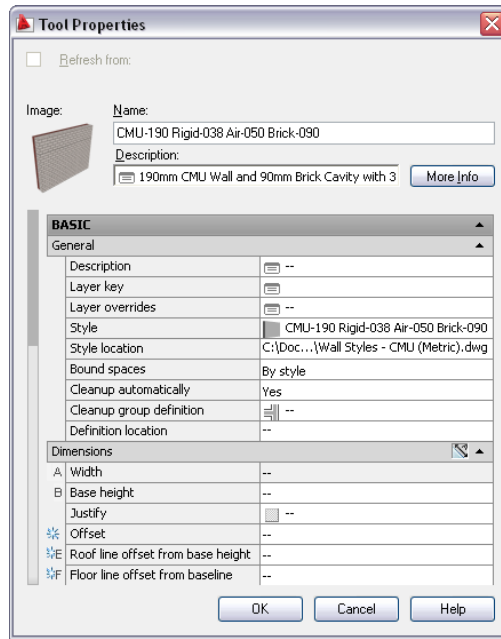

- Tool name
- Tool description (also used as the tooltip and as the tool description when the copied to a tool catalog in the Content Browser)
- Description of objects inserted with this tool
- Layer key of objects inserted with this tool
- Layer overrides of objects inserted with this tool
- Object style (if the tool is style-based)
- Location of object style (if the tool is style-based)

In addition, you can define object-specific properties that apply to this object type. For example, if you create a wall tool, you can set the wall cleanup, width, height, baseline settings, and the roof/floor lines for all walls inserted with this tool.

1 Click Window menu ► Tool Palettes.

2 Click a tool palette.

3 Select the tool, right-click, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 Expand Basic, and expand General.

7 Enter a description of the objects that you can create using this tool.

8 Specify a layer key and any layer key overrides; otherwise, the layer assignments specified in the layer key style in the drawing are used.

9 Click Browse for Style location, if the location is other than the current drawing to select an object style.

10 Add object-specific properties.

NOTE When you click a property to enter a value, the value underneath the current property is hidden and the property field is highlighted. Enter a value for the current property in the appropriate location.

11 Click OK.

Changing a Tool Icon

Use this procedure to change the icon of a tool.

A new tool is inserted with either the icon of the tool it was copied from or with a default icon. You can change the icon by selecting a new one from an image file or from an object in the drawing. You can also choose to display the icon as simple monochrome linework.

Changing the tool icon

You can use the following image formats for tool icons:

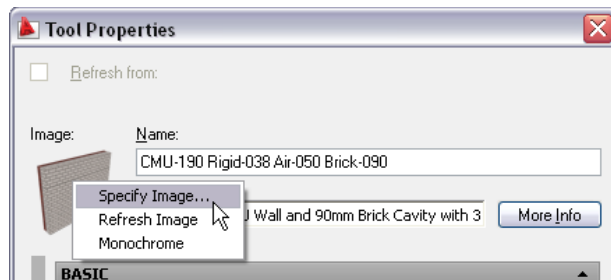

- PNG
- GIF
- JPG
- BMP
- TIFF

NOTE PNG is the recommended image format for tool icons.

Icons in the tool palettes can have a maximum size of 64 x 64 pixels. Larger images are scaled when inserted.

In the tool itself, you can only define the tool icon. To change the display size of the tool on the palette, see [Defining the Appearance of Tool Palettes](#) on page 71.

- 1 Click Window menu ► Tool Palettes.
- 2 Click the tool palette that contains the tool for which you want to select a new icon.
- 3 Select the tool, right-click, and click Properties.
- 4 On the Tool Properties worksheet, right-click the existing icon, and click Specify Image.

- 5 In the Select Image File dialog box, select the image you want to use as a tool icon, and click Open.
- 6 Click OK.
- 7 To display a tool as simple monochrome linework, on the Tool Properties worksheet, right-click the existing icon, and click Monochrome.

The monochrome option is not available for all tools.

To create an icon from an object in the drawing, select the tool in the tool palette, right-click, and Set Image from Selection. Then select the object in the drawing you want to use as a tool icon, and press *ENTER*.

The tool icon is created with the last-used view direction and display configuration set in the viewer of the properties of this tool type. For example, if the tool viewer of the last-used wall is set to Top view and the Medium Detail display configuration, any wall you select in the drawing as a tool icon is displayed in Top view and with the Medium Detail display configuration.

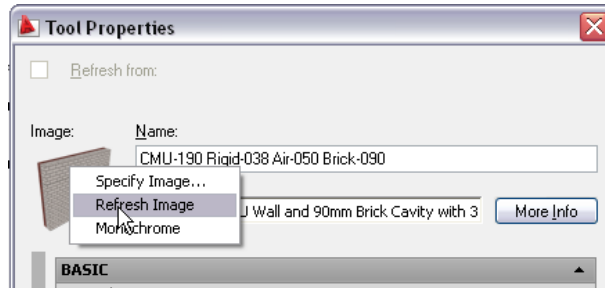

You cannot create icons from objects that contain custom blocks, curtain walls, or door/window assemblies with nested styles. If you need to create an icon based on a custom block, specify an external image.

Refreshing a Tool Icon

Use this procedure to refresh a tool icon after editing the viewer settings of the tool.

- 1 Click Window menu ► Tool Palettes.

- 2 Click the tool palette that contains the tool icon you want to refresh.
- 3 Select the tool, right-click, and click Properties.
- 4 On the Tool Properties worksheet, change the Viewer settings of the tool.
For example, switch from a SW Isometric view to a Top view.
- 5 Right-click the existing icon, and click Refresh Image.

- 6 Click OK.

Creating a Tool from an Object in the Drawing

Use this procedure to create a tool from an object in the drawing.

You can create only object tools with this method. For information on creating command tools, see [Using Command Tools](#) on page 84.

Creating a tool from an object in the drawing

- 1 Create an object with the appropriate style and properties in the drawing.

IMPORTANT The drawing containing the style should be saved to a location where it will be available in the future. Otherwise, the tool will not be able to access the style, and will revert to the Standard style.

- 2 Open the tool palette where you want to create the new tool.
- 3 Select the object, and drag it to the tool palette.
- 4 Define additional properties for the tool, if necessary.
For more information, see [Changing the Tool Properties](#) on page 79.

Copying a Tool from a Tool Palette

Use this procedure to copy a tool from one tool palette to another.

- 1 Open the tool palette that contains the tool you want to copy.

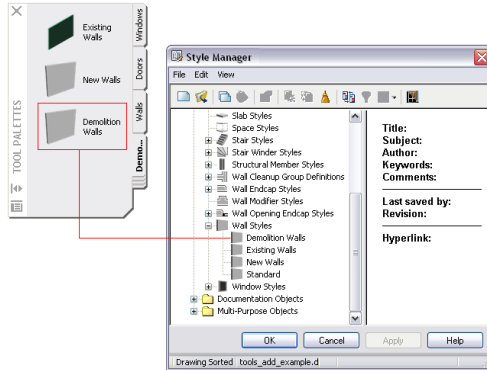

- 2 Select the tool, right-click, and click Copy.
- 3 Open the tool palette onto which you want to copy the tool, right-click, and click Paste.
- 4 Change the properties of the tool, if necessary.

For more information, see [Changing the Tool Properties](#) on page 79.

Creating a Tool from the Style Manager

Use this procedure to create a tool from a style in the Style Manager.

Creating a tool from the Style Manager

- 1 Open the tool palette where you want to create the new tool.
- 2 On the Format menu, click Style Manager, and navigate to the style you want to use.
For example, if you want to create a wall tool with the Demolition style, expand Wall Styles, and select the Demolition style.

- 3 Drag the style to the tool palette.

A new tool with the selected style is inserted in the tool palette.

- 4 Click OK to close the Style Manager.
- 5 Define additional properties for the tool in the tool palette, if necessary.

For more information, see [Changing the Tool Properties](#) on page 79.

Creating a Tool from AEC Content in DesignCenter

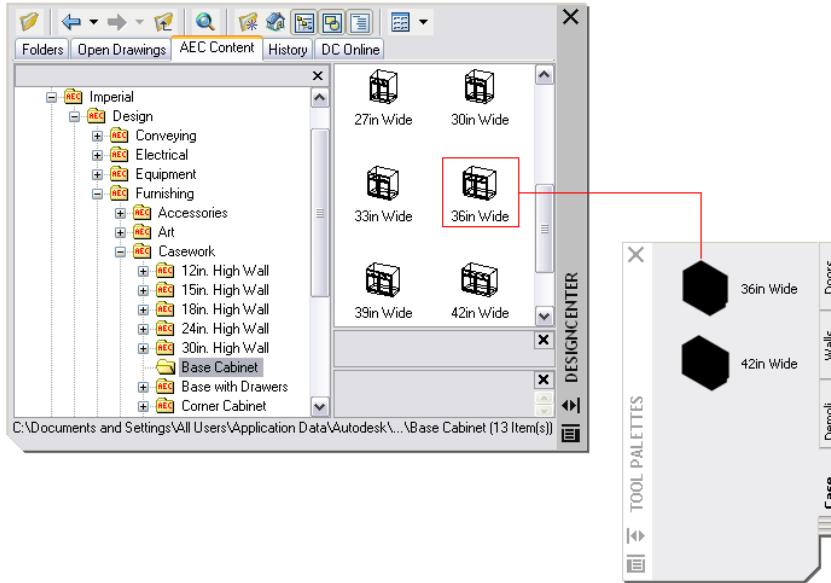

Use this procedure to create a tool on a tool palette from an AEC Content item in DesignCenter.

NOTE You can also create tools from blocks in DesignCenter, but they have slightly different tool options.

You can drag and drop AEC content items from a DesignCenter folder to a tool palette. For more information on creating AEC Content, see [Adding AEC Content to Drawings](#) on page 2602.

AutoCAD Architecture provides the Design Tool Catalog and the Documentation Tool Catalog in the Content Browser. These catalogs already have tools set up for predefined AEC Content and sample object styles. The catalogs are available for both metric and imperial units.

Creating a tool from AEC Content in DesignCenter

- 1 Open the tool palette where you want to create the new tool.
- 2 On the Insert menu, click DesignCenter, and navigate to the AEC Content item from which you want to create a tool.
- 3 Drag the item to the tool palette.

A new tool is inserted on the tool palette.

To change the icon of the new tool, see [Changing a Tool Icon](#) on page 80.

NOTE An AEC Content tool uses the last-used Viewer settings of this tool type to generate the tool icon. If the last-used Viewer setting is Gouraud 3D view, and the user creates a tool from a 2D AEC Content item, the tool icon will be invisible. In this case, you need to change the Viewer setting of the tool to a Top view, and wireframe.

- 4 Define additional properties for the tool, if necessary.
For more information, see [Changing the Tool Properties](#) on page 79.

Using Command Tools

A command tool is a utility that allows you to create a graphical representation of a frequently used command on a tool palette. For example, the Browse Property Data tool opens a dialog box for browsing the property data of all objects in a drawing; the Renumber Data tool renumbers property data in selected property sets. There are a number of preconfigured command tools in the software; you can, however create a user-defined command tool from any AutoCAD and AutoCAD Architecture command, AutoLISP routines, VBA macros and applications, and scripts.

Using Predefined Command Tools

AutoCAD Architecture provides the following predefined command tools for commonly used tasks in a default US install:

Tool	Palette Group/Palette	Description
Horizontal Section	Design/Design	Generates a horizontal section.
Vertical Section	Design/Design	Generates a vertical section.
Renumber Data	Document/Tag	Lets you renumber objects that are included in a schedule or linked to schedule tags.
Edit Property Set Data	Document/Scheduling	Lets you edit the property set data attached to selected objects and their styles.
Browse Property Set Data	Document/Scheduling	Lets you access and view the data for all property sets in a drawing.
Space Evaluation	Document/Scheduling	Starts the space evaluation.
AEC Entity Reference	Content Browser/Stock Tool Catalog/Helper Tools	Lets you create a reference copy from one object to another in AutoCAD Architecture.
Quick Slice	Content Browser/Stock Tool Catalog/Helper Tools	Lets you define a cross section through one or more three-dimensional (3D) objects in a drawing (including mass groups, AutoCAD blocks, and external references) and extract a polyline outline that can be used to produce a profile shape.
Hidden Line Projection	Content Browser/Stock Tool Catalog/Helper Tools	Lets you create flat 2D projections with hidden background lines from a 3D view of objects in your drawing.
Napkin Sketch	Content Browser/Stock Tool Catalog/Helper Tools	Lets you create freehand sketch geometry from objects in a drawing.
Chamfer	Content Browser/Stock Tool Catalog/Drafting Tools	Lets you chamfer two walls in a drawing.
Hatch and Gradient	Content Browser/Stock Tool Catalog/Drafting Tools	Lets you define the boundaries, pattern type, pattern properties, and other parameters for hatch and gradient fill objects.
Shrink Wrap	Content Browser/Stock Tool Catalog/Drafting Tools	Lets you create a profile or shrinkwrap outline around any collection of contiguous linework entities, including architectural objects.

Tool	Palette Group/Palette	Description
Welding Symbols	Content Browser/Stock Tool Catalog/Drafting Tools	Lets you create and edit welding symbols.
Area	Content Browser/Stock Tool Catalog/Measurement Tools	Lets you measure the area of an object or a user-defined space.
Attribute Extraction	Content Browser/Stock Tool Catalog/Measurement Tools	Lets you extract object data from drawings so that it can be exported to a table or external file.
Distance	Content Browser/Stock Tool Catalog/Measurement Tools	Lets you measure the distance between 2 user-selected points.
Point ID	Content Browser/Stock Tool Catalog/Measurement Tools	Lets you display the coordinates of a user-selected location.
Region/3D Solid Mass Properties	Content Browser/Stock Tool Catalog/Measurement Tools	Lets you calculate the mass properties of regions or 3D solids
Cell Anchor	Content Browser/Stock Tool Catalog/Parametric Layout & Anchoring Tools	Lets you attach objects to cell positions on layout grids and volume grids.
Curve Anchor	Content Browser/Stock Tool Catalog/Parametric Layout & Anchoring Tools	Lets you attach AEC objects to the base curve of other AEC objects or linework, such as lines, arcs, circles, mass elements, polylines, roofs, or walls.
Leader Anchor	Content Browser/Stock Tool Catalog/Parametric Layout & Anchoring Tools	Lets you anchor objects to nodes on layout curves or grids with leaders.
Node Anchor	Content Browser/Stock Tool Catalog/Parametric Layout & Anchoring Tools	Lets you attach objects to nodes on layout curves or grids.
Object Anchor	Content Browser/Stock Tool Catalog/Parametric Layout & Anchoring Tools	Lets you attach an AEC object to the base curve of another AEC object.

Using preconfigured command tools

- 1** Navigate to the location of the desired command tool in the tool palettes or in Content Browser.
- 2** If the command tool is located on a tool palette, click it to start the command sequence.
- 3** If the command is located in Content Browser, either drag it to the drawing area to directly start the command, or drag it to a tool palette, and start the command from there.

Using User-Defined Command Tools

AutoCAD Architecture has 2 blank command tools that can be customized for user-defined commands.

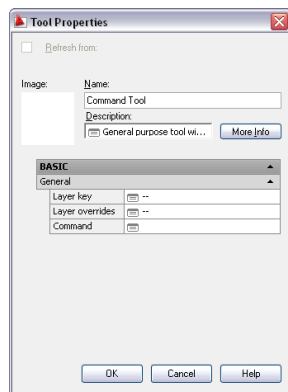

- **Command Tool:** A simple blank command tool that lets you execute a number of command sequences. Allowed commands include AutoCAD and AutoCAD Architecture commands, VBA macros and applications, AutoLISP routines, and scripts.
- **Command Tool with Properties:** Use this tool for commands that generate AutoCAD objects like lines, AutoCAD dimensions, or solids. The property settings for color, layer, linetype, and linewidth you can set in the tool will only be used when creating AutoCAD objects. If you were to create an AEC object with this tool, the layer, color, and linetype settings specified in the display system for this object take precedence. If you want to create AEC objects with a command tool, it is recommended that you use the simple Command Tool.

Command tools are created by copying the blank command tool from Content Browser to a tool palette, and editing the command properties.

Creating a Simple Command Tool

- 1 Open Content Browser and navigate to Stock Tool Catalog ► Helper Tools.
- 2 Move the cursor over the i-drop icon next to the regular command tool and drag the tool to a tool palette.
- 3 On the tool palette, select the command tool, right-click, and click Properties.

Command tool properties

- 4 Change the following tool properties as necessary:

Property	Description
Name	Lets you replace the generic command tool name with a name that describes the function of the tool.
Description	Lets you add a more detailed description to the command tool.
Layer key	Specifies the layer key to define the layer on which objects created with this command will be inserted.
Layer overrides	Defines overrides for the selected layer key.

Property	Description
Command	Specifies the command to be executed by the tool. The following command types are valid within the Command Tool: <ul style="list-style-type: none">■ AutoCAD and AutoCAD Architecture commands■ AutoLISP routines■ VBA macros and applications■ Scripts
Image	By default, the command tool has no associated image. To add an image that illustrates the function of the tool, right-click in the empty image area, and select an image as described in Changing a Tool Icon on page 80.

5 Click OK.

Working with Tools from a Central Location

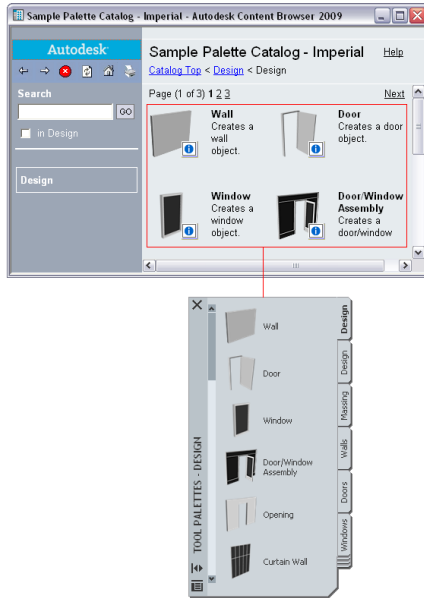

You can use the Content Browser to store and organize catalog tools in a central location. A number of stock tools are available in the AutoCAD Architecture Stock Tool Catalog. Additionally, sample catalogs contain tools with styles from the Styles drawings. You can copy these tools to a tool palette and modify them. You can also create your own tool palettes and tools in a catalog in the Content Browser, copy them to a tool palette, and retain the link from the Content Browser to the tool palette. In this case, the tool is refreshed on the tool palette when it is modified in the catalog in the Content Browser.

NOTE If you want to link a complete tool palette from the Content Browser to AutoCAD Architecture, see [Adding a Tool Palette from a Tool Catalog in the Content Browser](#) on page 75.

Linking a Tool from a Catalog in the Content Browser

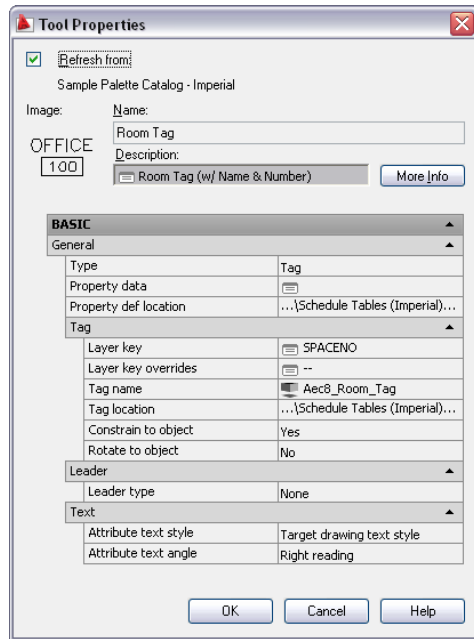

Use this procedure to link a tool from a catalog in the Content Browser to a tool palette in AutoCAD Architecture.

Linking a tool from a catalog in the Content Browser

- 1 Open the tool palette on which you want to place a tool from the Content Browser.
- 2 On the Window menu, click Content Browser, and navigate to the tool palette or category in the tool catalog that contains the tool you want to copy.
For more information, see [Searching for Items in a Tool Catalog](#) on page 138.
- 3 Move the pointer over the i-drop icon next to the tool, so that the pointer image changes to an eyedropper ().
To copy multiple tools, press and hold *CTRL* while clicking each tool; then position the eyedropper over any of the selected tools. You can also select all the tools in the current category by right-clicking, and clicking Select All.
- 4 Drag the eyedropper to a tool palette in the tool palettes set.
- 5 To refresh the tool, select it, right-click, and click Refresh Tool.
Alternatively, you can select the tool in the tool palette, right-click, and click Properties. Then select Refresh from on the Properties worksheet.

Updating a tool from the Properties worksheet

NOTE When you select Refresh from, all tool properties on the worksheet are set to read-only. Properties for this tool must be changed in the Content Browser.

6 Click OK.

Updating a Tool in AutoCAD Architecture from the Content Browser

Use this procedure to update a tool in a tool palette that has a link to the Content Browser.

NOTE You cannot change and update tools from the Stock Tool Catalog in the Content Browser. Those tools are read-only.

- 1 Open the tool palette that contains the tool you want to update.
- 2 Select the tool, right-click, and click Refresh Tool.

Updating a Tool in the Content Browser from a Linked Tool in AutoCAD Architecture

Use this procedure to update a tool in a catalog in the Content Browser with the properties of a linked tool from AutoCAD Architecture.

For example, perhaps you have a tool in the Content Browser that adds a Box mass element of 3 x 3 x 3 meters. You want to change the tool so that it adds a Box mass element of 4 x 4 x 4 meters. You would first link the mass element tool from the Content Browser to a tool palette in AutoCAD Architecture. Then, temporarily deactivate the link and change the dimension properties of the tool to 4 x 4 x 4 meters. Next, copy the tool back to the Content Browser. The Content Browser catalog is updated with the new tool properties. Finally, reactivate the link from the Content Browser tool to the AutoCAD Architecture palette.

- 1 Link a tool from a catalog in the Content Browser to a tool palette as described in [Linking a Tool from a Catalog in the Content Browser](#) on page 88.
- 2 Select the tool in the tool palette, right-click, and click Properties.
- 3 On the Tool Properties worksheet, clear Refresh from.
The tool properties can now be edited.
- 4 Make the necessary changes to the tool properties.
- 5 Click OK.
- 6 Select the tool in the tool palette, and copy it to its original location in the Content Browser catalog.

NOTE You can copy a tool to a catalog in the Content Browser using the Copy and Paste commands from the context menu, or by dragging the tool onto the Content Browser icon in the Windows task bar. To select multiple tools in a tool palette, use CTRL-A to select all or drag while holding the CTRL key to create a selection window.

- 7 Click Yes when prompted to overwrite the previous version of the tool.
- 8 If you want to refresh the tool in the AutoCAD Architecture tool palette from the new version stored in the Content Browser, go back to the AutoCAD Architecture tool, right-click, and on the Tool Properties worksheet, reactivate Refresh from.

Removing the Link of a Tool to a Catalog in the Content Browser

Use this procedure to permanently remove the link of a tool to its source tool in the Content Browser.

NOTE This action cannot be undone.

- 1 Open the tool palette that contains the tool you want to unlink from a catalog in the Content Browser.
- 2 Select the tool, right-click, and click Remove Catalog Link.

Applying the Properties of a Tool to an Existing Object

Use this procedure to apply the properties of a tool to an existing object.

You can apply the properties of a tool to an existing object in two ways:

- Apply the properties of a tool to an object of the same type: For example, apply the properties of a wall tool to an existing wall. All object tools have this functionality. In earlier releases of the software, you used the Match command to do this.
- Apply the properties of a tool to a different object type: Using this method, you convert the object to an object of the same type as the tool. For example, when you apply the properties of a wall tool to a polyline, the polyline is converted to a wall with the settings defined in the wall tool. Depending on their type, various object tool types may have commands for converting other objects. For detailed information, see the chapters for the individual objects.

- 1 Open the tool palette that contains the tool with the properties you want to apply to a different object.
- 2 Select the tool, and right-click.

3 Define the object type to which to apply the tool properties:

if you want to...	Then...
apply the properties of the tool to an object of the same type	click Apply Tool Properties to <Object>. For example, to apply the tool properties of a door tool to an existing door, click Apply Tool Properties to Door.
apply the properties of the tool to an object of a different type	click Apply Tool Properties to ► <Object>. For example, to apply the tool properties of a door tool to an opening, click Apply Tool Properties to ► Door/Window Assembly, Opening, Window.

4 Select the object to which to apply the tool properties, and press *ENTER*.

Re-Importing Styles for a Tool

Use this procedure to re-import the style of a tool that uses a style from an external Styles drawing.

When you create a tool, you can assign a style from the current drawing or from an external Styles drawing. Usually you assign a style from an external Styles drawing because you can then use that the tool in other drawings as well.

When the style in the external Styles drawing is changed, you need to update the tool to reflect these changes.

NOTE When you update the style of a tool, all existing objects inserted with this tool are also updated.

- 1 Open the tool palette that contains the tool for which you want to update the style.
- 2 Select the tool, right-click, and click Import <Style Name> <Object Name> Style.
For example, if you want to update the Brick-4 Furring-4 style of a wall tool, click Import 'Brick-4 Furring-4' Wall Style.

Deleting a Tool

Use this procedure to delete a tool from a tool palette.

When you delete a tool from a tool palette, objects in the drawing that were inserted with this tool are not deleted.

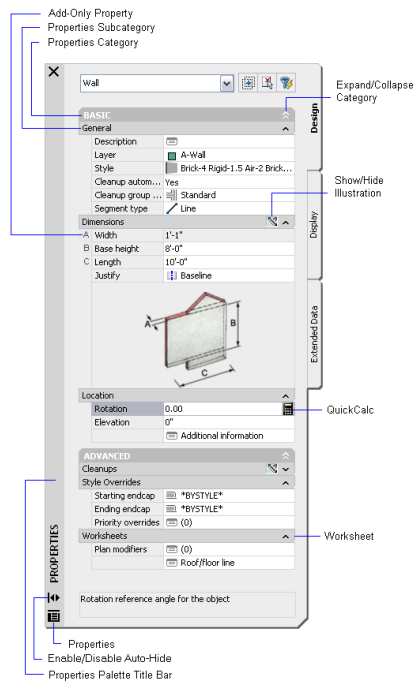

NOTE If you linked a tool palette from the Content Browser to the tool palettes set as described in [Adding a Tool Palette from a Tool Catalog in the Content Browser](#) on page 75, you cannot delete individual tools from it. To delete the tool, delete it from the palette in the Content Browser, and then update the palette in AutoCAD Architecture as described in [Updating a Tool Palette from a Tool Catalog in the Content Browser](#) on page 76.

- 1 Open the tool palette that contains the tool you want to delete.
- 2 Select the tool, right-click, and click Delete Tool.

The Properties Palette

The Properties palette provides a central location to view and modify both the physical and graphical properties of an object you are about to draw, or of objects that are selected in the drawing area. Using the

Extended Data tab of the Properties palette, you can also attach other kinds of information to an object, such as classifications, notes, reference documents, hyperlinks, and property set data. You typically keep the Properties palette open during an AutoCAD Architecture session.

Opening the Properties Palette

Use any of the following methods to open the Properties palette:

- Click Window menu ► Properties Palette.
- On the Navigation toolbar, click  .
- Press **CTRL+1**.
- Select an object in the drawing, right-click, and click Properties.
- Double-click an object in the drawing.
- Select a tool from a tool palette.

Setting the Appearance of the Properties Palette

The Properties palette is usually kept open during an AutoCAD Architecture session, because it is the central location from which you add and change properties of an object.

Docking the Properties Palette

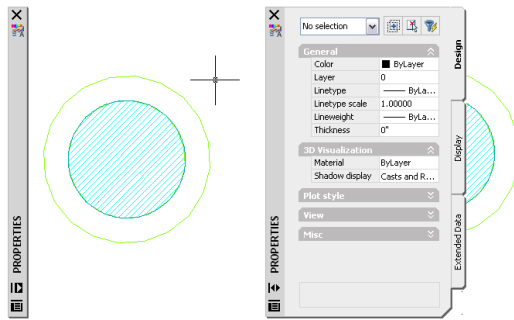

Use this procedure to dock the Properties palette on the left or right side of your workspace.

- 1 In the title bar of the Properties palette, click , and then click Allow Docking.
- 2 Position the cursor over the title bar, and drag the Properties palette to one side of your workspace.
A preview graphic shows the new position of the Properties palette.
- 3 Release the Properties palette at the correct location.

Hiding the Properties Palette

Use this procedure to hide the Properties palette when it is not in use. The Properties palette can be configured to hide when you move the cursor away from it, leaving only the title bar visible. When you move the cursor over the title bar, the Properties palette is re-displayed.

Properties palette hidden (left) and re-displayed (right)

- 1 In the title bar of the Properties palette, click  (Auto-hide).
The Properties palette is hidden, except for the title bar.
- 2 To re-display the Properties palette, move the cursor over the title bar.

Adjusting the Transparency of the Properties Palette

Use this procedure to adjust the transparency of the Properties palette. The more transparent the Properties palette, the better you can see objects in your drawing underneath it.

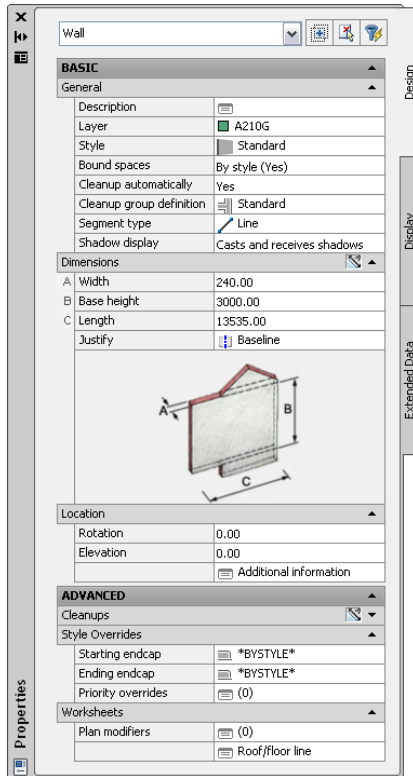

NOTE Transparency is not available if hardware acceleration is enabled.

- 1 In the title bar of the Properties palette, click , and then click Transparency.
- 2 To adjust the transparency of the Properties palette, drag the slider towards Less or More.
- 3 To turn off transparency, select Turn off window transparency.
- 4 Click OK.

The Design Tab

Most properties of an object are entered on the Design tab of the Properties palette.

Design tab of a wall

Based on the object, some general object properties you can enter may include:

- Description of the object
- Layer key of the object
- Layer overrides of the object
- Object style
- Location of object style

These properties are defined by the properties set in the tool used to create the object. You can change these properties for an individual object instance. For more information, see [Changing the Tool Properties](#) on page 79.

On the Design tab, you also enter object-specific design properties. The properties that are available depend on the object you are editing.

- **Dimensions:** Most objects in AutoCAD Architecture have dimension settings for width, height, and other basic features. Many objects have additional settings and the option to use AutoCAD QuickCalc. A wall, for example, has additional length and baseline justification settings, and you can use QuickCalc to calculate and apply a new rotation. For more information, see “Use the QuickCalc Calculator” in AutoCAD Help.
- **Location:** Most objects in AutoCAD Architecture have settings for the object location. Anchored objects like windows and doors also have Anchor properties.

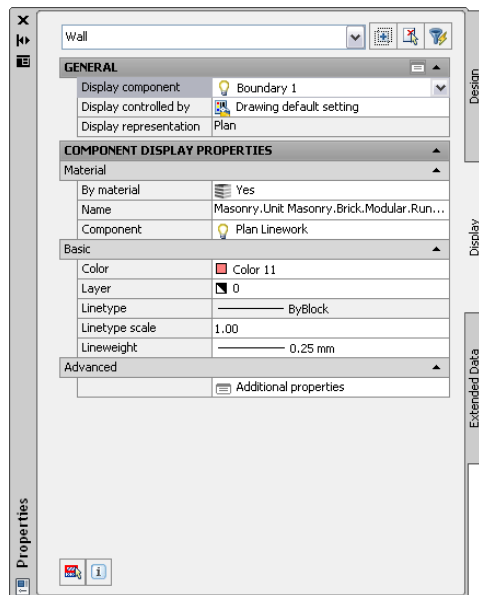

For detailed information about entering properties for a specific object, see the individual object sections.

The Display Tab

Just as the Design tab of the Properties palette lets you control the physical properties of an object, the Display tab lets you control the graphical properties of an object by adjusting the settings for its individual display components, such as boundaries and hatches. The changes you make on this tab are immediately visible in the display representation currently in effect, such as Plan or Model, and you have the option of applying your changes to other display representations as well. Also, while Design tab settings apply only to the currently selected object(s), you can specify whether a change you make to a Display tab property will apply to the selected component for all objects of that type, all objects of that style, or only the selected object. If the display component is controlled by material, your changes will apply to any object that uses that material. For detailed information on how to set up and manage the display of objects in AutoCAD Architecture, see [Display System](#) on page 537.

NOTE To hide the Display Tab (or show it if it is currently hidden), enter the following command on the command line: `AecChangeDisplayTabStatus`.

Display properties on the Display tab

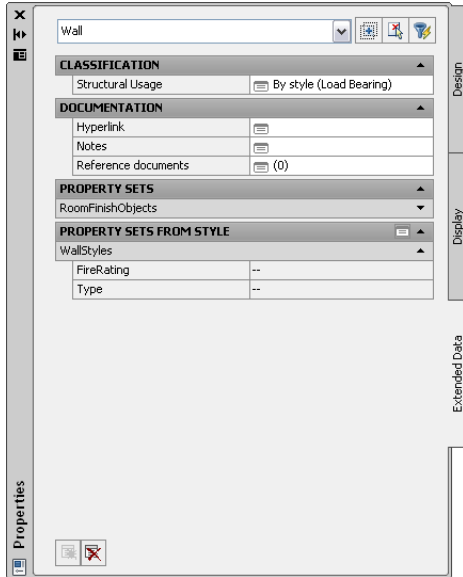

The Extended Data Tab

The Extended Data tab of the Properties palette contains the following object properties:

- **Hyperlink:** You can add a hyperlink to an object. For more information, see “Add Hyperlinks to a Drawing” in AutoCAD Help.
- **Text Notes and Reference Files:** You can add a note or an associated reference file to an object.
- **Property Sets:** You can add, edit, and remove property set data for an object. For more information, see [Attaching Property Set Data to Objects](#) on page 2534.
- **Property Sets From Style:** You can add, edit, and remove property set data for the object style. For more information, see [Property Set Data](#) on page 2534.
- **Detail Component Data:** You can add, edit, and remove detail component data for an object. For more information, see [Editing Detail Components in a Drawing](#) on page 2347.

Property set data on the Extended Data tab

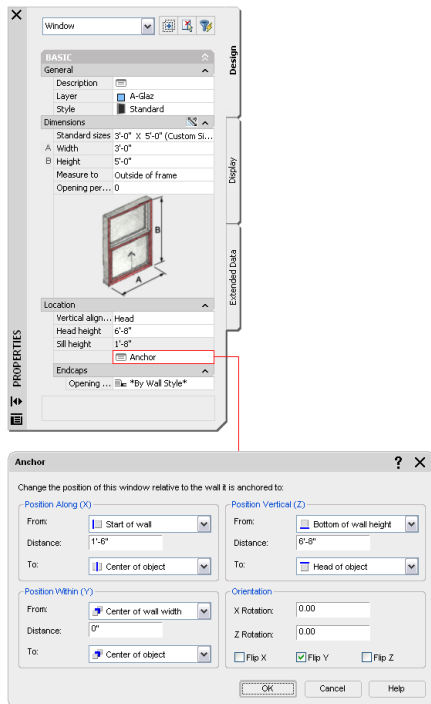

Worksheets

The properties of an object are entered and changed on the Properties palette. Most properties are directly entered and immediately updated on screen. Some objects have complex properties that are entered on worksheets accessed from the Properties palette.

Worksheets are designed to focus on a particular object-specific task. They appear only when they are launched from a palette or from an object. They cannot be accessed from the pull-down menus, as they always refer to a specific object or object tool.

Opening the Anchor worksheet

A worksheet is a modal dialog that must be closed before continuing to work in the drawing.

Direct Editing with Grips and Dynamic Dimensions

You can make design changes in the workspace without using dialog boxes. With a single click, you can perform design changes such as adjusting door width and window height, modifying a wall roofline, or reversing the wall direction. For some grips, the CTRL key gives you additional manipulation options. These are indicated in the grip tips. For example, the “Width” grip of a wall can maintain either the wall baseline or the opposite face of the wall when dragging. To switch between these two options, you use the CTRL key. As you make design changes, dynamic dimensions appear, ensuring that your changes are precise and accurate.

Window dimension grips in Plan view and Model view

Different grips are available, depending on the object type. For example, a wall and a freestanding railing have a direction (arrow) grip to change the direction of the object. A railing that is attached to a stair or a structural member does not have a direction grip.

Objects can also have different grips depending on the current view. For example, a structural beam has an additional “Roll” grip in Model views that is not visible in Plan views. Because rolling a beam is a 3D operation that you can perform only in an isometric view, it makes no sense to display the Roll grip in Plan views. Similarly, roof and floor line grips are useful only in a 3D view; therefore, they are displayed only in Model views.

Curtain wall grips in Plan view and Model view

For detailed information about the grips for AutoCAD Architecture objects, refer to the illustrations and descriptions in the grip-editing sections of the individual object sections.

Grip Tips

For a quick description of the function of a specific grip, you can hover your pointing device over the grip to display its grip tip. Each grip has its name displayed in the grip tip, for example, “Flip” or “Lengthen.” In some cases, the grip tip contains additional information about the grip’s function.

Viewing the door Flip grip

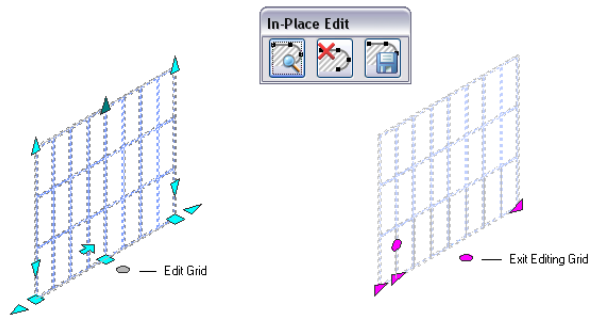

Grip Color

The color of a grip specifies whether the grip modifies a selected object or other objects in a drawing. Typically, a grip is used to change a property of a selected object. However, some grips might change the properties of all other objects in a drawing with the same style as the selected object. Other grips do not change the selected object at all, but are used to change the grip-editing mode of the object.

Grip Type and Default Color	Function
Object (Cyan)	changes a property of a selected object
Style (Magenta)	changes a property of a selected object and all other objects with the same style in the current drawing

Grip Type and Default Color	Function
Auxiliary (Gray)	does not change any property of any object

Different grip types display in different colors in an in-place editing session

You can change the color of these grips on the AEC Editor tab in the Options. For more information, see [Changing the AEC Editor Settings](#) on page 166.

Using the CTRL Key with Grips

Some object grips have multiple functions. For example, a face grip on a free form mass element has these possible grip modes:

- Move ortho
- Move
- Move plane
- Pull ortho
- Pull
- Push ortho

When a grip has multiple modes, this information is displayed in the grip tip. To switch between the different grip modes, use the *CTRL* key.

- 1 Select the object with the grip.
- 2 Hover your pointing device over the grip, to see what grip modes are available.
The first mode listed is the mode that will be started when you select the grip without using the *CTRL* key.
- 3 Select the grip.
- 4 Press *CTRL* to toggle to the next editing mode.

NOTE You need to press the *CTRL* key only once, and then release it. This toggles the grip to the next editing mode. After releasing the *CTRL* key, you can start editing the grip. Do not keep pressing *CTRL* while editing the grip.

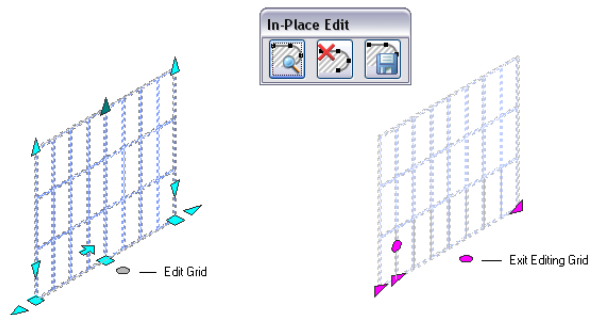

Trigger Grips

Trigger grips are a special type of grip. A trigger grip immediately performs an action on an object when you select it, as opposed to a normal drag grip, which changes a dimension property only when you drag it. You can use trigger grips to set discrete properties of an object, such as the swing direction of a door or the justification of a wall. You can also use trigger grips to change the grip-edit mode of an object. For example, selecting the Edit Grid grip in a curtain wall initiates an in-place editing mode for the curtain wall grid. Selecting the Edit In Place grip in an AEC dimension activates additional grips for the individual dimension chains, text strings, and extension lines. A trigger grip typically displays with a circle or an arrow.

AEC dimension before and after activating Trigger grip

In some cases, such as with the AEC Dimension trigger grip, the grip-edit mode is exited when the object is no longer selected. In other cases, you must click the trigger grip again to exit the grip-edit mode.

Dynamic Dimensions

When you use grips to change the dimension or angle of an object, temporary dimension objects show you the changes you are making. Use Dynamic Input to enter a precise value instead of moving a grip. This is active by default, and selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. Click DYN on the application status bar to toggle this off. For more information, see "Use Dynamic Input" in AutoCAD Help.

Using dynamic dimensions to change window width

These dynamic dimensions give you instant feedback about your changes. You can also use the dynamic dimensions to enter new dimension values directly on screen.

Three types of dynamic dimensions display on grips:

- Focal dimensions, which display highlighted in a white rectangular box. If you type a value while a dynamic dimension is focused, the edit box is displayed at the dimension text location.
- Editable dimensions, which display based on the drafting settings you specify. If you press *TAB* while a dynamic dimension is focused, the dimension focus shifts forward to the next editable dimension. You can continue pressing *TAB* to cycle forward through all editable dimensions, or press *SHIFT+TAB* to cycle backward through all editable dimensions.
- Non-editable dimensions, which display in black text. These dimensions typically display the current value of a property that you can modify with a grip.

You can apply different settings, such as the color of the dynamic dimension text box, on the Dynamic Input tab in the Drafting Settings dialog box. For more information, see “Use Dynamic Input” in AutoCAD Help.

You can select the color of grips and the dynamic dimension linetype on the AEC Editor tab in Options. For more information, see [Changing the AEC Editor Settings](#) on page 166.

NOTE When a dimension edit box is displayed, pressing *ENTER* sets the value of the property that you are editing and ends the grip operation. Pressing *TAB* sets the value, changes the focused dimension, and continues the same grip-editing operation.

NOTE When one or more editable dimensions are displayed, you can always press *TAB* to a state where no dimension has focus, during which you can use normal entry on the command line. You can always reach this non-focused state by pressing *SHIFT+TAB* immediately after selecting a grip.

- 1 Select the grip representing the dimension you want to change.
For example, to change the length of a curtain wall, select one of its Lengthen grips.
- 2 Enter the new value on screen.

Grip Constraints

When you select and drag a grip, its final position might not be the same as the current cursor position, which might be constrained. For example, for the Lengthen grip on a linear wall, the cursor position is projected to the nearest point on the wall. Whenever the constrained position of a grip differs from the current cursor position, dotted lines or arcs are drawn from the cursor to the grip to indicate how the grip was constrained.

A square-shaped grip typically indicates that the cursor movement is constrained to a plane. An isosceles triangle-shaped grip indicates that the cursor movement is constrained to a line or curve.

Temporary Grip Coordinate Systems

When you drag a grip, the current cursor position is typically projected to the XY plane of the current User Coordinate System (UCS). Some grip-editing operations are not possible in the current coordinate system. For example, if the current UCS is in plan, you cannot change the height of a wall while in an isometric view. For this reason, some grips have their own coordinate system that is temporarily set while the grip is active. Once the grip-editing operation is complete, the UCS is set back to its previous state. To identify whether a grip is setting a temporary coordinate system, set UCSICON to on, and display the icon at the origin.

In-Place Editing

In-place editing is a special editing mode for making on-screen changes to components of an object. For example, you can edit wall endcaps, wall or curtain wall roof lines, profile-based railing posts, or extruded mass element outlines. While in-place editing mode is active, all other commands and objects in the drawing are “frozen.” To access the commands and objects again, exit the in-place editing mode.

When you enter an in-place editing session, a temporary in-place edit profile is drawn around the object being edited. After making changes, you exit the in-place edit session, and save the changes. You may also discard changes upon exiting the in-place session, and the object reverts to the state it was in before the in-place editing session began.

In-place edit profile of extruded mass element

The in-place edit profile is displayed in a different color and hatching from the object it outlines. You can change the display of the in-place edit profile by changing its colors, lineweights, and hatching.

Sometimes, multiple in-place editing entities are created in a single session. This is the case for walls that have multiple sweeps or modifiers, or for roof slabs and slabs that have both a fascia and a soffit profile.

The in-place editing mode is invoked from the context menu of an object.

Invoking in-place editing from the context menu of a wall

To access the context menu, select the object, and right-click. Then select the appropriate in-place editing command. When you enter the in-place editing mode, a special toolbar helps you to zoom to the active in-place profile, to save changes to the component, or to discard all changes. When you exit the in-place editing mode, the toolbar is closed.

In-Place Editing of Polyline-Based Components

The following objects in AutoCAD Architecture can have custom components based on polylines attached to them:

- Wall endcaps
- Wall/curtain wall roof and floor lines
- Wall plan modifiers

Once you assign a polyline-based component to an object—for example, a wall endcap to a wall—you can edit it on screen with in-place editing. During an in-place editing session, the selected polyline is isolated for editing so that you can perform changes on its shape, such as grip-editing or adding and removing vertex points. Before you exit the in-place edit session, you can save the changes to the existing style, save to a new style, or discard the changes.

Endcap polyline highlighted for in-place editing

multi-wall
component

in-place
edit session

You can use in-place editing to modify the polyline-based components of a wall either in two-dimensional (2D) plan views or in three-dimensional (3D) model views.

When you edit a component in a 3D view, the UCS is aligned to the component, so that you can easily add or remove vertices and grip-edit the component.

The editing commands available for polyline-based components are listed on the context menu of the in-place editing profile. To access the context menu, select the in-place editing profile, and right-click.

The commands for editing polyline-based objects vary, depending on the object type. For example, a wall endcap in-place edit profile has commands for adding and removing vertices and hiding and replacing endcap components; the in-place edit profile of a wall roof/floor line has commands for adding gables and steps and projecting the roof and floor lines to a polyline. For more information, see the sections on the individual objects.

In-place editing: Adding a vertex to a wall endcap

select endcap component

add vertex

save changes

In-Place Editing of Profile-Based Objects and Components

You can use in-place editing for profile-based objects and object components. You can change the shape of the profile, add and remove rings and, for some profiles, move the insertion point.

The following objects are profile based or can have profile-based components to edit with in-place editing:

- Mass elements (extrusions)
- Mask blocks
- Wall sweeps
- Fascia and soffits of roof slabs and slabs
- Frames and mullions of curtain walls, curtain wall units, and window assemblies
- Custom (profile-based) shapes of doors, openings, windows, and window assemblies
- Custom (profile-based) shapes of rails and posts in railings

In-place edit profile on extruded mass elements

NOTE In-place editing for the objects in the previous list is available only if one or more components of the object are based on profiles. For example, if you have a railing for which no rails or posts are based on profiles, the in-place editing command is not available. However, if one or more railing components are based on a profile definition, you can select the appropriate in-place editing command from the context menu of the object.

Profile-based baluster in a railing

Context menu of railing component in-place edit profile

The following commands are available to edit a profile-based object component:

Command	Description
Add Vertex	adds a vertex to the selected profile
Remove Vertex	removes a vertex from the selected profile

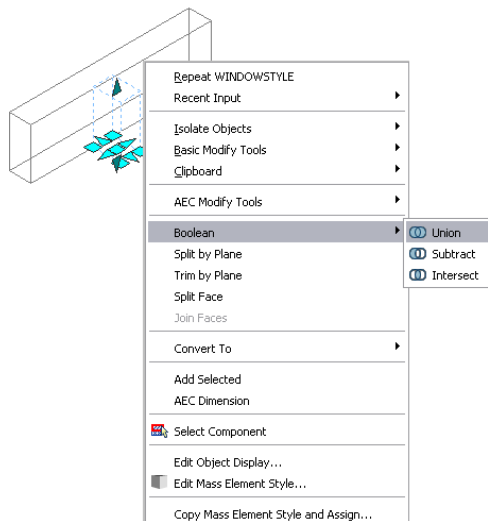

Command	Description
Add Ring	adds a closed polyline, circle, ellipse, or spline to the selected profile; you have the option to add the ring to the profile or to subtract it
Replace Ring	replaces the selected profile with a closed polyline, circle, ellipse, or spline
Save Changes	saves the changed geometry back to the profile
Save as New Profile	saves the changed geometry to a new profile definition
Discard All Changes	discards all changes to the geometry of the profile and reverts to the profile shape before the in-place edit session
Edit Object Display	changes the display of the in-place edit profile; you can change the display of the profile boundary, the profile hatch and—for polyline-based profiles—the display of the modifiable and hidden edges

For detailed information, see the sections for the individual objects.

In-Place Editing of 3D Body Modifiers

You can use in-place editing to edit a 3D body modifier on a wall. You can change the shape of the body and perform Boolean operations on the 3D body modifier.

Context menu of 3D body modifier in in-place edit mode

The following commands are available to edit a 3D body modifier:

Command	Description
Boolean ► Union	joins the body modifier with a selected 3D object
Boolean ► Subtract	subtracts a selected 3D object from the 3D body modifier
Boolean ► Intersect	creates an intersection object of the 3D body modifier and a selected object
Split Face	Splits a face of the selected 3D body modifier
Join Faces	Joins two previously split faces of a 3D body modifier
Save Changes	saves the changed geometry back to the 3D body modifier
Discard All Changes	discards all changes to the geometry of the 3D body modifier and reverts to the body shape before the in-place edit session
Edit Object Display	changes the display of the in-place edit profile

In-Place Editing of Material Hatches

You can make changes to the surface hatch of an object with an in-place edit profile, provided the surface hatch is coming from a material. Unlike the other in-place edit types, you do not change the shape of the object but only the display of the hatch on a specific object face.

In-place edit profile on a hatched wall

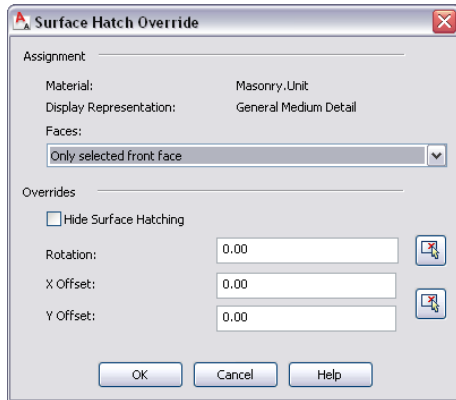

When you use the in-place edit profile to change the appearance of a surface hatch on an object face, you create a hatch override.

You can perform the following changes to a material hatch with in-place editing:

- Display/hide the surface hatch
- Change the rotation of the hatch pattern
- Change the vertical and horizontal offsets of the hatch pattern

You can apply these overrides to all corresponding object faces with the same material or to only the selected object face.

In-place editing a surface hatch

For more information, see [Working with Surface Hatches](#) on page 615.

0 degrees

45 degrees

90 degrees

Aligning the UCS to an Object Face

Use this procedure to align the currently active UCS to the face of an object.

You can align the UCS to the face of an AEC object or to the face of an AutoCAD solid. For detailed information about the UCS, see "Use Coordinates and Coordinate Systems" in AutoCAD Help. For more information about working with objects in a temporary section, elevation or plan view with the UCS correctly aligned, see [Isolating Objects](#) on page 112.

Aligning the UCS to a pyramid face

1 Click View menu ► New UCS ► Face.

Alternatively, you can click  on the UCS toolbar.

2 Select an object face to align to the UCS.

You can select the face of an AEC object or an AutoCAD solid here. When you hover your pointing device over a face, it is highlighted with a temporary hatch.

3 Select the UCS origin point on the selected face.

4 Enter a rotation value for the new UCS.

The UCS is aligned to the object face.

Matching Object Properties

AutoCAD users are likely to be familiar with the Match Properties command (MATCHPROP), which allows you to quickly copy properties such as layer, color, and linetype from one AutoCAD entity and apply them to another. Beginning with the 2009 releases of AutoCAD Architecture and AutoCAD MEP, you can also use this command to match style and object display properties between AEC objects of the same type (for example, 2 different sizes of door) or between AutoCAD MEP objects of the same type. For AEC objects of different types (for example, a door and a window) you can use the command to match basic AutoCAD properties. Likewise, you can match basic AutoCAD properties between an AutoCAD entity and an AEC object.

When you match properties between style-based AEC objects, both the style properties and the display properties of the selected source object are applied to one or more selected destination objects. For non-style-based objects, only display properties are matched. In either case, the display properties are applied to all display representations of the destination object.

Object Types for Which Both Style and Display Properties Are Matched

Zone

Overrides

When you use the Match Properties command, any style or object overrides in effect for the source object are applied to all display representations of the destination object. Overrides currently in effect for the destination object will be removed if they conflict with corresponding settings for the source object. If you want to change a setting for a particular display property in a particular display representation, the recommended method is to use the Display tab of the Properties palette. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

To run the Match Properties command:

- 1 On the Standard toolbar, click  (Match Properties).
The cursor changes to a paintbrush symbol.
- 2 Select the source object whose properties you want to copy.
- 3 Select one or more destination objects to which you want to apply the properties of the source object.
Source object properties are applied to each destination object as it is selected.
- 4 When finished selecting destination objects, press ENTER.

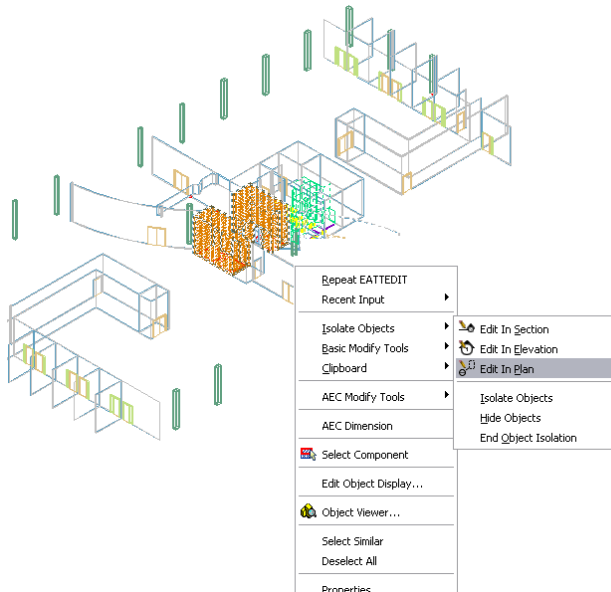

Isolating Objects

AutoCAD Architecture offers an easy-to-use feature for temporarily hiding and displaying selected objects in your drawing. This feature is useful when you want to focus on individual areas of your drawing.

You can perform the following operations with the Isolate Objects feature:

- Create an object selection set to hide or display
- Fine-tune the selection set by adding objects
- Save a drawing with the visibility settings you have selected
- Edit objects in a temporary section, elevation or plan view with the UCS aligned

Selecting objects to isolate

Displaying only the isolated objects from previous illustration

You can select specific objects and work on them in a temporary section, elevation or plan view regardless of the view you are working in currently. When you use Edit in View, the objects you select are isolated and switched to the temporary view. The UCS is aligned appropriate to the temporary view you selected and makes complex design projects easier to modify. All other objects in the drawing are hidden from view while you make modifications. You are returned to the view and UCS you were working in previously, and all objects that were hidden become visible, when you exit Edit in View.

For example, if you are working in a design with an angled wall and want to add a body modifier in an elevation view, you can switch to a temporary elevation, add the detail, and exit the elevation. You are returned to your working view, and you must save any modifications at this point. This option might also be useful if you were working in an isometric view and wanted to look at the endcaps of a wall opening in a section view or wanted to change the UCS to add a section line through objects at an angle.

Isolating Objects to Edit in a Section View

Use this procedure to modify your drawing in a temporary section view. When you isolate objects to look at them in a section view, other objects in the drawing are hidden from view as you work. You must save your drawing after you exit Edit In Section.

- 1 Select the objects you want to edit, right-click and click Isolate Objects ► Edit In Section. The Edit in View Toolbar opens.
- 2 Specify the first and second points for the section line or press *ENTER* to change the UCS.

- 3 Specify the extent of the section.
Only the objects you selected are displayed.
- 4 Modify the objects in the section view.
- 5 Click  to exit Edit In View.
You are returned to the view you were working in previously.
- 6 Save your changes to your drawing after you exit Edit In View.

Isolating Objects to Edit in an Elevation View

Use this procedure to modify your drawing in a temporary elevation view. When you isolate objects to look at them in an elevation view, other objects in the drawing are hidden from view as you work. You must save your drawing after you exit Edit In Elevation.

- 1 Select the objects you want to edit, right-click and click Isolate Objects ► Edit In Elevation.
The Edit in View toolbar opens.
- 2 Select linework, the face of an object or a reference point for the view direction.
Only the objects you selected are displayed.
- 3 Modify the objects in the elevation view.
- 4 Click  to exit Edit In View.
You are returned to the view you were working in previously.
- 5 Save your changes after you exit Edit in View.

Isolating Objects to Edit in a Plan View

Use this procedure to modify your drawing in a temporary plan view. When you isolate objects to look at them in a plan view, other objects in the drawing are hidden from view as you work. You must save your drawing after you exit Edit In Plan.

- 1 Select the objects you want to edit, right-click and click Isolate Objects ► Edit In Plan.
Only the objects you selected are displayed.
- 2 Modify the objects in the plan view.
- 3 Click  to exit Edit In Plan.
You are returned to the view you were working in previously.
- 4 Save your changes after you exit Edit in View.

Isolating Objects to Display

Use this procedure to isolate objects that you want to display in a drawing. This method of working is preferable when you have a large drawing with many objects and need to display only a small number of them.

Displaying only a chair and a cabinet in a drawing

You can work with the Isolate Object command from the context menu of an object, or from the drawing window status bar.

Isolate Objects command on the drawing window status bar

- 1 Select the objects in the drawing that you want to isolate and display.
- 2 Right-click, and click Isolate Objects ► Isolate Selected Objects.

Alternatively, you can click  on the right side of the drawing window status bar, then click Isolate Objects, and select the objects to isolate.

NOTE When you have isolated objects in your drawing, the light bulb in the drawing window status bar turns red  .

- 3 If you want to isolate additional objects in your selection set, select one or more isolated objects, and run the Isolate Objects command again.

Alternatively, you can click the red light bulb  in the drawing window status bar, and click Isolate Additional Objects.

When you end the object isolation, as described in [Ending the Object Isolation in a Drawing](#) on page 116, all objects are redisplayed.

Isolating Objects to Hide

Use this procedure to isolate objects that you want to hide in a drawing. This method of work is preferable when you want to display a large number of objects and hide only a few of them.

Hiding a chair and a cabinet in a drawing

- 1 Select the objects in the drawing that you want to hide.
- 2 Right-click, and click Isolate Objects ► Hide Selected Objects.
The objects you selected are now hidden in the drawing.

Alternatively, you can click the light bulb  in the drawing window status bar, and click Hide Objects.

NOTE After isolating and hiding objects multiple times, it may be difficult to know whether any objects are hidden, or whether all objects are displayed in the drawing. When you have isolated objects in your drawing, the light bulb on the right side of the drawing window status bar is displayed in red . When all objects are displayed and none are isolated or hidden, the light bulb is displayed in yellow . Alternatively, to ascertain that no objects are hidden, select an object in the drawing, right-click, and click Isolate Objects. If the End Object Isolation command is unavailable, all objects are displayed. If the context menu command End Object Isolation is active, there are hidden objects in the drawing. To display all objects, see [Ending the Object Isolation in a Drawing](#) on page 116.

Ending the Object Isolation in a Drawing

Use this procedure to end the object isolation in a drawing and to redisplay all hidden objects.

Redisplaying all objects in a drawing

- 1 Select an object in the drawing.
- 2 Right-click, and click Isolate Objects ► End Object Isolation.

Alternatively, you can click  on the right side of the drawing window status bar, and click End Object Isolation.

NOTE If no objects have been isolated, the End Object Isolation command is unavailable and the light bulb in the drawing window status bar is displayed in yellow . In that case, no further action is necessary.

Saving Isolated Objects

You can save a drawing in which some objects are isolated for viewing while others are hidden. The next time you open the drawing, it displays with the isolation settings you defined.

For example, you could save a specific view setting to distribute the file to a contractor who needs to see only a specific part of the drawing. You could also save a specific view setting in a drawing that is used as an external reference within another drawing.

To save a drawing with isolated objects, create the appropriate object selection set as described in [Isolating Objects to Display](#) on page 114 and [Isolating Objects to Hide](#) on page 115, and then save the drawing. The isolation settings you chose are saved in the drawing and are displayed accordingly when you reopen the drawing.

NOTE If you want to distribute a drawing with isolated objects, make sure that you and the recipient of the drawing are working with the same version of AutoCAD Architecture. A recipient who is working with an earlier version of the software, plain AutoCAD, or Object Enabler is not able to display the hidden objects. In this case, end the object isolation before saving and distributing the drawing.

Isolating Objects in External References

When you are working with external references, you can hide and isolate objects. Consider the following points:

- You can isolate an external reference within a host drawing as a whole by selecting it and isolating at as described in [Isolating Objects to Display](#) on page 114.
- You can isolate individual objects within an external reference by opening the external reference, isolating and hiding objects as needed, saving the external reference drawing, and then reloading the external reference.
- You cannot isolate or hide objects in an external reference while editing it with REFEDIT in the host drawing. You need to use XOPEN and save the desired Hide/Isolate settings within the external reference.
- You cannot redisplay hidden objects in an external reference while editing it with REFEDIT in the host drawing. You need to use XOPEN and save the desired Hide/Isolate settings within the external reference.

Styles and Support Files

Styles are contained in Styles drawings from which you select a style to add to your drawing. This ensures smaller templates and a clearer structure of your drawings. In previous releases, these same style drawings existed and contained the same styles that were also in the templates. In addition, to conform to Microsoft® Windows® standards some file paths have changed.

Support files are in the following locations:

Files	Location
Plotter Configurations	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Plotters</i>
Plot Styles	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Plot Styles</i>
DesignCenter Content	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\AEC Content</i>
Details	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Details\<UK or US></i>
Layer Standards drawing	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Layers</i>
Styles drawings	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles</i>
Material Definitions	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\<Imperial or Metric>\Material Definitions.dwg</i>
Schedule Tables	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\<Imperial or Metric>\Schedule Tables.dwg</i>
Drawing templates	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Template</i>
Area Evaluation templates	<i>C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Template\Evaluation Templates</i>
Sample Drawing Management Project	<i>\\Program Files\AutoCAD Architecture 2009\Sample\AutoCAD Architecture 2009 Sample Project</i>
Default User Workspace Catalog	<i>C:\Documents and Settings\<Username>\Application Data\Autodesk\ACD-A 2009\enu\Support\WorkspaceCatalog (Imperial/Metric)</i>
Stock Tool Catalog	<i>\\Program Files\AutoCAD Architecture 2009\Catalogs\StockToolCatalog</i>
Structural Member Catalog	<i>\\Program Files\AutoCAD Architecture 2009\Catalogs\Structural</i>
Sample Tool Palette Catalogs	<i>\\Program Files\AutoCAD Architecture 2009\Sample\Sample Palette Catalog (Imperial/Metric)</i>
Sample Render Material Catalog	<i>\\Program Files\AutoCAD Architecture 2009\Sample\Autodesk Render Material Catalog</i>

Integration of AutoCAD Architecture and AutoCAD

AutoCAD Architecture is integrated with the AutoCAD design platform. The commands and features of both applications are blended within the tool palettes, menus, and toolbars. There are some differences between working in a pure AutoCAD environment and accessing AutoCAD commands from within AutoCAD Architecture. These differences are listed in this section.

AutoCAD Tools

Differences with the AutoCAD tools:

- AutoCAD tools do not use the Properties palette during adding them to the drawing.
- AutoCAD tools do not have the same tool properties as AutoCAD Architecture tools; for example, the layer key.
- AutoCAD Hatch tools and Block tools cannot have a user-defined tool image.
- The tool properties of AutoCAD tools cannot be applied to an existing AutoCAD object in the drawing.

AutoCAD Tool Palettes

Differences with the AutoCAD tool palettes:

- When working in AutoCAD, you cannot create and link AutoCAD tool palettes from the Content Browser.
- AutoCAD tool palettes do not support palette properties.

Other Differences

Other differences with AutoCAD:

- **Properties Palette:** When working in AutoCAD, you cannot set the Properties palette to be transparent.
- **Revision clouds:** The Revision cloud feature in AutoCAD is not identical to the Revision cloud feature in AutoCAD Architecture. Revision clouds in AutoCAD Architecture have additional scaling and layer key functionality, as well as the option of adding a Delta symbol.
- **Units:** Running the **UNITS** command from the command line opens the AutoCAD Architecture Drawing Setup dialog. If you want to open the AutoCAD Units dialog, enter **ddunits** on the command line.

WARNING To change the drawing setup of AutoCAD Architecture, you must use the Drawing Setup command of AutoCAD Architecture. If you change the units in the AutoCAD Units dialog box, AutoCAD Architecture drawing units are not affected.

Content Browser

3

The Content Browser lets you store, share, and exchange AutoCAD Architecture content, tools, and tool palettes. The Content Browser runs independently of the software, allowing you to exchange tools and tool palettes with other Autodesk applications.

Understanding the Content Browser

The Content Browser is a library of tool catalogs containing tools, tool palettes, and tool packages. You can publish catalogs so that multiple users have access to standard tools for projects.

Tool Catalogs and Websites

AutoCAD Architecture 2009 tools and content are shared in the Content Browser using tool catalogs and websites. A tool catalog can contain one or more of the following items:

- **Tools:** For example, you might select a tool to create a customized wall used throughout a building project.
- **Tool palettes:** These contain tools used to support a particular workflow or task. For example, a tool palette may contain a set of annotation tools used in a project, or a set of tools to draw each type of door used in a project. A tool palette is treated as a single object.
- **Tool packages:** These are collections of tools that users can select and use. For example, a tool package may contain a set of productivity tools and utilities.

A single copy of a tool catalog can be shared among users on your local area network. If tools in the catalog are updated, you have immediate access to the latest version of the tools.

Websites containing AutoCAD Architecture tools, and content that you can download using i-drop® technology, can also function as tool catalogs.

Several tool catalogs are provided with AutoCAD Architecture, and you can create additional catalogs of your own.

Catalog Libraries

Tool catalogs are organized into catalog libraries, and each AutoCAD Architecture user has a personal catalog library.

Tool catalog data is not stored in the catalog library. Rather, the catalog library contains pointers to the physical tool catalogs. It is like the card catalog in a real library—it tells you where to find a book, but it does not contain the book itself.

You can sort the catalogs in the library by Last Used, Publisher, Title, or Type. You can filter the list of catalogs by Type.

You cannot create additional catalog libraries, but you can open the personal catalog library of another user if you are authorized to do so.

Tool Catalogs Supplied with AutoCAD Architecture

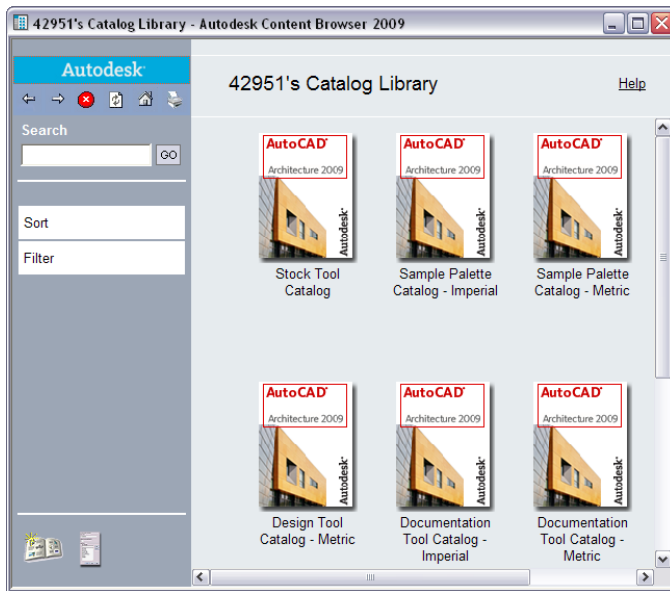

The following tool catalogs are supplied with your personal catalog library:

Catalog Name	Contents
Design Tool Catalog - Imperial	Content tools in imperial units for design and documentation of multi-view blocks and symbols.
Design Tool Catalog - Metric	Content tools in metric units for design and documentation of multi-view blocks and symbols.
Documentation Tool Catalog - Imperial	Content tools in imperial units for annotation and documentation.
Documentation Tool Catalog - Metric	Content tools in metric units for annotation and documentation.
My Tool Catalog	An empty tool catalog provided so that you can create your own tool set.
Visualization Catalog	A tool catalog containing render materials, lights, cameras and visual styles.
Sample Palette Catalog - Imperial	A sampling of tools in imperial units for objects such as doors, walls, and windows.
Sample Palette Catalog - Metric	A sampling of tools in metric units for objects such as doors, walls, and windows.
Stock Tool Catalog	A catalog that contains the standard stock tools in AutoCAD Architecture.

You cannot add or remove items from the Autodesk-supplied tool catalogs, but you can create your own tool catalogs. You can also copy other tool catalogs and website links into your catalog library using the Publish catalog feature.

Exploring the Content Browser

To open the Content Browser, click  on the Navigation toolbar.

The Content Browser window usually is divided into two panes (web pages displayed in the Content Browser occupy the entire window). Tool catalogs and their contents are displayed in the right pane. When you start the Content Browser, your personal catalog library, named *<user_name>'s Catalog Library*, displays in the right pane. The left pane is used for navigation, searching for tools, sorting catalogs, and filtering catalog display. The buttons at the top of the left pane work much like the equivalent controls in a web browser.

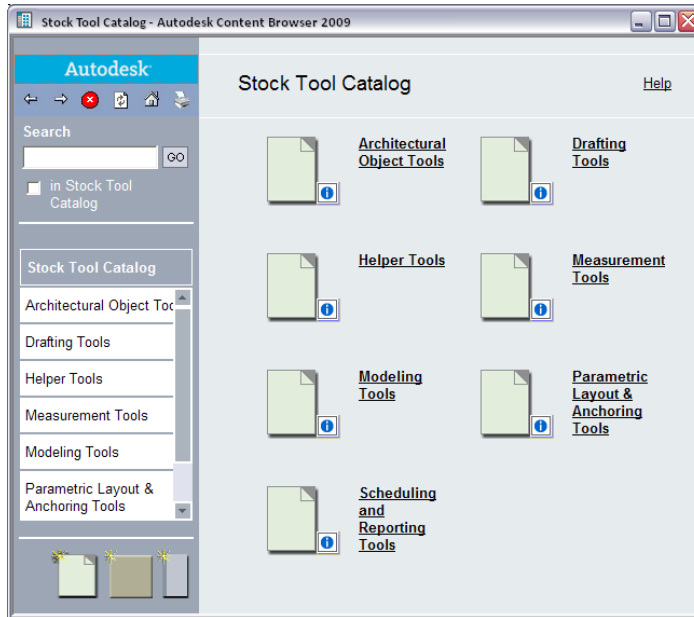

Click  to display the top level of the catalog library in the right pane. This view is either all the catalogs in the library, or a group of catalogs filtered by type.

You can have more than one instance of the Content Browser open at a time. To open an additional Content Browser window, press *CTRL+N*. For more information, see [Working with Multiple Content Browser Windows](#) on page 150.

Viewing a Tool Catalog

To view a tool catalog, click the catalog in the catalog library. For example, click the Stock Tool catalog to display a window like the following illustration:

View of the Stock Tool catalog

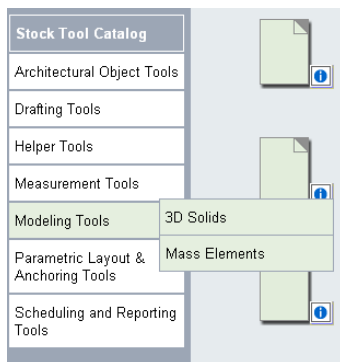

When you open the Stock Tool catalog, a cover page describing the catalog is displayed in the right pane. If no cover page is defined for a tool catalog, items contained in the tool catalog are displayed in the right pane. For information about specifying a cover page, see [Editing Tool Catalog Properties](#) on page 135.

To continue past the cover page to the contents of the tool catalog, click the catalog name in the left pane of the Content Browser window.

The contents of a tool catalog can be organized into categories. When a tool catalog is open in the right pane, any categories are listed in the left pane. For example, the Stock Tool catalog is organized into the categories shown in the previous illustration.

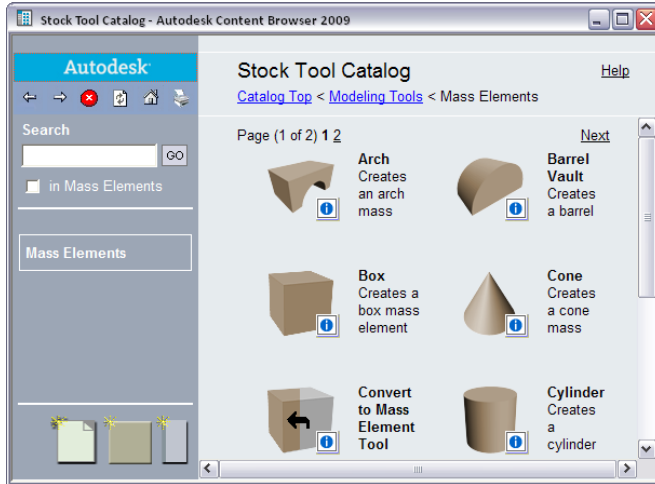

Categories can be subdivided into one or more levels. If subcategories exist, a list of subcategories appears when you move the pointer over the category name in the left pane. For example, in the Stock Tool catalog, move the pointer over Modeling Tools to see the Mass Element Tools and 3D Solids subcategories.

Displaying subcategories in a category

To open a category or subcategory, click it. For example, click Mass Element Tools to display the following window:

Mass Element Tools category of the Stock Tool catalog

Associated with each item in the tool catalog is the following i-drop[®] icon: .

You click the i-drop icon to drag a tool or other tool catalog item into the AutoCAD Architecture 2009 workspace or into another catalog, tool palette, or tool package.

You can modify the contents and properties of a tool catalog if you are authorized to do so, unless the catalog is read-only. Read-only tool catalogs are identified in the Content Browser title bar when you open the catalog.

A tool catalog category may contain more items than can fit on a page. If multiple pages are needed, navigation controls appear at the top and bottom of each page. The Mass Element Tools category shown earlier requires two pages to display its contents. You can specify the page to be displayed by clicking the page number or by clicking Next or Prev. (Note that these controls appear at the bottom of the page too.) You can also change the number of items that display on a Content Browser page.

Specifying the Number of Rows on a Content Browser Page

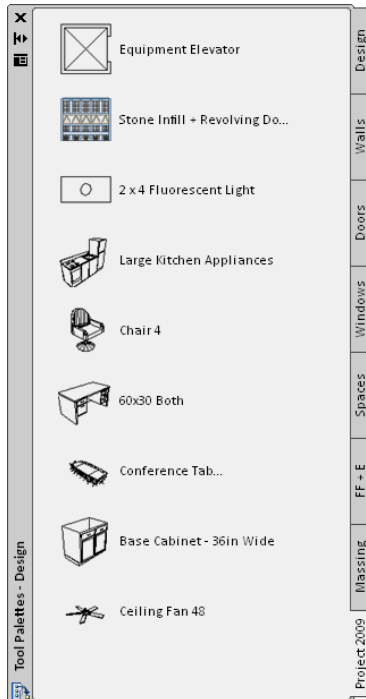

Use this procedure to specify the number of rows that display on a Content Browser page.

- 1 Click  to display the catalog library.
- 2 Click  to display the Content Browser Preferences dialog box.
- 3 In the Content Browser Preferences dialog box, enter the number of rows to be displayed on each page. You can specify up to 100 rows, and you must specify at least 5.
- 4 Click OK.

Using the Items in a Tool Catalog

To use a tool catalog item in AutoCAD Architecture 2009, drag the item into the software's workspace. Dragging a tool palette into the workspace adds the tool palette to the default tool palette set.

AutoCAD Architecture 2009 tool palette set, with added tool palette

Once added to the tool palette set, the palette remains a part of the set and is available each time you start AutoCAD Architecture.

You can drag a tool directly into the drawing area from the Content Browser. For example, with the Mass Element Tools category open in the Stock Tool Catalog, drag the Arch tool into the drawing area with the i-drop® icon to begin adding an Arch mass element to your drawing.

If you use a tool frequently, you will save time if you add the tool to a palette in the tool palette set, where you can access it without using the Content Browser.

Managing Your Catalog Library

You manage your catalog library by adding and deleting tool catalogs and website links and by setting catalog properties as needed. You can create a new catalog or customize existing ones to meet your needs. You can reorganize tool catalogs by moving and copying items among them.

Creating a New Tool Catalog

Use this procedure to create a new tool catalog in your catalog library.

1 Click  to display the catalog library.

2 Click  to create a catalog.

3 In the Add Catalog dialog box, select Create a new catalog.

4 Enter a name for your tool catalog.

Tool catalog names can include spaces and can contain any characters except the following:
/ : * ? " < > |

NOTE The full path name of the catalog file cannot exceed 255 characters, so be careful about using long catalog names.

The name you assign is used for both the file containing the catalog definition and the folder containing the catalog's contents. The name is also used in the title identifying the tool catalog in the catalog library. You can change the title displayed in the catalog library without affecting the file and folder name. For information about changing the title, see [Editing Tool Catalog Properties](#) on page 135.

5 Identify the folder in which to store your tool catalog:

If you want to...	Then...
store the tool catalog in the default location	click OK.
store the tool catalog in a different location	click Browse, select the folder in which to store the catalog, and then click OK.

The tool catalog is displayed in the catalog library with the following default graphic image:  . For information about changing the graphic image and other tool catalog properties, see [Editing Tool Catalog Properties](#) on page 135.

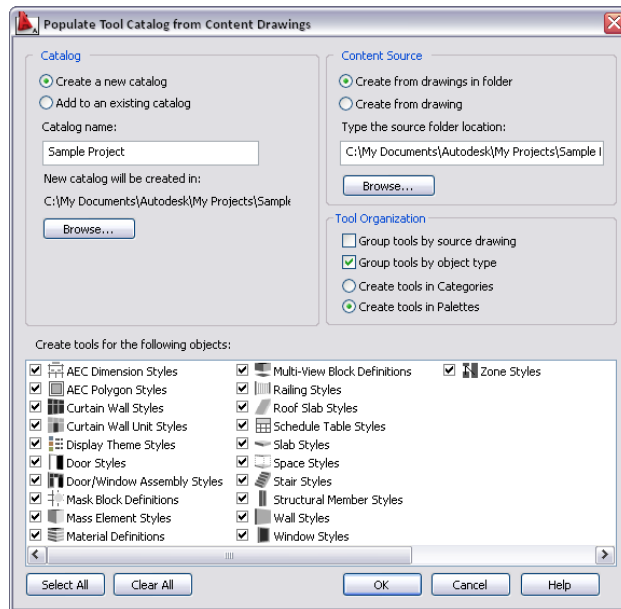

Creating a Tool Catalog from Content Drawings

Use this procedure to create a new tool catalog based on existing standards from the styles in one or more drawings. You specify the styles from which tools will be created and whether the new tools are organized in categories or palettes. Note that Content Browser does not have to be open to create a tool catalog.

WARNING Converting large numbers of tools can slow down your computer considerably. Depending on your processor and RAM equipment the conversion process can take a long time and the application may appear to be non-responsive. To avoid this, do not convert more than 3000 tools in one Tool Catalog Generator session. Instead, break up the source drawings, and use multiple instances of Tool Catalog Generator to achieve the conversion.

- 1 Click CAD Manager menu ► Tool Catalog Generator.

NOTE If the CAD Manager menu is not visible in your menu bar, click Window menu ► Pulldowns ► CAD Manager.

2 Under Catalog, select Create New Catalog.

3 Enter a name for the new catalog.

4 Click Browse to define the location of the catalog.

By default, a new catalog is saved in *C:\My Documents*.

5 Under Content Source, specify whether you want the new catalog to be created from multiple drawings in a folder or from a single drawing. Then, enter the path for the folder or drawing.

NOTE When you specify a folder as the catalog source, any nested folders are included in the new tool catalog.

6 Under Tool Organization, specify how you want the tools organized in the new catalog.

- To organize the new tools by their source drawing, select *Group tools by source drawing*. This option is well suited for a tool catalog that is generated from a number of styles drawings. The resulting tools could be placed in categories or palettes named “Wall Styles - Concrete (Imperial)”, “Wall Styles - Brick (Imperial),” etc.
- To organize the new tools by their object type, select *Group tools by object type*. This option is well suited if you want to merge styles from various drawings into palettes or categories. The resulting tools will be placed in categories or palettes named “Walls”, “Doors,” etc.

NOTE If both options are enabled, the catalog is first grouped by the drawings and then by the object type, generating categories from the drawings, and palettes from the object types. This is implemented because palettes cannot be nested. In this case the radio buttons for categories and palettes are disabled, and the *Create tools in palettes* option is selected for the catalog.

NOTE If neither of the two options is enabled, all new tools will be generated in the top category of the catalog.

- To organize the new tools in categories, select *Create Tools in Categories*.

If you select Group tools by source drawing, a category will be created for each source drawing.
If you select Group tools by object type, a category will be created for each object type.

- To organize the new tools in palettes, select Create Tools in Palettes.
If you have selected to group tools by their source drawing, then for each source drawing a palette will be created. If you have selected to group tools by their object type, then for each object type a palette will be created.

7 Under Create tools for the following objects, select the object styles you want to appear as tools in the new catalog.

By default, all available style types are selected. Use the Select All and Clear All buttons as necessary.

8 Click OK.

A progress bar in the application status bar informs you of the progress of the catalog generation. This can take a few moments for a large catalog.

NOTE Each category and each palette is created in its own ATC file. The category and palette ATC files are stored in the Palettes or Categories subfolders within the folder where the new catalog is created.

After creating a new catalog, you can add it to your Content Browser library, as described in [Adding an Existing Tool Catalog to Your Catalog Library](#) on page 131.

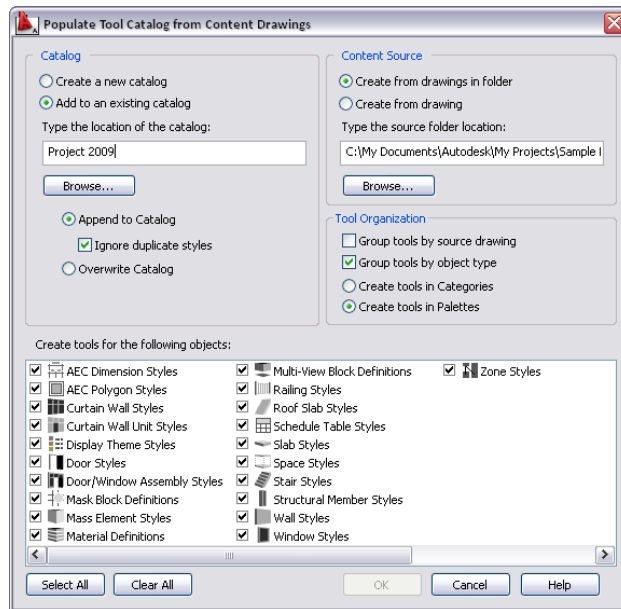

Adding Tools from Content Drawings to a Tool Catalog

Use this procedure to add tools from one or more drawings to an existing catalog.

WARNING Converting large numbers of tools can slow down your computer considerably. Depending on your processor and RAM equipment the conversion process can take a long time and the application may appear to be non-responsive. To avoid this, do not convert more than 3000 tools in one Tool Catalog Generator session. Instead, break up the source drawings, and use multiple instances of Tool Catalog Generator to achieve the conversion.

1 Click CAD Manager menu ► Tool Catalog Generator.

NOTE If the CAD Manager menu is not visible in your menu bar, click Window menu ► Pulldowns ► CAD Manager.

- 2 Under Catalog, select Add to an existing catalog.
- 3 Enter the name and the path of the catalog.
- 4 Click Append to Catalog and select Ignore Duplicate Styles if you want existing styles from being overwritten by styles with the same name and file path from the appended drawing.
If you clear Ignore Duplicate Styles, existing styles are overwritten with styles from the appended drawing if they have the same name and file path.
- 5 If you want to overwrite the existing catalog, click Overwrite Catalog.
This deletes the whole catalog and replaces it with the palettes, categories, and tools from the source drawing(s).

WARNING You should use that option with great caution, as it will delete the complete existing catalog. If you just want to overwrite tools with their up-to-date versions from a content drawing, select Append to Catalog instead, and verify that Ignore Duplicate Styles is cleared.

- 6 Under Content Source, select a project standards drawing or standards folder to use as source for the new tools.

If you want to...	Then...
add tools from multiple drawings in a folder	select Create from drawings in folder, and then enter the path and folder name under Type the source location.
add tools from a single drawing	select Create from drawing, and then enter the path and drawing name under Type the source drawing.

- 7 Under Tool Organization, specify how the tools should be organized in the catalog.
 - To organize the resulting tools by their source drawing, select Group tools by source drawing.

This option is well suited for a tool catalog that is generated from a number of styles drawings. The resulting tools could be placed in categories or palettes named “Wall Styles - Concrete (Imperial),” “Wall Styles - CMU (Imperial),” etc.

- To organize the resulting tools by their object type, select Group tools by object type. This option is well suited if you want to merge styles from various drawings into a new catalog. The resulting tools will be placed in categories or palettes named “Walls,” “Doors,” etc.

NOTE If both options are enabled, then the tools are first grouped by the drawings and then by the object type, generating categories from the drawings, and palettes from the object types. This is implemented because palettes cannot be nested. In this case the radio buttons below are disabled and the Create tools in palettes option is selected for the tools.

NOTE If neither of the two options are enabled, all new tools will be generated in the top category of the catalog.

- To organize the new tools in categories, select Create Tools in Categories. If you have selected to group tools by their source drawing, then for each source drawing a category will be created. If you have selected to group tools by their object type, then for each object type a category will be created.
- To organize the new tools in palettes, select Create Tools in Palettes. If you have selected to group tools by their source drawing, then for each source drawing a palette will be created. If you have selected to group tools by their object type, then for each object type a palette will be created.

8 Under Create tools for the following objects, select which object styles should appear as tools in the catalog.

By default, all available style types are selected. Use the Select All and Clear All buttons as needed to make your selections.

9 Click OK.

A progress bar in the application status bar indicates the progress of the tool generation. When a large number of tools are being added, the process can take a few moments.

NOTE Each category and each palette is created in its own ATC file. The category and palette ATC files are stored in the Palettes or Categories subfolders in the folder in which the new catalog is created.

Adding an Existing Tool Catalog to Your Catalog Library

Use this procedure to add an existing tool catalog to your catalog library.

Adding a tool catalog to a catalog library does not physically move or copy any files. Instead, a pointer to the catalog’s location is added to the catalog library. If you add a tool catalog that resides on another computer, and then a tool in that catalog is updated, you always reference the latest version of the tool in the catalog library.

1 Click  to display the catalog library.

2 Click  to create a catalog.

3 In the Add Catalog dialog box, select Add an existing catalog or website.

- 4 Enter the location of the tool catalog you want to add, or click Browse and select a catalog.
Tool catalog files typically have the extension *.atc*.
- 5 Click OK.

NOTE Alternatively, you can drag and drop an ATC file from Windows Explorer to the Content Browser library pane.

Creating a Catalog Install File

Use this procedure to create a registry file that adds catalogs to other users' Content Browser libraries.

When you add a catalog in Content Browser, it is automatically added to your Content Browser library (CBL). However, as a CAD manager, you might also want to automatically install new catalogs into other user's libraries. In that case, you can either add a pointer to a catalog in an existing registry file, or create a new registry file that adds that catalog to the user's library.

Creating a catalog install file

- 1 Click  on the Navigation toolbar to open Content Browser.
- 2 Select the catalog that you want to add to a registry file.
When you add a catalog to a registry file, make sure that the network location of the catalog and all its affiliated files can be accessed by all users to whom you want the catalog distributed.
- 3 Shift-Rightclick the catalog.
- 4 Click Convert to Registry File.

If you want to...	Then...
create a new registry file for the catalog	browse to the desired folder location, enter a name for the registry file, and click Open. In that case, a new registry file (REG) is created, containing the registry information for the selected catalog.
enter the catalog into an existing registry file	browse for the registry file, select it and click Open. In that case, an entry containing the registry information for the selected catalog is appended to the registry file.

NOTE When you select an existing registry file, the file is not overwritten, as in standard Windows Save dialogs; the catalog entry is simply added to the registry file. If you want to overwrite an existing registry file, you need to delete it from Windows Explorer, and then create a new one of the same name.

Entering a catalog in a users' library

- 5 To enter the catalog reference into the local registry, and thereby into the user's catalog library (CBL), run the new registry file.
- 6 Either place the generated REG file on a generally accessible network folder, or copy it to the local user machine where the catalog should be entered.
- 7 Double-click the REG file on the user's computer.
- 8 Click Yes when asked whether you want to add the information into the local registry.
The catalog is entered into the users' registry and catalog library.

Publishing Tool Catalogs

The Publish Catalog feature helps you make tool catalogs available for use by multiple users on a network. You can move and copy catalogs or make them available from their current location. The feature handles dependent file paths during the publish catalog operation.

1 Right-click the tool catalog you want to publish, and click Publish *<catalog_name>*.

2 In the Publish Tool Catalog - Step 1 of 4 dialog box, do one of the following:

If you want to...	Then...
move the catalog to a new location when publishing it	click Move it to a new location.
copy the catalog to a different location	click Copy to another location.
publish the catalog from its current location	click Leave it in its current location.

3 Click Next.

If you are moving or copying the catalog, you are prompted to specify the destination location.

4 In the Publish Tool Catalog - Step 2 of 4 dialog box, specify the destination for the tool catalog.

You can enter a path, or click [...] to navigate to the destination location. You can specify an existing location or create a new folder.

5 Click Next.

6 In the Publish Tool Catalog - Step 3 of 4 dialog box, specify the location for any dependent files.

You can enter a path, or click [...] to navigate to the destination location. You can specify an existing location or create a new folder.

Dependent files contain information referenced by the tools; for example, style information. If you select the option Automatically move (or copy) tool dependent files into the above folder to be referenced by the publish catalog, the feature attempts to copy all of the dependent files referenced in the catalog to the dependent file location you specify. If you do not select this option, you must verify that the files are already present in the dependent location. If you select the option Report invalid catalog references, the feature generates a report of any dependent files it cannot locate.

7 To have the publish catalog feature move (or copy) dependent files, click Automatically move (or copy) tool dependent files into the above folder to be referenced by the publish catalog.

8 Click Report invalid catalog references to generate an HTML file containing any dependent files that were not found, and then click Next.

9 In the Publish Tool Catalog - Step 4 of 4 dialog box, do one of the following:

If users will...	Then...
access the catalog directly from the network location you specify	Click Directly from the location provided.
access the catalog from an alternate or aliased location	Click From an <i>http://</i> site or mapped drive, and enter the location name.

10 To make the catalog read-only, select Set items in catalog to be read-only.

- 11 To prevent catalog items from refreshing when they are dropped in the workspace, select Set items in catalog to not be refreshable when drag/dropped into the workspace, and click Finish.

Individual users can specify the location of dependent files, such as styles for tools, on the AEC Content tab in the Options dialog box. The variable %AECCONTENT_DIR% is used for tool-dependent file references. This variable is updated to use the path specified. For example, <Style href="%AECCONTENT_DIR%\<DoorStyles\DoorStyles.dwg"/>. For more information, see [Changing the AEC Content Settings](#) on page 168.

Adding a Website to Your Catalog Library

Use this procedure to add a website link to your catalog library. Links are useful for websites containing AutoCAD Architecture 2009 tools and content that you can download using i-drop® technology.

You can also add a website link by dragging the URL from the Address bar of Internet Explorer into the Content Browser window.

- 1 Click  to display the catalog library.

- 2 Click  to create a catalog.

- 3 In the Add Catalog dialog box, select Add an existing catalog or website.

- 4 Enter the location of the website to link:

If you want to...

Then...

link to a website on the Internet or on an intranet

enter the URL of the website, including the *http://* prefix.

TIP Here is the easiest way to specify a URL: 1. Open a web browser, such as Internet Explorer. 2. Open the web page you want to link to. 3. Copy the URL from your browser's address bar. 4. Paste the URL into the Add Catalog dialog box.

link to a web page in an HTML file on your computer or on your network

enter the file name, or click Browse and select the file you want to link to.

- 5 Click OK.

The link to the website is represented in the catalog library by a default graphic image, which you can change. For information about changing this image and other Tool Catalog properties, see [Editing Tool Catalog Properties](#) on page 135.

Opening Web Pages in the Content Browser

Use this procedure to open a web page through a website link in your catalog library.

TIP If you have any problem viewing a web page in the Content Browser window, try opening the page in Internet Explorer.

- Move your pointer over the website link you want to open, and do one of the following:

If you want to...	Then...
view the web page in the Content Browser window	click the link.
view the web page in a new Content Browser window	right-click the link, and click Open in New Window.
view the web page in a new Internet Explorer window	right-click the link, and click Open With Internet Explorer.

Editing Tool Catalog Properties

Use this procedure to view and modify the properties of a tool catalog. If you have write access to the tool catalog, you can select a different source file or target, and you can change the cover page.

1 With the catalog library open in the right pane of the Content Browser, right-click the desired tool catalog, and click Properties.

2 Edit the properties:

If you want to...	Then...
change the graphic image that represents the tool catalog in the catalog library	click the image in the Properties dialog box, and then select a graphic file to use. You can use a BMP, JPEG, PNG, or TIFF file for your graphic. The graphic image is displayed at 90 × 120 pixels. If you specify an image of a different size, the image is scaled to fit. NOTE The graphic file you select is copied into the tool catalog's image folder.
change the title displayed beneath the tool catalog's graphic image in the catalog library	enter a new title. You can also right-click the catalog and click Rename <i><catalog_name></i> .
change the descriptive text that displays when you move the pointer over the tool catalog's graphic image	enter a new description.
change the tool catalog file or website	enter the new file in File or Target, or click Browse to select a tool catalog file.
change or specify the HTML file that displays when the tool catalog is opened	enter the new HTML file in Cover Page, or click Browse to select a cover page.
change the publisher of the tool catalog	enter a new publisher name.

If you want to...	Then...
change the type designation for the catalog	select a type from the Type list. For information on assigning types to catalogs, see Creating Catalog Types on page 136.
define that tools and palettes from this catalog should be automatically linked to the Content Browser when dropped onto the tool palettes set of AutoCAD Architecture 2009	select Link items when added to workspace. For information on linking tools to the Content Browser, see Using Tool Catalog Items in AutoCAD Architecture on page 146 and Working with Tools from a Central Location on page 88.
define that tools and palettes from this catalog should not retain a link to the Content Browser when dropped onto the tool palettes set of AutoCAD Architecture 2009	clear Link items when added to workspace. Inserting tools without retaining a link to Content Browser would be the right choice if you want to make changes to a tool in AutoCAD Architecture that should not be overwritten by the tool properties in Content Browser; also, unlinked tools create a better general performance in AutoCAD Architecture 2009.

3 Click OK.

Creating Catalog Types

Use this procedure to create catalog types. You can assign a type property to a catalog and then sort and filter your catalogs by type.

- 1 Click  to display the catalog library.
- 2 Click  to display the Content Browser Preferences dialog box.
- 3 In the Catalog Types area, under New Catalog Type, enter the name of the type you want to create.
- 4 Click OK.
- 5 The new type is added to the list of available types. You can now assign this type to catalogs by editing their properties. Once the type is assigned to a catalog, you can sort or filter the display of catalogs in the Library View by this type.
- 6 To remove a type, click the type name and click Remove.

NOTE The Type catalog property is cleared for any catalogs associated with this type.

Sorting Catalogs in the Library View

Use this procedure to sort the display of catalogs by last-used date, publisher, title, or type.

- 1 Click  to display the catalog library.
- 2 With the catalog library open in the right pane of the Content Browser, position the pointer over Sort in the left pane.

3 From the list of available sort options, click the method you want to use to sort catalogs in the library.

If you want to...	Then...
sort chronologically by when you last used each catalog	click By Last Used.
sort alphabetically by the publisher name of each catalog, and then by title	click By Publisher. If the catalog does not have a publisher property, the catalog appears at the bottom of the display.
sort alphabetically by catalog title	click By Title.
sort by catalog type	click By Type. If the catalog does not have a type assigned, the catalog appears at the bottom of the display.

Filtering Catalogs in the Library View

Use this procedure to filter the display of catalogs in the Library View.

- 1 Click  to display the catalog library.
- 2 With the catalog library open in the right pane of the Content Browser, position the pointer over Filter in the left pane.
- 3 From the list of available types, click the type of catalog you want to view.
To display all the catalogs in the library, click All Catalogs.

NOTE To filter catalogs by Type, you must assign a type to each catalog in the library. For more information, see [Creating Catalog Types](#) on page 136.

Removing a Tool Catalog or Website Link

Use this procedure to remove a tool catalog or website link from your catalog library.

When you remove a tool catalog or website link, only a pointer to the item is removed; no files or web pages are physically deleted.

- 1 With the catalog library open in the right pane of the Content Browser, right-click the tool catalog or website link to delete, and click Remove *<catalog_name>* from Library.
- 2 When prompted, click Yes to confirm deletion, or click No to cancel deletion.

Opening a Different Catalog Library

Use this procedure to open a catalog library other than your personal catalog library, or to reopen your personal catalog library.

A catalog library is stored in a file having the extension *.cbl*. The default file name for your personal catalog library is *ContentBrowserLibrary.cbl*; it is stored in the folder *My Documents\My AEC Content Browser Library*.

- 1 Click  to display the current open catalog library.
- 2 Right-click the catalog library name, and click Open New Library.
- 3 In the Open dialog box, select the catalog library that you want to open.

Renaming a Catalog Library

Use this procedure to rename the currently open catalog library. The name change affects the title of the catalog library displayed in the Content Browser, but no files are renamed.

- 1 Click  to display the catalog library.
- 2 Click  to display the Content Browser Preferences dialog box.
- 3 Under Library Name, enter the new library name.
- 4 Click OK.

Searching for Items in a Tool Catalog

You can use the Search feature to help you find a particular tool. You can search across multiple catalogs or search a particular tool catalog, tool palette, or tool package. For example, if you are looking for a tool to help you create a 3D desk, you could search on the keywords *3D desk*. The search applies to all the catalogs currently displayed (filtered). Narrow the search by filtering the catalog display.

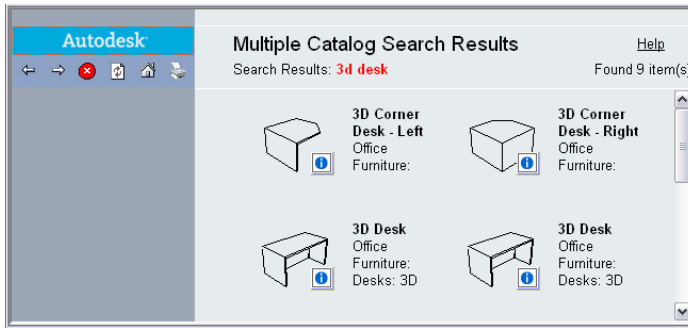

The Search feature looks at the text in the following properties of tool catalog items for the keywords you specify:

- Name
- Description
- Keywords

The Search tool is only as helpful as the tool names and descriptions that you assign. A tool name should indicate the tool's function, and the description should indicate the tool's use.

If you enter a search term containing more than one word, the Search feature looks for items containing both words. You can also join multiple search words with AND, &, or +. To retrieve items containing any of the search words, enter OR or | between search terms. To exclude a word from the search, precede the word with !. Use * as a wild-card string and ? as a wild-card character. Search is not case sensitive by default. To use a particular case in a search, surround the word in quotes.

Search results are displayed in the right pane of the Content Browser window. The following illustration shows the results of a search on the term *3D desk* in the Content catalogs group:

The search term and the number of items found are listed on the line below the tool catalog name. If multiple pages are returned, you can specify the page to display by clicking the page number or by clicking Next or Prev.

Performing a Search

Use this procedure to search across multiple catalogs or to search all or part of a tool catalog.

1 Filter the library to display the catalogs you want to search:

If you want to...	Then...
search for tools across multiple catalogs	display the catalog library and then filter the display to include the catalogs you want to search.
search for tools only within a specific catalog	open the tool catalog you want to search.
search for tools only within a specific category and its subcategories	open the category you want to search, and select the box labeled <i>in <category name></i> .
search for tools only on a specific tool palette	open the tool palette you want to search, and select the box labeled <i>in <palette name></i> .
search for tools anywhere in the open catalog	leave the box under the search term clear.

2 Enter the terms to search for under Search.

3 Click GO.

Items that match your search criteria are displayed in the right pane of the Content Browser. To go to the catalog containing an item, click that item. To view the source catalog of an item, right-click the item.

4 To perform another search, click the  button located near the top of the left pane.

Adding Content to a Tool Catalog

Tool catalogs can contain tools, tool palettes, and tool packages, which may be organized into categories.

Categorizing the Items in a Tool Catalog

You can define categories and subcategories in a tool catalog to organize a large number of items. For example, the Stock Tool catalog contains dozens of tools. If these tools were not grouped into categories, you would have to scroll through page after page to find a particular tool. To make it easier to find tools, the Stock Tool catalog is organized into categories and subcategories, as shown in the following diagram:

Category Name	Contents
Architectural Object Tools	<ul style="list-style-type: none">■ Wall, Curtain Wall, and Curtain Wall Unit■ Opening, Door, Window, and Door/Window Assembly■ Roof, Roof Slab and Slab■ Ceiling Grid■ Stair, Stair Tower, and Railing■ Space and Space Boundary■ Structural Members and Column Grid
Drafting Tools	<ul style="list-style-type: none">■ AEC Dimensions■ Callouts and Title Mark■ Text, Leaders, Keynotes, Legend■ Masking Block■ Hatching and Gradient■ Chamfer and Fillet■ Shrink Wrap Tool■ Welding Symbols
Helper Tools	<ul style="list-style-type: none">■ AEC Entity Reference■ AEC Polygon■ Camera■ Horizontal and Vertical Design Sections■ Hidden Line Removal Tool and Napkin Sketch
Measurement Tools	<ul style="list-style-type: none">■ Area, Distance, and Point ID
Modeling Tools	<p>Mass Element Tools:</p> <ul style="list-style-type: none">■ Box, Arch, Pyramid, Extrusion, and so on■ Mass Group■ Convert to Mass Elements <p>3D Solids Tools:</p> <ul style="list-style-type: none">■ 3D Solid Box, Cylinder, Convert to 3D Solids
Parametric Layout and Anchoring Tools	<ul style="list-style-type: none">■ Layout Curve

Category Name	Contents
	<ul style="list-style-type: none"> ■ Layout Grid (2D and 3D) ■ Object Anchor, Node Anchor, Cell Anchor, Volume Anchor
Scheduling and Reporting Tools	<ul style="list-style-type: none"> ■ Space Evaluation ■ Display Theme ■ Tag Tool ■ Schedule Table ■ Property Data Browse and Renumber Tools

About Tool Palettes

A tool palette is a collection of tools used to support a task. For example, a palette might contain tools to create the different types of doors (single-hinged, double-hinged, revolving, and so on) used in a building project. Storing a tool palette in a tool catalog makes the palette available to multiple users.

The date and time at which the tool palette was created and last modified are identified in the Tool Palette Properties dialog box. To view the dialog box, right-click the tool palette, and click Properties. For information about other tool palette properties, see [Adding a Tool Palette to a Tool Catalog](#) on page 142.

About Tool Packages

A tool package is a group of tools stored together for distribution. For example, a package might contain a set of productivity tools and utilities.

The date and time at which the tool package was created and last modified are identified in the Tool Package Properties dialog box. To view the dialog box, right-click the tool package, and click Properties. For information about other tool package properties, see [Adding a Tool Package to a Tool Catalog](#) on page 142.

Customizing Tools

You customize a tool by copying it to a palette in the AutoCAD Architecture 2009 tool palette set, modifying the tool's properties, and then copying it back to its original location in the tool catalog.

Defining Categories in a Tool Catalog

Use this procedure to define categories and subcategories in a tool catalog.

Categories are listed in the left pane of the Content Browser, below the name of the open tool catalog.

1 Open the tool catalog in which to define categories.

2 Select the location for the new category:

If the tool catalog...

Then...

already has one or more categories defined and you want to add a subcategory

in the left pane of the Content Browser, navigate to the desired category, and click the category name.

If the tool catalog...	Then...
is not currently divided into categories and is open to a cover page	in the left pane of the Content Browser, click the catalog name.
is not currently divided into categories and the content page is displayed	do nothing; this is where you define your first category.

- In the right pane of the Content Browser window, right-click a blank area, and click Add Category.
- Enter a name for the category, and click OK.
- To define additional categories and subcategories, continue from step 2.

Adding a Tool Palette to a Tool Catalog

Use this procedure to add a tool palette to a tool catalog. You must have write access to the tool catalog in order to add a palette.

You can also drag a tool palette from the AutoCAD Architecture 2009 workspace into a tool catalog. Click the tab of the tool palette to drag it.

- In the Content Browser, open the tool catalog in which to add the tool palette.
To add the palette to a specific category in the catalog, open that category.
If no graphics appear at the bottom of the left pane, the tool catalog is read-only, and you cannot add a tool palette.

- Click  in the left pane of the Content Browser.
- In the Tool Palette Properties dialog box, enter a name for the tool palette, and enter any other desired properties:

If you want to...	Then...
add a description to be displayed in the tool catalog and queried in catalog search operations	enter a description.
define terms that will be found during a search of the tool catalog	enter the terms for keywords.
identify the publisher of the tool palette	enter a publisher.

Adding a Tool Package to a Tool Catalog

Use this procedure to add a tool package to a tool catalog. You must have write access to the tool catalog in order to add a package.

- In the Content Browser, open the tool catalog in which to add the tool package.
To add the package to a specific category in the catalog, open that category.

2 Click  in the left pane of the Content Browser.

3 In the Package Properties dialog box, enter a name for the tool package, and enter any other desired properties:

If you want to...	Then...
add a description to be displayed in the tool catalog and queried in catalog search operations	enter a description.
define terms that will be found during a search of the tool package	enter the terms for keywords.
identify the publisher of the tool package	enter a publisher.

If the tool catalog is read-only, the Package Properties dialog box is displayed, but you cannot enter anything in it.

Adding Tools to a Tool Catalog

Use this procedure to add a tool to a tool catalog or to a tool palette or tool package stored in a catalog. You must have write access to the tool catalog in order to add a tool to it.

You can also drag a tool from a tool palette in the AutoCAD Architecture 2009 workspace to a tool catalog in the Content Browser.

1 In the Content Browser, open the tool catalog in which to add a tool.

If you are adding the tool to a specific category in the catalog or to a palette or package in a specific category, open that category.

2 Double click the image to open the palette or package if you are adding the tool to a tool palette or tool package.

3 In the AutoCAD Architecture 2009 workspace, open the tool palette that contains the tool to add to the tool catalog.

4 Right-click the tool, and click Copy.

5 In the right pane of the Content Browser window, right-click in a blank area, and click Paste.

NOTE If there is no Paste option on the shortcut menu, then the pointer is probably positioned over a tool, even though the space may appear to be blank. Move the pointer and try again.

Copying and Moving Tool Palettes and Tool Packages

Use this procedure to copy or move tool palettes or tool packages between tool catalogs or between categories in the same catalog. To copy an item, you must have write access to the catalog you are copying to. To move an item, you must have write access to both the catalog you are copying from and the catalog you are copying to.

You can also open multiple Content Browser windows and drag tool palettes and tool packages from one window to another. For information about using multiple windows to copy and move items, see [Dragging Catalog Items Between Content Browser Windows](#) on page 151.

1 Open the tool catalog containing the tool palette or tool package to copy or move. If the item is located in a specific category of the catalog, open that category.

2 Right-click the item, and select an action:

If you want to...	Then...
add a copy of the tool palette or tool package in another location	click Copy.
move the tool palette or tool package to another location, deleting it from its original location	click Cut.

3 Select the item's destination:

If the destination is...	Then...
a category within the current tool catalog	click that category in the left pane of the Content Browser window.
another tool catalog	click  to return to the catalog library, and then click the tool catalog.
a category in another tool catalog	click  to return to the catalog library, click the tool catalog you are copying to, and then select its category in the left pane of the Content Browser window.

4 In the right pane of the Content Browser window, right-click in a blank area, and click Paste.

NOTE If there is no Paste option on the shortcut menu, then the pointer is probably positioned over a catalog item, even though the space may appear to be blank. Move the pointer and try again.

Copying and Moving Tools

Use this procedure to copy or move tools between tool palettes, tool packages, or tool catalogs.

You can also open multiple Content Browser windows and drag items from one window to another. For information about using multiple windows to copy and move items, see [Working with Multiple Content Browser Windows](#) on page 150.

1 Open the tool catalog containing the tool to copy or move.

2 Open the item containing the tool to copy or move:

If the tool is in...	Then...
a category of the tool catalog	open the category.
a tool palette in the tool catalog	open the category for that tool palette, if necessary, and then click the tool palette.

If the tool is in...	Then...
a tool package in the tool catalog	open the category for that tool package, if necessary, and then click the tool package.

3 Right-click the tool, and select an action:

If you want to...	Then...
add a copy of the tool in another location	click Copy.
move the tool to another location, deleting it from its original location	click Cut.

4 If the destination of the tool is in a different tool catalog, click  to return to the catalog library, and then click the tool catalog to open it.

5 Open the destination of the tool:

If the destination is...	Then...
a category of the tool catalog	open the category.
a tool palette in the tool catalog	open the category for that tool palette, if necessary, and then click the tool palette.
a tool package in the tool catalog	open the category for that tool package, if necessary, and then click the tool package.

6 In the right pane of the Content Browser window, right-click in a blank area, and click Paste.

NOTE If there is no Paste option on the shortcut menu, then the pointer is probably positioned over a catalog item, even though the space may appear to be blank. Move the pointer and try again.

Customizing a Tool

Use this procedure to modify a tool that is stored in a tool catalog.

When you begin this procedure, both the AutoCAD Architecture tool palette set and the Content Browser window should be visible, so that you can drag items between them.

1 In the Content Browser, open the tool catalog that contains the tool to customize. If the tool is located in a specific category of the catalog, open that category.

2 Move the pointer over the i-drop[®] icon next to the tool you want, so that the pointer image changes to an eyedropper ().

3 Click the eyedropper and drag it to a palette in the tool palette set.

If the tool palette does not accept the tool, it might be because the palette is set to allow updates only from a linked tool palette in a tool catalog. To check this, right-click on the palette, click Properties, and look at the Refresh from setting. If Refresh from is selected, the palette is linked

to a palette in a tool catalog. To break the link, clear Refresh from. For more information about linked tool palettes, see [Using the Items in a Tool Catalog](#) on page 125.

4 Right-click the copy of the tool in the tool palette set, and click Properties.

5 In the Tool Properties worksheet, clear Refresh from.

If Refresh from is selected, the tool is linked to its source in the tool catalog and can be updated only from the source tool.

6 Make any property changes, and then click OK.

7 Drag the tool from the tool palette set back to its original location in the Content Browser.

TIP Right-click the title bar of the Autodesk Content Browser, and select Always on Top before dragging the tool to the Content Browser.

8 When prompted to confirm catalog item replacement, click Yes.

Deleting Tool Catalog Items

Use this procedure to delete a tool palette, tool package, or tool in a tool catalog. You must have write access to the tool catalog in order to delete items.

1 Open the tool catalog containing the item to delete. If the item is located in a specific category of the catalog, open the category.

2 Right-click the item, and click Delete.

3 When prompted, click Yes to delete the item, or click No to cancel deletion.

Using Tool Catalog Items in AutoCAD Architecture 2009

Tools from catalogs can be used immediately in the drawing area or stored in a palette in the tool palette set. You can add a catalog tool palette or tools in a tool package to the tool palette set.

TIP To keep the Content Browser window in view while other applications are active, right-click the title bar of the Autodesk Content Browser, and select Always on Top.

Linked and Unlinked Tool Catalog Items

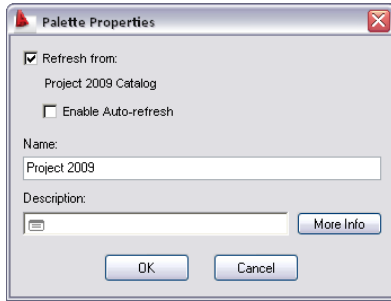

When you copy a tool or tool palette from the Content Browser to the tool palette set, you can choose whether the copy retains its association with the original. Linking the copy to the original means that, if you copy the item back to its original location, the Content Browser assumes you are updating the original item. This is the default behavior. If you change the original, you can update a linked copy using a single mouse click. To make working easier for you, you can set a whole tool catalog to be linked or unlinked. When a tool catalog is linked, all tools and palettes contained in it are dropped into the AutoCAD Architecture palettes set as linked items by default. When a tool catalog has been set to unlinked, all items in it are dropped as unlinked.

An unlinked copy of a tool or tool palette is treated as a new item, with no relationship to the original item. If you copy an unlinked item back to its original location in a tool catalog, the Content Browser simply adds it to the catalog; you end up with two copies of that item with the same name.

Any time you copy an item from the Stock Tool catalog to the tool palette set, the item is treated as unlinked.

You can tell whether an item in the tool palette set is linked by right-clicking the item and clicking Properties. If Refresh from is activated and a source is listed, as shown below, the item is linked.

Refresh from property of a linked palette

If you select Enable Auto-Refresh, each time you start the software, any linked tool palettes will be updated to reflect any changes made to the tool palette and its contents in the tool catalog.

Using a Tool in the AutoCAD Architecture Workspace

Use this procedure to use a tool from a tool catalog in the AutoCAD Architecture 2009 workspace. You can also copy tools stored in a tool package to a tool palette in the tool palette set.

- 1 Open the tool catalog containing the tool you want to use. If the tool is located in a specific category of the catalog, open that category.
- 2 Move the pointer over the i-drop[®] icon next to the tool, so that the pointer image changes to

an eyedropper ().

To select multiple tools to copy, press and hold *CTRL* while clicking each tool; then position the eyedropper over any of the selected tools. You can also select all the tools in the current category by right-clicking and clicking Select All.

- 3 Drag the eyedropper according to the desired action:

If you want to...

Then...

use the tool immediately

click the eyedropper and drag it into the drawing area.

store a linked copy of the tool on a tool palette in the tool palette set

click the eyedropper and drag it to a tool palette in the tool palette set.

NOTE A linked copy will only be created when the tool catalog has been set to linked. If the catalog has been set to non-linked, any tool from that catalog will be inserted as non-linked tool onto the AutoCAD Architecture tool palettes set. For more information about linking tool catalogs see [Editing Tool Catalog Properties](#) on page 135.

If you want to...	Then...
create an unlinked copy of the tool on a tool palette in the tool palette set	press and hold <i>alt</i> . Then click the eyedropper, and drag it to a tool palette in the tool palette set.
	<p>NOTE If the tool catalog containing the tool has been set to unlinked, you do not need to hold down <i>alt</i> while dragging the tool. It will be inserted as unlinked in any case.</p>

NOTE If a tool palette does not accept a tool, it might be because the palette is set to allow updates only from a linked tool palette in a tool catalog. To check this, right-click on the palette, click Properties, and look at the Refresh from setting. If Refresh from is selected, the palette is linked to a palette in a tool catalog. To break the link, clear Refresh from.

Copying a Tool Palette to the AutoCAD Architecture Workspace

Use this procedure to store a copy of a tool palette in the tool palette set.

You can create a linked or unlinked copy of the tool palette. A linked copy remains connected to the original in the tool catalog, so that you can easily update the copy with any changes made to the original. An unlinked copy is treated as a new tool palette, with no relationship to the original. For more information about linked and unlinked tool palettes, see [Using the Items in a Tool Catalog](#) on page 125.

- 1 Open the tool catalog containing the tool palette to copy to the tool palette set. If the palette is located in a specific category of the catalog, open that category.
- 2 Move the pointer over the i-drop[®] icon next to the tool palette, so that the pointer image changes to an eyedropper ().
To copy multiple tool palettes, press and hold *CTRL* while clicking each palette; then position the eyedropper over any of the selected palettes.
- 3 Drag the eyedropper according to the desired action:

If you want to...	Then...
store a linked copy of the tool palette in the tool palette set	click the eyedropper and drag it to a tool palette in the tool palette set.
	<p>NOTE A linked palette will only be created when the tool catalog has been set to linked. If the catalog has been set to non-linked, any palette from that catalog will be inserted as non-linked tool palette onto the AutoCAD Architecture tool palettes set. For more information about linking tool catalogs see Editing Tool Catalog Properties on page 135.</p>

If you want to...	Then...
create an unlinked copy of the tool palette in the tool palette set	press and hold <i>alt</i> . Then click the eyedropper, and drag it to a tool palette in the tool palette set.
<p>NOTE If the tool catalog containing the palette has been set to unlinked, you do not need to hold down <i>alt</i> while dragging the palette. It will be inserted as unlinked in any case.</p>	

Copying a Tool Package to the AutoCAD Architecture Workspace

Use this procedure to copy a tool package to a palette in the tool palette set.

You can create linked or unlinked copies of the tools in the package. A linked copy remains connected to the original in the tool catalog, so that you can easily update the copy with any changes made to the original. An unlinked copy is treated as a new tool, with no relationship to the original. For more information about linked and unlinked tools, see [Using the Items in a Tool Catalog](#) on page 125.

1 Open the tool catalog containing the tool package to copy into the tool palette set. If the package is located in a specific category of the catalog, open that category.

2 Move the pointer over the i-drop[®] icon next to the tool package, so that the pointer image

changes to an eyedropper ().

To copy multiple tool packages, press and hold *CTRL* while clicking each package; then position the eyedropper over any of the selected packages.

3 Drag the eyedropper according to the desired action:

If you want to...	Then...
store linked copies of the package's tools in the tool palette set	click the eyedropper and drag it to a tool palette in the tool palette set.
<p>NOTE Linked tools will only be created when the tool catalog has been set to linked. If the catalog has been set to non-linked, any tool in that package will be inserted as non-linked tool package onto the AutoCAD Architecture tool palettes set. For more information about linking tool catalogs see Editing Tool Catalog Properties on page 135.</p>	
create unlinked copies of the package's tools in the tool palette set	press and hold <i>alt</i> . Then click the eyedropper, and drag it to a tool palette in the tool palette set.
<p>NOTE If the tool catalog containing the package has been set to unlinked, you do not need to hold down <i>alt</i> while dragging the tool. It will be inserted as unlinked in any case.</p>	

Refreshing Linked Tools

Use this procedure to update a linked tool with the contents of its source copy in a tool catalog.

- In the tool palette set, right-click the tool you want to refresh, and click Refresh Tool. If Refresh Tool is not listed on the shortcut menu, click Properties. Then, in the Tool Properties worksheet, select Refresh from.

Refreshing Linked Tool Palettes

Use this procedure to update a linked tool palette with the contents of its source copy in a tool catalog.

- In the tool palette set, right-click the tool palette you want to refresh, and click Refresh Palette. If Refresh Palette is not listed on the shortcut menu, click Properties. Then, in the Tool Palette Properties worksheet, select Refresh from.

Specifying Refresh Options for Linked Tool Palettes

Use this procedure to determine whether a linked tool palette and its tools are refreshed from the tool catalog when you start AutoCAD Architecture 2009.

- 1 In the tool palette set, right-click the desired tool palette, and click Properties.
- 2 Select an Auto-refresh option:

If you want...	Then...
the tool palette and all its tools to automatically refresh when you start AutoCAD Architecture 2009	select Enable Auto-refresh. NOTE Refresh from must also be selected in order to enable Auto-refresh.
no automatic refreshing of the tool palette	clear Enable Auto-refresh.

- 3 Click OK.

Working with Multiple Content Browser Windows

You can open more than one copy of the Content Browser and you can move or copy items by dragging them between the windows. You can copy tool palettes, tool packages, and tools; you cannot copy tool catalogs between Content Browser windows. Only one catalog library can be open at any time.

When you drag tool catalog items between Content Browser windows, the following rules apply:

- If a different catalog is open in each Content Browser window, dragging an item copies it to the new location and leaves the original item in place.
- If the same catalog is open in both Content Browser windows, dragging items from one window to the other moves the item (for example, from one category to another), removing the original item.

If you have the same tool catalog open in multiple windows, and you add an item to the catalog, the tool catalog display is updated in all open Content Browser windows.

Opening Additional Content Browser Windows

You can open a new instance of the Content Browser by pressing *CTRL+N* in the Content Browser. You can also open a specific tool catalog, tool palette, or tool package in a new Content Browser window.

Closing Content Browser Windows

Closing one Content Browser window has no effect on other Content Browser windows. You can close all open Content Browser windows at once by right-clicking in the title bar of any window and selecting Close All Windows.

Opening a Tool Catalog in a New Content Browser Window

Use one of the following procedures to open a tool catalog in a new Content Browser window or display an open catalog in a new Content Browser window.

- With the catalog library displayed in the right pane of the Content Browser window, right-click the catalog to open, and click Open in New Window.
- If a tool catalog is already open in the right pane of the Content Browser window, right-click in a blank area of the catalog, and click New Window.
You can open a specific category of the tool catalog in a new Content Browser window by opening the category.

Opening Catalog Items in a New Content Browser Window

Use this procedure to open a tool palette or tool package in a new Content Browser window.

- 1 Open the catalog containing the desired tool palette or tool package. If the item is located in a specific category of the catalog, open that category.
- 2 Right-click the tool palette or tool package, and click Open in New Window.

Dragging Catalog Items Between Content Browser Windows

Use this procedure to send tools, tool palettes, or tool packages from one catalog location to another by dragging them between two Content Browser windows. Moving an item removes it from its original location, while copying an item retains the original.

NOTE You must have write access to the original catalog before you can move it.

- 1 Open two Content Browser windows.
- 2 In the first Content Browser window, display the catalog item that you want to move or copy.
- 3 In the second Content Browser window, open the catalog, category, tool palette, or tool package to send the item to (only tools can be sent to palettes and packages).

4 In the first Content Browser window, move the pointer over the i-drop icon associated with the item to be moved, so that the pointer image changes to an eyedropper ().

If you want to...

Then...

move an item to another location in the same catalog

right-click  and drag the item to its destination catalog or category in the second Content Browser window, and click Copy Here.

copy an item to another location in the same catalog

press *CTRL*; then  and drag the item to its destination catalog or category in the second Content Browser window.

move an item to a different catalog

press *CTRL*; then click  and drag the item to its destination catalog or category in the second Content Browser window.

copy an item to a different catalog

click  and drag the item to its destination catalog or category in the second Content Browser window.

move a tool to a tool palette or tool package in the same catalog

click  and drag the item to its destination palette or package in the second Content Browser window.

copy a tool to a tool palette or tool package in the same catalog

press *CTRL*; then click  and drag the item to its destination palette or package in the second Content Browser window.

move a tool to a tool palette or tool package in a different catalog

press *CTRL*; then click  and drag the item to its destination palette or package in the second Content Browser window.

copy a tool to a tool palette or tool package in a different catalog

click  and drag the item to its destination palette or package in the second Content Browser window.

Starting the Content Browser from a Windows Command Prompt

Use this procedure to open the Content Browser from a Windows command prompt, even if AutoCAD Architecture 2009 is not currently open.

1 Click Start (Windows) menu ► Command Prompt.

The location of the Command Prompt application varies from one version of Windows to another. It is most likely to be found either in Programs or on the Accessories menu within Programs.

- 2** At the command prompt, specify the AutoCAD Architecture program folder as the current directory.
- 3** Enter the command *aeccb*, followed optionally by the path to the tool catalog you want the Content Browser to open. For example:

aeccb "c:\my documents\my aec content browser library\mystuff\mystuff.atc"

Creating and Saving Drawings

4

Drawings have common properties that you can specify when you create a new drawing. You can specify:

- the template on which to base the drawing, or create a drawing that is not based on any template.
- units, scale, layer standard, layer key style, and default display properties.
- options that control drawing performance and behavior.

You also have a number of options for saving files to use with other applications. These options are useful if you work with vendors and consultants who do not use AutoCAD Architecture.

About Templates

The templates included in the software are drawing files with predefined settings. Predefined settings include drawing units, drawing scales, and annotation plot sizes. You can use these templates to create new drawings without going through any additional setup.

Templates are installed in the folder Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Template.

NOTE The Template folder is marked as hidden in Windows by default. To display hidden folders, enable that option on the View tab of the Folder Options command in Windows Explorer.

Templates also contain predefined display configurations. Display configurations allow you to produce different architectural displays, such as floor plans, reflected plans, elevations, 3D models, or schematic displays. For more information, see [Display System](#) on page 537. If you are working with a project, as described in [Drawing Management](#) on page 217, you can assign display configurations directly to the project as a project standard. For more information, see [Configuring Project Standards](#) on page 416.

If you are a new user of the software, it is recommended that you use a template to create your drawings. You always have the option to modify a template or create your own template after you become more familiar with the software.

You can modify a template to conform to your office standards by changing the settings and then saving it as a new template, or you can import settings from another template into the current drawing, and then saving the current drawing as a template. For more information about creating your own template, see “Use

a Template File to Start a Drawing” in AutoCAD Help. For more information about importing display settings to a custom template, see [Using Display Settings in Multiple Drawings](#) on page 574 and [Creating and Editing Display Configurations](#) on page 559.

Creating a Drawing from a Template

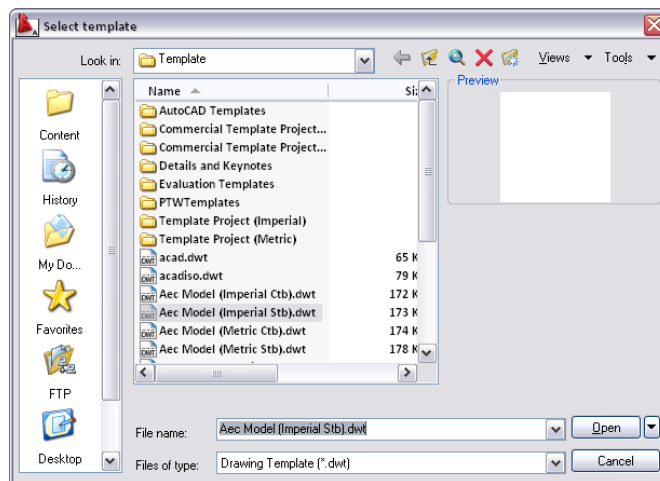

Use this procedure to create a drawing from a template. The drawing templates provided with the software are located in Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Template. Template files have the extension dwt.

NOTE To create a drawing that you want to include in a project, see [Process Overview: Working in a Project Environment](#) on page 217.

1 Click File menu ► New.

NOTE Be sure to choose the New command from the File menu to select a template. The “new” icon on the Standard toolbar is actually a shortcut to the “QNew” command which creates a new drawing based upon a default template file. You can configure the default template file used for QNew in the Options dialog. For more information, see “QNEW Command” in AutoCAD Help.

2 Select the template you want to use, or click Tools ► Find, and navigate to the template you want to use.

3 Click Open.

To view or change the default drawing settings for units, scale, layers, and display, see [Setting Up a Drawing](#) on page 158.

Creating a Drawing Without a Template

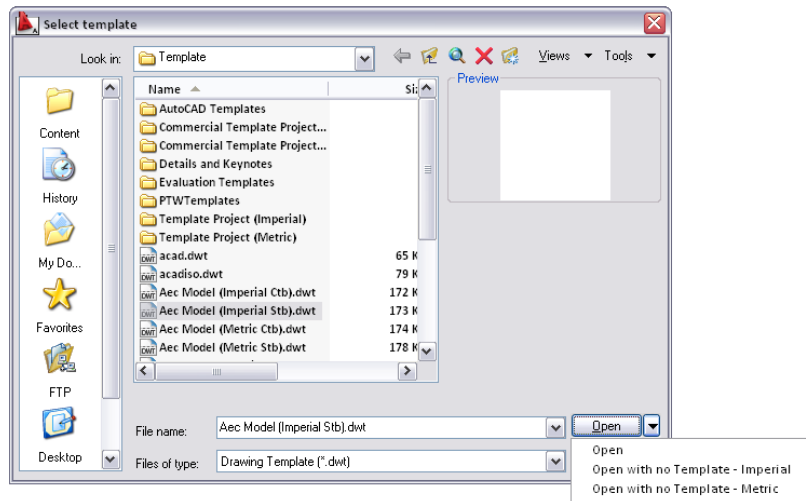

Use this procedure to create a drawing that is not based on a template. Drawings that are not based on templates contain no customized or predefined settings, such as display configurations or architectural units. Drawings without a template use the settings specified in the Drawing Setup dialog box.

If you are a new user use one of the templates provided to create drawings until you are comfortable working with display configurations and other settings. After you are more familiar with the program, you can create

your own templates and customize your drawing settings. For more information, see [Creating a Drawing from a Template](#) on page 156.

NOTE To create a drawing to include in a project, see [Process Overview: Working in a Project Environment](#) on page 217.

- 1 Click File menu ► New.
- 2 Click the arrow next to Open.

- 3 Select Open with no Template - Imperial to begin a drawing in imperial units, or select Open with no Template - Metric to begin a drawing in metric units.

For more information, see [Setting Up a Drawing](#) on page 158.

Opening Legacy Drawings

Keep the following points in mind when you open drawings from earlier releases:

- To upgrade a drawing from an earlier release to the current release, open the legacy drawing and then save the drawing. If the drawing references other legacy drawings, open and save those externally referenced (xref) drawings to upgrade them to the current release.
- Drawings from Release 2 are always fully opened; the partial open option is not available.
- If you try to edit an external reference drawing within a legacy drawing, you are prompted to update the external reference drawing to the current release. It is recommended that you use the same version for your external references and host drawings.
- If you open a legacy drawing in the Style Manager, the drawing is marked as read-only; you can copy styles from that drawing to drawings in newer current versions. If you copy styles from the current version to legacy drawing, you have to save the legacy drawing under a new name and in the current release file format.
- Open and save a legacy drawing in the current version if you want to be able to edit it in DesignCenter®.

IMPORTANT Any time you combine a drawing from a previous version with a drawing from the current version, you should first open the previous version drawing and save it. For example, before inserting a drawing as a block or attaching it as an xref, open the drawing and save it to promote all the objects to the current version.

Setting Up a Drawing

When you create a drawing from a template, the drawing setup options are predefined. You can use these settings or customize them as needed. For example, you may want to use different drawing scales for different drawings.

When you create a drawing without a template, settings such as layer standards and layer key styles are imported into the drawing. For more information, see [Creating a Drawing Without a Template](#) on page 156.

You can specify the drawing units, drawing scale, and layer options as the default settings for any drawing that you start, with or without a template. If you save the settings specified as the default, they override settings in the template.

If you are unfamiliar with the display system or layer management, you may want to read more in [Display System](#) on page 537 and [Managing Drawing Layers](#) on page 488 before specifying the layering and display options.

Specifying the Drawing Units

Use this procedure to specify the drawing units in a new or existing drawing. If you change the drawing units, you can specify whether existing objects in the drawing are scaled to the new units or retain their original size. You can also specify whether objects inserted from a drawing that uses different units are scaled to the units in the current drawing, or retain their original size.

You can specify the unit type and precision for linear, angular, area, and volume units. The precision values specify only the number of decimal places displayed in the interface. They do not determine the number of decimal places used in the software to make calculations.

When you change the drawing units, the default options under Area and Volume change to reflect the new drawing units. The drawing scale options on the Scale tab also change to reflect the new drawing units.

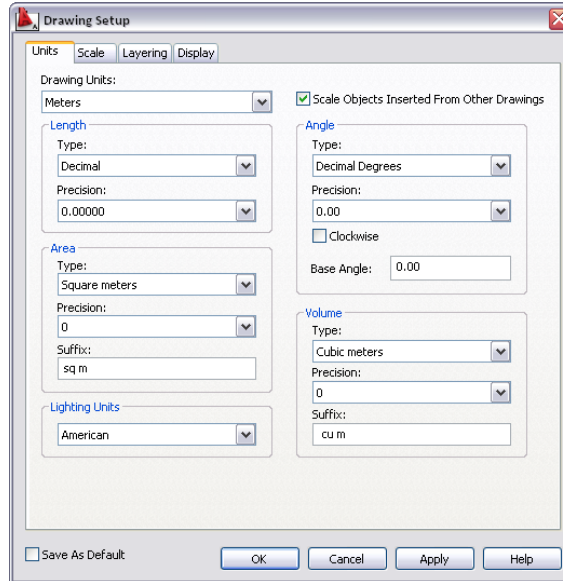

1 In the Drawing Window status bar, click  .

2 Click Drawing Setup.

NOTE Alternatively, you can choose Drawing Setup from the Format menu.

3 Click the Units tab.

Specifying default units options for the current drawing

4 Under Drawing Units, select the desired units.

Various imperial and metric units are available. The units that you select determine the unit of measurement that each unit in your drawing represents. For example, if you select Inches, each drawing unit equals one inch.

5 To scale objects that you insert into the current drawing from drawings with different drawing units, select Scale Objects Inserted from Other Drawings.

Clear this option to insert objects at their original size without scaling. For example, if an item that is one inch long were inserted into a drawing set to millimeters, this setting would scale the item to 25.4 mm in length when enabled. With this setting disabled, it would remain one unit long, (which would now be only one millimeter rather than one inch).

6 Under Length, select a unit type and desired precision.

7 Under Angle, select an angle type and desired precision.

If you want to measure angles clockwise instead of counterclockwise, select Clockwise.

8 Under Base Angle, enter a value for the default 0 angle direction. The default is 0 degrees (East) and a counter-clockwise direction.

Imported survey drawings may include drafting instructions where changing the base angle might be desirable to properly orient the data.

The following values match these directions:

Value	Direction
0	East
90	North
180	West
270	South

9 Under Area, select an area type and precision.

If you do not want to use the default suffix that is displayed for the drawing units that you specify, enter a new suffix.

10 Under Volume, select a volume type and precision.

If you do not want to use the default suffix that is displayed for the drawing units that you specify, enter a new suffix.

11 Save the units settings:

If you want to...	Then...
save the units settings as default settings for new drawings that you start from scratch or from templates that do not contain drawing setup information	select Save as Default. Settings on the Scale and Layering tabs are also saved as default settings.
save the units settings only for the current drawing	clear Save as Default, and then click Apply.

NOTE You can save one default drawing units set per unit type with the save as Default option. Define a set of imperial drawing units defaults, and click Save as Default. Then, define a set of metric default units, and click Save as Default again. When you start a drawing without a template with imperial units, the imperial default settings will be used. When you start a drawing without a template with metric units, the metric default settings will be used. If you start a new drawing with a template, the settings saved within that template file will be used regardless of the saved default settings.

12 Click OK.

You are prompted to specify whether existing objects in the current drawing should be scaled for the new units.

13 Specify scaling of existing objects for Model Space and Paper Space:

If you want to...	Then...
scale existing objects in Model Space	select Scale model-space objects in current drawing to reflect new units.
leave objects in Model Space at their current size	clear Scale model-space objects in current drawing to reflect new units.
scale existing objects in Paper Space	select Scale paper-space objects in current drawing to reflect new units.
leave objects in Paper Space at their current scale	clear Scale paper-space objects in current drawing to reflect new units.

14 Click OK.

Specifying the Drawing Scale

Use this procedure to specify the drawing scale and the plot size of annotations in model space.

The drawing scale determines how many drawing units in the drawing represent one inch (for imperial drawings) or one millimeter (for metric drawings) in the plotted drawing. A drawing scale of 1/8"=1'-0" (or

1:96 - eight eighths per inch times 12 inches per foot) in a drawing that has inches as default drawing units means that 8 feet in the drawing are represented by 1 inch on the plotted out plan. Likewise, if a drawing has a scale of 1:200 and a drawing unit of millimeters, then 200 millimeters in the drawing will be represented by one millimeter on the plotted out plan.

Annotation plot size, multiplied by the drawing scale factor, determines the height of plotted annotation text. Scale-dependent objects in a drawing are scaled automatically upon insertion to reflect the units that are specified in a drawing. Any content that you create can be built to take advantage of these settings and is thus scaled appropriately.

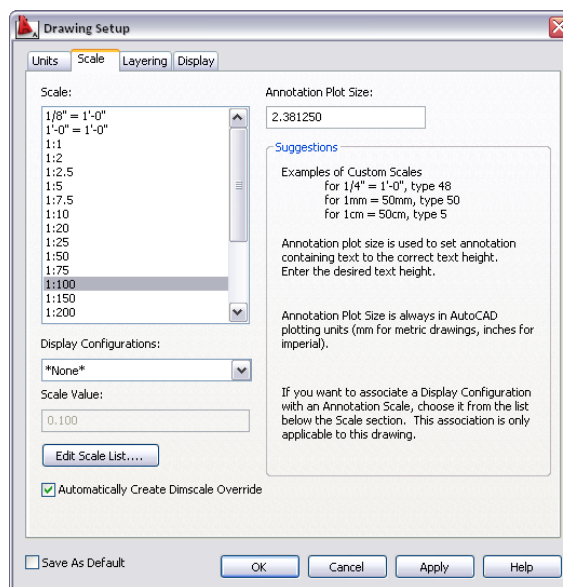

1 In the Drawing Window status bar, click .

2 Click Drawing Setup.

NOTE Alternatively, you can choose Drawing Setup from the Format menu.

3 Click the Scale tab.

Specifying default scale options for the current drawing

4 Under Scale, select the drawing scale that you want to use.

NOTE The scale values in the Drawing Scale list reflect the current drawing units. To change the drawing units, see [Specifying the Drawing Units](#) on page 158.

If the scale you want to use does not exist in the list, you can click Other, and enter a scale value under Custom Scales.

5 To edit an existing scale or add a new scale, click Edit Scale List.

- To edit an existing scale, select it, and click Edit.
- To add a new scale, click Add, and enter a display name and scale values.
- To rearrange the order of the scale entries, use the Move up and Move down buttons.

6 Click OK.

7 Select Automatically Create Dim Scale Override, if you want to make the dimension scale match your drawing scale.

The override applies a scale factor to the dimension style properties.

NOTE AEC dimensions added with tools are not affected by the dimension scale override because an AEC dimension style depends on which display representation is active. For more, see [AEC Dimensions](#) on page 2243.

If you clear Automatically Create Dim Scale Override, the software is prevented from automatically applying an override to the current dimension scale style in the drawing.

8 Enter a value for Annotation Plot Size.

The annotation plot size is always measured in millimeters for metric drawings and in inches for imperial drawings. Annotation plot size, multiplied by the drawing scale factor, determines the height of plotted annotation text.

9 Save the scale settings:

If you want to...	Then...
save the scale settings as default settings for new drawings that you start from scratch or from templates that do not contain drawing setup information	select Save as Default. Settings on the Units and Layering tabs are also saved as default settings.
save the scale settings only for the current drawing	clear Save as Default, and then click Apply.

NOTE You can save one default drawing scale set per unit type with the Save as Default option. Define a set of imperial drawing scale defaults, and click Save as Default. Next, define a set of metric scale defaults, and click Save as Default again. When you start a drawing without a template with imperial units, the imperial default scale will be used. When you start a drawing without a template with metric units, the metric default scale will be used. When you start a drawing without a template with metric units, the metric default settings will be used. If you start a new drawing with a template, the settings saved within that template file will be used regardless of the saved default settings.

10 Click OK.

If you also changed the drawing units, you are prompted to specify whether existing objects in the current drawing should be scaled for the new units. For more information, see [Specifying the Drawing Units](#) on page 158.

Specifying a Layer Standard and a Layer Key Style

Use this procedure to specify the layer standard and layer key style to determine the layers on which objects are placed in a drawing. You can specify the layer key style to use in the current drawing. You can also specify a layer standard and a layer key style to be imported when you set up a new drawing.

There are a number of layer standards and layer key styles in AecLayerStd.dwg, located in Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Layers.

By default, AecLayerStd.dwg (located in the Layers folder mentioned above) is loaded automatically. This file contains layer standards and layer key styles.

NOTE If you are unfamiliar with layer keying, you may want to read the overview of layer keying before specifying layering options. For more information, see [Working with Layer Keys](#) on page 514.

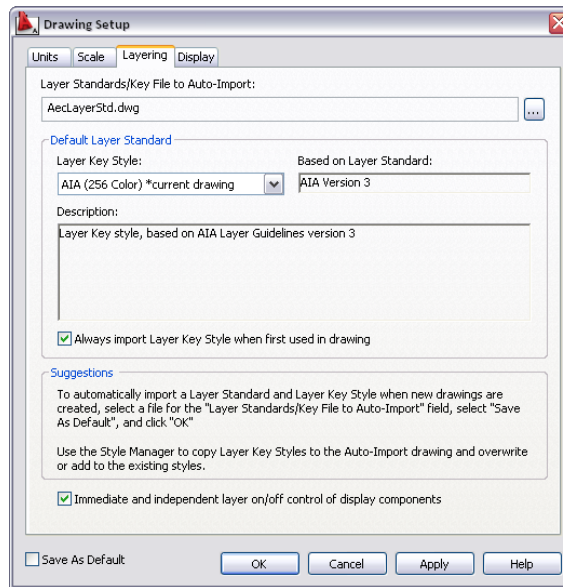

1 On the Drawing Window status bar, click .

2 Click Drawing Setup.

NOTE Alternatively, you can choose Drawing Setup from the Format menu.

3 Click the Layering tab.

Specifying default layering options for the current drawing

4 Under Layer Standards/Key File to Auto-Import, enter the name of the layer standards drawing (DWG or DWT) you want to use.

You can click the Browse button to navigate to a file.

5 Under Default Layer Standard, select the layer key style that you want to use in your drawing.

6 To re-import the layer key style from the layer standard you specified at the start of each drawing session, select Always import Layer Key Style when first used in drawing.

Selecting this option has the effect of checking the current drawing to see if the selected layer key style exists. If it does exist, the date and time stored on it are compared with the external file. If the external layer key style drawing is newer, then it re-imports the layer key style and standard. This action occurs each time the drawing file is opened; therefore, to force a re-import of the layer key style, you must close and reopen the drawing.

7 Define the on/off behavior of secondary components within an object.

You can place different components of an AEC object on different layers. This is accomplished with the object's display properties. For example, the current layer key style might place a wall on the layer named A-Wall, while the wall's material definitions place its internal boundaries on the layer named A-Wall-Comp. Turning off the layer A-Wall would typically make the entire wall (including its internal boundaries) invisible, even though those components were assigned to a different layer. Selecting Immediate and independent layer on/off control of display components allows the internal boundary components on A-Wall-Comp to remain visible, even though the primary object's layer (A-Wall in this case) is off. This behavior can be desirable in some plan representations.

NOTE Freezing the primary object's layer (A-Wall in this case) makes the entire wall, including its internal boundaries, invisible regardless of the value of this setting. This setting applies only to the Off layer state.

If you want to...

Then...

turn off secondary object components on different layers when the main component layer is turned off

clear Immediate and independent layer on/off control of display components.

If you want to...	Then...
turn on and off secondary object components independently of the main object component layer settings	select Immediate and independent layer on/off control of display components.

8 IMPORTANT If you select Save as Default, the layer key style you select is the default layer key style for all new drawings created without a template or from templates that do not have different default layer key standards assigned.

Save the layer settings:

If you want to...	Then...
save the layers settings as default settings for all new drawings that you start without a template or from templates that do not contain drawing setup information	select Save as Default, and click OK. Settings on the Units and Scale tabs are also saved as default settings.
save the layer settings only for the current drawing	clear Save as Default, click Apply, and then click OK.

If you also changed the drawing units, you are prompted to specify whether existing objects in the current drawing should be scaled for the new units. For more information, see [Specifying the Drawing Units](#) on page 158.

Specifying the Default Display Representations

Use this procedure to specify the default display representations of AEC objects. You can also specify the default display configuration for the Model tab and new viewports. In addition, you can specify whether the drawing uses its own display configurations or those of a host drawing when the drawing is referenced as an overlay xref.

You may find it easier to select and modify display representations using the Display Manager. For more information about the display system, see [Display System](#) on page 537. For more information about using the Display Manager, see [The Display Manager](#) on page 552.

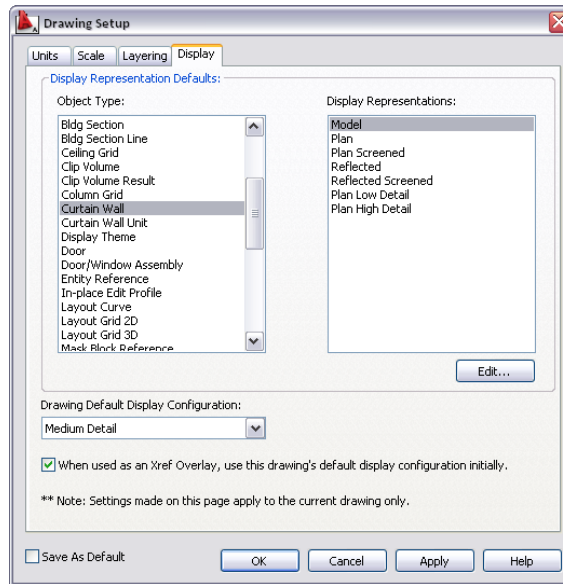

NOTE Changes you make on the Display tab apply only to the current drawing. New drawings are not affected. Save as Default has no effect on this tab.

- 1 On the Drawing Window status bar, click  .
- 2 Click Drawing Setup.

NOTE Alternatively, you can choose Drawing Setup from the Format menu.

- 3 Click the Display tab.

Specifying default display options for the current drawing

- 4 To make changes to a display representation for an object type, select it, and click Edit.

For general information about display representations, see [Display Representations](#) on page 544. For information about the display properties of an object type, see the chapter about the relevant object. For example, for information about wall display properties, see [Specifying the Display Properties of a Wall Style](#) on page 889.

- 5 Select a display configuration for Default Display Configuration.

The display configuration is applied to the Model tab and new viewports in paper space layouts.

- 6 To use the display configurations in the current drawing when the drawing is referenced as an overlay xref in a host drawing, select When used as an Xref Overlay use Display Configurations from this drawing only.

Clear this option if you want objects in the current drawing to use the display configurations of the host drawing when the current drawing is an overlay xref.

For information about overlaying xrefs in drawings, see “Reference Other Drawing Files (Xrefs)” in AutoCAD Help.

- 7 Click OK.

If you also changed the drawing units, you are prompted to specify whether existing objects in the current drawing should be scaled for the new units. For more information, see [Specifying the Drawing Units](#) on page 158.

Specifying AEC Options

There are several tabs in the AutoCAD Options dialog box where you can select specific AEC options. You can use these settings to specify default values for some architectural objects, to specify the location and type of content files, and to control performance while you are working in architectural drawings.

Changing the AEC Editor Settings

Use this procedure to specify settings to control the following aspects of the software:

- the display of diagnostic messages and solution tips
- the placement of dialog boxes and viewers on the screen
- whether objects retain their layer, color, and linetype when you export them to an AutoCAD or DXF file

To improve drawing performance, you can limit the snap points provided by certain display representations, and decrease the layer loading time of the Layer Manager.

You can also specify settings for grip colors, and specify whether dynamic dimensions appear when you select and move grips to change the geometry of an object.

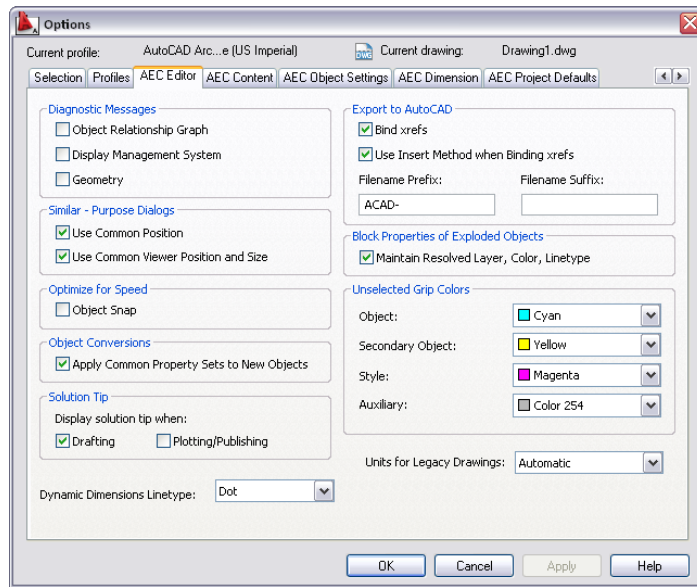

The AEC Editor settings that you specify are saved in the Windows® registry.

1 Click Format menu ► Options.

You can also display the Options dialog box by right-clicking in the command line area, and clicking Options.

2 Click the AEC Editor tab.

Specifying default AEC Editor options for the current drawing

3 Under Diagnostic Messages, select options for displaying diagnostic messages on the command line:

If you want to...

Then...

display data about the relationship between objects in the drawing

select Object Relationship Graph.

display Display System errors

select Display Management System.

display object geometry-specific data

select Geometry.

All diagnostic messages are off by default.

4 Under Similar-Purpose Dialogs, select options for the default position of dialog boxes and viewers:

If you want to...	Then...
use a common position on the screen for similar dialog boxes	select Use Common Position. Some dialog boxes, such as those containing style properties, are always displayed in the center of the screen, regardless of this setting.
use a common position for similar-purpose viewers	select Use Common Viewer Position and Sizes. Some viewers are not controlled by this setting.

5 Under Optimize for Speed, select Object Snap to limit certain display representations to respond only to the Node and Insert object snaps.

This setting affects stair, railing, space boundary, multi-view block, masking block, slice, and clip volume result (building section) objects.

6 Under Object Conversions, choose Apply Common Property Sets to New Objects if you wish to have common property sets automatically applied to new objects when applying tool properties.

When you apply the properties of a tool to an object in the drawing, the result can often be a new object. For instance, when you apply the tool properties of a door to an existing window, a new door object is created in place of the existing window. With this setting enabled, any property sets that were assigned to the existing window will automatically be preserved and applied to the new door provided that the property set definitions in question applies to both types of objects (in this case, both doors and windows are selected on the property set's applies to tab).

7 Under Solution Tip, specify whether you want solution tips to be displayed during the listed activities. Drafting is selected by default. Plotting/Publishing is cleared by default. For more information, see [Solution Tips](#) on page 57.

8 To specify the units of measure for AutoCAD drawings when they are opened in the software, select Metric or Imperial for Units for Legacy Drawings.

This option enables the software to ignore the value for the AutoCAD MEASUREMENT variable to ensure that the software respects the correct units when an AutoCAD drawing is opened in the software. Select Automatic if you want AutoCAD drawings to use the units that are current in the software.

9 Choose your preferred Palette Theme: either AutoCAD Architecture or Windows. You must restart the software for your change to take effect.

10 Under Export to AutoCAD, select Use Insert Method when binding Xrefs if you want all objects from an xref drawing referenced in the file you export to be incorporated into the host drawing.

If you select this option, the names of the xref drawings are discarded when the exported drawing is created. In addition, their layers and styles are incorporated into the host drawing. For example, all exploded walls, regardless of their source (host or xref) are located on the same layer.

Clear Use Insert Method when binding Xrefs if you want to retain the xref identities, such as layer names, when you export a file to AutoCAD or to a DXF file. For example, the blocks that define walls in the host drawing are located on A-Wall in the exploded drawing. Walls in an attached xref drawing are located on a layer whose name is created from the drawing name and the layer name, such as Drawing1\$0\$A-Wall.

11 Enter a prefix or a suffix to be added to the drawing file name when the drawing is exported to an AutoCAD drawing or to a DXF file.

12 Under Block Properties of Exploded Object, select Maintain Resolved Layer, Color, Linetype to maintain the layer, color, and linetype of AEC objects when you explode them.

When you explode an AEC object, you create several primitive objects grouped in a block definition. If this option is selected, any objects whose component layer, color, and linetype properties are set to ByBlock take the layer, color, and linetype of the parent object. If this option is cleared, when you explode an object, properties that are ByBlock remain ByBlock. Clear this option if you want to explode the block definition even further.

13 Under Unselected Grip Colors, select the colors you want to use for each type of grip.

14 Under Dynamic Dimensions Linetype, select either Continuous or Dot.

The dimensions identify the current value of the dimension being edited, such as the length of a wall, the difference between the current value and the new dimension based on the position of the grip, and the total value. For example, when you select and move a Lengthen grip on a wall, the dimensions shown are the current length, the difference between the current length and the length based on where you moved the grip, and the total new length of the wall.

The dynamic dimensions will display in either continuous or dot linetype based on your selection.

15 Click OK.

Changing the AEC Content Settings

Use this procedure to specify the location of the content files accessed by the Custom View in AutoCAD DesignCenter, to choose between imperial and metric content, and to specify whether the Edit Property Data dialog box is displayed when you insert schedule tags. You can also specify the location of dependent files, such as styles for tools.

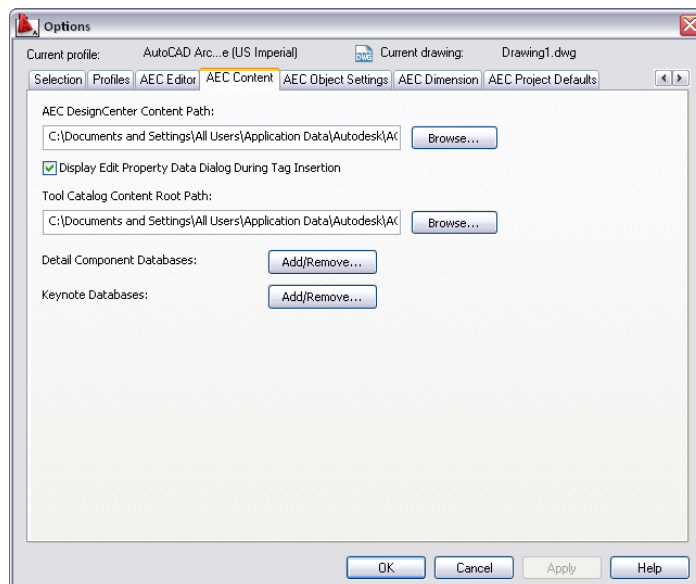

The AEC Content settings that you specify are saved in the Windows® registry.

1 Click Format menu ► Options.

You can also display the Options dialog box by right-clicking in the command line area, and clicking Options.

2 Click the AEC Content tab.

Specifying default AEC Content options for the current drawing

- 3 Under AEC DesignCenter Content Path, edit the path and location of your content files, or click Browse to locate content files.
- 4 To display the Edit Property Data dialog box when you insert a schedule tag in the drawing, select Display Edit Property Data Dialog During Tag Insertion.
When this option is chosen, a worksheet will display after each tag is placed, allowing you to edit property set values. If you clear this option, no worksheet will appear during tagging.
- 5 Under Tool Catalog Content Root Path, edit the path and location of your style drawings, or click Browse to locate files.
The variable, %AECCONTENT_DIR%, used for tool-dependent file references, is updated to use the path you specify. For example, <Style href="%AECCONTENT_DIR%\Door Styles\DoorStyles.dwg"/>.
- 6 Click Add/Remove next to Detail Component Databases to add or remove additional Detail Component Databases.
- 7 Click Add/Remove next to Keynote Databases to add or remove additional Keynote Databases.
- 8 Click OK.

Specifying AEC Object Settings

Refer to the following topics to specify AEC options for walls, stairs, spaces, and the display of curved objects:

- [Specifying Drawing Defaults for Walls](#) on page 776
- [Specifying AEC Options for Stairs](#) on page 1395
- [Setting Up Adjacency Relations between Space Surfaces](#) on page 2037
- [Specifying the Display Resolution of Objects with Facets](#) on page 169

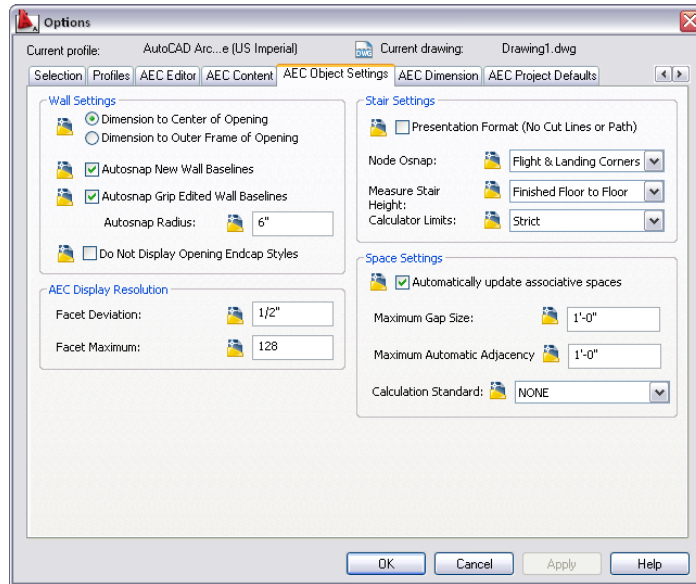

Specifying the Display Resolution of Objects with Facets

Use this procedure to specify the facet deviation and the maximum number of facets that can be used to display a curved object, such as a Cylinder mass element or a curved wall. The values you specify apply to the current drawing.

The number you specify for facet deviation defines the maximum distance from the chord to the arc, the chord being an edge that is created from faceting the curve to the true mathematical arc. The facet deviation must be greater than zero (0). It has no upper limit.

- 1 Click Format menu ► Options.
You can also display the Options dialog box by right-clicking in the command line area, and clicking Options.
- 2 Click the AEC Object Settings tab.

Specifying default AEC Object Settings options for the current drawing

3 Under AEC Display Resolution, enter a value for Facet Deviation.

The default value is 1/2" for drawings created from imperial templates and 12.7 mm for drawings created from metric templates. The value you enter is stored in the AecFacetDev variable.

4 Enter the maximum number of facets that can be used to draw curved objects.

You can enter a value between 100 and 10,000. The value you enter is stored in the AecFacetMax variable.

The default value is 128 for new drawings.

5 Click OK.

Changing the AEC Project Defaults

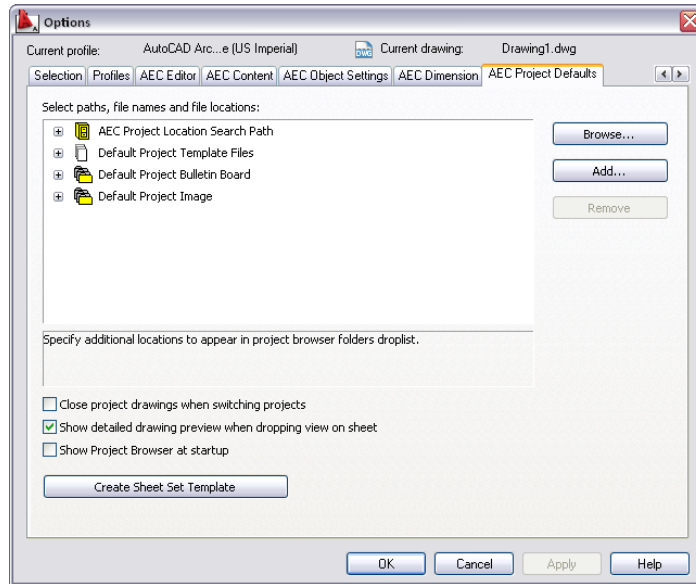

Use this procedure to specify the default folders in which the software searches for projects, palettes, templates, and other project files. These settings are used to create new projects without using a template. If a new project is created from a template project, the settings of the template project are used instead.

1 Click Format menu ► Options.

You can also display the Options dialog box by right-clicking in the command line area, and clicking Options.

2 Click the AEC Project Defaults tab.

Specifying default AEC Project Defaults options for the current drawing

3 Expand a category, and select a path.

4 Change, add, or remove a path:

If you want to...	Then...
change the current path	select the path, and click Browse. Navigate to the new path, and click OK.
add a path to the list of paths	select the category, such as Default Project Template Files, and click Add. Specify the new path, and click OK. If Add is unavailable, you can specify only one path for this category.
remove a path	select the path, and click Remove. If Remove is unavailable, you can edit the path but you cannot delete it.

5 Select Show Project Browser at startup if you want the Project Browser to open when you open the software.

6 To launch the Create Sheet Set wizard, click the Create button next to New Sheet Set Template. This will launch a wizard to assist you in creating your own Sheet Set Template to use for your projects.

7 Click OK.

Sharing Drawings with AutoCAD Users

There are 2 methods for making drawings available to users who are working with AutoCAD:

- Working with Proxy Graphics
- Exporting drawings to AutoCAD DWG or DXF

The method you choose depends on the software the others are using, on how exactly the drawing must match the original drawing, and on the particular views the other users require.

Turning on Proxy Graphics

When you turn on proxy graphics in a drawing, users who do not have AutoCAD Architecture but do have another AutoCAD-based product (AutoCAD 2000 or newer), can view and plot AEC objects and design data.

Exporting to AutoCAD Drawings and DXF Files

You can export drawings created with the software to AutoCAD drawings for the following versions:

- AutoCAD 2007
- AutoCAD 2004 (including 2005 and 2006)
- AutoCAD 2000 (including 2000i and 2002)
- AutoCAD R14

You can also export a drawing to a drawing interchange format (DXF) file. A DXF file is a text or binary file that contains drawing information that can be read by other CAD systems. For more information about DXF files, see “DXF Files” in AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

You can export drawings to the following DXF formats:

- AutoCAD 2007 DXF
- AutoCAD 2004 DXF (including 2005 and 2006)
- AutoCAD 2000 DXF (including 2000i and 2002)
- AutoCAD Release 12 DXF

Exporting a drawing to an AutoCAD drawing or to a DXF file creates a separate drawing in which all AEC objects, such as walls, doors, windows, and roofs, are exploded to AutoCAD primitive objects, such as lines, arcs, and 3D faces. The resulting AutoCAD objects cannot be restored to AutoCAD Architecture objects. Export AutoCAD Architecture drawings to DXF instead of saving them as DXF files.

NOTE You can open DXF files generated in earlier versions of the software if the files do not contain any AEC objects. DXF files that contain AEC objects cannot be imported into the software.

Comparing Methods of Sharing Drawings

The following table lists the features of the various methods of sharing drawings with AutoCAD users:

Use Case	Proxy Graphics	Object Enabler	Export to AutoCAD (DWG or DXF)
Use of AEC objects in other AutoCAD-based applications	View, plot AEC objects and design data; no manipulation of objects	View, plot, copy, manipulate AEC objects and design data	View, plot, manipulate exploded AEC objects

Use Case	Proxy Graphics	Object Enabler	Export to AutoCAD (DWG or DXF)
Status of AEC objects in other applications	AEC objects are displayed as proxy graphics with no intelligence	AEC objects are maintained as intelligent objects	No AEC objects
Multiple representations of objects in different viewports	No	Yes	Separate exploded copies are generated
AEC objects still exist when reopened in the software	Yes	Yes	No
Drawings used in a previous version	Yes	No	Yes

Generating Proxy Graphics

Use this procedure to create proxy graphics in a drawing to be made available to users who do not have the software.

Proxy graphics store the last-viewed image of AEC objects, which lets users view your drawing without modifying the original objects. Proxy graphics store only the display representation for the currently active viewport.

NOTE Depending on its complexity and density, a drawing saved with proxy graphics turned on can become extremely large and can slow drawing performance. It is recommended that you make a copy of the drawing before turning proxy graphics on if you want to share the drawing with other users.

- 1 Arrange the view for which you want to create proxy graphics.
- 2 At the command line, enter **proxygraphics**.
- 3 Enter **1**.
- 4 Save the drawing.
- 5 To turn off proxy graphics, enter **proxygraphics**, and then enter **0**.

Exporting a Drawing to AutoCAD

Use this procedure to export a drawing created in the software to AutoCAD. This process creates a new AutoCAD drawing with all AEC objects exploded. The original drawing is not affected.

Depending on the size and complexity of the original drawing, the resulting AutoCAD drawing may contain a large number of primitive objects, which can affect drawing performance.

NOTE When you export a drawing to an AutoCAD drawing, all AEC objects are exploded to AutoCAD primitive objects. Reopening the file in the software does not restore these primitive objects to AEC objects.

WARNING If you export a drawing that has Mviews to AutoCAD R14, only the layout active at the time of exporting will be preserved in AutoCAD R14. Any non-rectangular (polygonal or object) Mviews are converted to rectangular Mviews.

1 Choose whether to export a single representation of the AEC objects or all visible representations.

If you want to...	Then...
export the currently active representation of the AEC objects in the drawing	activate the Model tab. Only those representations in the currently active view will be generated.
export all representations of the AEC objects in the drawing	activate any layout tab. The representations for all layouts will be generated.

TIP This will usually result in duplicate graphics on the Model tab, which makes the drawing less useful.

For example, when creating a drawing for a consultant to use as an xref-attached background, you should display a top view in the active Model tab viewport. When creating a drawing to be used to produce a rendering, you should display an isometric view in the active Model tab viewport.

To create a drawing that includes the exact graphics used in all layout tab viewports, activate any layout tab. These drawings can be sent to a printing service, for example, to make plots without the need for AutoCAD Architecture or the Object Enabler.

2 Press F2 to display the command window.

3 On the command line, enter `ExportToAutocad`.

A list with the currently active export settings from the AEC Editor options page is displayed:

- File Format
- Bind Xrefs
- Bind Type
- Filename prefix
- Filename suffix

4 Alternatively, enter `AecToAcad` on the command line.

For more information, see “ExportToAutoCAD” in AutoCAD Help.

5 To change the AutoCAD file format to which the drawing should be exported, enter `F` (Format) and press `ENTER`.

The following AutoCAD file format versions are available:

- AutoCAD 2007
- AutoCAD 2004 (including 2005 and 2006)
- AutoCAD 2000 (including 2000i and 2002)
- AutoCAD R14

6 To specify whether to bind xrefs when exporting a drawing, enter `B` (Bind Xrefs), press `ENTER`, and select `Y` (Yes) or `N` (No).

NOTE If you want to retain visual fidelity in the exported drawing, selecting Yes is recommended. Visual fidelity can be affected by exporting individual drawings and binding them later, because when opened individually the xref may appear differently than it does in the host drawing.

7 To select the desired bind type for xrefs when exporting the drawing, enter **T** (bind Type), and choose one of the following:

If you want to...	Then...
discard the names of the xref drawings and incorporate their layers and styles into the host drawing when the exported drawing is created	enter I (Insert). In this case, for example, all exploded walls, regardless of their source (host or xref) are located on the same layer.
retain the xref identities when binding xrefs, such as layer names, when exporting the drawings	enter B (Bind). In this case, for example, the blocks that define walls in the host drawing are located on A-Wall in the exploded drawing. Walls in an attached xref drawing are located on a layer whose name is created from the drawing name and the layer name, such as Drawing1\$0\$A-Wall.

8 To specify whether the object properties in the exported AutoCAD drawing should be maintained, enter **M** (Maintain) and press *ENTER*:

- If you want the object properties to be resolved and be directly assigned to the exploded objects, enter **Y** (Yes).
- If you want objects to remain in blocks and have their properties set ByLayer and ByBlock, enter **N** (No).

9 To select a prefix or suffix for the drawing name, enter **P** (Prefix) or **S** (Suffix), press *ENTER*, and type in the desired prefix or suffix.

10 To enter a name for the exported AutoCAD drawing and start the export, press *ENTER*, and type in a file name.

TIP You can also start an export to AutoCAD by clicking File menu ► Export to AutoCAD, and then selecting the desired export format. In that case, the export settings defined on the AEC Editor tab of the Options dialog are used for exporting. For more information, see [Changing the AEC Editor Settings](#) on page 166.

IMPORTANT The `-AecExportToAutoCAD` command has been added to the Object Enabler in the software, enabling you to export a drawing to an AutoCAD format from within AutoCAD or other AutoCAD based vertical applications.

Exporting a Drawing to a DXF File

Use this procedure to export a drawing created in AutoCAD Architecture to a drawing interchange format (DXF) file. A DXF file is a text file that contains drawing information that can be read by other CAD systems. For more information about DXF files, see “DXF Files” in AutoCAD Help.

You can export drawings to the following DXF formats:

- AutoCAD 2007
- AutoCAD 2004 DXF (including 2005 and 2006)
- AutoCAD 2000 DXF (including 2000i and 2002)
- AutoCAD Release 12 DXF

Exporting AutoCAD Architecture drawings to a DXF format provides more consistent results than saving drawings as DXF files. Exporting creates a new DXF file with all AEC objects exploded. The original drawing is not affected.

Depending on the size and complexity of the original drawing, the resulting AutoCAD drawing may contain a large number of primitive objects, which can affect drawing performance.

NOTE When you export a drawing to a DXF file, all AEC objects are exploded to AutoCAD primitive objects. Reopening the file in the software does not restore these primitive objects to AEC objects.

1 On the File menu, click Export to AutoCAD, and click the DXF format you want to use.

2 Enter a file name, and specify a path, if necessary.

The DXF extension for the file name is specified by default. The default file name also includes any prefix or suffix that you specified on the AEC Editor tab of the Options dialog box. For more information, see [Changing the AEC Editor Settings](#) on page 166.

3 Click Save.

Viewport Layer Mapping

AEC objects have the ability to display themselves differently in each viewport. When AEC objects are exploded into AutoCAD primitive entities, each display representation must create a different set of primitives. For each viewport, a new layer and a new block definition are created to hold all exploded entities. A block reference (INSERT) to this definition is also created and placed on the given layer. For the given viewport, all layers created for other viewports are then frozen so that only the graphics for the display representation that was originally visible remain visible.

For a given layout tab, the following block definitions are created:

```
AecObjExplode_LayoutName_Pspace_<number> containing AEC objects in paper space
AecObjExplode_LayoutName_Vport_<VportHandle1> containing AEC objects from MVIEW 1
AecObjExplode_LayoutName_Vport_<VportHandle2> containing AEC objects from MVIEW 2...
AecObjExplode_LayoutName_Vport_<VportHandleN>
```

LayoutName is the name of the specific layout tab, and *VportHandle#* is the unique AutoCAD entity handle for that specific viewport.

NOTE To determine the handle for a viewport, enter **list** at the command line and select the viewport boundary. The handle is a hexadecimal number, such as 4D2A.

A layer is also created with the same names so that the blocks that do not apply to that viewport can be on a frozen layer, and thus not visible.

The “template” used to generate the block and layer names is stored in the Windows Registry under the key (note that the language code, shown as 409, will vary depending on your locale):

```
HKEY_CURRENT_USER\Software\Autodesk\AutoCAD\R17.0\ACAD-5004:409\Profiles\AutoCAD Architecture
- Imperial\Dialogs\AecObjExplode50-Options
```

You can change this template to another character string, but it must contain the “%1!s!” and similar format specifiers that are present. The format specifiers are replaced by the layout name and the viewport handle number in the final block and layer names.

NOTE When in the Model tab (TILEMODE=1), all representations are visible at the same time. This is because there is no way to freeze a layer in a tiled viewport without freezing it in all paper space viewports. However, you can freeze all but one of the viewport layers to get the desired representation.

Interoperability with Other Applications

5

AutoCAD Architecture 2009 is compatible with other Autodesk software applications (such as Autodesk® Land Desktop and Autodesk® DWF™ Viewer) as well as applications that are IFC certified. Interoperability features expand the usability of AutoCAD Architecture. For example, you can import LandXML data and use the topographical information to site your building appropriately.

Importing and Exporting IFC Files

Based on established, international standards for common objects in the building industry, the Industry Foundation Classes (IFC) file format provides an interoperability solution between different software applications. Using IFC reduces the loss of information when files are transmitted.

AutoCAD Architecture is IFC-certified for importing and exporting version 2x3 IFC files. IFC files from versions 2x2 and 2x can also be imported if the data is compatible with 2x3 and is consistent with implementation agreements as defined for the IFC 2x3 coordination view. For more detailed information, go to <http://www.iai-international.org> and search for IfcWiki Web resource.

IFC certification enhances your ability to share project information across disciplines and technical applications over the life of the project. Using the IFC format, you can export these drawings to other IFC-certified applications that could not otherwise open a DWG file. For example, building models drawn in AutoCAD Architecture are saved to a DWG file format. You can export the drawing using the IFC format. Likewise, you can import an IFC file to create and work in a DWG that was originally created in a format other than DWG.

Visual fidelity for three-dimensional (3D) objects is maintained in model views. This means that dimensions are maintained for 3D objects exported to IFC. Objects must be dimensionally accurate in the single IFC model because it is shared by diverse applications.

For information about other methods of sharing drawings with external users, see [Sharing Drawings with AutoCAD Users](#) on page 171.

How Drawing Files Are Exported to IFC

Only a currently active drawing can be exported to IFC. The export process generates 2 files:

- An IFC file that contains information specified for project number and name, file path, and external references (xrefs).
- A LOG file that contains data about information (objects and geographic location) in the drawing. This file is stored in the same location as the IFC file.

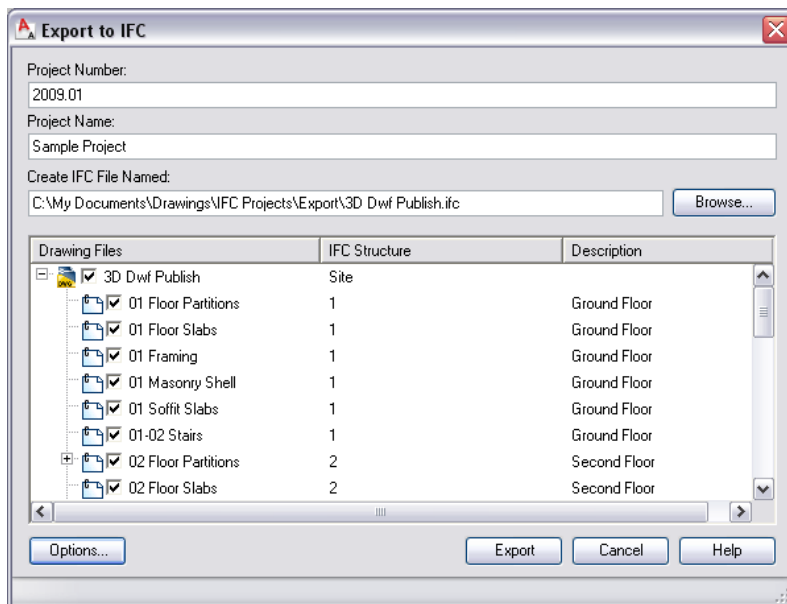

The current display configuration for the drawing being exported is what defines the graphical information and geometry for the IFC file. Objects that would typically display in the current display configuration are exported regardless of whether their layers are frozen or turned off. For more information, see [Display Representations](#) on page 544.

AutoCAD Architecture Project Drawings

When you export a drawing file from an AutoCAD Architecture project folder, the drawing file is mapped to (Ifc)Site by default. The (Ifc)Site drawing may contain building objects and site geometry as well as xrefs.

Identifying information displays by default in the project, including project number, project name, and level assignments of xrefs, when you select a project drawing for export.

You control which xrefs in the project file are exported and how they display in the IFC file by either accepting the default level assignments or by specifying a different label. Each of these drawings becomes an IfcBuildingStorey within the IfcSite file.

Exporting a Drawing from an AutoCAD Architecture Project

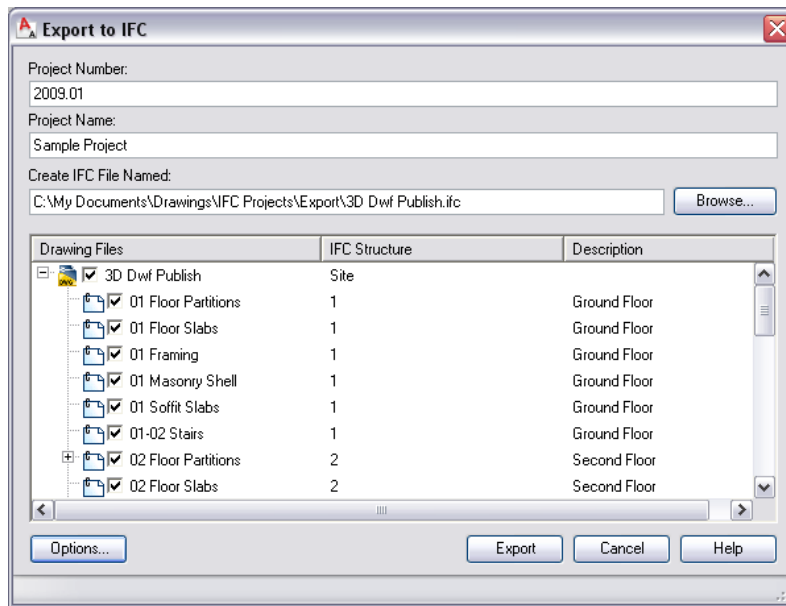

Use this procedure to export a project drawing as an IFC file. Select the drawing from the Constructs, Views, or Sheets tab of Project Navigator.

Xrefs contained in the drawing being exported are listed in the tree view below the drawing name. If they were unloaded in the drawing, they are shaded in the Export to IFC dialog. For more information, see [Before You Begin: External References](#) on page 226.

If the drawings were assigned to levels as part of the AutoCAD Architecture project, a corresponding label is displayed by default under IFC Structure. Otherwise, they are mapped to Level 1 by default.

If there are objects you want to classify by a different name for export, the drawing with the classified objects must have been previously saved. For more information, see [Classifying AEC Objects for Export](#) on page 186.

- 1 On the Constructs, Views, or Sheets tab in Project Navigator, open the drawing that you want to export as an IFC file.
- 2 Click File menu > IFC > Export to IFC.

- 3 In the Export to IFC dialog, the project number and project name display by default. Modify these if necessary.
- 4 If you want to change the default value for Create IFC File Named, enter a new name; or click Browse, navigate to the file, and select it.
- 5 Under Drawing Files, select the drawing files to be exported.
If you select an xref at the top level, all xrefs nested within this drawing are selected as well. Expand the top level, and select xrefs individually if necessary.
- 6 If you want to change the labels for the drawing files selected, click the label in the IFC Structure column, and select a different level from the drop-down list, or enter text in the field.

If you want xrefs to display as a distinct level within the IFC file, specify different identifying labels under IFC Structure. You can specify the same identifier, such as Level (1), for multiple xrefs to combine the objects within those xrefs into one IfcBuildingStorey.

7 Enter a description of the file for export.

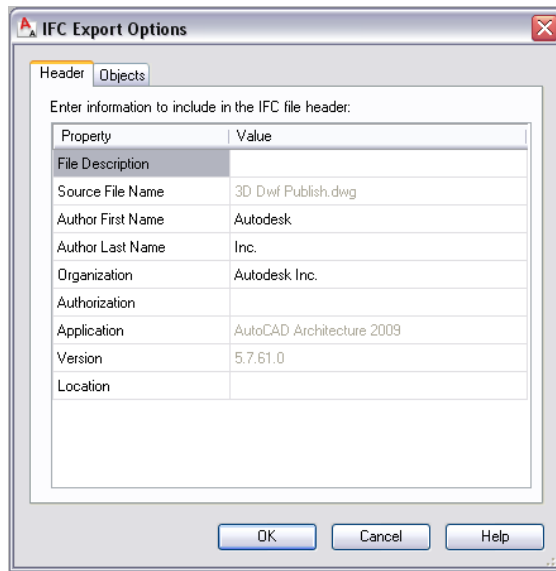

You can select multiple drawing files and change all labels or descriptions at the same time.

Click Options, and select export options.

The name of the drawing active on your screen displays on the Header tab of the IFC Export Options dialog. You can add information about the drawing file to be exported, such as a description of the drawing, the author and company name, authorization data, and the geographic location of the building. For example, you could enter the description of a structural drawing as Structure for Commercial Building 152 on the Header tab. This information displays in the header of the IFC file when the file is viewed.

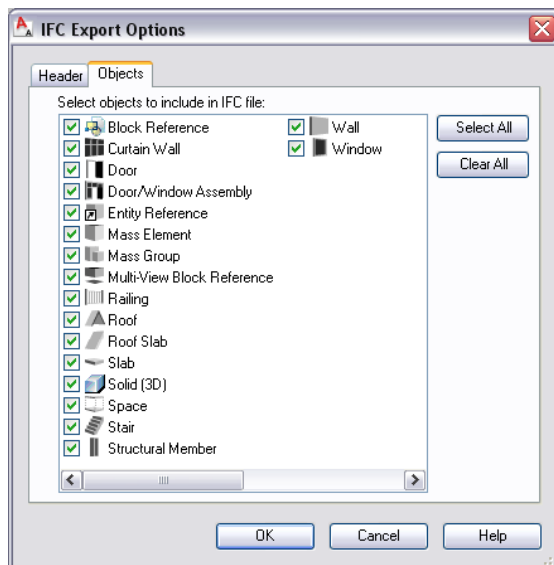

Other data is exported with the drawing by default and includes the name of the source drawing file and the name and version of the application in which it was created.

8 On the Header tab in the IFC Export Options dialog, enter data, and click OK.

You can also select or exclude objects for export with the drawing file. When the IFC file is viewed, the only objects included will be those that you selected. For example, you could select Slab and Structural Member and exclude all other objects from exporting.

9 On the Objects tab in the IFC Export Options dialog, select the objects for export, and click OK.

When you specify export options for your objects, the following constraints apply:

- The classification of an object takes precedence over the object type. For example, if you classify a mass element as a ramp and then export the drawing without Mass Element selected on the Objects tab, the newly-classified mass element is not included in the export process.
- Any change you make to either tab in the Export Options dialog, become the new default settings.
- For selected objects to be exported, their display representations must be active in the current display configuration.

10 Click Export.

Exporting Standalone Drawings

Drawings created outside of an AutoCAD Architecture project can be exported to an IFC file with or without xrefs.

- If you are exporting a drawing file that contains xrefs, the host drawing file is mapped to (Ifc)Site by default. The (Ifc)Site file may contain building objects and site geometry as well as xrefs.
- If you are exporting a drawing that does not contain any xrefs, all of the objects in the drawing are contained in (Ifc)Building. The IFC file will not contain an IfcSite or an IfcBuildingStorey. Without IfcSite, geographic location information, such as longitude and latitude, cannot be exported. This information is tracked in the LOG file. For more information, see [How Drawing Files Are Exported to IFC](#) on page 178.

Exporting a Drawing with External References

Use this procedure to export a drawing as an IFC file and include selected xrefs. The drawing for export must be active on your drawing screen. It is mapped to (Ifc)Site by default.

If there are objects you want to classify by a different name for export, the drawing with the classified objects must have been previously saved. For more information, see [Classifying AEC Objects for Export](#) on page 186.

Xrefs contained in this drawing are listed in the tree view below the drawing name, and are mapped to Level (1) by default. If the xrefs are missing in the drawing, they are unavailable in the Export to IFC dialog. If they were unloaded in the host drawing, the icon next to the file name displays a red, downward-pointing arrow.

Drawing Files	IFC Structure	Description
Small Commercial Building	Site	
01 Floor Partitions	Level (1)	
01 Spaces	Level (1)	
01-02 Stairs	Level (1)	
02 Floor Partitions	Level (1)	
Typical Core	Level (1)	
02 Spaces	Level (1)	
Atrium Spaces	Level (1)	
Column Grid		
Plan 96 MSV Boundary		

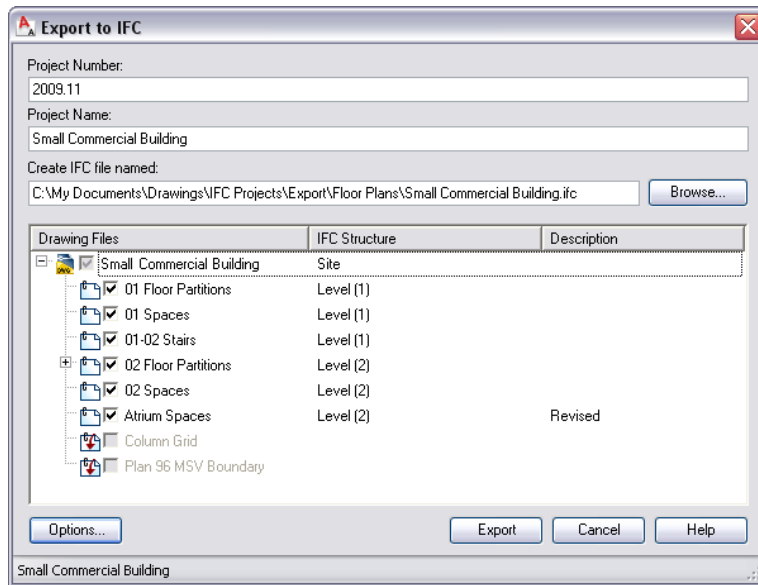

- 1 Open the drawing that you want to export as an IFC file.
- 2 Click File menu ► IFC ► Export To IFC.

Drawing Files	IFC Structure	Description
Small Commercial Building	Site	
01 Floor Partitions	Level (1)	
01 Spaces	Level (1)	
01-02 Stairs	Level (1)	
02 Floor Partitions	Level (1)	
Typical Core	Level (1)	
02 Spaces	Level (1)	
Atrium Spaces	Level (1)	
Column Grid		
Plan 96 MSV Boundary		

- 3 In the Export to IFC dialog, for Project Number, enter a project number for the drawing.
- 4 The name of the drawing being exported displays for Project Name by default. Modify this if necessary.
- 5 To change the default value for Create IFC File Named, click Browse, navigate to the desired file, and select it.
- 6 Under Drawing Files, select the drawing files to be exported.
If you select an xref at the top level, all xrefs nested within this drawing are selected as well. Expand the top level, and select xrefs individually if necessary.
- 7 To change the label in the IFC Structure column, select or add a different level from the drop-down list, or enter text in the field.
If you want xrefs to display as a distinct level within the IFC file, specify different identifying labels. You can specify the same identifier, such as Level (1), for multiple xrefs to combine the objects within those xrefs into one IfcBuildingStorey.

Atrium Spaces	Level (1)	
Column Grid	Site	
Plan 96 MSV Boundary	Level (1)	
	Add level...	

- 8 Enter a description of the file for export.
You can select multiple drawing files and change all labels or descriptions at the same time.

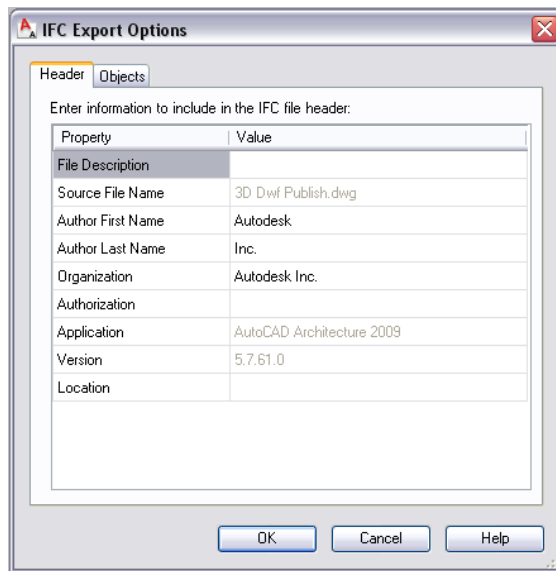

Click Options, and select export options.

The name of the drawing active on your screen displays on the Header tab of the Export Options dialog. You can add information about the drawing file to be exported, such as a description of the drawing, the author and company name, authorization data, and the geographic location of the building. For example, you could enter the description of a structural drawing as Structure for Commercial Building 152 on the Header tab. This information displays in the header of the IFC file when the file is viewed.

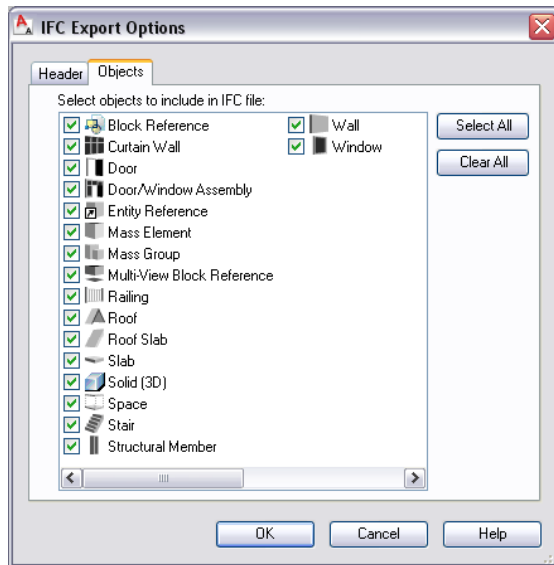

Other data is exported with the drawing by default and includes the name of the source drawing file and the name and version of the application in which it was created.

- 9 On the Header tab in the IFC Export Options dialog, enter data, and click OK.

You can also select or exclude objects for export with the drawing file. When the IFC file is viewed, the only objects included will be those that you selected. For example, you could select Slab and Structural Member and exclude all other objects from exporting.

- 10 On the Objects tab in the IFC Export Options dialog, select the objects for export, and click OK.

When you specify export options for your objects, the following constraints apply:

- The classification of an object takes precedence over the object type. For example, if you classify a mass element as a ramp and then export the drawing without Mass Element selected on the Objects tab, the newly-classified mass element is not included in the export process.
- Any change you make to either tab in the Export Options dialog, become the new default settings.
- For selected objects to be exported, their display representations must be active in the current display configuration.

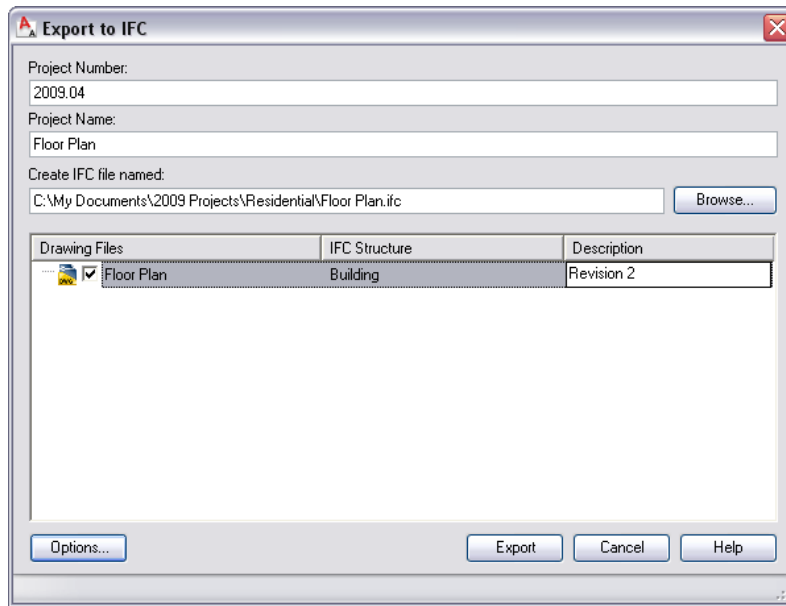

11 Click Export.

Exporting a Drawing Without External References

Use this procedure to export a drawing as an IFC file when the drawing does not contain xrefs. The drawing for export must be active on your drawing screen. It is mapped to (Ifc)Building by default.

If there are objects you want to classify by a different name for export, the drawing with the classified objects must have been previously saved. For more information, see [Classifying AEC Objects for Export](#) on page 186.

- 1 Open the drawing that you want to export as an IFC file.
- 2 Click File menu ► IFC ► Export To IFC.
- 3 In the Export to IFC dialog, for Project Number, enter a project number for the drawing.
- 4 The name of the drawing being exported displays for Project Name by default. Modify this if necessary.
- 5 If you want to change the default value of where the IFC file is exported, click Browse, navigate to the desired file, and select it.
- 6 Enter a description of the file for export.

7 Enter a description of the file for export.

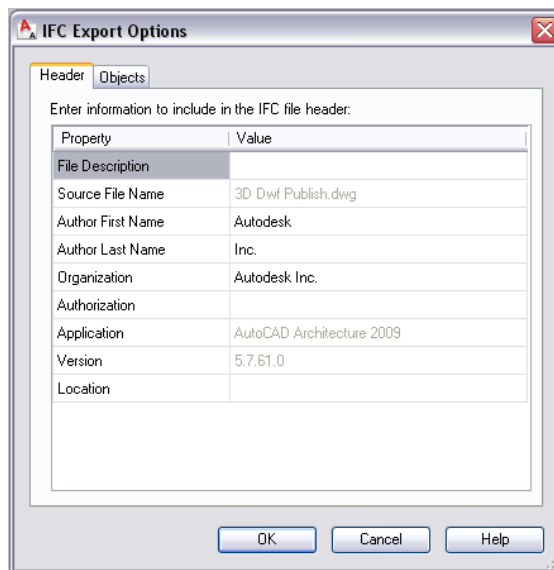

You can select multiple drawing files and change all labels or descriptions at the same time.

Click Options, and select export options.

The name of the drawing active on your screen displays on the Header tab of the Export Options dialog. You can add information about the drawing file to be exported, such as a description of the drawing, the author and company name, authorization data, and the geographic location of the building. For example, you could enter the description of a structural drawing as Structure for Commercial Building 152 on the Header tab. This information displays in the header of the IFC file when the file is viewed.

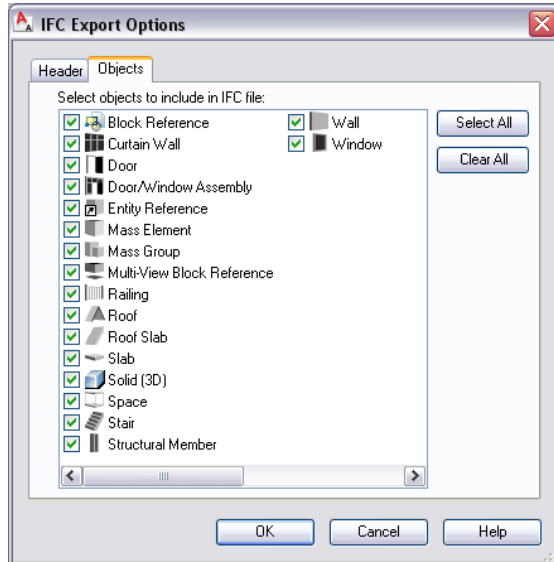

Other data is exported with the drawing by default and includes the name of the source drawing file and the name and version of the application in which it was created.

8 On the Header tab in the IFC Export Options dialog, enter data, and click OK.

You can also select or exclude objects for export with the drawing file. When the IFC file is viewed, the only objects included will be those that you selected. For example, you could select Slab and Structural Member and exclude all other objects from exporting.

9 On the Objects tab in the IFC Export Options dialog, select the objects for export, and click OK.

When you specify export options for your objects, the following constraints apply:

- The classification of an object takes precedence over the object type. For example, if you classify a mass element as a ramp and then export the drawing without Mass Element selected on the Objects tab, the newly-classified mass element is not included in the export process.
- Any change you make to either tab in the Export Options dialog, become the new default settings.
- For selected objects to be exported, their display representations must be active in the current display configuration.

10 Click Export.

Classifying AEC Objects for Export

Using classification definitions allows you to assign three-dimensional AEC objects different names. This is helpful if you want to export the object in your drawing as something different for the IFC file. For example, you can draw a mass element, classify it as a ramp, and export it as a ramp. For more information about classifications, see [Classification Definitions](#) on page 2574.

A folder of classifications that can be used for objects at export is available in the software and can be found in Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles. For more information, see [Classifying AEC Objects for Export](#) on page 186.

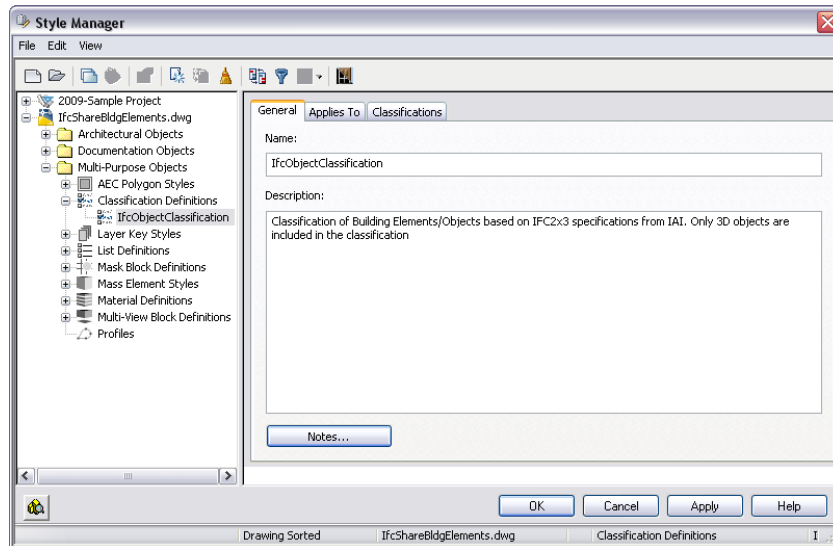

Use this procedure to classify an AEC 3D object to display as something different in the IFC file. For example, you can draw a mass element and classify it as a ramp. Two files of classifications for objects at export are available in the software and can be found in Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\IfcProductExtension.dwg (or IfcShareBldgElements.dwg). For more information about assigning classifications to objects, see [Classification Definitions](#) on page 2574.

1 Open the drawing that contains the objects you want to classify for export.

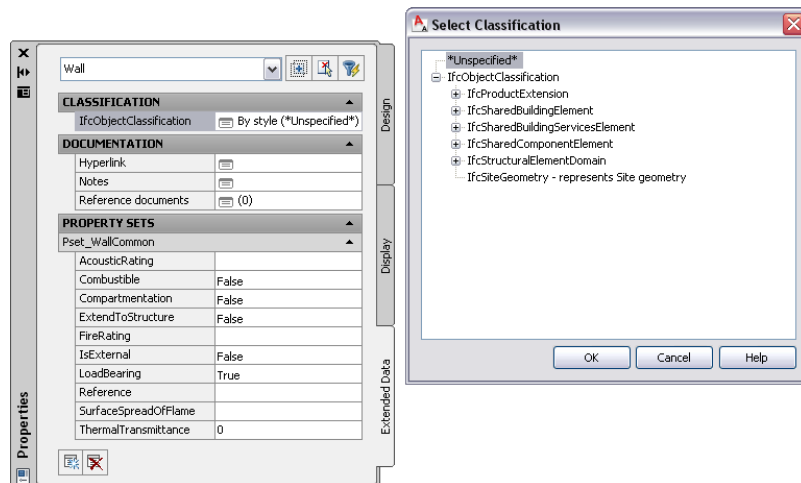

2 Click Format menu ► Style Manager.

For more information, see [Style Manager](#) on page 589.

- 3 Click File menu ► Open drawing, and in the Open drawing dialog, navigate to Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\IfcProductExtension.dwg (or IfcShareBldgElements.dwg), and click Open.
- 4 Expand an IFC drawing file, expand Multi-Purpose Objects, and expand Classification Definitions.

- 5 Right-click Classification Definitions, and click Copy.
- 6 In the Style Manager, select the drawing into which to add the IFC classifications (the drawing opened in step 1), right-click, and click Paste.
- 7 Click OK to close Style Manager.
- 8 On the drawing screen, select the objects to classify, open the Properties palette, and click the Extended Data tab.
- 9 Under Classification, select IfcObjectClassification.

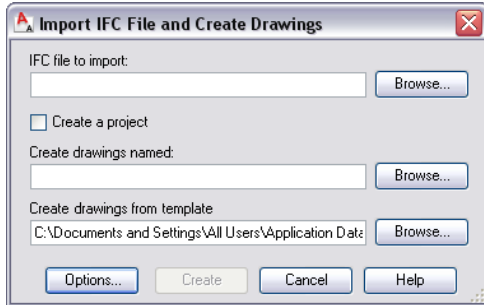

- 10 In the Select Classification dialog, select the classification, and click OK.
- 11 Save your drawing before continuing to export it to an IFC file.

IMPORTANT Save this drawing file with the classifications before exporting the file as either the host drawing or an xref.

How IFC Files Are Imported

When you import an IFC file, drawing files are created that correspond to each part of the IFC project structure. The files are xrefed together into a main host file that represents the entire IFC file. In addition, a LOG file is created when you import a drawing. It contains data about information (objects and geographic information) in the drawing. This file is stored in the same location as the imported IFC file. IFC files can be imported as drawing files into an AutoCAD Architecture project or as standalone drawings.

In some instances, such as surfaces of spaces, you may need to turn on some display components of objects for them to display after you import an IFC file. For more information, see [Display Representations](#) on page 544.

When you import an IFC file, you specify a name for the drawing that is being created from the IFC file. This drawing contains xrefs only. For example, importing an IFC file and naming it Small Office Building, creates a DWG called Small Office Building.dwg that contains all of the xrefs that correspond to each part of the project structure contained in the IFC file. During the import process, the following occurs:

- A site drawing is created with field information if it existed in the IFC file. If the IfcSite file does not have a name assigned, a site drawing file is created with –Site appended. If there is an IfcSite name specified in the IFC file, a default drawing is created with the name of Site.dwg. The geographic location is imported by default if the IfcSite file contained the latitude and longitude of the site. You can see this information in the Geographic Location dialog. For more information, see “View the Geographic Location Information” in the AutoCAD Help.

If the IFC file is imported as...	Then...
<ul style="list-style-type: none"> ■ an AutoCAD Architecture project 	the IfcBuilding name is used with the name of the project. (Please note that AutoCAD Architecture uses the project name from the Export to IFC dialog as the IfcBuilding name. This is noticeable if you are importing an IFC file that originated in AutoCAD Architecture.)
standalone drawings	the drawing is created with the original project name appended. Using the Small Office Building example, the drawing name would be Small Office Building-Commercial Project.dwg because Commercial Project was the IfcBuilding name in the IFC file.

- A drawing is created for each IfcBuildingStorey contained in the IFC file. The files are created using the drawing name with the name of the IfcStorey appended. These files are referenced into the project file.
- Objects in files with colors specified as 0, 0, 0 or 255, 255, 255 display with the AutoCAD Color Index (ACI) 7 assigned by default.

Architectural Objects and IFC

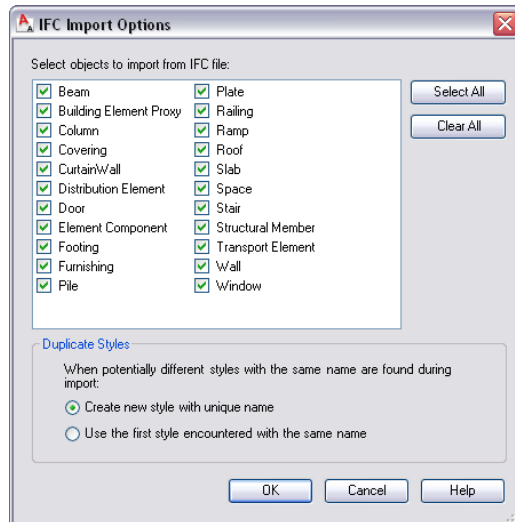

As shown in the following table, most common building objects imported from an IFC file are created as the corresponding AutoCAD Architecture objects in the resulting drawing file. However, in the case of an IFC object with complex geometry that does not directly correspond to the components of its AutoCAD Architecture counterpart, a custom display block is created in the model display representation. Therefore, 3D geometry in the Model display representation may not always correspond exactly to the Plan display representation. For more information, see [Display Representations](#) on page 544.

When you import an...	AutoCAD Architecture creates a...
IfcBeam	Beam
IfcColumn	Column
IfcCurtainWall	Curtain wall
IfcDoor	Door
IfcElementAssembly	Multi-view block
IfcOpening	Opening
IfcMember	Brace
IfcRailing	Multi-view block
IfcRamp	Multi-view block
IfcRoof (object with geometry)	Multi-view block
IfcSlab	Slab
IfcSlab (object with predefined type of Roof or an aggregate of slabs such as a gabled roof)	Roof slab
IfcSpace	Space
IfcStair	Multi-view block
IfcWall	Wall
IfcWallStandardCase (an upright wall with uniform thickness)	Wall
IfcWindow	Window
IfcBuildingElementProxy (for example, IFC objects that represent furniture)	Multi-view block

When you import all other IFC objects with a 3D geometric representation (for example, IFC objects that represent pipes or ducts), AutoCAD Architecture creates a multi-view block.

Options for Importing AEC Objects

When you import an IFC file, you can specify objects to import. For example, if you want to create a drawing file that displays only the curtain walls from the IFC file, you can clear all other objects listed in the IFC Import Options dialog. When the drawing is viewed, the only objects included will be those that you selected.

Style names stored in the IFC file display on the Properties palette and in Style Manager. If there are no specific style names in the IFC file, style names are created incrementally, such as IFCSTYLE(0).

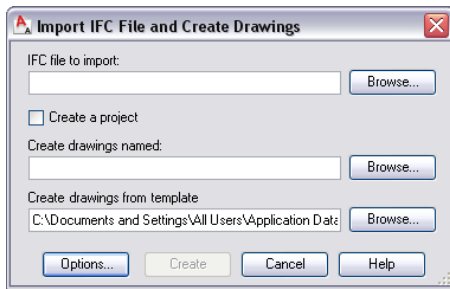

You can specify how and when styles are created if there are multiple styles with the same name in the IFC file. They can either display incrementally with a number suffix or display with the name first encountered, regardless of whether the styles are the same, during the import.

Importing an IFC File

Use this procedure to import an IFC file. When you select an IFC file to import, you specify whether to create the drawings in an AutoCAD Architecture project or as a set of standalone drawings.

- 1 Click File menu ➤ IFC ➤ Import from IFC.

2 In the Import IFC File and Create Drawings dialog, click Browse for IFC file to import, navigate to the desired IFC file, and select it.

3 Specify if the imported file is to be part of a project:

If you want to...

Then...

import the file and create a project and project drawings

select Create a project, and enter a folder name for Create project under folder; or click Browse, navigate to the desired folder, and select it.

The drawings are imported with the structure of an AutoCAD Architecture project. For more information, see [Concepts of Drawing Management](#) on page 218.

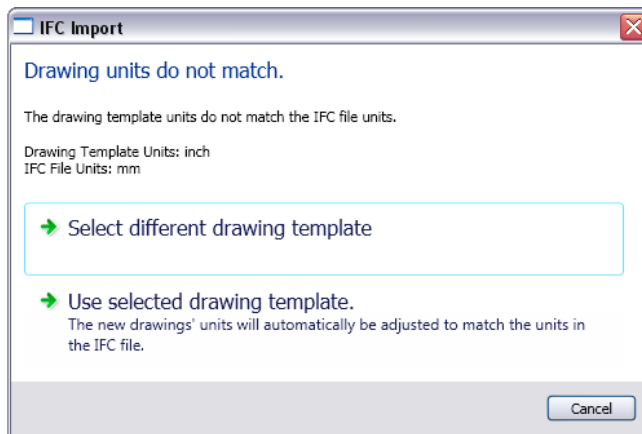

import the file as standalone drawings

enter a drawing name for Create drawings named; or click Browse, navigate to the desired file, and select it.

Unless you specify otherwise, the drawing is created at the same location as the IFC file by default.

4 If you want to change the default value for Create Drawings from Template, click Browse, navigate to the desired DWT file, and select it.

If the template (DWT file) you select does not have the same units as the IFC file being imported, you are given the choice to continue with that template or select a different template. If you choose to continue with the selected template, the units in the IFC file will override the units in the template file.

NOTE The template you select becomes the new default template.

5 Select additional import options:

If you want to...	Then...
change the default value of importing all objects to selecting specific objects to import	click Options. In the IFC Import Options dialog, select the objects for import, and click OK. For more information, see Options for Importing AEC Objects on page 190.
have a new style name created to correspond with each instance of the style name in the IFC file	click Options. In the IFC Import Options dialog, select Create new style with unique name, and click OK. For more information, see Options for Importing AEC Objects on page 190. If multiple occurrences of the same style name exist, a number displays incrementally at the end of the name.
use the first instance of the style name for all objects	click Options. In the IFC Import Options dialog, select Use the first style encountered with the same name, and click OK. For more information, see Options for Importing AEC Objects on page 190.

6 Click Create.

If you...	Then...
created project drawings when you imported the IFC file	the Project Navigator opens on your drawing screen. Use Project Navigator to browse the project drawings created at import. For more information, see Process Overview: Working in a Project Environment on page 217.
created standalone drawings and want to view the top-level drawing	click Yes.
created drawings outside of an AutoCAD Architecture project and want to view a different drawing	click No.

If there is a component of an object that does not display after you import an IFC file, open the display representation for the object, and on the Layer/Color/Linetype tab, turn on the display component by selecting the light bulb icon under Visible. For more information, see [Display Representations](#) on page 544.

IMPORTANT If AutoCAD Architecture runs out of memory during import, a message displays on the command line, and the import process fails. Continuing to use AutoCAD Architecture under these conditions may affect subsequent work. The correct procedure is to close and then restart the application. You can retry the import after:

- Closing all other applications.
- Limiting the objects for import in the IFC Import Options dialog.
- Switching to a 64-bit system.

Importing LandXML

LandXML data can be imported and converted to objects. LandXML is the standard XML data format for civil engineering and survey data used in the land development and transportation industries. LandXML provides a data format suitable for long-term data archiving and offers a standard format for electronic design submission.

With LandXML, building professionals can extend the downstream value of their data from design to construction, and for scheduling and maintenance by using a format that can be read by many applications.

LandXML files are based on the LandXML schema, an XML schema definition for civil and survey data.

Residential area layout from Autodesk® Land Desktop

NOTE For more information about LandXML, visit <http://www.landxml.org>.

You cannot convert AutoCAD Architecture objects to LandXML data or export DWG files to the LandXML format.

Schema Version

To import LandXML files, create them with the LandXML schema version 1.1. Note that LandXML files created with earlier versions of LandXML (for example version 0.88) cannot be imported. You can download the latest version of the LandXML schema from <http://www.landxml.org>.

Supported Data Types

AutoCAD Architecture can read and convert the following LandXML data types:

- Parcels
- COGO points
- Surfaces

Parcels

Parcels are two-dimensional shapes created from closed lines, arcs, and polylines. When a parcel is imported, the parcel name and the lines (segments) and curves (arcs) that make up the parcel boundary are used for the conversion.

Parcels in a street layout from Autodesk® Land Desktop

You can convert parcels to spaces or polylines. When you convert parcels to spaces, you can define a space style that is applied to the spaces generated from the parcels, and the parcel name is used as the space name. When the parcel is converted to a polyline, the parcel name is lost.

Parcel data in LandXML

```
<Parcel name="444" area="12846.9020">  
  <Center>325.15651476 409.45999549</Center>  
  <CoordGeom>  
    <Line>  
      <Start>304.67904916 281.77993878</Start>  
      <End>401.62704976 468.02002165</End>  
    </Line>  
    <Line>  
      <Start>401.62704976 468.02002165</Start>  
      <End>269.16344536 478.58002603</End>  
    </Line>  
    <Line>  
      <Start>269.16344536 478.58002603</Start>  
      <End>304.67904916 281.77993878</End>  
    </Line>  
  </CoordGeom>  
</Parcel>
```

COGO (Coordinate Geometry) Points

You can import LandXML COGO (Coordinate Geometry) points and convert them to AutoCAD points.

Civil engineers create COGO points to locate crucial surveying locations. A COGO point can be a project benchmark point - a common datum that the entire civil team works off and from which all critical dimensions are located.

NOTE A LandXML file usually contains a large number of COGO points. In most cases, you need only a small set to work within the drawing. You do not need to import all COGO points, only those that have a special meaning for the drawing.

COGO points are the foundation for any civil engineering or surveying project. In Land Desktop, you can use description keys to place points in the drawing with symbols on specific layers. When importing a LandXML file you can map selected points to the appropriate layer.

When a COGO point is imported it is defined by its coordinates in the form of “northing easting” or “northing easting elevation.”

For example, a COGO point could be represented as: `<CgPOINT NAME="1" DESC="MYPOINT">248.04605951 359.53997314 1.000000</CgPOINT>`.

COGO points on a map

NOTE Autodesk Land Desktop uses two coordinate systems for locating points: X,Y and northing/easting. When you start a new project, these values all default to 0 so that the Y coordinate is the same as the northing, and the X coordinate is the same as the easting. Unless you change that in Land Desktop before exporting a drawing to LandXML, the exported northing value will be identical to Y and the exported easting value will be identical to X.

Surfaces

In most surveying and civil engineering operations, you gather information about elevations to generate surface contours that represent a model of the ground surface. The surfaces in LandXML are made up of many faces which are either TINs (Triangular Irregular Networks) or quadrilaterals. Points or contours are usually a primary part of the original surface information and are supplemented with break lines and boundaries. You can create a surface in LandXML, and then import it. It is converted to a Free Form mass element.

In the following cases, importing surfaces can create errors or fail altogether:

- Surfaces with vertical faces
- Surfaces with tiny gaps between the individual faces
- Surfaces with very narrow faces

If the import fails, an error message is displayed on the command line, such as “Failed to create mass element from terrain.”

Surface model in Autodesk® Land Desktop

A surface model is usually a complex structure with many defining points and faces. When you convert a surface model to a Free Form mass element, the points and faces are merged into one composite mass element body.

Surface model detail

A Free Form mass element contains a large number of grips. Displaying all grips can slow down the performance and be unnecessary for using the mass element. There are two ways to control the display of grips on mass elements:

- By default, the grips on a Free Form mass element are only displayed if their number does not exceed 2000 grips per element.
- You can turn off the display of grips in the drawing altogether if you click **Format** ► **Options**, then click the **Selection** tab, and under **Grips**, clear **Enable Grips**.

A surface in the LandXML Schema contains information about the surface name, type, 2D and 3D area, and the maximum and minimum elevations. It also contains information about each of the points and faces that comprise the surface. The surface information is merged into one composite mass element body, which can have thousands of faces. Applying a surface hatch or texture map to a complex mass element can be quite time-consuming.

Surface data in LandXML

```
<Surfaces>
  <Surface name="Area1" desc="Area1">
    <Definition surfType="TIN" area2DSurf="73335.0380" area3DSurf="188927.3561"
      elevMax="127.6600" elevMin="0.0000">
      <Pnts>
        <P id="1">4838972.630000 315816.970000 116.4700</P>
        <P id="2">4838971.920000 315797.470000 117.6300</P>
        <P id="3">4838965.720000 315798.350000 117.5900</P>
        <P id="4">4838968.400000 315818.170000 116.4000</P>
        ...
      </Pnts>
      <Faces>
        <F>534 214 533</F>
        <F>88 2 3</F>
        <F>256 255 240</F>
        ...
      </Faces>
    </Definition>
  </Surface>
</Surfaces>
```

File Validation

When you import a LandXML file, the file is automatically validated before it is imported and opened. The LandXML file has to conform to the LandXML 1.1 schema definition to be used.

Importing LandXML Data

Use this procedure to import LandXML data.

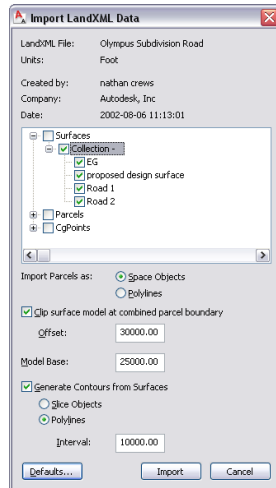

When you import a LandXML file, you can select different object types to import. For a complete list, see [Supported Data Types](#) on page 193. Depending on the object type, you can define additional conversion parameters. For example, if you want to import LandXML parcels, you can choose to convert them to space objects or standard polylines.

NOTE A LandXML file contains information about the drawing units in which it is measured. When you import a LandXML file into a drawing with different units, the LandXML data is converted to the units in the current DWG. When a LandXML file based on meter units is imported into a drawing based on millimeters, the resulting coordinates may exceed the range in which accurate calculations can be made.

- 1 Click **Insert** menu ► **LandXML**.
- 2 Select a LandXML file to import, and click **Open**.

NOTE If you have selected an invalid LandXML file, an XML file not based on the LandXML Schema, or an XML file based on a LandXML Schema version earlier than 1.1, you receive an error message and cannot import the file. Select another file that conforms to the LandXML 1.1 schema, or update the existing file accordingly.

3 Select the import options.

If you want to...

Then...

import surfaces from the LandXML file

select Surfaces. This selects all surfaces from the imported file. To import only individual surfaces, expand Surfaces, expand Collection, and then select the surfaces you want to import.

import parcels from the LandXML file

select Parcels. This selects all parcels from the imported file. To import only individual parcels, expand Parcels, expand Collection, and then select the parcels you want to import.

import COGO points from the LandXML file

select CgPoints. This selects all COGO from the imported file. To import only individual points, expand CgPoints, expand Collection, and then select the points you want to import.

4 If you are importing parcels, indicate the form to which you want them converted by selecting either Space Objects or Polylines.

Parcels converted to spaces (left) and polylines (right)

5 If you want to clip the surface model using the boolean union of all parcels as the model boundary, select Clip Surface Model at Combined Parcel Boundary.

If this check box is selected, you can also enter an offset from the boundary.

6 Enter a value for Model Base.

This creates an extrusion of the surface outer boundary from the value you enter starting at the lowest surface point.

7 If you want to generate contours from the surface data you are importing, select Generate Contours from Surfaces.

NOTE If you want to see the actual surfaces of the converted mass element, such as a TIN model, you can display the mass element without Gouraud shading.

8 Indicate how you want the contours to be created by selecting either Polylines or Slice Objects.

9 Enter an interval value for the vertical spacing of the contours.

NOTE Because slice objects shade their entire area, they can interfere with the appearance of the surface itself in shaded or hidden line views.

10 Click Import.

Selecting Layer Keys for LandXML Data

Use this procedure to set a default layer key for the different types of LandXML data being imported. You can set layer keys individually for COGO points, parcels, surfaces, and contour lines.

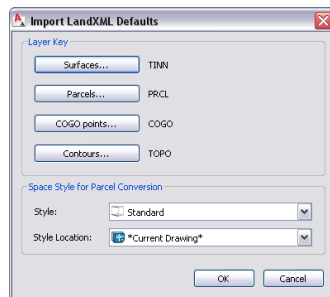

If you do not define specific layer keys for your LandXML data, the imported data is placed on the default layer keys specified for LandXML data, TINN (Surfaces), PRCL (Parcels), COGO (COGO Points), and TOPO (Contours).

You can also define a specific space style for parcels that are imported as spaces.

1 Click Insert menu ► LandXML.

2 Select a LandXML file to import, and click Open.

3 Click Defaults.

4 Select a layer key default for the imported objects.

If you want to...

Then...

select a layer key default for imported surfaces

click Surfaces.

select a layer key default for imported parcels

click Parcels.

select a layer key default for imported COGO points

click COGO points.

If you want to...	Then...
select a layer key default for imported contours	click Contours.

5 Select a layer key, and click OK.

6 If you want to import LandXML parcels as spaces, select a space style and a style location if necessary.

7 Click OK.

8 Import your LandXML data as described in [Importing LandXML Data](#) on page 196.

Publishing Drawing Files to Autodesk MapGuide

You can publish objects and property set data to the Autodesk MapGuide® product suite.

The MapGuide product suite provides the tools to create, publish, and display maps, drawings, designs, schematics, facilities management plans, and associated attribute data over the Internet, an intranet, or an extranet with the services of a web server and a web browser.

You can find a number of sample MapGuide projects under <http://data.mapguide.com/SampleApps/fm/default.htm>.

Prerequisites

To publish graphic objects and property set data to MapGuide, the MapGuide SDF Component Toolkit must be installed on your computer.

The MapGuide SDF Component Toolkit is a development library that allows developers to read, write, and modify point, line, and polygon data within SDF files. SDF files are the native Spatial Data File format of MapGuide, created from stand-alone applications or CGI applications.

You can download the Autodesk MapGuide SDF Component Toolkit from <http://www.autodesk.com>.

Published Data Types

You can publish the following data types from a drawing to MapGuide.

- **Graphic data:** All graphic objects can be exported to MapGuide in an SDF (Spatial Data File) file. Areas and spaces are converted to polygons in the appropriate SDF files. All other graphic objects are converted to polylines.
- **Property set data:** Property set data attached to an exported object is exported to a Microsoft® Access Database consisting of a series of tables representing the individual property sets. Each object record within a table is assigned a unique object key matching the corresponding object key in the SDF file in order to associate the record in the database with the appropriate SDF geometry.
- **Blocks and MVBlocks:** Blocks and MVBlocks are exported as SDF files and point databases. Since the blocks and MVBlocks are exported in SDF format as well, the point databases provide an option for users to use symbols rather than the SDF geometry to represent Blocks and MVBlocks in MapGuide. There is a point geometry SDF format, but since AutoCAD Architecture does not work with geospatial coordinate systems, a table in an external database presents a better data source for point-related data. The Publish To MapGuide command does not create bitmap files (BMP) or Windows Metafiles (WMF) representing the geometry of blocks or MVBlocks. If you want to generate WMFs, you need to use either the AutoCAD® *WmfOut* command or the MapGuide SDF Loader.

The SDF Loader is a utility used to create Spatial Data Files (SDF) and their accompanying Spatial Index Files (SIF) from a variety of GIS data formats.

You can download the SDF Loader utility from <http://www.autodesk.com>.

- External references: objects and property set data from external references are exported as if they actually resided in the host drawing.

NOTE The external reference name prefix of the layer name is removed when exporting data to MapGuide. This means that objects of the same type that are on the same layer in separate externally referenced files are placed in the same SDF files.

Generating a MWX File

The Publish To MapGuide feature creates, in addition to the data types listed in [Published Data Types](#) on page 199, a default map file (MWX file) that combines the exported data in a MapGuide® project. The map contains one layer for each generated SDF file. Each layer is visible and selectable.

An Overview of the Published Data Structure

When you publish data to MapGuide®, a data structure is created that facilitates the incorporation of the data into an MWX project. The exported files are placed in a series of folders representing the relevant portions of an MWX project folder hierarchy. If the following folders do not already exist below the folder you select for exporting your data, they are created and the appropriate files placed in each folder.

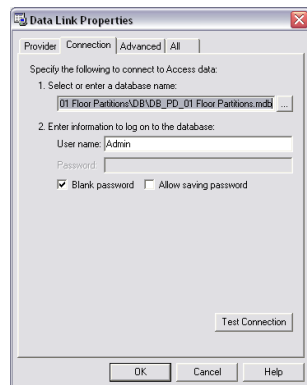

Directory structure of exported data

The following files are contained in the individual folders:

- Data Sources folder: In the Data Sources folder, you can find the data links to the MDB database and the SDF directory. The Publish To MapGuide options allow you to place the Data Sources in an alternate location.

Data link to exported database

- DB: The DB folder contains the Microsoft® Access Database created on export.

Exported database file

- MWX: the MWX folder contains the MapGuide project file combining the exported spatial and non-spatial data. To view and edit the exported data in MapGuide, you open the MWX file.
- SDF: The SDF folder contains the exported SDF (Spatial Data File) and SIF (Spatial Index File) files from the graphic objects.

An Overview of the Database Structure

When you publish data to MapGuide®, a Microsoft® Access Database (MDB) is created that contains information about the exported graphic objects and property set data.

Exported database file

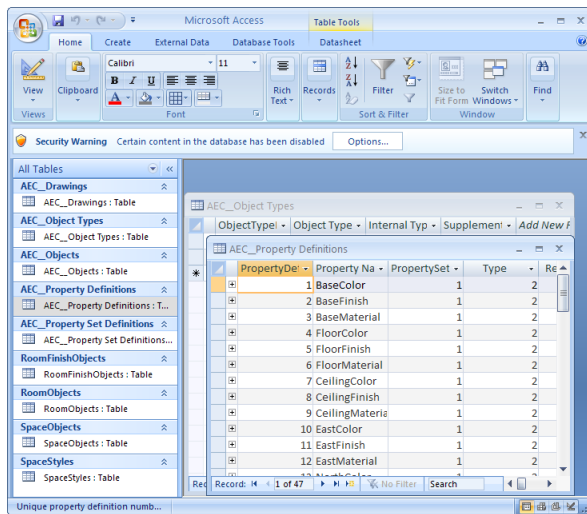

Table Name

Content

ADT_Drawings

This table lists information about the drawing from which the data is exported. Information includes file name, path, date of last modification, and the units of the drawing.

Table Name	Content
ADT_Object Types	This table provides a listing of the object types and object styles contained in the exported data. Each type and style is assigned an ID, which is later used to identify individual objects in the ADT_Objects table.
ADT_Objects	This table lists all individual objects contained in the exported data.
ADT_Property Set Definitions	This table provides a listing of the property set definitions contained in the exported data. Each property set definition is assigned an ID, which is later used to identify individual properties.
ADT_Property Definitions	This table lists all properties contained in the exported data. To identify individual properties, use the PropertySetId from the ADT_Property Set Definitions table.
<Object>	For each object type that has property data attached directly to one or more of its objects, a table is created that contains the objects and their associated property data. For example, if an exported drawing contains a number of doors with attached properties for frame depth and frame width, a DoorObjects table is created that lists all of these doors and their frame depths and frame widths.
<Object>Styles	For each object type that has property data attached via an object style, a table is created that contains the objects and the property data derived from their styles. For example, if an exported drawing contains a number of doors with a style controlling the louver height and louver width, a DoorStyles table is created that lists all doors of that style with their louver heights and louver widths.

NOTE For a detailed view and description of the individual tables, select a table in Microsoft® Access, right-click, and click Design View.

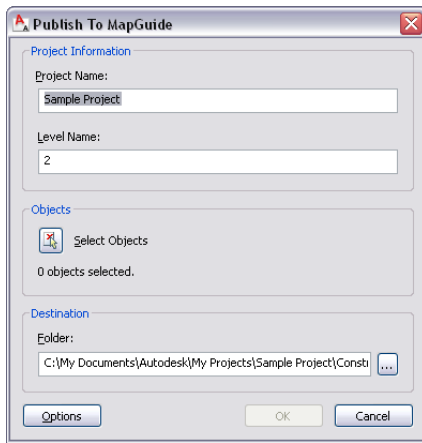

When you export data to an MDB, make sure that your property set definitions names, property definition names, and layer names meet the following naming criteria.

- Names must not exceed 64 characters. Longer names will be truncated after 64 characters.
- Names must not contain the following special characters: period (.), exclamation mark (!), accent grave (`), and brackets ([]).

Publishing Data to Autodesk MapGuide

Use this procedure to publish data to MapGuide®.

- 1 Click File menu ► Publish To MapGuide.

If the drawing from which you want to publish objects is part of a building project, the project name and level assignment of the drawing display in the Publish to MapGuide dialog.

If the drawing is not part of a building project, the name of the drawing and “Level 1” display by default. You can change these entries.

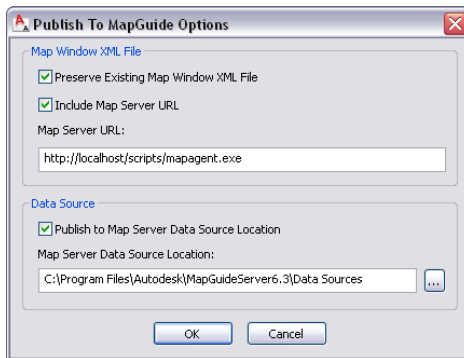

NOTE The project name that you enter here is not used as the name of the source MapGuide project folder and project files. The name of the project source folder and project files is created from the name of the drawing.

- 2 Under Objects, click .
- 3 Select the objects you want to publish, and press *ENTER*.
- 4 Under Folder, select the location for the project files.

For a detailed description of the files and folders generated on export, see [An Overview of the Published Data Structure](#) on page 200.

- 5 Click Options.

- 6 Specify additional export options:

If you want to...

Then...

preserve the existing Map Window XML file

select Preserve Existing Map Window XML file. This option will prevent an existing MWX file in this location from being overwritten. This will allow users to preserve any changes they made to the MWX file (secondary data source table selections, layer properties, or themes) when updating or re-publishing the underlying data or geometry.

If you want to...	Then...
include an URL to a Map Server	select Include a Map Server URL, and enter a server address.
publish your data to a Map Server data location	select Publish to Map Server Data Source Location, and browse for a location.

For more information about Map Server data locations, see the online Autodesk MapGuide® User's Guide.

7 Click OK twice.

Depending on your selection set, the export may take extra time. A progress bar shows you the state of the export.

Exporting Property Set Data to an MDB

Use this procedure to export property set data in a drawing to a Microsoft® Access Database (MDB).

- 1 Click File menu ► Export Property Data.
- 2 Select the objects that contain the property data that you want to export.
- 3 Press *ENTER*.
- 4 In the Export Property Data dialog, enter a path and a name for the exported MDB.
- 5 Click Save.

The property set data of the objects you selected is exported to a Microsoft® Access database.

Publishing Drawings to DWF and DWFx

The Design Web Format™ (DWF™) is the Autodesk® method of publishing design data to a file that can be posted on the Internet or on an intranet. You can view DWF files with a web browser, like Microsoft® Internet Explorer, or with the free downloadable Autodesk® Design Review, from where you can also plot the file. You can send a published DWF file as an e-mail attachment, share it using a project collaboration site such as Autodesk® Buzzsaw®, or you can post it to a company website.

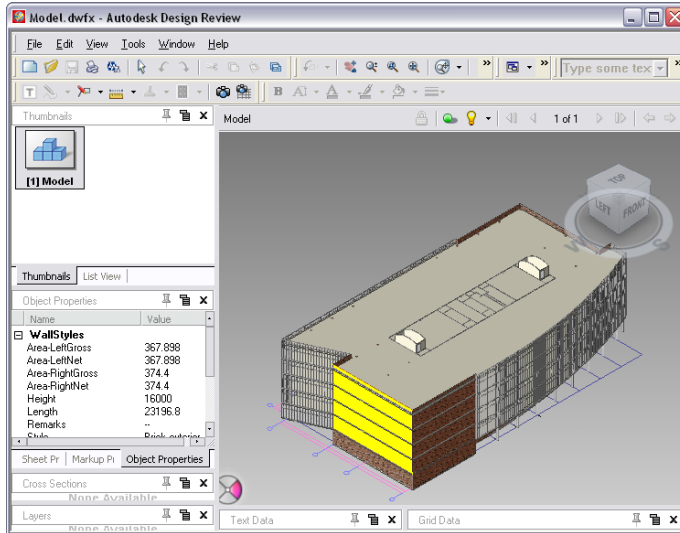

DWFx is the next version of the DWF file format. The DWFx file format is a blend of DWF and the Microsoft XPS (XML Paper Specification) format.

You can publish your DWG files as 2D or 3D model with the included property set data to DWF or DWFx. When these files are viewed with Autodesk® Design Review, users can select components that represent objects and display the object information on the Object Properties palette.

For more information about property set data, see [Property Set Definitions](#) on page 2542.

TIP To view published DWF or DWFx files, you need to install Autodesk Design Review. You can download the latest version of Autodesk Design Review from <http://www.autodesk.com>.

DWFx file published to Autodesk Design Review

Conditions and Limitations to Publishing Drawings to 3D DWF or DWFx

When publishing a drawing to 3D DWF or DWFx, the following conditions apply:

- Most types of hatches (patterns, solid, graphics) are published.
- The 3D DWF or 3D DWFx file uses the display configuration that is active in the DWG file during publishing.

NOTE When you publish 3D objects to DWF or DWFx, only the display set used for 3D views of the drawing is published. For 3D views, this is usually a Model display set, for example Model Medium Detail, Model High Detail, or Model Low Detail. You can view the objects in Top view in Design Review; this is however only a Top view of the Model display, and not a Plan view. Objects with no display representation in the Model display set are not displayed in the published DWF or DWFx. Objects that typically are not displayed in Model views are tags, annotations, dimensions, and 2D Plan symbols. If you want these to display in the DWF or DWFx, you can either activate them for the Model display set, or generate a 2D DWF or 2D DWFx file. For more information about the display system, see [Display System](#) on page 537.

- If Render materials are enabled, the transparency is translated to the DWF or DWFx file. For more information, see [Materials](#) on page 601.
- Live Section objects are published.
- Property set data attached to objects or styles is published to DWF or DWFx.

The following limitations apply:

- Infinite lines, like construction lines (xlines) and rays, are not published.
- Text fonts in the DWG file are all converted to Arial. Text formatting like Bold, Italic, and Underline are not currently supported.
- Clip Planes and Xref Clipping are not supported.
- OLE objects as well as inserted images are not supported.
- Linetypes and lineweights are currently not supported.

- Hyperlinks are not published (but are visible for non-AEC objects.)

Exporting Property Set Data to a DWF or DWFx File

You can export different types of property set data to a DWF or DWFx file.

Automatic Property Set Data

Each object in AutoCAD Architecture has a set of automatic properties attached to it. For example, every wall has a width, length, and height. Automatic properties are a subgroup of all property set data that can be attached to an object (or object style) with a property set definition.

You can automatically export all automatic properties of an object to a DWF or DWFx file. Automatically exporting all automatic properties has the advantage that you do not need to set up property set definitions for individual objects; it does not allow you however to select which properties to export and which to ignore.

For information on how to export automatic property set data, see [Publishing a 3D DWF or 3D DWFx File with Automatic Property Set Data](#) on page 208.

User-Defined Property Set Data

User-defined property set data is data from a property set definition that you have created and attached to an object or object style. Property set data can include automatic object properties, like height and width of a wall, but also manually defined data such as fire ratings or manufacturing information, project information, and more.

When publishing user-defined property set data, you specify which property set definitions to include and which to exclude. For example, some property sets in your drawing can contain confidential information, which you do not want to expose to others. In other cases, the recipient of a published file might need only very specific property set information about one aspect of the drawing, and does not want to search for that information among a large amount of unrelated information.

When publishing user-defined property set data, you must attach property set definitions to the objects in your drawing, and select a PPL (Published Properties List) file that contains these property sets. For example, you attach the property set definition DoorObjects to a number of doors in your drawing. Then, you add the DoorObjects property set definition to your PPL file. When you publish the drawing to DWF or DWFx, the property set data from these doors is published. In the same PPL file, you add the WindowObjects property set definition. However, you do not attach the WindowObjects property set definition to any windows in your drawing. When you publish the drawing to DWF or DWFx, no property set data from the WindowObjects property set definition is published.

In order to publish user-defined property set data to a DWF or DWFx file, you need to perform the following high-level steps:

- 1 Create property set definitions for objects and apply them to an object or an object style.
For more information, see [Property Set Definitions](#) on page 2542.
- 2 Define in the PPL file (Published Properties List) which property set definitions from your drawing should be exported.
For more information, see [Creating a New Published Property List \(PPL\)](#) on page 215.
- 3 Publish the drawing to DWF or DWFx, as described in [Publishing a 3D DWF or 3D DWFx file with User-Defined Property Set Data](#) on page 210 and [Publishing a 2D or 3D DWF or DWFx file with Property Set Data](#) on page 212.

Publishing Property Set Data from External References

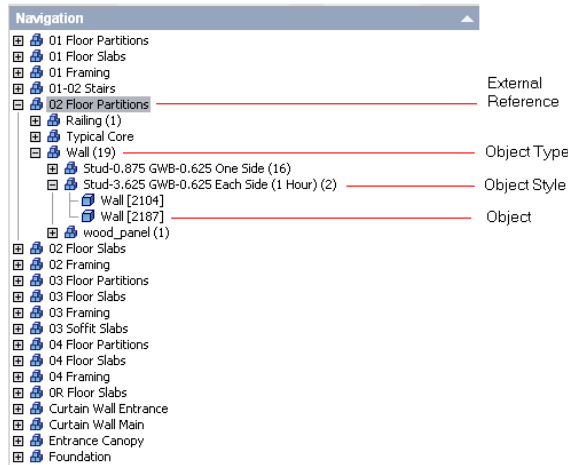

Property set data works across external references, and you can publish data from an external reference to a DWF or DWFX file. To make sure that data from the external reference is published correctly, make sure that the following conditions are met:

- The data structure of property sets coming from an external reference must be identical to the structure of any corresponding property sets in the host drawing. For example, if an external reference has a property set definition called Doors that reports Height, Width, and Door Number, the host drawing cannot have a property set definition called Doors that reports Fire Rating, Leaf Width, and Glass thickness.
- The same property data format must be applied to property set definitions from external references and corresponding property set definitions in the host drawing. For example, if an external reference property set definition called Doors specifies architectural units with 1/4 inch precision, the host drawing cannot have a property set definition called Doors that specifies architectural units with 1/16 inch precision. If the property data formats differ, the format of the host drawing is used for the external reference.

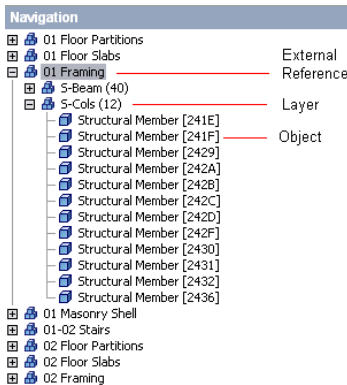

Property Set Data Structure

You can specify how property data is organized when exporting property set data from a DWG file to a DWF or DWFX file. This can be helpful when exporting large drawings with many object properties.

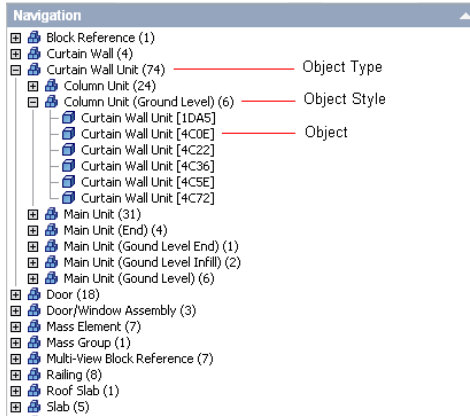

- Grouping property set data by external reference first, and then by object type and object style:

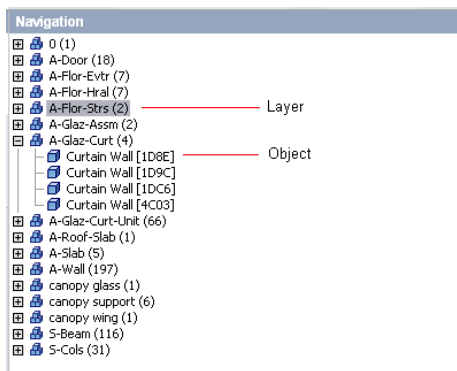

- Grouping property set data by external reference first, and then by layer:

- Grouping property set data by object type first, and then object style:

- Grouping property set data by object layer:

For information on setting the data structure, see [Publishing a 3D DWF or 3D DWFx File with Automatic Property Set Data](#) on page 208 and [Publishing a 3D DWF or 3D DWFx file with User-Defined Property Set Data](#) on page 210.

Publishing a 3D DWF or 3D DWFx File with Automatic Property Set Data

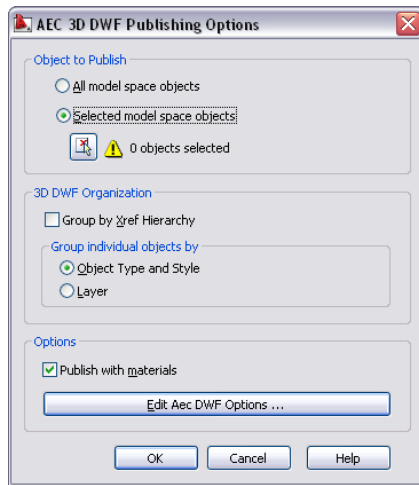

NOTE This instruction lets you create a single 3D DWF or 3D DWFx file of the model you are working on with automatic property set data. If you want to create multiple DWF or DWFx files for different sheets with automatic property set data, see [Publishing a 2D or 3D DWF or DWFx file with Property Set Data](#) on page 212.

1 Do one of the following:

- Click File menu ► Export.
- Click Drawing Menu () and click Publish to 3D DWE.
- Enter **3ddwf** on the command line.

2 In the Export 3D DWF dialog, select 3D DWF or 3D DWFx for Files of type. (By default 3D DWFx is selected.)

3 Click Tools menu ► Options.

4 Under Objects to Publish, select either the whole model or click Selected Model space objects, and pick objects in the drawing to include in the exported DWF or DWFX file.

5 Under 3D DWF Organization select in which order xrefs and objects will be displayed in the exported file.

If you want to...

Then...

group the objects by their external reference, and then by their object type and style

check Group by Xref Hierarchy. Under Group individual objects by, select Object Type and Style.

group the objects by their external reference, and then by their layer

check Group by Xref Hierarchy. Under Group individual objects by, select Layer.

group the objects by their type and style

uncheck Group by Xref Hierarchy. Under Group individual objects by, select Object Type and Style.

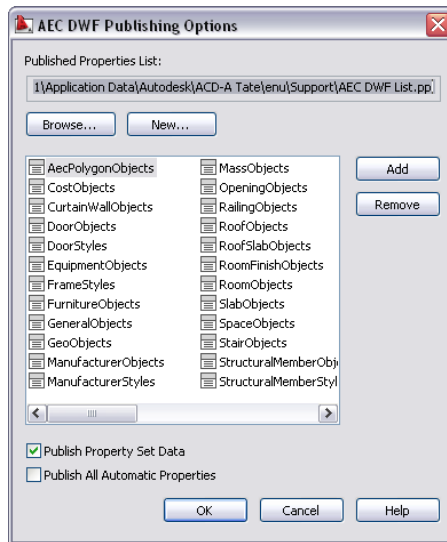

group the objects by their layer

uncheck Group by Xref Hierarchy. Under Group individual objects by, select Layer.

For example illustrations, see [Property Set Data Structure](#) on page 207.

6 Select Publish with materials in order to include the material definitions from the DWG file in the DWF or DWFX file.

7 Click Edit AEC DWF Options.

8 In the AEC DWF Publishing Options dialog, click Publish All Automatic Properties.

This will publish all automatic properties associated with the objects you have selected for exporting to the DWF or DWEx file.

9 If you want to publish user-defined property set data, see [Publishing a 3D DWF or 3D DWEx file with User-Defined Property Set Data](#) on page 210.

10 Click OK, and then Save.

By default, the automatic property data exported will be listed under a property group called Aec+<object type>. For example, if you export the automatic properties of a door, they will be listed under AecDoor. If you are exporting additional user-defined property set definitions and one of them already uses the name Aec+<object type>, the automatic properties will be listed in a property group called Aec+<object type> (2). In the door example that would mean that if you are exporting a user-defined property set definition named AecDoor, then the automatic door properties will be listed under AecDoor (2).

If an object property is both an automatic property and is also included in a property set definition, it will be listed both under the automatic properties and under the property set definition it is part of in the DWF or DWEx file.

Publishing a 3D DWF or 3D DWEx file with User-Defined Property Set Data

NOTE This instruction lets you create a single DWF or DWEx file of the model you are working on with user-defined property set data. If you want to create multiple DWF or DWEx files for different sheets with user-defined property set data, see [Publishing a 2D or 3D DWF or DWEx file with Property Set Data](#) on page 212.

1 Do one of the following:

- Click File menu ► Export.
- Click Drawing Menu () and click Publish to 3D DWF.
- Enter **3ddwf** on the command line.

2 In the Export 3D DWG dialog, select 3D DWF or 3D DWEx for file format. (By default, 3D DWEx is selected.)

3 Click Tools menu ► Options.

4 Under Objects to Publish, select either to publish the whole model or click Selected Model space objects, and pick objects in the drawing to include in the exported DWF or DWFX file.

5 Under 3D DWF Organization select in which order xrefs and objects will be displayed in the exported file.

If you want to...	Then...
group the objects by their external reference, and then by their object type and style	check Group by Xref Hierarchy. Under Group individual objects by, select Object Type and Style.
group the objects by their external reference, and then by their layer	check Group by Xref Hierarchy. Under Group individual objects by, select Layer.
group the objects by their type and style	uncheck Group by Xref Hierarchy. Under Group individual objects by, select Object Type and Style.
group the objects by their layer	uncheck Group by Xref Hierarchy. Under Group individual objects by, select Layer.

For example illustrations, see [Property Set Data Structure](#) on page 207.

6 Select Publish with materials in order to include the material definitions from the DWG file in the DWF or DWFX file.

7 Click Edit AEC DWF Options.

8 Verify that Publish Property Set Data is selected.

9 To add a property set definition to the exported DWF or DWFX file, click Add.

In the Add Property Sets dialog, by default the currently active drawing and the property set definitions in it are displayed.

10 To select one of the listed property set definitions, check its mark and click OK.

11 To select property set definitions from another drawing file, click Browse, and navigate to the desired drawing. Then, proceed to add property set definitions as described above.

12 Click OK.

13 To remove a property set definition from the exported DWF or DWFX file, select it, and click Remove.

14 To create a new PPL file, click New, and follow the instructions in [Creating a New Published Property List \(PPL\)](#) on page 215.

15 To select a different PPL file, click Browse and select a new file.

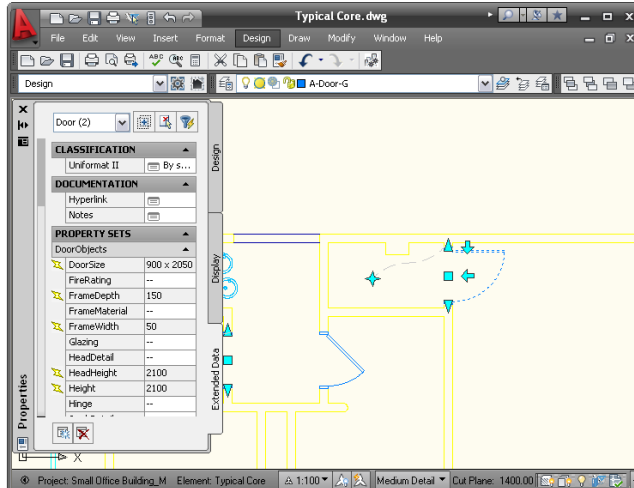

16 Click OK twice, and then click Save.

When the export is finished, you are asked whether you want to view the DWF or DWFX file. Click Yes to open the exported file in Autodesk Design Review.

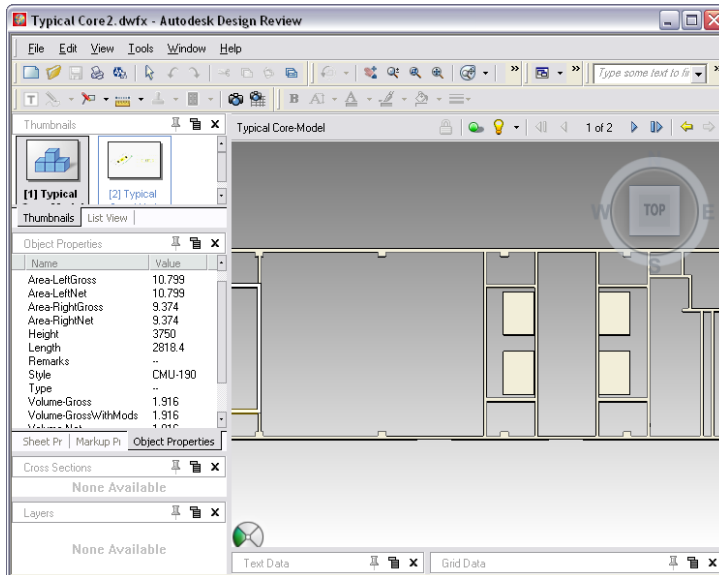

Publishing a 2D or 3D DWF or DWFX file with Property Set Data

When you create a DWF or DWFX file with the Publish dialog, you can create both 2D and 3D DWF or DWFX files. You can also create multiple DWF or DWFX files for individual sheets in your drawing. If you export property set data, the property set data will be displayed in each DWF or DWFX file.

DWG file with property set data

DWFx file with property set data

1 Click File menu ► Publish.

NOTE If you want to publish sheets from a project, see [Publishing Sheet Sets](#) on page 362.

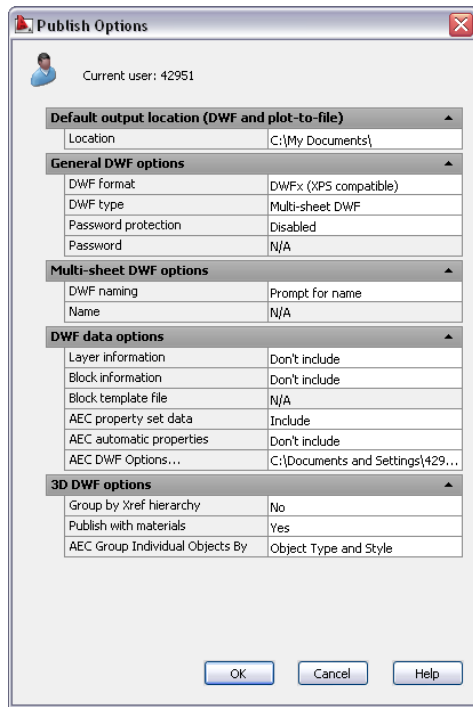

2 Under Page Setup, select if you want to publish a 2D or 3D DWF or DWFx file:

- To publish a 2D DWF or DWFx file, select a 2D page setup, or select <Default: None>.
- To publish a 3D DWF or 3D DWFx file, select <3D DWF>.
If the <3D DWF> option is not available, no valid 3D display configuration has been set for the drawing.

3 Under Publish to, select DWF format.

4 Depending on whether you want to create DWF or DWFx, select the appropriate option below DWF Format.

5 Click Publish Options.

6 Specify the general DWF options as described in “Publish Options Dialog Box” in the AutoCAD help.

7 If you want to publish user-defined property set data, select Include for AEC property set data.

8 If you want to publish all automatic properties of the objects in the drawing, select Include for AEC automatic properties.

NOTE Automatic properties can be published instead of or in addition to user-defined property set data.

9 In order to add or remove user-defined property sets for the exported DWF or DWFX file, click the Browse button under AEC DWF Options.

10 If you are creating a 3D DWF or 3D DWFX file, define the organization of published AEC objects in Autodesk Design Review:

If you want to...	Then...
group the objects by their external reference, and then by their object type and style	select Object Type and Style for AEC Group Individual Objects by. Then, select Yes for Group by Xref Hierarchy.
group the objects by their external reference, and then by their layer	select Layer for AEC Group Individual Objects by. Then, select Yes for Group by Xref Hierarchy.
group the objects by their type and style	select Object Type and Style for AEC Group Individual Objects by. Then, select No for Group by Xref Hierarchy.
group the objects by their layer	select Layer for AEC Group Individual Objects by. Then, select No for Group by Xref Hierarchy.

For example illustrations, see [Property Set Data Structure](#) on page 207.

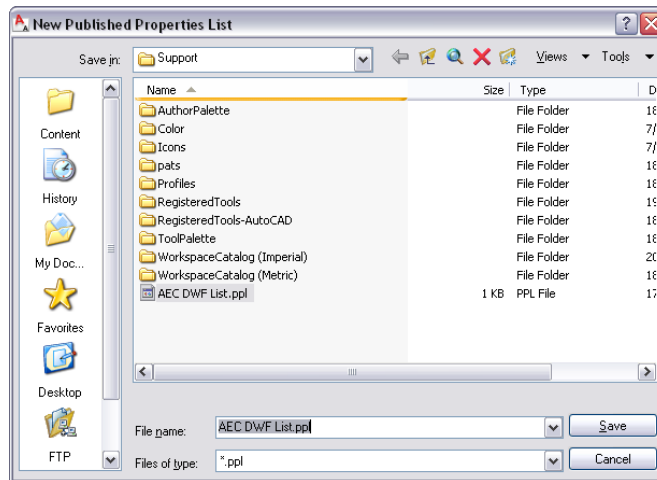

- 11 If you are creating a 2D DWF or 2D DWEx file, select a sorting option under AEC Group Individual objects by.
- 12 Click OK.
- 13 Click Publish.

The publishing process is initiated and notifies you when it is finished.

Creating a New Published Property List (PPL)

Use this procedure to create a new, Published Property List (PPL). The Published Property List specifies which property set definitions in a DWG file will be exported to DWF or DWEx, provided the property set definition has been added to objects or styles in the drawing.

- 1 Click File menu ► AEC DWF Publishing Options.
- 2 Click New.

- 3 Browse for the folder in which you want to save the new PPL file, and enter a name for the new PPL file.
- 4 Click Save.
The new PPL file is opened in the AEC DWF Publishing Options dialog. By default it does not contain any property set definitions.
- 5 Click Add.
By default the currently active drawing and all property set definitions in it are displayed.
- 6 If you want to add property set definitions from another drawing, click Browse to navigate to the desired file.
- 7 Select all property set definitions that should be included in the new PPL either by selecting their check marks or by using the Select All button.
- 8 If the PPL is complete, click OK.
- 9 If you want to add more property set definitions to it, click Add again, and repeat step 6 - 7.
- 10 Click OK twice.

Drawing Management

6

The Drawing Management feature formalizes and automates the processes relating to building model design and documentation. The feature provides automated tools that aid you in the management, viewing, and construction of your building.

When you manage your project files with this feature, you have consistency throughout all aspects of the project. Everyone on your design team has a centralized project environment for accessing the most current documents, from project templates to sections and elevations.

The Drawing Management feature enables you to create and manage projects, create and manage levels, and automate sheet creation.

Process Overview: Working in a Project Environment

The Drawing Management feature has 2 main components—the Project Browser and the Project Navigator. In the Project Browser, you define the current project, create new projects, and set high-level project information such as project name and number. On the Project Navigator palette, you perform project tasks, like creating and editing project drawings or sheets.

In a project environment, drawing files are connected to a project file. A drawing created within a project environment is edited and saved within the project structure. You can create specific views of your building constructs and define tailor-made plot sheets for views. You can also define categories such as Architectural, Structural, or HVAC to help organize your project.

The process of managing drawings in a project environment has the following basic steps.

- 1 Create a new project.
New projects can be either based on a template, an existing project, or be built from scratch. For more information, see [Creating a New Project](#) on page 235.
- 2 Define the project settings.
Project settings include name and number, drawing templates, and various other options. For more information, see [Working with Project Properties](#) on page 239.
- 3 Define levels and divisions in the project.
For more information, see [Levels](#) on page 271 and [Divisions](#) on page 276.
- 4 Create constructs of your building project.
For more information, see [Elements](#) on page 304 and [Constructs](#) on page 287.

- 5 Create views of your building project; for example, a first-floor plan view or a structural framing plan view.
For more information, see [Views](#) on page 318.
- 6 Create sheets.
For more information, see [Sheets](#) on page 342 and [Annotating a Project](#) on page 374.
- 7 Place views on sheets.
For more information, see [Placing a View Drawing onto a Sheet](#) on page 331 and [Placing a Model Space View onto a Sheet](#) on page 335.

Concepts of Drawing Management

The Drawing Management feature of AutoCAD Architecture lets you create large building projects distributed among many drawing files, levels, and divisions (wings). The following sections describe the key concepts of this feature.

Project

At the highest level, building models are organized conceptually into projects. A project is composed of 2 parts: the building model and the reports generated from the model. The building model is composed of constructs and elements, while reports consist of views and sheets. Within a project, elements are referenced into constructs, constructs are referenced into views, and views are referenced into sheets.

Project Standards

The Project Standards feature provides a mechanism for users to establish, maintain, and synchronize styles and display settings across an AutoCAD Architecture project. Within a project, you can specify standard styles, display settings, and AutoCAD standards that are used across all project drawings. Standard styles and display settings are defined in standards drawings associated with the project. The project is synchronized with these standards throughout the project life cycle. For more information, see [Project Standards](#) on page 409.

Project Tool Palettes and Content Browser Library

In addition to standards drawings, you can also set up project-specific tool palettes and a Content Browser library in the project setup. A user-definable root path for tool content ensures that the tools always reference the correct content drawing for their definition.

External Reference Management

The basis of the Drawing Management feature is an external reference mechanism that allows your source files to be distributed over many different locations on your computer or on a network. You can assign schedule tables, annotation tags, and dimensions to external references easily. Different people can work simultaneously on the same project.

You specify whether reference paths are full external or relative external paths.

For more information on external references, see “Reference Other Drawing Files (Xrefs)” in AutoCAD Help.

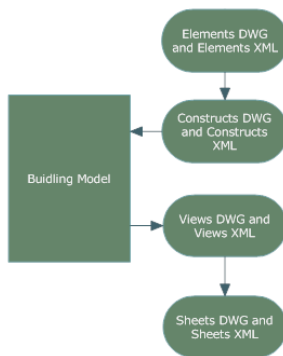

For more information on annotating external references in a project, see [Annotating a Project](#) on page 374.

Mapped Drives

AutoCAD Architecture supports mapped drives within the Drawing Management feature. You can map the same identifying drive letter on different servers with the same project structure. If you use mapped drives within an AutoCAD Architecture project, you are not prompted to repath each time you open the project drawing files from different servers. For more information, see [Working with Design Teams Located Remotely](#) on page 231.

XML Structure

A project has an underlying XML structure. For each drawing file you create within a project—for example, a floor drawing or a structural drawing—an accompanying XML file is created. The XML file contains project-relevant information, such as level and division information. You can reuse any drawing file created within a project outside the project as well, because the drawing file itself does not contain project-relevant information.

Levels and Divisions

The project provides a framework of levels and divisions (also called wings). By default, a new project consists of one level and one division. You can add levels and divisions throughout the lifetime of a project. The matrix of levels and divisions provide the framework to help uniquely identify the building components. For example, you could have a construct in your building assigned to First Floor—West Wing.

Levels and divisions schematic

Building objects, such as curtain walls and elevator shafts, can span multiple levels and divisions. You can use a spanning construct for these types of building objects.

For more information, see [Levels](#) on page 271 and [Divisions](#) on page 276.

Constructs

A construct describes one unique portion of a building project and is assigned to a specific level and division within the project. Spanning constructs, like curtain walls, can be assigned to multiple levels and divisions.

Plan view of curtain wall spanning construct

For example, the first level of your building project may consist of an exterior shell construct, a first-level core construct, and a first-level interior partitions construct.

A construct can contain drawing objects like walls and doors, external references to elements, or a combination of both. For example, a first-level core construct can contain the core walls directly drawn into the construct and an elevator element inserted as an external reference.

Constructs are referenced into views.

You can create and modify constructs within the current project. You can also import drawings and convert them or add them to constructs. You can import constructs into the project physically or by creating a link.

For more information, see [Constructs](#) on page 287.

Elements

Elements are used for pieces of the building that are repeated multiple times. For example, you could use an element to create a repeating design object like a desk/chair combination for multiple cubicles in an office building.

3D view of cubicle element

You can place the same element in different levels and divisions. An element is a generic building block for multiple use. If you create a bathroom layout as an element, you can use it on the second floor of the west wing as well as on the first floor of the east wing. To place the element on a specific floor and wing, you reference it into a construct. For example, you could create an element named Generic Bathroom Layout and reference it into constructs named First Floor—Left Apartment, First Floor—Middle Apartment, First Floor—Right Apartment, and so on.

For more information, see [Elements](#) on page 304.

Views

After the structure of the building is defined, and constructs are assigned to levels and divisions, you can generate reports (views and sheets) from the building model. A view drawing automatically references a number of constructs to present a specific view of the building project. To create a view drawing, you first decide what portion of the building you wish to look at and the type of view to generate. You could, for example, create a first-floor reflected ceiling plan or a second-floor framing plan.

You could also create a composite view of all floors in the building as shown:

3D view of entire building view

View drawings automatically reference the appropriate constructs according to their location within the building. For example, to create a floor plan of the west wing of the second floor, you would create a view that references all constructs assigned to the second floor and the west wing. This would also include a curtain wall spanning the first through fifth floors. You can reference additional constructs that you want to see in the view even though they do not lie on that floor, such as a building outline.

In a view drawing you can also add data like annotation, dimensions, and schedules. Whether to create the annotation in a view drawing or on a sheet is a decision you make based on your workflow and individual needs.

- General view drawing
- Detail view drawing
- Section/Elevation view drawing

Three different types of view drawings, each with its own template and identified by a different icon, can be used as organizational tools.

For more information on the view system in AutoCAD Architecture, see [Views](#) on page 318.

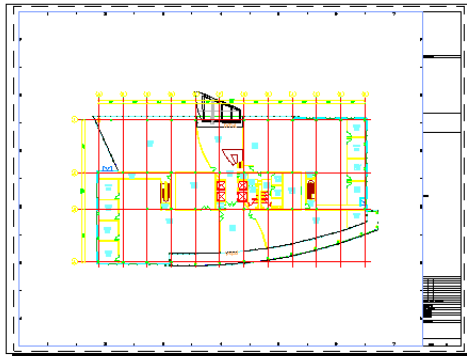

Sheets

Sheets are used to plot drawings of your building project.

The sheet system in AutoCAD Architecture consists of the following components:

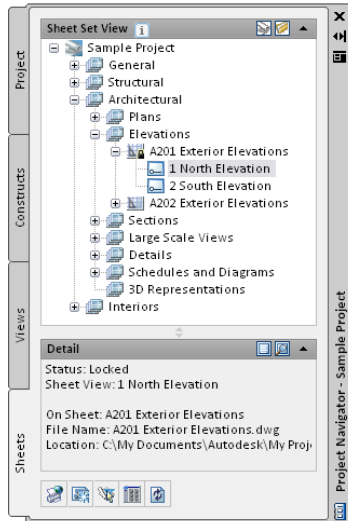

- **Sheet:** A sheet is a paper space layout that has been registered as a sheet. A sheet can contain one or more sheet views. For more information, see “Work with Model Space and Paper Space” in AutoCAD Help.

Sheet with building plan sheet view

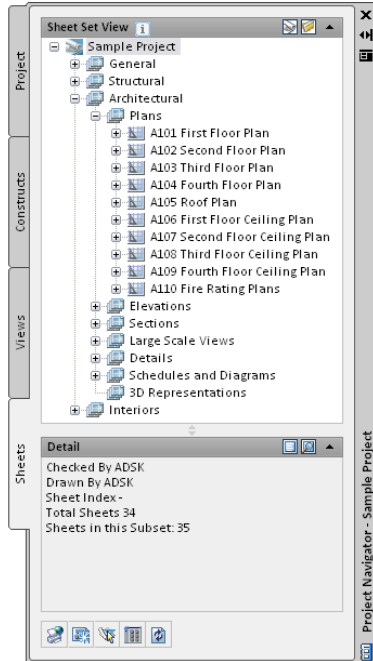

- **Sheet views:** A sheet view is a paper space viewport created by dragging a model space view from a view drawing in the Drawing Explorer onto a sheet.

Sheet view created from model space view

- Sheet set: A sheet set is a named and ordered collection of sheets. Sheet sets are similar to the physical set of bound sheets that are the primary communication medium for a typical building project. Sheet sets are tailored for efficient output of printed or electronic documents through the Publish command.

Sheet set for AutoCAD Architecture project

Each project in AutoCAD Architecture has a simple project sheet set, which contains all sheets for the project.

- Sheet drawing: A sheet drawing is a DWG file containing one or more sheets.

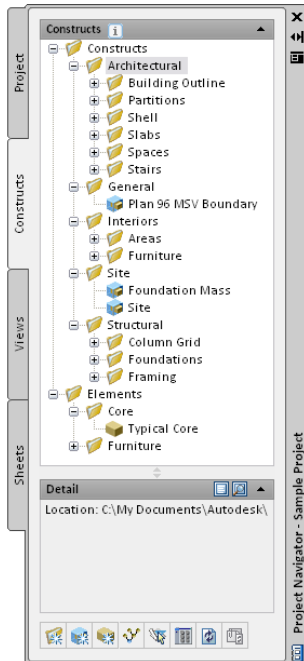

Sheet set, sheets, sheet views, sheet drawings, and model space views are listed on the Sheets and Views tabs of the Project Navigator.

Although it is recommended to place annotation in a view, you can add annotation like tags, dimensions, and schedule tables to a sheet. For more information, see [Sheets](#) on page 342.

Categories

To help organize the building, the parts of the building project—elements, constructs, views, and sheets—can be categorized. You can use categories like shell, core, and interior partitions. Categorizing a construct lets you filter that construct when generating views.

Construct categories in the Project Navigator

For more information, see [Categories](#) on page 279.

The Project Structure

When you create a new project, AutoCAD Architecture automatically creates a project environment to connect the individual files into one project. This environment has 3 main components:

The Project (APJ) File

The project (APJ) file contains:

- the project name and number
- information about levels and divisions
- settings for drawing templates, project details, project standards, project palettes, and the method of linking xrefs

You also configure standards styles, display settings, and AutoCAD standards here. For more information, see [Working with Project Properties](#) on page 239. An existing APJ file can serve as the template for a new project. For more information, see [Creating a New Project Based on a Template \(Copying a Project\)](#) on page 235.

NOTE The APJ file is a well-formed XML document. You can open and modify it using an XML editor.

The Default Category Structure

When you create a new project, the following default category structure is created:

These categories are empty unless you created the new project from an existing project with drawing files.

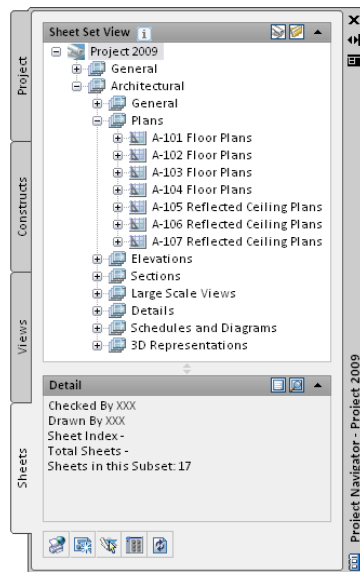

These top-level categories can be redirected to point to other folders. Each top folder must use a unique folder, and they cannot be an ascendant or descendant of each other in the tree structure. You can create subcategories in each of them. For more information, see [Categories](#) on page 279.

The Project Sheet Set

In AutoCAD Architecture, project sheets are collected in sheet sets or a project. A sheet set allows you to have common publishing setups across a number of sheets.

When you create a new project, a unique sheet set is created for this project. The project sheet set is displayed on the Sheets tab of the Project Navigator.

Project sheet set in AutoCAD Architecture Project Navigator

Only one sheet set can be associated with a project. You cannot change the sheet set for an existing project, but you can change its properties. For more information, see [Setting the Properties of the Project Sheet Set](#) on page 347.

Before You Begin: External References

The Drawing Management feature uses external references (xrefs) as a means to create a project and maintain it. Elements are referenced into constructs, constructs are referenced into views, and views are referenced into sheets. The mechanism of referencing is identical to the regular AutoCAD External References Management feature. However, the background methods employed have additional features.

Xrefs that are created in drawing management can automatically make use of project data, while those that are created manually through the xref palette or command line cannot. For example, a construct that is placed on a specific level will use that level's elevation data (as defined by the project) to control the Z-axis insertion point when being xrefed into a view.

If you are working in a project environment, the best practice for referencing project drawings into other project drawings is to use the Project Navigator rather than the standard AutoCAD Xref Manager. The AutoCAD Xref Manager cannot differentiate between project drawings and non-project drawings. If you reference a non-project file into a project file by mistake, you cannot use the full Drawing Management functionality on that file.

Whenever you define a project drawing on the Project Navigator, an accompanying XML file is created. The XML file is vital for the project. Under no circumstances should you delete it (unless you are deleting the entire project). That XML file contains:

- information about level and division assignments
- viewport and content information appropriate for the type of drawing

Keep these considerations in mind when working with a project:

- Do not delete any XML files generated by the Drawing Management feature. They are vital for the project.
- Use the Project Navigator to create, modify and reference project files within the project. If you want to use existing non-project files in a project, convert them to project files first. For more information, see [Converting a Drawing to an Element](#) on page 308 and [Converting a Drawing to a Construct](#) on page 292.
- Drawing Management supports the use of relative paths for external references. In the project setup, you can decide whether to use full paths or relative paths. Working with relative xref paths makes moving the project and transmitting it easier and reduces the need to repath the project. For more information on relative and full paths, see “Set Paths to Referenced Drawings” in AutoCAD Help.

NOTE Changing full xref paths to relative xref paths or relative paths to full paths in an existing project will change existing paths. An exception is if the xref path points to a location that is outside the project folders or is otherwise not supported by relative paths. For information on adding project location search paths, see [Specifying the Default Project Options](#) on page 229.

Before You Begin: Working in a Network Environment

When you are working on a large project, the project may be hosted on a network server and accessed by multiple users simultaneously. For a seamless workflow, keep these points in mind:

- **Keep the project tree current:** When multiple users are working on a project simultaneously, it is possible that one user's view of the project will not reflect changes made by another user. For example, user 1 might be adding/moving/deleting constructs in a project at the same time that user 2 is annotating sheets. User 2 is not notified that the coworker has removed some constructs from the project. If user 2 tries to open a removed construct from the Project Navigator on his machine, an error message results.

To prevent this situation, refresh the Project Navigator by clicking  (Refresh Project) so that all items are updated to reflect the current project status. For more information, see [Refreshing the Project Navigator](#) on page 373.

- **Icons reflect the status of drawings:** A lock symbol is automatically appended to the drawing icon if the drawing is in use. When you hold the cursor over the drawing name, a tooltip displays information about the drawing file.

- **Access restrictions on the network server:** You can limit other users' ability to edit and delete project files by using network permissions. You can limit the Delete rights for the entire project, so that users cannot delete files from the project or move files around within the project. You might consider limiting Delete rights to the top project folder (containing the APJ file) while allowing deletions in the subfolders.
- **Mapped drives:** The Drawing Management feature supports working with mapped drives. You can place the project APJ file or project drawings on a mapped drive and mirror the server information for users in multiple locations. For more information, see [Working with Design Teams Located Remotely](#) on page 231.

Project Support Files

A project can be associated with multiple support files. Normally these files are used to provide standards that ensure consistency across the project, or across multiple projects. Some support files are mandatory, while others are optional.

NOTE You can find all project-related templates under `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Template`.

The following support files can be used in an AutoCAD Architecture project:

- Project template (optional)
- Drawing templates (mandatory)
- Sheet set template (mandatory)
- Project standards drawings (optional)
- Project tool palette group (optional)
- Project Content Browser library (optional)
- Project structure templates (optional)

These support files are described below.

Project Template

A project template is an existing project that can be used as a template when creating a new project. When you create a project based on a template project, all drawing files, settings, and support files of the new project are taken from the template project. Alternatively, you can use only the structure and the support files of a project as the basis for the new project. For more information, see [Creating a New Project Based on a Template \(Copying a Project\)](#) on page 235 and [Creating a New Project with the Structure of an Existing Project](#) on page 237.

Drawing Templates

When you create a new project, you can define default templates for new elements, constructs, and model views created in the project. For more information, see [Creating and Saving Drawings](#) on page 155. Sheet templates are defined in the project sheet set template.

The Project Sheet Set Template

Each project has a unique sheet set that collects and organizes the sheets in a project when the project is created. The sheet set is created from a template in which the user defines the sheet set structure, the default sheet template, and page setup overrides. When you create a project based on a template project, the sheet

set of that project is used as a sheet set template. When you create a new project without using a template, the default sheet set template defined in [Specifying the Default Project Options](#) on page 229 is used.

You cannot change the sheet set template after creating a project. You can, however, change the properties of the sheet set in the project.

By default, following sheet set templates are shipped with the software:

- Aec Sheet Set (Imperial ctb).dst
- Aec Sheet Set (Imperial stb).dst
- Aec Sheet Set (Metric ctb).dst
- Aec Sheet Set (Metric stb).dst

Project Standards Drawings

You can define project-specific drawings that contain standard styles and display settings, as well as AutoCAD standards for a project. For more information, see [Specifying Project Standards](#) on page 243.

Project Tool Palette Group

You can define a tool palette group to be used in the project. If your project is not based on a template that includes a project-specific tool palette group, you can define one as described under [Setting up Standard Tools in a Project](#) on page 425.

Project Content Browser Library

You can define a project-specific Content Browser library that opens by default when you start Content Browser from within Project Navigator. The project library contains standard tools and palettes for the project. For more information, see [Setting up Standard Tools in a Project](#) on page 425.

Specifying the Default Project Options

Use this procedure to set the default options for your AutoCAD Architecture projects. The following options can be specified for projects:

- Location search paths
- Template files for constructs, elements, views and sheet sets
- Project bulletin board
- Project image

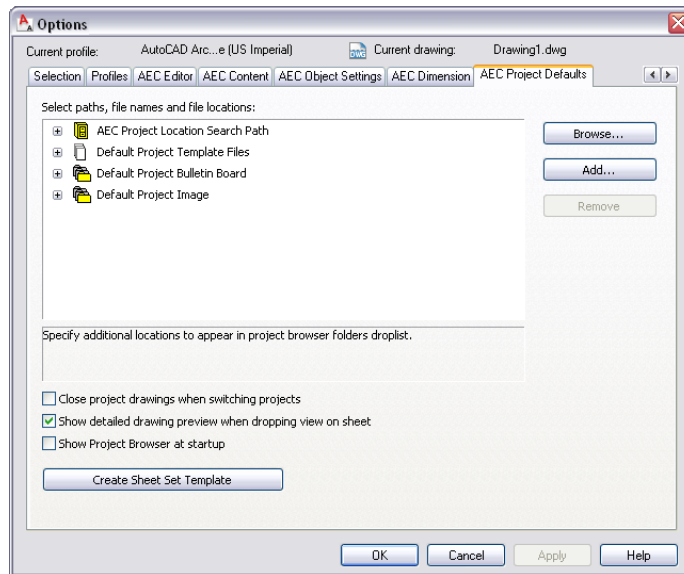

NOTE When you create a new project based on a template project, the default templates, bulletin board, and project image of the template project are used in the new project. If the new project is not based on a template project, the settings defined in the project defaults are used.

In addition, you can specify settings that affect your workspace when:

- Starting the application
- Switching between projects
- Dragging and dropping a view onto a sheet

To specify project defaults:

- 1 Click Format menu ► Options.
- 2 Click the AEC Project Defaults tab.

3 Expand AEC Project Location Search Path:

The paths also display in the Project Browser drop-down list (above the list of projects), providing shortcuts to folders containing projects.

If you want to...

Then...

change an existing project location search path

click the path you want to change, and click Browse. In the Browse for Folder dialog, select the new search path, and click OK.

add a search path

click Add. In the Browse for Folder dialog, select the additional search path, and click OK.

remove a search path

click Remove.

4 Expand Default Project Template Files.

5 To change any of the default templates, the bulletin board, or the image, expand the category, select the existing file, and click Browse. Then in the Select File dialog, select the new file, and click Open.

6 Specify how your workspace displays:

If you want to...

Then...

close all drawing files that are open in your current project when you change to a different project

select Close project drawings when switching projects. This setting is only in effect if the option of Always perform selected action in the Project Browser-Close Project Files dialog is also selected. For more information, see [Closing All Project Files](#) on page 251.

If you want to...	Then...
improve performance by displaying only the model space view name within the frame of the view when dropping it on a sheet	clear Show detailed drawing preview when dropping view on sheet.
specify that the Project Browser opens every time you open AutoCAD Architecture	select Show Project Browser at startup.

7 To create a new sheet set template, click Create Sheet Set Template, and see [Creating a Sheet Set Template](#) on page 363.

8 Click OK.

Working with Design Teams Located Remotely

The best practice for working with members of a remote team is to set up the structure for a project on a dedicated drive of a central network server. If you must mirror a server drive, communicate the location to remote teams so they can assign the same drive letter. When remote locations use the same mapped drive, the extended team can work on the project without being prompted to repath the project when it is set current.

If you want to specify mapped drives for an existing project, organize the full project on the specific drive first. Then use Project Browser to browse for the project using the mapped drive letter.

Opening a Project From a Mapped Drive

Use this procedure to open a project located on a mapped drive. You must already have the project structure defined on that drive.

1 Click File menu ► Project Browser.

2 Click  .

3 In the Project Files dialog, browse to the mapped drive (indicated by letter) on which your project is located, and click Open.

4 To set this project current, select the APJ file, and click Open.

5 Click Close on the Project Browser.

The Project Browser

The Project Browser is where you perform high-level project-related tasks, such as creating a new project, selecting the currently active project, and setting project properties.

Opening the Project Browser

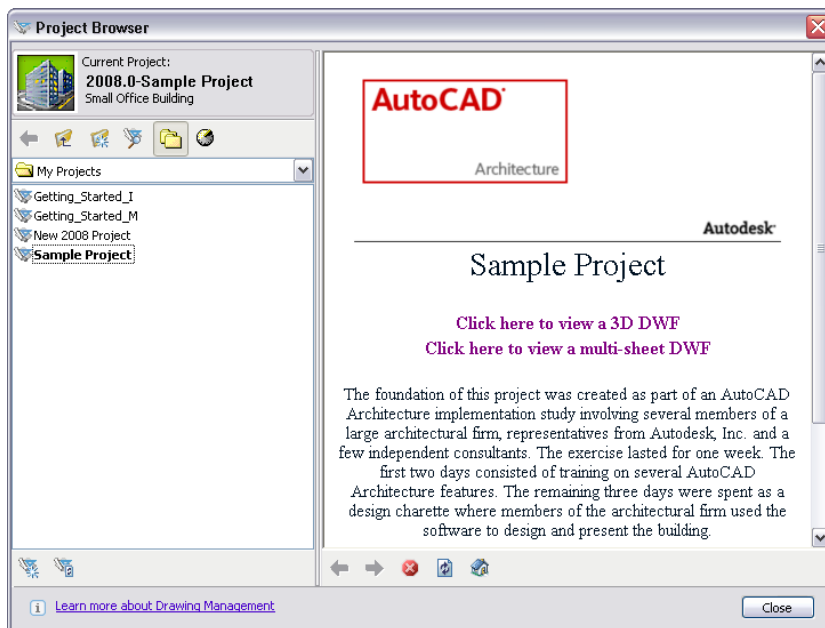

Use this procedure to open the Project Browser.

■ Click File menu ► Project Browser.

Alternatively, you can click  on the Navigation toolbar, or enter *AecProjectBrowser* on the command line.

Using the Project Browser

In the Project Browser, you create new projects, configure the project settings and project standards, add detail information, and select the current project. When you set a project current, either from the context menu or by double-clicking the file name, the project is migrated to a format compatible with the current version of AutoCAD Architecture. If you also repath the project, all project drawings are migrated as well, and you will be unable to open the project in any older version of the software. For more information, see [Repath the Project](#) on page 372.

Project Browser

On the left side of the Project Browser, you select the current project, create new projects, browse existing projects, and view the project history. On the context menu, you can also edit project properties, close a project, copy the project structure, eTransmit a project, and archive a project. All information you enter here pertains to the project as a whole. On the right side of the Project Browser, an embedded Internet Explorer allows you to browse your project home page.

NOTE The projects you create in the Project Browser display as files and folders in Windows Explorer. As a general rule, you should not perform any file operations on a project file there, except in those cases where a procedure explicitly states that you should. Changes in Windows Explorer are not always updated correctly in the Project Browser or Project Navigator, and you could get an inconsistent view of your project data. Any changes you make to the project within the Project Browser are managed and coordinated by AutoCAD Architecture. Changes made outside the software might not be correctly coordinated and processed.

The Project Header

The currently selected project is displayed in the upper-left area of the Project Browser. The header contains the project name, project number, a user-selected bitmap representing the project, and an optional short

project description. You enter this information when you create a new project or edit properties of an existing project.

Project header

The Project Navigation Bar

Below the project header, toolbar buttons help you to navigate in your folder structure.

Button	Description
	Returns you to the previously displayed folder.
	Displays the folder one level above the currently displayed folder.
	Takes you to the Project File Navigator, where you can browse for project (APJ) files.
	Lets you create a new folder in the specified location.
	Displays the projects in the folder selected in the list below. For detailed information, see The Project Selector on page 233.
	Displays a historic list of projects sorted by various criteria. For detailed information, see The Project Selector on page 233.

The Project Selector

The project selector on the left side of the Project Browser displays the projects you have created in AutoCAD Architecture.

Project selector

You have 2 main options for displaying projects:

Displaying Projects by Folder Structure

You can display the projects on your computer or network based on the Windows Explorer folder structure. When you navigate to a folder, all projects and subfolders contained in that folder are displayed.

- 1 Click File menu ► Project Browser.

- 2 In the project navigation bar, click  .

The project selector displays the folder structure of your computer. The contents of the currently selected folder are displayed in the project selector. Project files are displayed with the project icon  . The current project is displayed in bold letters.

- 3 To switch to another folder, select it in the drop-down list.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

- 4 To navigate to the parent folder of the current folder, click  .

Displaying Projects by History

In the project selector, you can display projects based on their history.

- 1 Click File menu ► Project Browser.

- 2 In the project navigation bar, click  .

- 3 Select the option by which you want to sort projects.

- If you select Most Recently Used, the last eight projects you have made current are displayed in descending order in the project selector.
- If you select By Date, a list of project dates is displayed, sorted by current day, current week, and previous weeks.
- If you select By Project, a list of project names is displayed, sorted alphabetically.
- If you select By Location, a list of folders containing project files is displayed, in alphabetical order. If you double-click a folder, the projects contained in it are displayed.

Project files are displayed with the project icon  . The current project is displayed in bold letters.

- 4 If you want to remove a project from the history, select the project, right-click, and click Remove from History List. Click Yes in the subsequent message box.

NOTE You cannot remove the current project from the history list.

- 5 If you want to remove the complete history list except for the current project, select a project, right-click, and click Reset History list. Click Yes in the subsequent message box.

The Embedded Internet Explorer View

A project can connect to a bulletin board HTML page. You could do this, for example, to provide a link to your company's home page or a project web site. The HTML page is displayed in the right pane of the Project Browser. At the bottom of the page, there is a standard Internet Explorer navigation bar with buttons for Back, Forward, Stop, Refresh and Project Home.

Setting a Project Current

Use this procedure to set a project to be the current project.

To work within the project environment, you must define the current project. Only one project can be current at a time, and all project operations you perform, such as adding constructs and elements or changing levels and divisions, are done within the current project.

When you select a project as the current one, its project header and default HTML bulletin board are displayed in the Project Browser, and the name appears on the Project Navigator palette.

NOTE If your Project Browser does not yet contain any projects, see [Creating a New Project](#) on page 235.

1 Click File menu ► Project Browser.

2 In the project selector, select a project.

Projects are displayed with a project icon .

3 Right-click, and click Set Project Current.

NOTE Alternatively, you can double-click the project.

The selected project is loaded in AutoCAD Architecture, and you can work with it until you close it or select another one.

4 In the Project Browser, click Close to begin working on the Project Navigator palette.

If you working on the same project in more than one session of the same version of AutoCAD Architecture, and you make changes in one session, you can automatically refresh the project in the other session(s) by opening the Project Browser there.

Creating a New Project

There are 3 options for creating a new project. You can copy an existing project and all its settings; you can create a project with the folder structure and support files of an existing project; or you can create a new project from scratch, with no predefined files and settings.

Creating a New Project Based on a Template (Copying a Project)

Use this procedure to create a project using an existing project as a template.

This is the quickest and easiest way to create a project with predefined settings and support files. When you use this method, the following files and structures are copied to the new project:

- All project DWG files and XML files

- Project standards files
- AutoCAD standards files
- Project standards synchronization settings
- Sheet set template
- Project details
- Drawing templates
- Keynote and detail component databases
- Project tool palette group
- Tool content root path
- Project Content Browser library

NOTE Project standards files, the project tool palette group, and the project Content Browser library are copied to the new project only if they are located within the original project folder. Standard components located outside the project folder will be referenced by the new project, but not copied to it.

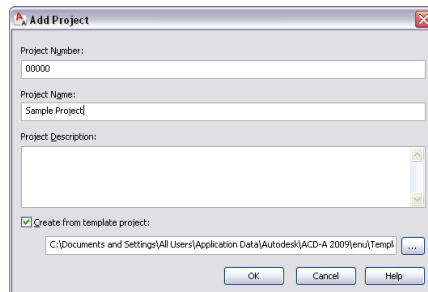

Creating a new project based on a template will copy all files that are in the project folder. If you want only the support files and structure of the project to be copied, but not its drawing files, see [Creating a New Project with the Structure of an Existing Project](#) on page 237.

If you redirected a project folder (elements, constructs, views, or sheets) to a folder that is not beneath the root project folder (location of the APJ file), the project cannot be used as a template project. For more information, see [Specifying the Location of Top-Level Categories](#) on page 283.

1 Click File menu ► Project Browser.

2 Right-click on an existing project or folder in the project selector, and click New ► Project.

Alternatively, you can click  in the toolbar below the project selector.

3 In the Add Project dialog, enter a number for the new project.

Each project needs a unique identification number. You can use numerals, alphabetic characters, or a combination, such as 100A. The project number appears in the project header.

The number you assign here can be used as a prefix for all drawings you create in the project. You can also use the number as a property for a title block. For more information, see [Project Schedule Properties](#) on page 378.

4 Enter a name for the new project.

5 Under Project Description, if desired, enter a description brief enough to be displayed in the project header.

Details about the project can be entered on a separate worksheet. For information, see [Adding Detailed Information to Project Properties](#) on page 242.

6 Select Create from template project.

7 Enter the path and name of an existing APJ file, or click  to navigate to an APJ file.

8 Click OK.

NOTE You cannot specify all support files and paths directly when creating a new project; you can only define name, number, description, and project template. The remaining settings can only be defined after the project has been created. If you create the project based on a template, the settings of the template are used for the initial setting. To define the project settings, see [Working with Project Properties](#) on page 239.

Creating a New Project with the Structure of an Existing Project

Use this procedure to create a new project that is based on the structure and support files of an existing project. However, if you redirected any categories in the project on which you want to base your new project, it cannot be used as a template. For more information, see [Specifying the Location of Top-Level Categories](#) on page 283.

When you use this method, the following files and settings are copied to the new project:

- Project standards files
- AutoCAD standards files
- Project standards synchronization settings
- Sheet set template
- Project details
- Drawing templates
- Keynote and detail component databases
- Project tool palette group
- Tool content root path
- Project Content Browser library

1 Click File menu ► Project Browser.

2 In the project selector, locate the folder in which the project of which you want to copy the structure and support files is located.

3 Select the project, right-click, and click Copy Project Structure.

4 In the Duplicate Project dialog, enter a number for the new project.

Each project needs a unique identification number. You can use numerals, alphabetic characters, or a combination, such as 100A. The project number appears in the project header.

The number you assign here can be used as a prefix for all drawings you create in the project. You can also use the number as a property for a title block. For more information, see [Project Schedule Properties](#) on page 378.

5 Enter a name for the new project.

6 Under Description, if desired, enter a description brief enough to be displayed in the project header.

Details about the project can be entered on a separate worksheet. For information, see [Adding Detailed Information to Project Properties](#) on page 242.

7 Under Copy to, select a folder in which you want to save the copied project.

8 Click OK.

Creating a New Project Without Using a Template

Use this procedure to create a new project that is not based on a template but uses the drawing templates, sheet set template, and project bulletin board specified in the AEC Project Defaults, as described in [program default options](#) on page 229. Note that you still need to define project details and project standards.

1 Click File menu ► Project Browser.

2 Right-click on an existing project or folder in the project selector, and click New ► Project.

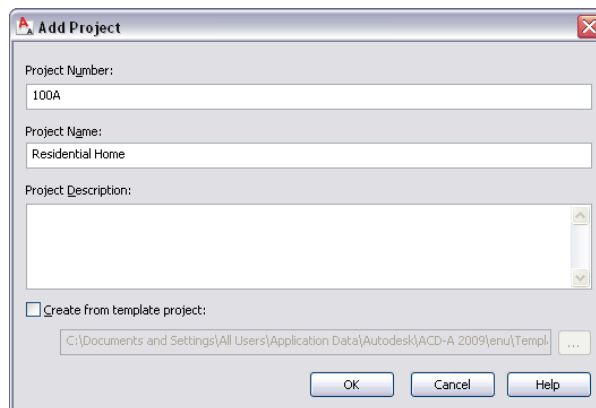

Alternatively, you can click  in the toolbar below the project selector.

3 In the Add Project dialog, enter a number for the new project.

Each project needs a unique identification number. You can use numerals, alphabetic characters, or a combination, such as 100A. The project number appears in the project header.

The number you assign here can be used as a prefix for all drawings you create in the project. You can also use the number as a property for a title block. For more information, see [Project Schedule Properties](#) on page 378.

4 Enter a name for the new project.

5 Under Project Description, if desired, enter a description brief enough to be displayed in the project header.

Details about the project can be entered on a separate worksheet. For information, see [Adding Detailed Information to Project Properties](#) on page 242.

6 Verify that Create from template project is not selected.

7 Click OK.

NOTE You cannot specify all support files and paths directly when creating a new project; you can only define name, number, description, and project template. The remaining properties are defined after the project has been created. If you create the project based on a template, the properties of the template are used for the initial setting. If you create a project without using a template, the properties will initially be empty or are defined by the AEC default project options. To define the project properties, see [Working with Project Properties](#) on page 239.

Working with Project Properties

When you have created a new project, the following properties may be defined or can be changed:

- Project bulletin board
- Project image
- Relative or full paths for external references
- Synchronization of view drawing layer settings with sheet views
- Project tool palette file location
- Project tool palette storage type
- Project tool content root path
- Project Content Browser library
- Drawing templates for elements, constructs and views
- Project details
- Project detail component databases and keynote databases
- Project standards settings

When you have created a project based on a template project, these settings are initially taken from that project. You can change them, if necessary.

NOTE The project sheet set template is defined during the creation of the project; either it is the sheet set used in the template project, or, if you have chosen to create a new project without using a template, it is the default project sheet set template defined in [Specifying the Default Project Options](#) on page 229.

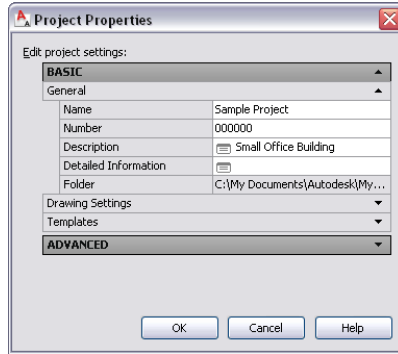

Specifying Basic Project Properties

Use this procedure to define or change basic properties for a project. Basic properties are divided into 3 categories:

- General
- Drawing Settings
- Templates

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project. The Project Properties dialog is displayed.

- 3 Under General define or change the following properties as needed.

Property	Description
Name	The project name is defined when you create the project. If you change the name here, only the name displayed in Project Browser and Project Navigator is changed; the APJ file and the project folder in Windows Explorer retain the original name. The recommended procedure for renaming project is described in Renaming a Project on page 250.
Number	The project number is defined when you create the project. You can enter a new number here. NOTE Under Drawing Settings, you can specify that the project number is added as a prefix to each project drawing created in the project. If you change the project number during the project life cycle, the existing file names will be changed and repathed.
Description	To add a description or change the current one, click  , enter the desired text, and click OK.
Detailed Information	To attach user-defined information to a project, such as project data and site description, click  . For more information see, Adding Detailed Information to Project Properties on page 242.
Folder	This path is read only and identifies where the project is located.

4 Under Basic, expand Drawing Settings, and define or change the following properties as needed:

Property	Description
Use Relative Xref Paths	<p>Select Yes to have external references within the project attached using relative paths whenever possible. This makes it easier to move or electronically transmit a project.</p> <p>After the progress bar indicates the project files have been renamed, you are given the option to repath the project now or repath the project later.</p> <p>Changing full xref paths to relative xref paths or relative paths to full paths for existing xref paths will change existing paths accordingly. An exception to this behavior is if the xref path points to a location outside the project folders or otherwise not supported by relative paths.</p>
Match Sheet View Layers to View	<p>Select Yes to use the view drawing layer settings in any sheet views generated from the view drawing or one of its model space views. The settings are updated in the sheet view when they change in the view drawing. For more information, see Synchronizing View Drawing Layers with Sheet View Layers on page 338.</p>
Prefix Filenames with Project Number	<p>Select Yes to have the project number prefixed to the file names of drawing files created within this project. If you select No, no prefix is added to drawing files created within this project.</p> <p>NOTE When you add or change the prefix setting in an existing project, extended file names are changed and repathed. Filename prefixes do not display in the Drawing Explorer.</p>

5 Under Basic, expand Templates, and define or change the following properties as needed:

Property	Description
Use Common Model/View Templates	<p>Specify whether you want to base your elements, constructs, and view drawings on a single common template or define separate DWT files as templates for each drawing type. For an overview of the drawing types, see Concepts of Drawing Management on page 218. If the value of Use Common Model/View Templates is Yes, the Common Model/View Template property specifies the location of the common template for elements constructs, and view drawings.</p> <p>To change this value, click , select a different drawing template, and click Open.</p>
Element Template Construct Template General View Template Section/Elevation View Templates Detail View Template	<p>If the value of Use Common Model/View Templates is No, these properties specify the location of the default template file. To change any of these values, click , select a different drawing template, and click Open.</p>

Property	Description
Sheet Template	Specifies the location of the default template file for creating new sheets. To change this value, click  , select a different drawing template, and click Open. If the sheet set is locked for the project, this property is read only.

6 Click OK to return to the Project Browser.

Adding Detailed Information to Project Properties

Use this procedure to add detail information to a project.

Project details are user-defined information items that can be attached to a project. Details might include contact information about contractors, legal representatives, or others. You can also use project details to track changes and improvements to the project.

You can create detail categories such as Financial Data which might contain detail items such as Loan Amount or Grant Amount. The details worksheet lets you create an information model that meets your needs.

If you create a project based on a project template, you can use the project detail categories and items from an existing project. For more information, see [Creating a New Project](#) on page 235. If you create a new project without a template, no project details exist.

NOTE Detailed information is saved in the project APJ file in XML format. You can open the project APJ file in an XML editor in order to edit the detail information.

Project details are not only used in the project APJ file, but are also displayed as manual properties in the schedule data of a project. You can use the details to create schedule tables for your project or build title blocks for sheets. For more information, see [Project Schedule Properties](#) on page 378.

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 Select the project to which you want to add details, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

- 3 If necessary, expand Basic ► General and for Detailed Information click .
- 4 Add or modify project details as needed:

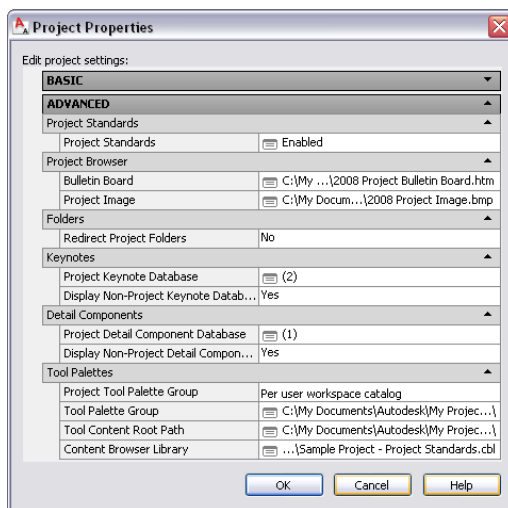

If you want to...	Then...
add or edit the value of the detail item	enter the information in the right column of the appropriate detail row.
add a detail category	click  , enter a name for the new detail category, and click OK.
add a detail item within a detail category	select the category, click  , enter a name for the new detail, and press <i>ENTER</i> .

If you want to...	Then...
remove a detail item	select the detail item, and click  .
remove a detail category	first delete all detail items in the detail category; then select the category, and click  .

5 When you are finished editing, click OK twice.

Advanced Project Properties

You can define or modify advanced project properties such as standards, images, keynotes, detail components, and tool palettes.

Specifying Project Standards

Use this procedure to configure project standards. The Project Standards feature is disabled by default and lets you establish, maintain and synchronize standards across all drawings in an AutoCAD Architecture project. Project standards include standard styles, display settings, and AutoCAD standards that are used across all project drawings. Standard styles and display settings are specified in one or more standards drawings associated with the project. Project drawings can then be synchronized with these standards throughout the project life cycle, either automatically, or on demand.

The AutoCAD Architecture Project Standards feature integrates the AutoCAD Standards checker, allowing you to set up one or more DWS files for AutoCAD components. AutoCAD components that can be included in a standards check are:

- AutoCAD dimension styles
- AutoCAD layers
- Text styles

■ Linetypes

In the Configure AEC Project Standards dialog, you define which drawings to use as the source for standard styles and display settings, which drawings to use as the source for AutoCAD layers, dimension styles, text styles, and layers, and how to synchronize the standards in the project. For detailed information about configuring project standards, see [Project Standards](#) on page 409.

Specifying Project Browser and Bulletin Board Images

Use this procedure to specify a BMP image for the project header and an HTML file for the project bulletin board. You can specify that the HTML file points to your company home page or a project web site. The current project header and default HTML bulletin board display in the Project Browser.

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

- 3 Under Advanced, define or change the Project Browser project properties as needed.

- 4 For Bulletin Board, click , select the HTML page to display in the Project Browser, and click Open.

The page selected is displayed in the right side of the Project Browser in an embedded Internet Explorer.

- 5 For Project Image, click , select the bitmap file to display in the project header, and click Open.

TIP Due to the relatively small size of the header (64x64 pixels), a simple image with clear contrasts creates the best effect.

- 6 Click OK to return to the Project Browser.

Specifying Locations for the Project Folders

Use this procedure to change the location of the project folders. Ideally, the project folders will not be redirected and will be located under your project folder as Elements, Constructs, Views, and Sheets. If you change the location of the project folders, you will need to repath. For more information, see [Specifying the Location of Top-Level Categories](#) on page 283.

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

3 Under Advanced, define or change the Folders project properties as needed.

Property	Description
Redirect Project Folders	Specify whether you want to redirect your elements, constructs, views, and sheets folders to a different location. If the value of Redirect Project Folders is No, the default folder location for the project is used. For more information, see Specifying the Default Project Options on page 229.
Elements Folder	If the value of Redirect Project Folders is Yes, these properties specify the location of the project folders. To change any of these values, click the value, click Browse, select a different folder location, and click OK.
Constructs Folder	
Views Folder	
Sheets Folder	

4 Click OK to return to the Project Browser.

NOTE Folders must be unique and not ancestors or descendants of the project folder.

Specifying the Keynote Databases for a Project

To ensure the compliance with a specific keynoting standard, for example the CSI standard, you can use the following procedure to specify the relevant keynote databases for a project. For more information, see [Annotation and Keynoting Tools](#) on page 2381.

1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.

2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

3 Under Advanced, define or change the Keynotes project properties as needed.

4 For Project Keynote Database, click . (The number of databases associated with the current project is noted.)

5 In the Add/Remove Keynote Databases dialog, click Add to add a keynote database to the project.

6 To remove a database from the list of databases available in the project, select the database, and click Remove.

7 Click OK.

8 For Display Non-Project Keynote Databases, specify whether all keynote databases included on the AEC Content tab in the Options dialog display in addition to keynote databases specified for the project.

9 Click OK to return to the Project Browser.

Specifying the Project Detail Component Databases for a Project

Use this procedure to specify the relevant detail component databases for the project. For more information, see [Detail Components](#) on page 2339.

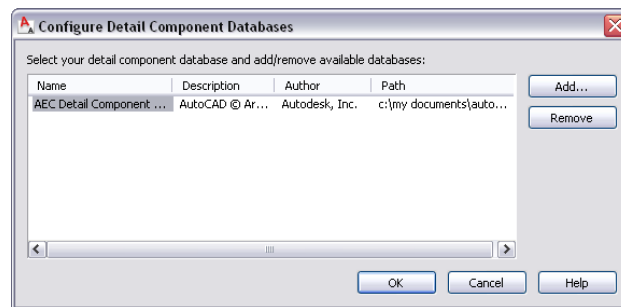

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

- 3 Under Advanced, define or change the Detail Components project properties as needed.

- 4 For Project Detail Component Database, click . (The number of databases associated with the current project is noted.)
- 5 In the Configure Detail Component Databases dialog, click Add to add a detail component database to the project.

NOTE Only correctly structured detail component databases can be added here; if you try to add a database with a different structure, you receive an error message.

- 6 To remove a database from the list of databases available in the project, select the database and click Remove.
- 7 Click OK.
- 8 For Display Non-Project Detail Component Databases, specify whether all detail component databases included on the AEC Content tab in the Options dialog display in addition to detail component databases specified for the project.
- 9 Click OK to return to the Project Browser.

Adding a Project Content Browser Library and Tool Palette Group

You can define a project tool palette group and specify a Content Browser library to be associated with the project. Then, each time the Content Browser opens from the Project Navigator palette, the project library is displayed.

Project Tool Palette Group

Each project may have a specific tool palette group (ATC files) associated with it. Depending on how you created the project, the tool palette group can be created and displayed in different ways.

For a new project, the project tool palette group is empty by default, unless the project settings point to an existing palette group.

Tool Content Root Path

Setting a tool content root path can help you keep your tools consistent if the project or the standards drawings are moved during the project life cycle.

When tools on the project tool palettes point to the tool content root path specified in the project settings, the content root path is created as a variable (%AECPROJECT_DIR%) in the XML definition of the tool. When the tool content root path in the project settings is changed, the path of the tools is changed accordingly.

For example, if all project tools point to content stored under *<Project Root Folder>\Standards\Content\Content 1*, you can move the content to *<Project Root Folder>\Standards\Content\Content 2*, adjust the tool content root path in the project setup accordingly, and all tools will now point correctly to *<Project Root Folder>\Standards\Content\Content 2.*

Another example is if a user creates an eTransmit package of the project and its tool content files in order to work offline. When the eTransmit package is unpacked on the local computer, the tool content root path can be redirected to a different drive, and all content remains valid.

Later, when the drawings the user modified offline are copied back to the main project on the P server, the content root path will automatically change back to *P:\ <Project Root Folder>\Standards\Content\Content*, because this is the path of the original APJ file.

Project Content Browser Library

For a large project, the CAD manager may want to set up a Content Browser library on a shared network volume, so that all project users have quick access to standard tools. When the Content Browser opens from the Project Navigator palette, the library associated with the project will automatically open.

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

The Project Properties dialog is displayed.

Tool Palettes	
Project Tool Palette Group	Per user workspace catalog
Tool Palette Group	c:\my documents\autodesk\my projects\sample project\
Tool Content Root Path	C:\My Documents\Autodesk\My Projects\Sample Project\Standa...\
Content Browser Library	C:\My Documents\Autode...\Sample Project - Project Standards.cbl

- 3 Under Tool Palettes, specify the location for the project tool palette group. You can select a local folder or a network folder.

If you do not specify a location, the following default behavior is automatically selected based on how you created your project:

Project Type	Tool Palette Group File Location	Project Tool Palette Group
Legacy project from Architectural Desktop 2005/2006	pointing to new empty ATC file under \<ProjectName>\Standards\ Work-spaceToolPalettes\ <ProjectName>.atc	Created, but not displayed. To display the tool palette group in the tool palettes set and add tools to it, see Displaying the Project Tool Palette Group on page 434 and Building the Tool Palette Group on page 435.
New project not based on a template	pointing to new empty ATC file under \<ProjectName>\Standards\ Work-spaceToolPalettes\ <ProjectName>.atc	Created, but not displayed. To display the tool palette group in the tool palettes set and add tools to it, see Displaying the Project Tool Palette Group on page 434 and Building the Tool Palette Group on page 435.
New project based on default AutoCAD Architecture template project	pointing to new ATC file under \<Project-Name>\Standards\ Work-spaceToolPalettes\ <ProjectName>.atc. By default, one empty tool palette is already inserted.	Created and displayed with empty default tool palette. To add tools and palettes, see Building the Tool Palette Group on page 435.
New project based on user-defined existing template project	If the tool palette group of the template project is located within the template project folder, it will be copied with all contained palettes to the corresponding folder of the new project. The tool palette file location of the new project will point to the copied tool palette group. If the tool palette group of the template project is located outside the template project folder, the tool palette file location of the new project will point to the same location, sharing the tool palette group with the template project.	Displayed as either copied tool palette group or referenced tool palette group

4 For Project Tool Palette Group, select Shared Workspace Catalog, Per User Workspace Catalog, or None.

If you select Shared Workspace Catalog, the path selected for Tool Palette Group is added to your project profile (AWS), and the tool catalog is accessed from the specified location. If you select Per User Workspace Catalog, a folder is created under \\Documents and Settings\<User Name>\ and the tool palettes are copied to that folder. If you select None, the project tool palette group is disabled for this project, and the other properties under Tool Palettes do not display.

5 For Tool Content Root Path, you can specify a root path for the tools used in the project tool palette group. When tools on project palettes are created with the tool content root path specified in the project setup, the content root path is created as a variable (%AECPROJECT_DIR%). When the tool content root path in the project setup is changed, and the referenced style drawings are moved to the new location, the path of the project tools is changed accordingly.

NOTE When a project is repathed, and the content root path is within the project folder, it will be repathed accordingly.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

- 6 For Content Browser Library, select the default Content Browser Library (CBL) to be displayed when the Content Browser is opened from the Project Navigator.
- 7 Click OK to return to the Project Browser.

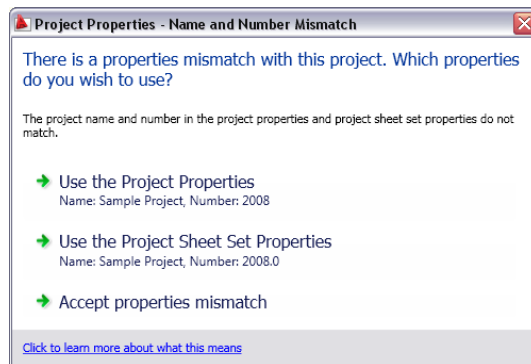

Consolidating Inconsistent Project and Sheet Set Information

If the project name and project number you have entered in the sheet set properties ([Creating a Sheet Set Template](#) on page 363) differ from the project name and number when you created the project ([Creating a New Project](#) on page 235), then the project information is inconsistent and needs to be consolidated. When you edit the properties of an inconsistent project, you are prompted to consolidate the project information.

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project for which to define the settings, right-click, and click Project Properties.

Alternatively, click  on the Project tab of the Project Navigator, next to Current Project.

If the project name and number of the project and the sheet set template do not match, a message is displayed:

Under Use the Project Properties, the name and number from the project properties are displayed. Under Use the Project Sheet Set Properties, the different project name and number from the sheet set is displayed.

If you want to...

consolidate the project information under the project name and number

Then...

select Use the Project Properties. The name and number of the sheet set are overwritten with the project name and number.

If you want to...	Then...
consolidate the project information under the project sheet set name and number	select Use the Project Sheet Set Properties. The project name and number are overwritten with the project sheet set name and number.
continue to use different names for the project and the project sheet set	select Accept properties mismatch.

Moving a Project

Use this procedure to move a project with all its associated files to a different file location.

When you move a project, all internal paths between the project files are automatically updated, so that all relationships between drawings are kept current.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

NOTE Do not use Windows Explorer to move a project file to a different location. This might result in inconsistent project data.

- 1 Verify that the project is closed. For more information, see [Closing All Project Files](#) on page 251.
 - 2 Click File menu ► Project Browser.
 - 3 Select the project you want to move, right-click, and click Move Project.
 - 4 Select the location to which you want to move the project.
 - 5 Click OK.
- The project and all its files and folders are moved to the new location.

Renaming a Project

Use this procedure to rename an existing project.

Renaming the project renames the following project files:

- Rename the project display name in Project Browser and Project Navigator
- Rename the APJ file
- Rename the top project folder

When you rename a project, all internal paths between the project files are automatically updated, so that all relationships between drawings are kept current.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

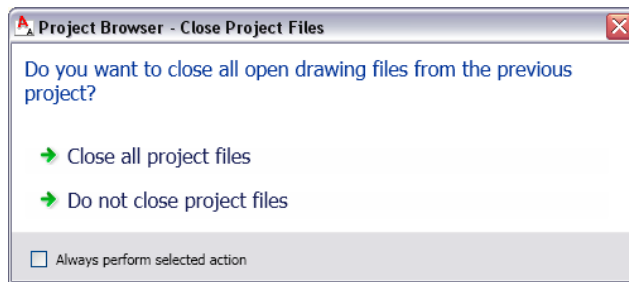

NOTE Do not use Windows Explorer to rename a project file. This might result in inconsistent project data.

- 1 Verify that the project is closed. For more information, see [Closing All Project Files](#) on page 251.
- 2 Click File menu ► Project Browser.
- 3 In the project selector, select the project you want to rename, right-click, and click Rename Project.
- 4 Enter the new name, and click OK.

Closing All Project Files

Use one of the following methods to close all drawing files in the current project.

- Click Window menu ► Close All Project Files.
This option closes all of the project drawings but leaves the project current and the Project Navigator displayed.
- On the Project Navigator palette, right-click below the file tree, and click Close All Project Files.
This option closes all of the project drawings but leaves the project current and the Project Navigator displayed.
- On the Project tab of the Project Navigator palette, click  , then specify your preferences in the Project Browser - Close Project Files dialog.

If you want to...

Then...

always close all project files, close the Project Navigator, and exit the project environment when you click 

select Always perform selected action, and then click Close all project files.

always close the Project Navigator and exit the project environment but leave all project files open, when you click 

select Always perform selected action, and then click Do not close project files.
This option lets you work on the files outside the project environment so that you do not accidentally make changes to the project.

close all project files, close the Project Navigator, and exit the project environment for this instance

click Close all project files.

If you want to...	Then...
close the Project Navigator and exit the project environment but leave all project files open for this instance	click Do not close project files. This option lets you work on the files outside the project environment so that you do not accidentally make changes to the project.

NOTE When you select Always perform selected action, the Close project drawings when switching projects option on the AEC Project Defaults tab of the Options dialog is also selected. See [Specifying the Default Project Options](#) on page 229. Note also that the Project Browser - Close Project Files dialog becomes a hidden message.

It will not display when you click  until you turn it back on as explained under Hidden Message Settings Dialog Box in AutoCAD Help.

Electronically Transmitting a Project

Use this procedure to create an electronic file set package for a project or to package files so they can be archived.

The electronic package can include the following:

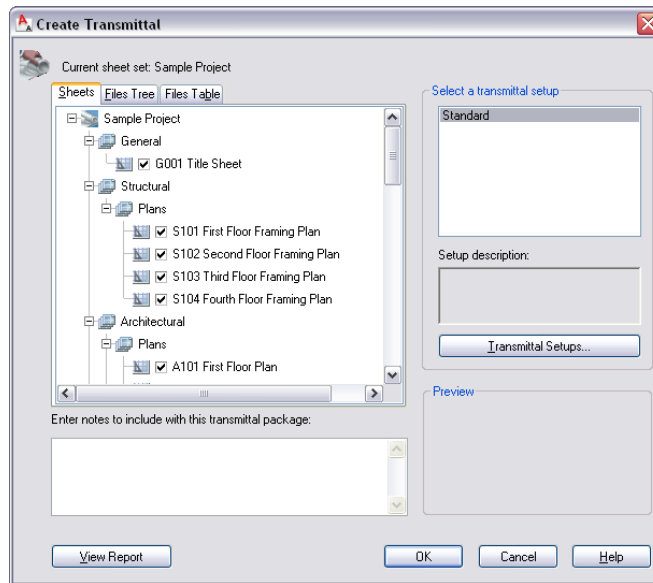

- All project drawing (DWG) files, including external references
- All project XML files
- The project (APJ) file
- All project templates
- The project sheet set (DST) file
- AutoCAD font map
- AutoCAD plot style tables

If you want to eTransmit a project, it is recommended that it uses relative xref paths. You can determine whether a project uses full xref paths or relative xref paths in the project setup. For more information, see [Creating a New Project](#) on page 235 and [Before You Begin: External References](#) on page 226.

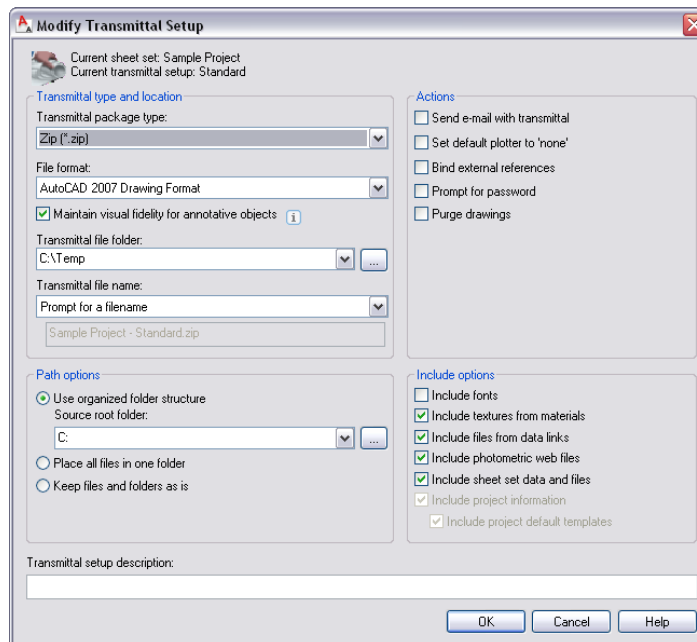

For more information about creating packages for electronic transmissions, see Package a Set of Files for Internet Transmission in AutoCAD Help.

- 1 Click File menu ► Project Browser, or click  at the bottom of the Project Navigator.
- 2 In the project selector, select the project from which you want to create an electronic package.
- 3 Right-click, and click eTransmit.

The Create Transmittal dialog is displayed. For more information, see Package a Set of Files for Internet Transmission in AutoCAD Help.

- 4 Select the components to include in the electronic package.
- 5 Select the transmittal setup for the package, and click Transmittal Setups.
- 6 In the Transmittal Setups dialog, click Modify.
The Modify Transmittal Setup dialog is displayed.

- 7 Under Transmittal package type, select the package type in which to export your project.
For more information, see Modify Transmittal Setup Dialog Box in AutoCAD Help.
- 8 Under File Format, select the format in which to export the drawing files. If you want to export the project drawings with their AEC objects:
 - intact (such as walls and doors), select the AutoCAD <version> Drawing Format.

- exploded (such as 3D faces and hatches), select the AutoCAD <version> Drawing Format with Exploded AEC Objects.

9 Under Transmittal file folder, select the folder in which to place the package.

For example, if you selected ZIP as the transmittal package type and C:\MyTransfer as the transmittal folder, the ZIP file containing your project will be placed under C:\MyTransfer\MyProject.zip.

10 Under Transmittal file name, specify the method for naming the transmittal package:

If you want to...	Then...
display a standard file selection dialog where you can enter the name of the transmittal package	select Prompt for a file name.
use a logical default file name and, if the file name already exists, overwrite the existing file name	select Overwrite if necessary.
use a logical default file name and, if the file name already exists, add a number to the end of the file name	select Increment file name if necessary.

11 Select the transmittal options:

If you want to...	Then...
duplicate the folder structure for the files being transmitted and make the root folder the top-level folder within the hierarchical folder tree	select Use organized folder structure. For more information, see Modify Transmittal Setup Dialog Box in AutoCAD Help. NOTE This option is not available if you are saving a transmittal package to an Internet location.
unpack all files to a single, specified target folder when the transmittal package is installed	select Place all files in one folder. WARNING Do not select this option when electronically transmitting project information. When you place all files in one folder the project structure will be flattened.
preserve the folder structure of all files in the transmittal package	select Keep files and folders as is. NOTE This option is not available if you are saving a transmittal package to an Internet location.

If you are transmitting a project, the following project-related information is always included in the transmittal package:

- Project (APJ) file
- XML files
- Project template files

12 Specify actions for the transmittal. For more information, see Modify Transmittal Setup Dialog Box in AutoCAD Help.

13 Identify options to include with the transmittal:

If you want to include...	Then...
the associated font files (TXT and SHX) with the transmittal package	select Include fonts. NOTE Because TrueType fonts are proprietary, they are not included with the transmittal package. If any required TrueType fonts are not present on the computer to which the transmittal package is copied, the font specified by the FONTALT system variable is substituted.
textures of materials with the transmittal package	select Include textures from materials that are attached to objects or faces.
external files referenced by a data link to the transmittal package	select include files from data links.
photometric web files that are associated with web lights in the drawing	select Include photometric web files.
the sheet set data and files (DST) in the transmittal package	select Include sheet set data and files.

14 Enter a description for the transmittal setup, and click OK.

This description is displayed in the Create Transmittal dialog box below the list of transmittal file setups. You can select any transmittal setup in the list to display its description.

15 Click Close, and then click OK to start the electronic transmittal.

Deleting a Project

Deleting a project is a system administrator task. Therefore, you do not perform it from within the Project Browser but from Windows Explorer.

Deleting the project folder deletes all DWG files, XML files, and the APJ file. Before you do this, make sure that you really do not need any of these files anymore. If you do not work on a project any longer but still want to save the DWG files in it, it is often sufficient to just remove the project context, as described in [Removing the Project Context](#) on page 256.

NOTE Before you delete a project, make sure that is not the current project in AutoCAD Architecture.

- 1 In Windows Explorer, navigate to the folder of the project you want to delete.
- 2 Delete the project folder.

Closing the Project Browser

Closing the Project Browser leads you to the next phase, where you are working on the actual building project, creating and editing elements, constructs, building views, and sheets. In this phase, you work mainly with the Project Navigator. For more information, see [The Project Navigator](#) on page 257.

Close the Project Browser with one of these buttons:

Button	Description
	Click the AutoCAD Architecture button in the dialog header, right-click, and click Close.
	Click the Close button in the lower-right corner of the Project Browser.
	Click the Windows Close button in the upper-right corner of the Project Browser.

Removing the Project Context

Use this procedure to remove all project-related information from the drawing files of a project. This may be desirable if you want to hand over the files to a contractor who does not work with the latest version of AutoCAD Architecture, or if the project no longer exists but you do not want to delete the drawing files.

Much of the project-related information associated with a drawing file does not reside in the drawing file itself, but in the accompanying XML file. This means that you can use all your project files at any time in a non-project-related drawing context. However, if you want to work permanently without the project context, it is recommended that you clean your file set of the unused project files.

Project-related information resides in the following files:

- The APJ file, which contains the general, high-level project data like name, number, project details, and project standards.
- The XML files, each of which stores the project information for an individual drawing file.

If you delete the APJ file and the XML files, the remaining drawing files no longer have connections to a project. They are regular AutoCAD Architecture drawing files and can be copied, edited, and deleted like any other drawing file.

The drawing files can contain standard styles and display settings, if standards have been set up for the project. When the XML and APJ files are deleted, any standard styles and display settings are no longer synchronized in the now standalone drawings.

NOTE Once the project context has been removed, there is no simple way to recreate it. If you have removed the project, and want to re-build a project around the remaining drawing files, build the project from scratch, and import the drawing files into it.

To remove project-related information

- 1 In Windows Explorer, navigate to the folder containing the project.
- 2 In the project folder, delete the APJ file. For example, if you have a project named Office Building, delete the file named Office Building.apj.
- 3 Open the Elements, Constructs, Sheets, and Views folders, and delete the XML files associated with your drawing files.
For example, if your Constructs folder contains First Floor Construct.dwg, select and delete the file named First Floor Construct.xml.
- 4 Repeat the previous step for each drawing file.

NOTE If you reorganize files into a different file structure, you may have to manually reset broken external reference paths in the drawings.

Opening a Project from Windows Explorer

You can open AutoCAD Architecture with a specific project set current by double-clicking the project APJ file in Windows® Explorer. If there is an AutoCAD Architecture session already open, the new project will become the active project within the same session. Based on the setting you specify, you are given the option to close all open drawing files from the previous project. For more information, see [Closing All Project Files](#) on page 251.

When you install AutoCAD Architecture 2009, and the APJ files extension has not previously been associated with another application, such as an XML editor, the file association between the APJ file extension and AutoCAD Architecture is automatically created. If you had previously associated the APJ file extension with another application, and want to change that association to AutoCAD Architecture, use the following steps:

- 1 On the Windows Start menu, click Settings ► Control Panel.
- 2 Double-click Folder Options.
- 3 Click the File Types tab.
- 4 Under Registered File Types, scroll to the APJ extension, and select it.

In the Details section, the default application for opening APJ files is listed. If the value of Opens with is AECLAUNCHCURRENTPROJECT.EXE, click OK. If not, click Restore, or click Change, select AutoCAD Architecture in the Open With dialog, and click OK.

To open AutoCAD Architecture from an APJ file, use the following steps:

- 1 In Windows Explorer, navigate to the project APJ file you want to open.

APJ files have a specific icon  in Windows Explorer.

- 2 Double-click the APJ file.

AutoCAD Architecture will be opened with the double-clicked project set as the current project.

The Project Navigator

After you have selected a project in the Project Browser, you open the Project Navigator to create and edit the actual building and documentation data. Here you create elements, constructs, model views, detail views, section views, and sheets, connecting them with one another.

NOTE Although project files and categories you create on the Project Navigator palette are shown as files and folders in Windows Explorer, you should not move, copy, delete, or rename project files from there. Such changes are not updated on the Project Navigator palette, and you could get an inconsistent view of your project data. Any changes you make to the project on the Project Navigator palette are managed and coordinated by the software. Also note that any changes you make on the Project Navigator palette (such as renaming, deleting, or changing the file's properties) cannot be undone using the AutoCAD Undo command.

Opening the Project Navigator

Use any of the following methods to open the Project Navigator.

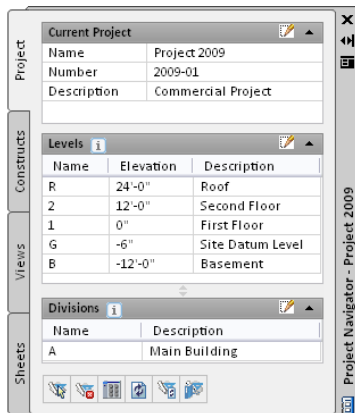

- Click Window menu ► Project Navigator Palette.
- Click  on the Quick Access toolbar.
- Click the Menu browser ► Window ► Project Navigator Palette.
- Click  on the Navigation toolbar.

The Tabs of the Project Navigator

The Project Navigator has 4 tabs on which you can enter project data. The tabs correspond to the main phases of project creation: general project information (levels and divisions), creating building data (constructs and elements), and creating building documentation (views and sheets).

The Project Tab

The Project tab of the Project Navigator palette is where you enter information pertaining to the entire project.

On the Project tab, you can do the following:

- Add, modify, and delete levels. For more information, see [Levels](#) on page 271.
- Add, modify, and delete divisions. For more information, see [Divisions](#) on page 276.
- Change project information.
- Launch the Project Browser.
- Launch the Content Browser to access the project library. For more information, see [Displaying the Project Content Browser Library](#) on page 270.

The Constructs Tab

The Constructs tab of the Project Navigator palette is where you add the basic building objects for your project. For information about commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.

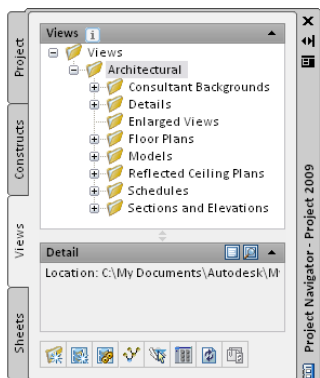

On the Constructs tab, you can do the following:

- Add, modify, and delete constructs and elements within the project. For more information, see [Constructs](#) on page 287 and [Elements](#) on page 304.
- Open and close existing element and construct drawings. For more information, see [Opening and Closing a Construct](#) on page 294 and [Opening and Closing an Element](#) on page 311.
- Create categories for constructs and elements. For more information, see [Categories](#) on page 279.
- Reference elements into constructs. For more information, see [Attaching an Element as an External Reference to a Construct](#) on page 296 and [Overlaying an Element as an External Reference to a Construct](#) on page 297.
- Launch the Content Browser to access the project library. For more information, see [Displaying the Project Content Browser Library](#) on page 270.

The Views Tab

The Views tab of the Project Navigator palette is where you create individual views of your building data. Views contain constructs and are the primary location for adding annotation like notes, tags, and dimensions within the project. After you have created a view drawing, you can create model space views in it. For information about commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.

On the Views tab, you can do the following:

- Add, modify, and delete general views, detail views, and section/elevation views. For more information, see [Creating a Model Space View Drawing from a Callout](#) on page 329.
- Add, modify, and delete model space views. For more information, see [Creating a Model Space View](#) on page 334.
- Open and close view drawings. For more information, see [Opening and Closing a View Drawing](#) on page 329.
- Change the contents of view drawings. For more information, see [Changing the Properties of a View Drawing](#) on page 330.
- Create categories for view drawings. For more information, see [Categories](#) on page 279.
- Launch the Content Browser to access the project library. For more information, see [Displaying the Project Content Browser Library](#) on page 270.

The Sheets Tab

The Sheets tab of the Project Navigator palette is where you create and organize sheets for your project. Sheets reference views and are used for plotting drawings.

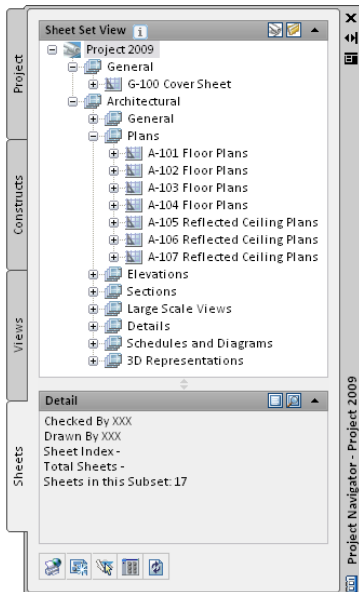

The Sheets tab is also where you manage the project sheet set, performing tasks such as creating a table of contents, managing page setups, or publishing to a plotter or to a DWF file. For information about commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.

The buttons at the top of the Sheets tab let you view sheet information in either of the following ways: Click the Sheet Set View button to see the sheet set view.

-  Sheet Set View
-  Explorer View

Sheet Set View

The Sheet Set View is a tree view of the project sheet set in which you have access to all publishing capabilities.

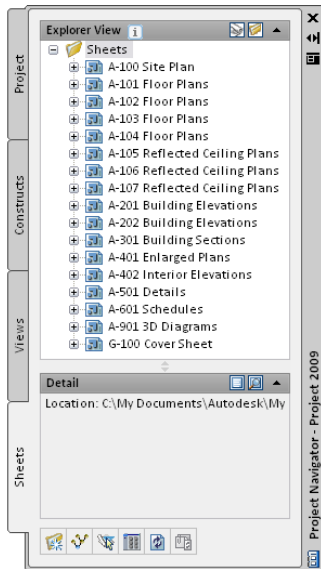

In the Sheet Set view, you can do the following:

- Add, modify, and delete sheets in the project. For more information, see [Creating a Sheet](#) on page 345.
- Create sheet subsets that define the logical structure of the sheet set. For more information, see [Creating a Sheet Subset](#) on page 348.
- Open and close sheet views. For more information, see [Opening a Sheet View](#) on page 354.
- Assign numbers to sheet views. For more information, see [Numbering Sheet Views](#) on page 354.
- Insert a table of contents. For more information, see [Inserting a Sheet List](#) on page 356.
- Electronically transmit the sheet set or a sheet subset. For more information, see [Electronically Transmitting Sheets and Sheet Sets](#) on page 360.
- Archive the sheet set or a sheet subset. For more information, see [Publishing Sheet Sets](#) on page 362.
- Publish the sheet set or a sheet subset to a plotter, a DWF file, a DWFx file, or to an alternate page setup. For more information, see [Publishing Sheet Sets](#) on page 362.
- Create sheet selections for specific tasks. For more information, see [Creating a Sheet Selection](#) on page 359.
- Manage page setups. For more information, see [Publishing Sheet Sets](#) on page 362.
- Launch the Content Browser to access the project library. For more information, see [Displaying the Project Content Browser Library](#) on page 270.

Explorer View

The Explorer View is a view of the folder structure and sheet drawings in the project.

In the Explorer View, you can do the following:

- Open, close, and delete sheet drawings. For more information, see [Deleting a Sheet Drawing](#) on page 353.
- Create categories for sheet drawings. For more information, see [Categories](#) on page 279.
- Launch the Content Browser to access the project library. For more information, see [Displaying the Project Content Browser Library](#) on page 270.

Using the Project Navigator

The Project Navigator is the main point from which you work with the project.

The Drawing Explorer

The Drawing Explorer is a tree view common to the Constructs, View, and Sheets tabs of the Project Navigator. This is where the drawing files are organized. Each tab of the Project Navigator except the Project tab has a Drawing Explorer tree where the associated project drawing files—elements, constructs, views, and sheets—are displayed.

- The Constructs tab organizes constructs and elements in the project.
- The View tab organizes view drawings, as well as their associated model space views.
- The Sheets tab organizes sheet drawings, sheets, sheet views and the sheet set.

Drawing Explorer

Drawing files belonging to a project are displayed on their respective tabs in the Drawing Explorer tree view, which lists the drawings in their category (folder). You can drag and drop, or copy and paste drawing files in the Drawing Explorer.

Drawing Explorer of Constructs tab fully expanded

The Preview and Detail Panes

Below the Drawing Explorer on the Project Navigator palette is the Preview or Detail pane. You display this pane by right-clicking at the bottom of the Project Navigator palette and selecting Preview/Details Pane from the Tooltips Style menu. For more information, see [Drawing Explorer Tooltips](#) on page 268.

With Preview/Details Pane selected, you can switch modes by clicking  (Preview) to display a preview or by clicking  (Detail) to display a description of the drawing file selected.

The Drawing Explorer Context Menu

When you right-click a drawing file in the Drawing Explorer of the Project Navigator palette, a context menu displays. The commands on the context menu can vary slightly based on the type and status of the file selected:

Command	Description
Open	Opens the selected drawing file within AutoCAD Architecture. Unavailable if the drawing file is in use or has a read-only attribute.
Bring to Front	Returns focus to the selected file if it is already open in the current drawing session.
Open read-only	Opens the selected file in read-only mode and displays it in the drawing area. If the drawing file is already open for write in the current session, clicking Open read-only opens a copy and brings that drawing file to the front.
Close	Closes the selected drawing file. For more information, see Closing All Project Files on page 251.
External References	Opens the External References dialog that lists all external references in the selected file and lets you unload, reload, and detach them from a context menu. For more information, see Displaying External References of a Construct on page 298, Displaying External References of a View Drawing on page 327, or Displaying External References of a Sheet Drawing on page 355.
New ► Category	Creates a new category for the file type selected: for example, an element category or a construct category. For more information, see Categories on page 279.
New ► Element Construct View Dwg (General, Section/Elevation, Detail) Model Space View Sheet	Creates a new project file of the specified type. For a description of these file types, see Concepts of Drawing Management on page 218.
Save Current Dwg as Element Construct View (General, Section/Elevation, Detail)	Converts pre-existing and non-project drawings into project file drawings. <hr/> NOTE The legacy file must be open to run this command. <hr/>

Command	Description
Xref Attach	<p>Attaches the selected drawing as an external reference (xref) to the currently active drawing.</p> <hr/> <p>NOTE The xref must be closed when you attach it.</p>
Xref Overlay	<p>Overlays the selected drawing as an external reference to the currently active drawing.</p> <hr/> <p>NOTE The xref must be closed when you overlay it.</p>
Insert as Block	<p>Inserts the selected drawing as a block into the active drawing.</p> <hr/> <p>NOTE The drawing being inserted as a block must be closed when you insert it.</p>
Cut	<p>Cuts the selected file from the Drawing Explorer. Use this command together with Paste to relocate drawing files within the Drawing Explorer.</p> <hr/> <p>NOTE You cannot cut a file that is open.</p>
Copy	<p>Copies the selected file. Use this command together with Paste to copy a file to a different location.</p>
Copy Construct to Levels	<p>Creates a new copy of the construct drawing for each level you specify.</p>
Attach Element to Constructs	<p>References the selected element into one or multiple constructs you specify.</p>
Paste	<p>Pastes a cut or copied file to a new file location that you specify with the Drawing Explorer. After pasting a file in a different location, you are prompted to repath the project to update the file information.</p>
Delete	<p>Deletes the selected file.</p> <hr/> <p>NOTE You cannot delete a file that is currently open.</p>
Rename	<p>Renames the selected file.</p> <hr/> <p>NOTE You cannot rename a file that is open. After you rename a file, you are prompted to repath the project to update the file information.</p>
Repath File	<p>Opens the Project Repath Queue dialog in which you can view the repath queue and repath or delete pending file paths. Unavailable if there are no files in the queue. For more information, see Working with Design Teams Located Remotely on page 231.</p>

Command	Description
	WARNING Selecting Repath migrates your drawings to the current version format. This means that you will be unable to open these drawings in any older version. For more information, see Repath the Project on page 372.
eTransmit	Creates an eTransmit package from the selected file, including all external references.
Properties	Opens the properties of the selected project drawing file. Depending on the file type, the properties can differ. A construct, for example, has settings for level and division assignment; a view has a list of constructs assigned to it. For detailed information on file properties, see the appropriate sections for the individual file types.

The Project Navigator Toolbar

As the following table shows, the buttons on the toolbar at the bottom of the Project Navigator vary according to which tab is active. Some of the same functions are also available on the context menu for the tab:

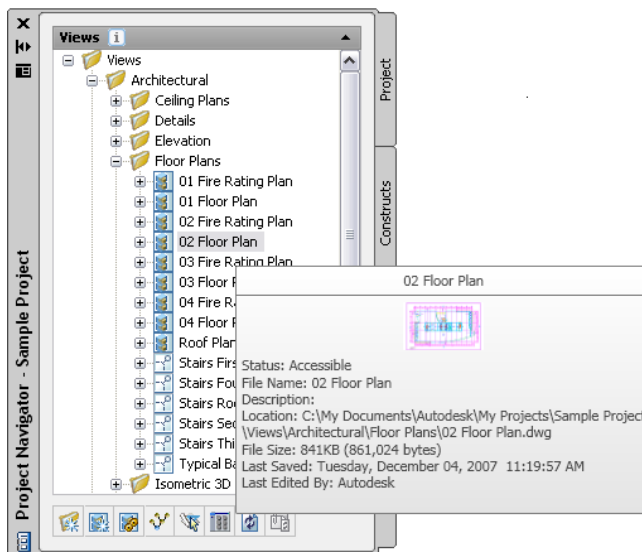

Button	Description	Tab Location
 Project Browser	Launches the Project Browser	All
 Content Browser	Launches the Content Browser. If a project library has been set for the project, it is displayed in the Content Browser.	All
 Refresh Project	Refreshes the project information in the Drawing Explorer to reflect any changes made. NOTE Refreshing the project frequently is especially important when you are working with a project on a network server.	All
 Close Current Project	Closes all project files of the current project. For more information, see Closing All Project Files on page 251	Project
 Synchronize Projects	Synchronizes a project with its project standards, if they have been established. For more information, see Synchronizing a Project with the Standards on page 440.	Project
 Configure Project Standards	Opens the Configure AEC Project Standards dialog in which you can set up or modify standards for the current project. For more information, see Configuring Project Standards on page 416.	Project

Button	Description	Tab Location
 Add Category	Adds a new category for elements, constructs, views, or sheets. You can nest categories and create an organizational tree.	Constructs, Views, Sheets
 Add Element	Creates a new element.	Constructs
 Add Construct	Creates a new construct.	Constructs
 Show External References	Opens the External References dialog that lists all external references in the selected file and lets you unload, reload, and detach them from a context menu. For more information, see Displaying External References of a Construct on page 298, Displaying External References of a View Drawing on page 327, or Displaying External References of a Sheet Drawing on page 355.	Constructs, Views, Sheets
 Repath Xref	Opens the Project Repath Queue dialog in which you can view the repath queue and then update the modified xref paths. Unavailable if there are no files in the queue. <hr/> WARNING Selecting Repath migrates your drawings to the current version format. This means that you will be unable to open these drawings in any older version. For more information, see Repath the Project on page 372. <hr/>	Constructs, Views, Sheets
 Add View	Creates a new view.	Views
 Regenerate View	Reloads all of the xrefs needed to generate the selected view after you have edited xrefs in the view, added new references, or changed the view properties.	Views
 Add Sheet	Creates a new sheet drawing.	Sheets
 Publish	Publishes the sheet set to the plotter, DWF, or DWFx that you specify.	Sheets

Drawing Explorer Tooltips

To specify the content of the tooltip that displays when you move the cursor over an item in the Drawing Explorer, right-click an open area on the toolbar and select one of the following options:

If you want to...	Then...
display the Preview or Detail pane at the bottom of the Project Navigator palette	select Preview/Details Pane.
close the Project Navigator palette	select Close.
display only the file name	select Tooltip Style, and then click Name.
display the name and an image of the content	select Tooltip Style, click Preview, and then click Small, Medium, or Large.
display details, such as the status, location, and who currently has the file open (if applicable)	select Tooltip Style, and then click Details.
display an image and details	select Tooltip Style, click Preview & Details, and then click Small, Medium, or Large.

Drag and Drop on the Project Navigator Palette

You can drag and drop files on a Project Navigator tab, from the tab to the drawing area, or to and from Windows Explorer. Afterwards, you are prompted to repath the project to update the file information.

The following drag and drop operations are supported:

- Dragging elements, constructs, views, and sheets from one category in the Drawing Explorer to another.

- Dragging elements, constructs, views, and sheets from the Drawing Explorer into the AutoCAD Architecture drawing area.
- Dragging and dropping objects from an open drawing in the drawing area onto an element or construct in the Drawing Explorer.
- Dragging drawing files from Windows Explorer to the Project Navigator; the drop location determines the file type. For example, a file dragged to a construct category becomes a construct.

The Drawing Status Bar

When you are working with a drawing in a project, the drawing status bar displays the name of the current project, the name of the project file, and the project file type. When you open a drawing that does not belong to a project, no project information is displayed.

Drawing status bar

Displaying the Project Tool Palette Group

Use this procedure to display the project tool palette group in the tool palettes set.

Depending on the setting of the tool palette file location (as described in [Adding a Project Content Browser Library and Tool Palette Group](#) on page 246), the project tool palette group can be displayed automatically after you set a project current and close Project Browser, or it can be empty and not be displayed on the tool palettes set. The project tool palette group is displayed automatically when it contains at least one palette.

Project tool palette groups that are not automatically displayed will not display in the following cases:

- A new project that is not based on a template, and does not point to an existing tool palette group
- A legacy project that is not manually redirected to an existing tool palette group
- A project that is based on a template project where the Project Tool Palette Group storage type is set to None.
- A project that is based on a template project without project tool palettes

If an empty tool palette group is created for a project, it is not displayed in the tool palettes set after the project is set current. To display it, add at least one tool palette.

1 Click Window menu ► Tool Palettes.

2 In the title bar of the tool palettes set, click .

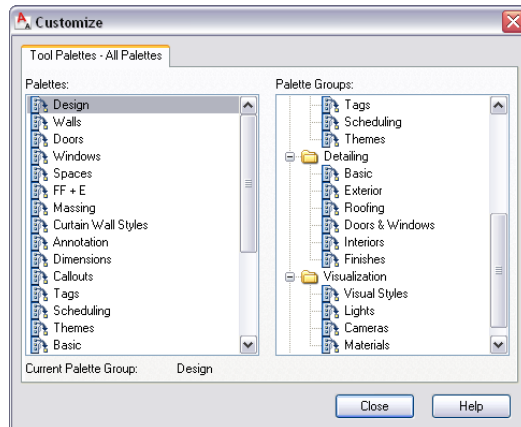

- If the project tool palette group contains at least one palette, it is displayed in the list of available tool palette groups and can be selected.

Selecting the project tool palette group

- If the tool palette group of the current project is empty, it is not displayed.

3 To add a new palette to the empty tool palette group so it will display the project tool palette group, click , and click Customize Palettes.

On the left, all available palettes are listed. On the right, all palette groups are listed. The empty project tool palette group is listed there.

- 4 Right-click in the palettes list on the left, and click New Palette.
- 5 Enter a name for the new palette.
- 6 Select the palette, and drag it on the project palette group on the right.
- 7 Click Close, and click  again.

The project tool palette group is listed under the available palette groups and can be selected and displayed.

Displaying the Project Content Browser Library

You can start the Content Browser directly from the Project Navigator, and display a project-specific Content Browser Library.

If you are working with project standards, the project library should contain tools referencing project standard styles. If you are not using project standards, the project library should contain the tools you need in this project.

For information on building a Content Browser library for a project, see [Setting up Standard Tools in a Project](#) on page 425.

- 1 Set the project current, as described in [Setting a Project Current](#) on page 235, and close the Project Browser.
- 2 Click Window menu ► Project Navigator.
- 3 On the Project Navigator palette toolbar, click  .
The Content Browser is opened with the project library displayed.

Levels

Buildings are segmented into levels (or floors) in the vertical plane. When you create a project, you determine the number of levels, their floor-to-floor height, and their floor elevation. When you add or remove levels, the project is updated with the new level information.

Plan view of identical building core levels

Level Defaults

By default, the first level is present in each new project. It has a floor elevation of zero and represents the ground floor. You can change the elevation value for the first level, which is then used as the default elevation for each new level you insert.

NOTE The unit in which the level height is displayed is dependent on the drawing defaults of the active drawing.

Copying Levels with Constructs

You can quickly and easily duplicate floors with identical plans. After creating one level and assigning the floor plan constructs to it—for example, a layout of apartments on the first floor—you can easily create new levels, which have copies of the first level's constructs assigned to them. You can edit and rename these constructs later on the Constructs tab.

TIP If you duplicate floor plans in this way, a construct is created for each new level. If you edit the floor plan later, for example, to add an extra door, edit each level and construct individually. If your floor plans are going to be absolutely identical, you can avoid this task. Create an element containing the floor plan, and reference it into the first construct. Then copy the constructs to the levels. Each of the copied constructs have the same reference, and you can change them quickly by changing the referenced element once.

For information on creating constructs and assigning them to levels, see [Creating a New Construct](#) on page 290.

For information on creating elements and referencing them into constructs, see [Creating an Element](#) on page 306, and [Attaching an Element as an External Reference to a Construct](#) on page 296.

Creating a New Level

Use this procedure to add levels to a building.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Project tab.
- 3 Under Levels, click .
- 4 If you want each new level to take its floor elevation from the height of the level below, click Auto-Adjust Elevation.
- 5 Add a level using one of the following methods:

If you want to...

Then...

add a level above the current level

click . The default floor-to-floor height of the new level is identical to the level below. If you have selected Auto-Adjust Elevation, the level's floor elevation starts on top of the previous level.

NOTE Alternatively, you can select the level above which you want to add a level, right-click, and click Add Level Above.

add a level below the current level

select the level below which you want to add a level, right-click, and click Add Level Below.

NOTE If you add a level below the ground floor and you have selected Auto-Adjust Elevation, the elevation of the new level is a negative height.

NOTE If you add a level between existing levels and you have selected Auto-Adjust Elevation, the elevations of all levels above or below the new level are automatically adjusted.

- 6 If necessary, edit the properties of the new level:

If you want to...

Then...

change the name of the level

click the name, and enter a new one. Note that you cannot give the same name to 2 different levels—the

If you want to...	Then...
change the base elevation of the level	<p>name is the unique identifier of the level when assigning constructs.</p> <p>enter a new value. If you have selected Auto-Adjust Elevation, the base elevation fits with the elevation and floor height of the level below, and you won't need to make changes here.</p> <p>NOTE The base elevation of a level determines where the level starts on the horizontal plane. Usually, the base elevation of a level is determined by the floor-to-floor height of the level below.</p>
change the floor-to-floor height of the level	enter a new value. If you add levels above this level and you selected Auto-Adjust Elevation, they use the floor height of this level is used as the base elevation.
change the ID of the level	enter a new ID. The ID can be used in schedule tables. For more information on scheduling a project, see Annotating a Project on page 374.
add a description to the level	enter a description for the level.

7 When you are finished adding levels to the project, click OK.

8 Click Yes in the subsequent dialog to update the changed level information throughout the project.

Copying a Level with Assigned Constructs

Use this procedure to copy an existing level and all its assigned constructs within the building.

3D view of copied levels with assigned constructs

When you create a new level, it is empty and has no constructs assigned. After you have assigned constructs to the level, as described in [Creating a New Construct](#) on page 290, you can copy that level and its constructs

within the building. For example, perhaps you have created a first-floor level and assigned 3 apartment constructs to it. To create a second-floor level with exactly the same layout, you can copy and paste the first level with its apartment constructs and rename it “Second Floor.”

1 Create a level and assign constructs to it.

For more information, see [Creating a New Construct](#) on page 290.

2 Click Window menu ► Project Navigator Palette.

3 Click the Project tab.

4 Under Levels, click .

5 Select the name of the level you want to copy, right-click, and click Copy Level and Contents.

6 Click the level above or below the one on which you want to place the copied level, right-click, and click Paste Level Above or Paste Level Below.

7 Rename the pasted level accordingly: for example, Second Level.

8 If necessary, edit the description and the ID.

9 Click OK.

10 Click Yes in the subsequent dialog to update the changed level information throughout the project.

11 Click the Constructs tab.

12 Locate the Constructs category.

The constructs that were created by copying the level and constructs are below the original construct. For example, if you copied the first-floor-level with a construct named First Floor—Left Apartment, you now have 2 constructs: First Floor—Left Apartment and First Floor—Left Apartment (2).

13 If necessary, rename the copied construct with an appropriate name: for example, Second Floor—Left Apartment.

14 To update the Drawing Explorer, click .

Changing the Properties of a Level

Use this procedure to change the properties of a level.

1 Click Window menu ► Project Navigator Palette.

2 Click the Project tab.

3 Under Levels, click .

4 Change the level information as needed:

If you want to...	Then...
change the name of the level	click the name, and enter a new one. Alternatively, you can select the name, right-click, and click Rename Level.

If you want to...	Then...
change the elevation of a level	click the floor elevation, and change it. NOTE If you have selected Auto-Adjust Elevation, the levels above and below the level are changed accordingly. To prevent this, clear Auto-Adjust Elevation before making changes to the elevation.
change the floor-to-floor height of a level	click the floor-to-floor height, and change it. NOTE If you have selected Auto-Adjust Elevation, the levels above and below the level are changed accordingly. To prevent this, clear Auto-Adjust Elevation before making changes to the elevation.
change the ID of a level	click the ID, and change it.
change the description of a level	click the description, and change it.

5 Click OK.

6 Click Yes in the subsequent dialog to update the changed level information throughout the project.

Deleting a Level

Use this procedure to delete a level from a building.

1 Click Window menu ► Project Navigator Palette.

2 Click the Project tab.

3 Under Levels, click .

4 Click the name of the level to delete.

5 Delete the level using either of the following methods:

- Right-click, and click Delete Level.

- In the Levels dialog, click .

6 Click OK.

7 Click Yes in the subsequent dialog to update the changed level information throughout the project.

NOTE Constructs assigned to the deleted level are not deleted.

Changing Levels: Interactions with the Project

Changes made to one part of a project frequently influence other parts of the project. The following information describes the changes you can make to a level and the effects of the changes on other parts of the building project:

- **Adding new levels:** When you add a new level to a project, you must assign constructs. You also need views and sheets to represent that level.
For more information, see [Constructs](#) on page 287, [Views](#) on page 318, and [Sheets](#) on page 342.
- **Changing the level name:** When you change the name of a level, the constructs assigned to it are automatically updated to reference the new name. For example, if you change the name of a level from 1 to First Floor, the constructs assigned to that level are automatically updated to be assigned to First Floor.
- **Changing the level ID:** Level IDs can be used in schedule tables. If you change the information here, the information in your schedule table changes.
- **Changing the floor-to-floor height of a level:** When you change the floor-to-floor height of a level and you have selected Auto-Adjust Elevation, all levels above the changed level are adjusted. The multi-level view regenerates to adjust for the change in height. For example, if you change the height of the first floor from 3 meters to 4 meters, the elevation of the second level changes from 3 meters to 4 meters. If you have chosen not to auto-adjust levels, you need to update all other levels manually to avoid gaps or overlapping levels. In any case, make sure that the objects in the assigned constructs retain the correct height for the level after changing it. That way, you avoid displaying 4 meter walls in a 3 meter level.
- **Changing the floor elevation of a level:** If you are changing the elevation of a level, the elevation above the level is adjusted. The floor-to-floor height of the level below the selected level is also changed, and the multi-level view regenerates to adjust for the change in elevation. For example, if you change the elevation of the second floor from 2.5 meters to 2.6 meters, the floor-to-floor height of the first floor below it is changed from 2.5 meters to 2.6 meters. Also, the floor elevation of all levels above the second level will be increased by 0.1 meter.
- **Deleting a level:** When you delete a level, constructs assigned to that level are not deleted with it. They remain in the project, but they are “orphaned,” that is, they have lost their level. You can choose what to do with them:
 - Delete them, because the level on which they are placed no longer exists.
 - Assign them to a different level within the project.
- When you delete a level that has been used for a view, the view is not deleted from the project. If you update the view, however, it is missing this level. You can choose among these actions:
 - Delete the view, because the level it was displaying no longer exists.
 - Create a new selection set for the view.
For more information, see [Views](#) on page 318.

Divisions

Divisions segment the building in the horizontal plane. A division might be a wing of a building. By default, each new project in AutoCAD Architecture has one division. You can add divisions, change their properties, and delete them.

Building and wing schematic

In most projects, you work with only one horizontal division.

Creating a New Division

Use this procedure to add divisions to a project.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Project tab.
- 3 Under Divisions, click .
- 4 Add a division using either of the following methods:
 - Right-click in the list, and click Add Division.
 - In the Divisions dialog, click .
- 5 If necessary, edit the division settings:

If you want to...

Then...

change the name of the division

click the name, and enter a new one. Alternatively, you can select the name, right-click, and click Rename Division.

NOTE You cannot give the same name to 2 divisions; the name is the unique identifier of the division when assigning constructs to it.

change the ID of the division

enter a new ID. The ID can be used for schedule tables. For more information on scheduling a project, see [Annotating a Project](#) on page 374.

add a description to the division

enter a description, and press *ENTER*.

NOTE The division names are displayed in the order of their creation.

- 6 When you have finished adding new divisions to the project, click OK.

Changing a Division

Use this procedure to change the properties of a division.

1 Click Window menu ► Project Navigator Palette.

2 Click the Project tab.

3 Under Divisions, click .

4 Change the division information as needed:

If you want to...	Then...
change the name of the division	click the name, and change it.
change the ID of the division	click the ID, and change it. The ID can be used in schedule tables.
change the description of the division	click the description, and change it.

5 Click OK.

Deleting a Division

Use this procedure to delete a division from the building project.

1 Click Window menu ► Project Navigator Palette.

2 Click the Project tab.

3 Under Divisions, click .

4 Click the name of the division to delete.

5 Delete the division using either of the following methods:

■ Right-click, and click Delete Division.

■ Click .

6 Click OK.

7 Click Yes in the subsequent dialog to update the changed division information throughout the project.

Changing Divisions: Interactions with the Project

Changes made to one part of a project frequently influence other parts of the project. The following information describes the changes you can make to a division, and the effects of the changes on other parts of the building project:

- **Adding new divisions:** When you add divisions to a project, you must assign constructs. You also need views and sheets to represent that division. For example, you might create a view named South Wing and a sheet Plan—South Wing. For more information, see [Creating a New View Drawing](#) on page 323.
- **Changing the division name:** When you change the name of a division, the constructs assigned to it are updated with the new name. For example, if you change the name of a division from SW to South Wing, the constructs assigned to that division are updated to be assigned to South Wing.

- **Changing the division ID:** Division IDs can be used in schedule tables. If you change the information here, the information in your schedule table changes.
- **Deleting a division:** When you delete a division, constructs assigned to that division are not deleted with it. They are considered orphaned and have lost their division. You can choose among the following actions:
 - Delete the constructs because the division in which they were placed no longer exists.
 - Assign them to a different division within the project.

When you delete a division that has been used for a view, the view is not deleted from the project. If you update the view, however, the deleted division is missing. You can choose among the following actions:

- Delete the view because the division it was displaying no longer exists.
- Create a new selection set for the view.

Categories

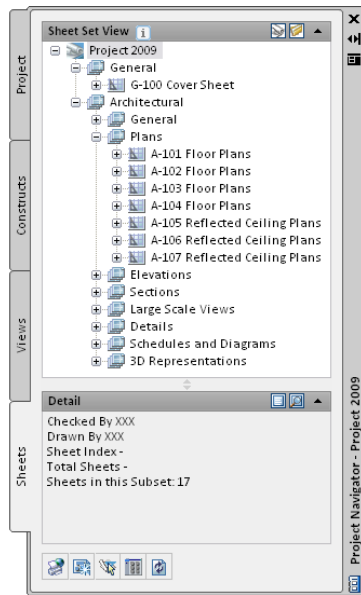

The basic categories are represented by folders in the Drawing Explorer within the project structure that help you organize your project files according to disciplines, drawing types, or aspects of your workflows.

The Basic Project Categories

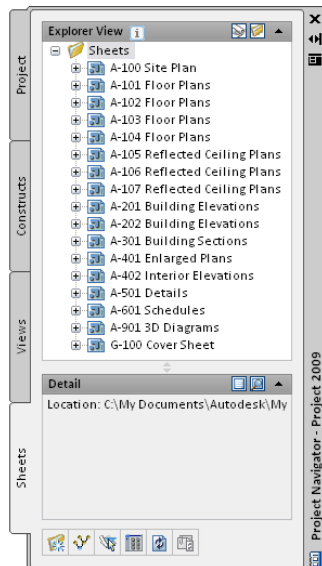

For every building project in AutoCAD Architecture, the following basic category structure is displayed on the Project tab of the Project Navigator palette:

- **<ProjectName>:** This is the top node in the project, represented by a folder with the project name.
- **Constructs:** This is the default category for constructs in the project. When you create a construct, it is saved into the Constructs category or one of its subcategories. For more information, see [Constructs](#) on page 287.
- **Elements:** This is the default category for elements in the project. When you create an element, it is saved into the Elements category or one of its subcategories. For more information, see [Elements](#) on page 304.
- **Views:** This is the default category for view drawings in the project. When you create a view drawing, it is saved into the Views category or one of its subcategories. For more information, see [Views](#) on page 318. If you create model space views within a view drawing, they are placed under the view drawing in the same category as the view drawing itself.
- **Sheets:** Sheets in the project can be viewed in 2 ways: the Sheet Set View and the Explorer View. The following image is a Sheet Set View.

The following image is an Explorer View.

Sheets are organized in sheet subsets in the Sheet Set View. Sheet subsets are a logical structure rather than a physical one. The sheet folder category does not need to be identical to the sheet subset in which the sheet is placed, however, to avoid confusion, it is recommended that you have parallel structures in the sheet set and the sheet categories.

You can rearrange sheets into different subsets within the Sheet Set View, but that will not change their physical location in the category or folder. Likewise, when you remove a sheet from a sheet subset in the Sheet Set View, only the reference of the sheet to the subset is removed; the layout itself and its containing sheet drawing are not deleted from the Sheets folder or subfolder. For more information, see [Sheets](#) on page 342.

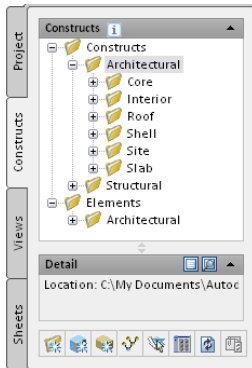

In the Explorer View, sheet drawings are placed in folder categories. When you create sheets or sheet views within a sheet drawing, they are placed in the sheet drawing.

User-Defined Categories

Within the main category structure which is fixed, you can create subcategories and subcategory trees. Subcategories usually represent aspects of your workflow. You might set up subcategories by discipline, by view type (such as working, presentation, section, and rendering), by sheet type (such as floor plan, ceiling plan, elevation), or by any other system that you find helpful.

NOTE You cannot mix basic category types. For example, you cannot create a construct subcategory within the Views category or an element subcategory within the Sheets category.

Your Constructs tab might look like this:

The Benefits of Categories

Categories offer optimal organization and transparency. Even small building projects contain a large number of individual drawings that are difficult to track. Putting them into descriptive categories helps you quickly find the correct files.

Categories help you to assemble views. When you create views of your building data, you can use categories as selection or filter criteria. For example, for a complete view of framing constructs in your building, you could set up a view that references a Framing subcategory, thereby referencing all drawing files from that category. If you add more framing construction to the Framing category later, the view is updated to include the appropriate constructs. For more information, see [Creating a View Drawing: Selecting the Constructs](#) on page 325.

Methods of Creating Categories

You can create categories on the Project Navigator palette or in Windows Explorer as described in the topics that follow.

Creating a Category in the Drawing Explorer

Use this procedure to create a new category in the Drawing Explorer.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Navigate to the tab for the category type you want to create.
- 3 If you want to create a sheet category, click the Sheets tab, and click  (Explorer View).
- 4 To create a category under an existing category, click the existing category in the tree, and create a new subcategory using either of the following methods:
 - Right-click, and click New ► Category.

- Click  on the toolbar at the bottom of the tab.

5 Enter a name for the category, and press *ENTER*.

You can now add project files to the new category.

Creating a Category from Windows Explorer

Use this procedure to create a new category in your project by dragging a folder from Windows Explorer into the Drawing Explorer of the Project Navigator palette. This adds a folder and its contents to your project.

1 Click Window menu ► Project Navigator Palette.

2 Navigate to the tab for the category type you want to create.

3 If you want to create a sheet category, click the Sheets tab, and click  (Explorer View).

4 Start Windows Explorer and position it next to the Project Navigator.

5 Select the folder in Windows Explorer from which you want to create a category.

6 Place the folder in the Drawing Explorer of the selected tab of the Project Navigator:

If you want to...

Then...

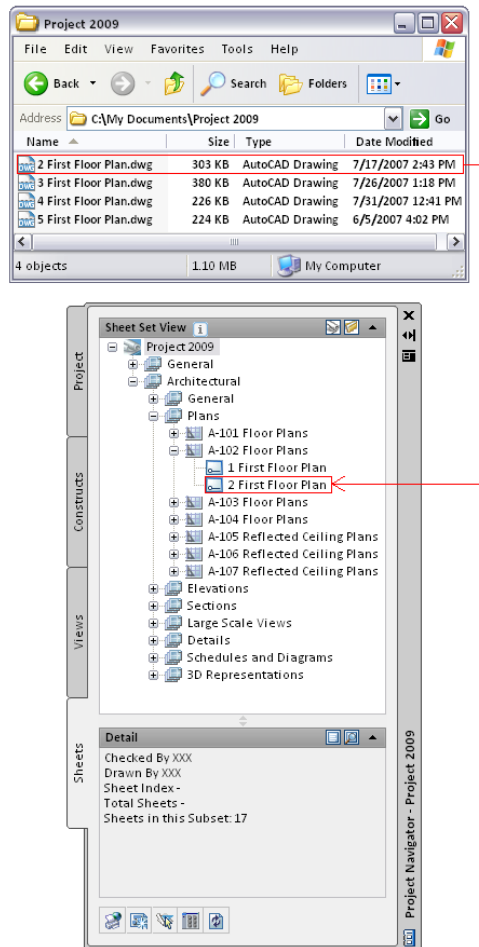

move the folder out of its current location

drag the folder to the desired location.

copy the folder from its current location

CTRL-drag the folder to the desired location

Dragging a folder from Windows Explorer to Project Navigator

NOTE If the folder you are dragging onto the Project Navigator palette contains drawing (DWG) files, you are prompted to add each one as a project file. For example, if you drag a folder into the Elements category in the Drawing Explorer, the Add Element dialog displays prompting you to add each DWG file within that folder as an element. For detailed information on converting existing drawing files into project files, see [Converting a Drawing to a Construct](#) on page 292 and [Converting a Drawing to an Element](#) on page 308.

For more information on updating files, see [Repath the Project](#) on page 372.

Specifying the Location of Top-Level Categories

When you want to specify an alternate location for the top-level category folders (Constructs, Elements, Views, and Sheets), the best practice is to start with a new project. Organize the project structure in Windows Explorer first, with the categories located in the same root folder as the APJ file. For example, you could structure your project with Constructs, Elements, Views, and Sheets under a category called Drawings. For more information, see [Creating a New Project](#) on page 235.

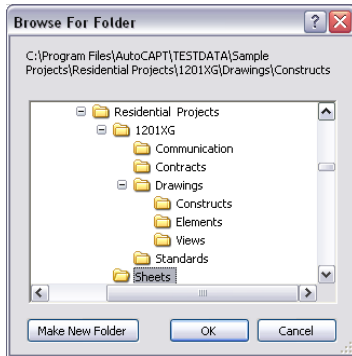

Top-level categories within project structure

These top categories can be directed to point to unique folders, but they cannot be an ascendant or descendant of each other in the tree structure. When you want to change the location of a category in an existing project, create the new category in Windows Explorer, and move the files from the old category into the new category in Windows Explorer first before you redirect the category.

NOTE If you locate top-level category folders outside the project folder, the project cannot be used as a template for new projects.

Top-level category located outside the project folder

Redirecting Top-Level Categories

Use this procedure when you want to change the location of the top-level categories in your project after you have created new category folders in Windows Explorer. You can redirect the path of Constructs, Elements, Views, and Sheets.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Project tab.
- 3 Under Current Project, click .
- 4 In the Project Properties dialog, click  for the category you wish to redirect, and browse to the location for the new folder.
- 5 Select the category, and click OK.
Paths for files within the category are redirected to the new location.

Changing the Subcategory of a Project File

By default each drawing file you create within a project is assigned to one of the top-level, predefined categories—Elements, Constructs, Views, or Sheets. After you have created a more detailed category system for your project, you can move drawing files into the subcategories.

Creating a File in a Subcategory

Use this procedure to create a project file within a subcategory.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Navigate to the tab for the file type you want to create.
- 3 If you want to create a file in a sheet category, click the Sheets tab, and click  (Explorer View).
- 4 Locate the subcategory in which you want to create a project file.
- 5 Select the subcategory, right-click, and click New ► Element/Construct/ General View Dwg/Section/Elevation/Detail/Sheet.

NOTE Alternatively, you can use the Add button at the bottom of the tab.

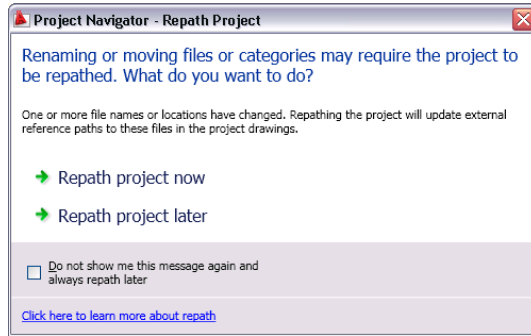

- 6 Specify the properties of the new file.
For more information on specifying new project files, see the appropriate sections for the individual file types.

Changing the Category of an Existing File

Use this procedure to change the category of an existing file.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Navigate to the tab for the category type you want to change.
- 3 If you want to change a sheet category, click the Sheets tab, and click  (Explorer View).
- 4 Locate the project file you want to move to another category.
- 5 Change the file category using any of the following methods:
 - Select the file, right-click, and click Properties. In the Modify dialog, change the file category, and click OK.
 - Select the file, and drag it into another subcategory.
 - Select the file, right-click, and click Cut. Select the destination category, right-click, and click Paste.

The Project Navigator - Repath Project dialog displays.

6 Update your files to display the changes to your project:

If you want to...

Then...

update all project files at this time

click Repath project now.

update all project files at another time

click Repath project later. If you close the project before repathing, the drawing files remain in a queue for update and display in the Project Repath Queue dialog the next time you open it.

7 Alternatively, click  to repath all files in the project at any time.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

Deleting a Category

Use this procedure to delete unneeded categories from a project.

If you delete a category that contains drawings, the drawings are deleted with the category.

NOTE Deleting a category from Windows Explorer may result in inconsistent project data.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Navigate to the tab for the category type you want to delete.
- 3 If you want to delete a sheet category, click the Sheets tab, and click  (Explorer View).
- 4 Select the category you want to delete, right-click, and click Delete.
- 5 Click Yes in the subsequent dialog.

Constructs

Constructs are the main building blocks (or base files) of the building model. A construct describes one unique portion of a building, such as a building core, an apartment, or an entire floor. You assign a construct to a level and a division within the project.

3D view of spanning curtain wall construct

Constructs and Levels and Divisions

Constructs are assigned to a level and a division. For example, you could assign an architectural construct named Interior Partitions—First Floor/South Wing to the first level and the south wing division of the building. You could also assign the structural construct Framing—First Floor/South Wing to the first level and south wing division, but it has a different purpose. Constructs can span more than one level, a requirement for objects such as curtain walls.

Constructs and Views

You use constructs to create views of a project. You could create a view named First Floor, which displays the following constructs:

- Interior Partitions—First Floor/South Wing
- Framing—First Floor/South Wing
- Ceiling—First Floor/South Wing
- Spanning Front Curtain Wall

This view would contain all objects in the South wing of the first floor. You select the constructs to include in the view when you identify view properties. You can add or remove constructs from views.

3D view of building first floor

Construct Files

A construct is a drawing (DWG) file. As opposed to non-project related drawing files, an additional XML file with the same name is created. The accompanying XML file contains information to connect the construct to the project.

NOTE The XML file is created and updated automatically. You do not need to edit it, but be careful not to accidentally delete it in Windows Explorer.

Construct Templates

When you create a project, you set a default template for new constructs.

For more information on project templates, see [Project Support Files](#) on page 228.

Copying Constructs to Levels

In multi-story buildings, levels may have identical floor plans. You can create the constructs for one level and copy them to the other levels in one quick step. For detailed information, see [Copying Constructs to Levels](#) on page 291.

Converting Legacy Drawings to Constructs

You can convert an existing drawing file into a construct within a project. You specify the subcategory into which to move or copy the source drawing.

When you convert a legacy drawing file into a construct:

- The drawing file is either moved, copied, or connected through a link to the project category you specify.
- You assign a level and a division to the construct.
- If necessary, you give the construct a different name, and add a description to it.

For detailed information, see [Converting a Drawing to a Construct](#) on page 292.

When To Start with Constructs

You would start creating constructs when you want to assemble the basic object of your building project into base files.

Typically, you begin a project by creating constructs. Adding optional elements often comes later in the process. For example, perhaps you know how many offices you need on a floor before you know the exact furniture layout of the offices. Therefore, you would first create the construct for the office walls and doors, First Floor—Office Space. Later, you could create elements for desk/chair combinations or generic printer/copier layouts and reference them into the construct with the office walls and doors.

Plan view of construct with highlighted furniture elements

Keep these considerations in mind when creating constructs:

- A construct can contain building objects, referenced elements, or a combination of both.
- A construct represents a unique portion of a building.

The Role of Constructs in the Building Project

Constructs are the main building blocks or base files of the building model. A construct can contain referenced elements and building objects, such as walls, roofs, and doors. It can also contain more abstract information, like structural grids, building outlines, and footpaths. After creating constructs, you can create different views of your building data. A view might contain the framing constructs for floors 1–4, the foundation construct, and the column grid construct. Or, a view of the first floor might include the partition walls of the first floor, the framing of the first floor, and the shell components of the building.

The Content of Constructs

There are 3 different types of content you can place in a construct:

- **Drawing objects:** You can draw an entire floor, apartment layout, a frame drawing, or a ceiling grid as a construct. Also, spanning objects like curtain walls or elevator shafts are usually created directly as constructs.
- **Element references:** You can display repeating components within the construct, such as desk/chair combinations, bathroom layouts, or stairs. For more information, see [Referencing Elements into Constructs](#) on page 296, and [Referencing an Element into Multiple Constructs](#) on page 297.
- **A combination of drawing objects and element references:** If you have a floor with different office types, but repeating furniture elements, you could draw the office walls directly in the construct but reference the furniture as elements.

You should not, as a general rule, reference constructs into constructs. A construct has a defined level and division assignment. If a construct were to be referenced into another construct, it may have 2 contradicting level and division assignments. However, there are situations where the necessity to do this can occur. For example, when you are checking the correct vertical alignment of a ceiling in the building, you could view a ceiling construct with an overlaid floor plan construct in it. Or, you might want to display alternating versions of a 2 car garage and a 3 car garage within a plan construct. If you encounter a situation where you would need to do this, there are several options that can serve as a work-around:

- Overlay the construct onto the other construct.
- Convert the first construct to an element, as described in [Converting a Construct to an Element](#) on page 302, and then reference it into the other construct.

WARNING Do not attach property set data to an overlaid construct from within the host construct. This data is not carried forward into views. Attach the property data locally in the overlaid construct.

- Create a view into which you reference both constructs. For more information, see [Creating a New View Drawing](#) on page 323.

Which of these options is best for you largely depends on your workflow and the results you want to achieve.

Creating a New Construct

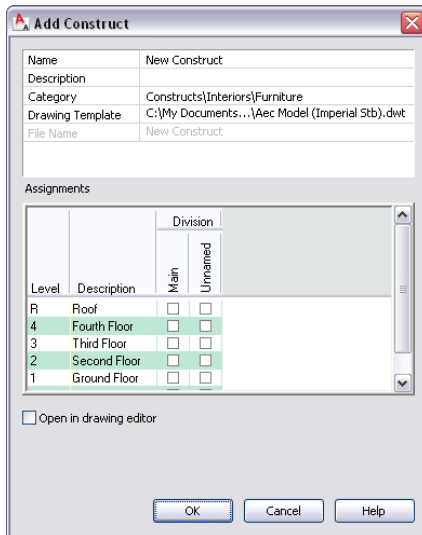

Use this procedure to create a new construct within a project.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the Constructs category or subcategory where you want to add the new construct.

3 Open the Add Construct dialog using one of the following methods:

- Right-click the category in which to place the new construct, and click New ► Construct.
- On the toolbar at the bottom of the Constructs tab, click . (You then specify the category in the dialog.)

4 Define the construct properties:

If you want to...

Then...

name the new construct

enter a name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on

If you want to...	Then...
enter a description for the construct	prefixes, see Specifying Basic Project Properties on page 239.
change the category of the construct	select a category from the Category list. By default, the category you chose in step 3 is suggested.
select a different template file	click  , and browse for a new template. The software uses the default template set for constructs in the project.
assign the construct to a level and a division	select the correct level and division in the assignments table. Select the desired level row and the division column, and check the appropriate box.

NOTE You should check only one level and division. Multiple levels and divisions create spanning constructs.

- 5 If you want to work in this construct immediately, select **Open** in drawing editor.
For information about other methods of opening constructs, see [Opening and Closing a Construct](#) on page 294.
- 6 Click **OK**.
- 7 Edit the construct as necessary:
 - Add objects to the construct.
 - Reference elements into the construct.
For information on adding content to constructs, see [The Content of Constructs](#) on page 289.
- 8 Close the construct using either of the following methods:
 - Right-click the construct in the Drawing Explorer, and click **Close**.
 - Click **File** ► **Close**.
- 9 Click **Yes** to save the changes in the drawing, if necessary.
- 10 To update the tree view in the Drawing Explorer, click  .

Copying Constructs to Levels

Use this procedure to copy a construct to multiple levels.

Copying constructs to levels is an easy way to fill multi-story buildings with content. You draw the construct for the first level, and then create a copy of that construct for each level you select.

Copying constructs to all levels schematic

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, select the construct to copy to multiple levels, right-click, and click Copy Construct to Levels.
- 3 Select the levels on which to create a copy of the construct.

NOTE The level on which the original construct is situated is selected by default. You cannot clear the selection here.

- 4 Click OK.

A new construct is created for each level selected. The level number is appended in brackets after the construct name.

NOTE To rename a copied construct, select it in the Drawing Explorer, right-click, and click Rename.

Converting a Drawing to a Construct

You may have drawing files in AutoCAD Architecture that you want to convert into constructs. When you convert a drawing into a construct:

- The drawing file is either moved, copied, or connected via a link to the project category you specify.
- You assign a level and a division to the construct.
- If necessary, you give the construct a different name, and add a description to it.

There are 2 ways to convert a drawing file into a construct: you can open the drawing file in AutoCAD Architecture and save it as a construct, or you can drag a drawing file from Windows Explorer to the Project Navigator.

Converting Drawing Files by Saving as a Construct

Use this procedure to convert a drawing file to a construct by opening the file in AutoCAD Architecture and then saving it as a construct.

- 1 Click File menu ► Open.
- 2 In the Select File dialog, select the file, and click Open.
- 3 Click Window menu ► Project Navigator Palette.
- 4 On the Constructs tab, locate the Constructs category or any of its subcategories.
- 5 Right-click, and click Save Current Dwg as Construct.
- 6 Define the construct properties:

If you want to...	Then...
change the name of the drawing file	enter a new name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see Specifying Basic Project Properties on page 239.
enter a description for the construct	click the setting for Description, enter a description of the construct, and click OK.
change the category of the construct	select one from the Category list. By default, the category you chose in step 4 is suggested.
assign the construct to a level and a division	select the correct level and division in the assignments table. Select the desired level row and the division column, and check the appropriate box.
	NOTE You should check only one level and division. Multiple levels and divisions create spanning constructs.

- 7 Click OK.

Converting Drawing Files Using Windows Explorer

Use this procedure to convert drawing files to constructs by dragging and dropping them from Windows Explorer.

Windows Explorer offers 3 different modes of conversion:

- Converting a file to a construct and moving it into a project folder
- Copying a file, and converting the copy to a construct in a project folder
- Converting a file to a construct and creating a link to its original location

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Constructs tab.
- 3 Start Windows Explorer, and position it next to the Project Navigator.
- 4 In Windows Explorer, open the folder that contains the drawing file.

5 Place the drawing in the Constructs category or one of its subcategories:

If you want to...	Then...
move the drawing into the selected category, and convert it to a construct	drag the drawing into the desired location in the Drawing Explorer.
move a copy of the drawing into the selected category, and convert it to a construct	CTRL-drag the drawing into the desired location in the Drawing Explorer.
create a link to the drawing in its original location, and convert it to a construct	ALT-drag the drawing into the desired location in the Drawing Explorer.

NOTE You can also drag an entire folder into the project. The folder is converted into a category, and all drawings within it are converted to constructs. For instructions on converting legacy folders to categories, see [Creating a Category from Windows Explorer](#) on page 282.

6 Define the construct properties:

If you want to...	Then...
change the name of the drawing file	enter a new name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see Specifying Basic Project Properties on page 239.
enter a description for the construct	click the setting for Description, enter a description of the construct, and click OK.
change the category of the construct	select from the Category list. By default, the category you chose in step 5 is suggested.
assign the construct to a level and a division	select the correct level and division in the assignments table. Select the desired level row and the division column, and check the appropriate box.

NOTE Unless you are defining a spanning construct, you should check only one level and division. Multiple levels and divisions create spanning constructs.

7 Click OK.

Opening and Closing a Construct

Use this procedure to open and close a construct. For information about additional commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.

1 Click Window menu ► Project Navigator Palette.

- 2 On the Constructs tab, locate the Constructs category or the subcategory that contains the construct to open.
- 3 Open the construct using either of the following methods:
 - Select the construct, right-click, and click Open.
 - Double-click the construct.

The construct is opened in the drawing area of AutoCAD Architecture.

When you open a construct, the status line in the AutoCAD Architecture drawing area displays the name of the associated project.

- 4 Close the construct using either of the following methods:
 - Right-click the construct in the Drawing Explorer, and click Close.
 - Click File ► Close.
- 5 Click Yes to save the changes in the drawing, if necessary.

Dragging Objects into a Construct

Use this procedure to drag and drop objects from the drawing screen into a construct.

When you create a new construct, you have several choices for adding content to it. You can draw objects within the construct, you can reference elements into a construct, or you can drag and drop objects from other drawing files into a construct.

- 1 Open the drawing that contains the objects you want to drag and drop into the construct.
The drawing containing the objects is not required to be a part of a project.
- 2 Click Window menu ► Project Navigator Palette.
- 3 On the Constructs tab, locate the Construct to which you want to add objects from another drawing file.
- 4 In the open drawing file, select the objects you want to drag and drop into the construct.
- 5 Move or copy the objects into the construct.

If you want to...	Then...
move the objects from the open drawing to the construct	drag them from the drawing onto the desired construct in the Drawing Explorer.
copy the objects from the open drawing to the construct	CTRL-drag them from the drawing onto the desired construct in the Drawing Explorer.

NOTE You can also drop objects on the category to create a new construct containing the objects.

Referencing Elements into Constructs

There are several ways to reference an element into a construct:

If you want to...	Then...
create a link from the element to the construct	attach an element as an external reference. Any changes to the referenced element are displayed in the construct when it is opened or refreshed. For more information, see Attaching an Element as an External Reference to a Construct on page 296.
create a link from the element to the construct	overlay an element as an external reference. An overlaid reference is not included when the construct is attached or overlaid as a reference to a view. For more information, see Overlaying an Element as an External Reference to a Construct on page 297.
cut off the link between the element and the construct	insert an element as a block reference. The inserted element is converted to a block and is not updated when the reference element is changed. You can, however, edit the block in the construct. For more information, see Inserting an Element as a Block into a Construct on page 297.

3D view of cubicle element referenced 4 times into office space construct

Attaching an Element as an External Reference to a Construct

Use this procedure to attach an element as an external reference to a construct.

For detailed information on attaching external references to drawings, see “Reference Other Drawing Files (Xrefs)” in AutoCAD Help.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, select the element to reference.
- 3 Reference the element into a construct using one of the following methods:
 - With a construct open in your drawing area, drag the element into the open construct drawing.
 - With a construct open in your drawing area, right-click the element, and click Xref Attach.
 - Right-click, click Attach Element To Constructs, and in the Attach Element to Construct dialog, select the constructs into which to reference the element, and click OK.

The element is attached as an external reference to the construct at 0, 0, 0.

NOTE If you cannot see the element, it may be inserted at 0, 0, 0. Use the AutoCAD Zoom Extents command to display it.

Overlaying an Element as an External Reference to a Construct

Use this procedure to overlay an element as an external reference to a construct.

For detailed information on overlaying external references to drawings, see “Reference Other Drawing Files (Xrefs)” in AutoCAD Help.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the construct into which to reference an element, right-click, and click Open.
- 3 On the Project Navigator palette, locate the element to overlay.
- 4 Select the element, right-click, and click Xref Overlay.
The element is inserted as an external reference into the construct.

NOTE If you cannot see the element, it may be inserted at 0, 0, 0. Use the AutoCAD Zoom Extents command to display it.

Inserting an Element as a Block into a Construct

Use this procedure to insert an element as a block into a construct.

For detailed information on blocks, see “Create and Use Blocks (Symbols)” in AutoCAD Help.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the construct into which to reference an element as a block, right-click, and click Open.
- 3 On the Project Navigator palette, locate the element to insert as a block.
- 4 Select the element, right-click, and click Insert as Block.
- 5 Specify the Insert options—such as insertion point, scale and rotation angle—and click OK.

Referencing an Element into Multiple Constructs

Use this procedure to reference an element into multiple constructs.

This procedure is useful for updating a number of similar floor constructs in a building.

Referencing an element into a construct

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the element to reference into multiple constructs, right-click, and click Attach Element to Constructs.
- 3 Check the boxes of the constructs into which to reference the element.

NOTE As a shortcut, you can select an entire category for referencing.

- 4 Define the referencing method:

If you want to...

Then...

attach the element as an external reference

select the construct, right-click, and click Set to Attach.

NOTE If the Set to Attach command is unavailable, the element is already set to attach.

overlay the element as an external reference

select the construct, right-click, and click Set to Overlay.

NOTE If the Set to Overlay command is unavailable, the element is already set to overlay.

- 5 Repeat steps 5-6 for each construct the element should be attached to.

- 6 Click OK.

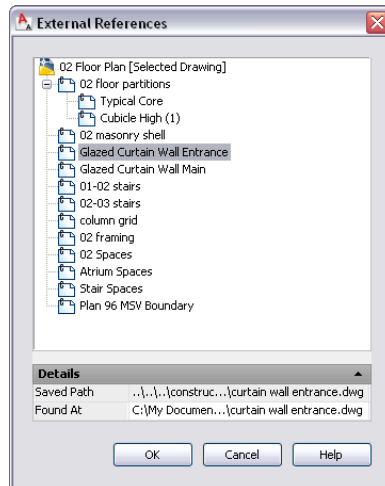

Elements are attached at 0, 0, 0.

Displaying External References of a Construct

Use this procedure to display a list of xrefs attached to a construct and to access the functions available for each xref.

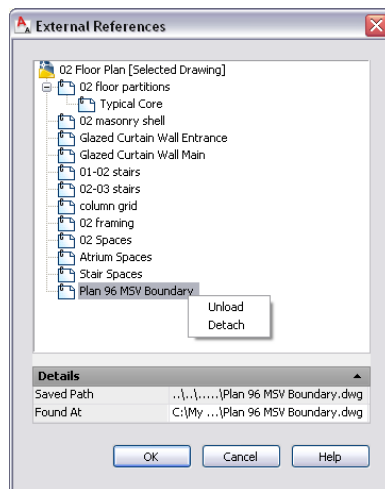

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Constructs tab.
- 3 In the Drawing Explorer, locate the construct for which to display external references, and select it.
- 4 Display the external references using either of the following methods:
 - Right-click, and click External References.
 - On the toolbar at the bottom of the Constructs tab, click  .

The External References dialog displays a list of xrefs in the construct.

5 Expand or collapse the list by clicking individual items, and right-click to change the status of the xref, if necessary.

From the context menu you can unload, reload, or detach the attached xref. For more information, see Reference Other Drawing Files in AutoCAD Help.

6 View the details of the xref:

- Saved Path displays the saved path, if any, that is used to locate the xref. This path can be a full (absolute) path or a relative (partially specified) path.
- Found At displays the path where the xref was found. If no path was saved for the xref, or if the xref is no longer located at the specified path, the program searches for the xref and displays the location here.

7 Click OK to close the dialog.

NOTE You can also display external references by opening the construct in the AutoCAD Architecture drawing area, and using the AutoCAD Xref Manager. For more information, see “Reference Other Drawing Files (Xrefs)” in AutoCAD Help.

Changing the Properties of a Construct

Use this procedure to change the properties of a construct.

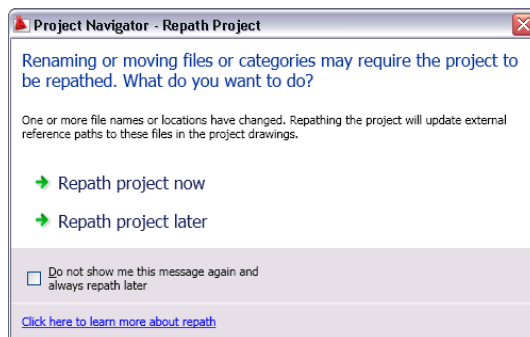

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the Constructs category or the subcategory that contains the construct you want to change, right-click, and click Properties.
- 3 Change the construct properties:

If you want to...	Then...
change the name of the drawing file	enter a name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see Specifying Basic Project Properties on page 239.
enter a description for the construct	click the setting for Description, enter a description of the construct, and click OK.
change the category of the construct	select one from the Category list. By default, the category you chose in step 3 is suggested.
assign the construct to a different level and a division	select the correct combination of both in the assignments table. Select the desired level row and division column, and check the appropriate box.

NOTE Unless you are defining a spanning construct, you should check only one level and division. Multiple levels and divisions create spanning constructs.

- 4 Click OK.

The Project Navigator - Repath Project dialog displays if you changed the name or category of the construct.

5 Update your files to display the changes to your project:

If you want to...

Then...

update all project files at this time

click Repath project now.

update all project files at another time

click Repath project later. If you close the project before repathing, the drawing files remain in a queue for update and display in the Project Repath Queue dialog the next time you open it.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

For more information on updating files, see [Repath the Project](#) on page 372.

Electronically Transmitting a Construct

Use this procedure to electronically transmit a construct drawing.

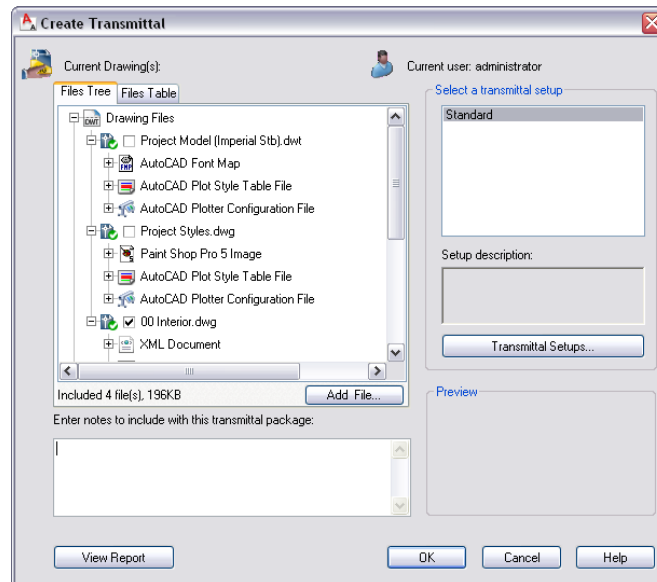

Electronically transmitting a drawing means that you package the drawing for delivery in electronic form. Drawing files in the transmittal package include all related dependent files such as external references and font files.

For more information about electronic transmittal, see “Package a Set of Files for Internet Transmission” in AutoCAD Help.

1 Click Window menu ► Project Navigator Palette.

2 On the Constructs tab, locate the Constructs category or the subcategory that contains the construct to transmit, right-click, and click eTransmit.

The Create Transmittal dialog is displayed.

3 In either the Files tree tab or the File Table tab, select the components to be included in the electronic package.

The Files Tree tab displays the included files sorted by type. The Files Table tab displays all files in a list view. You can sort the list by name, path, type, version, size, and date.

4 To include project information, double-click the setup under Select a transmittal setup, and in the Modify Transmittal Setup dialog, select Include project information under Include options.

For detailed information about packaging project information for an electronic transmittal, see [Electronically Transmitting a Project](#) on page 252

5 Click OK to start the electronic transmittal.

Deleting a Construct

Use this procedure to delete a construct.

For information on the consequences of deleting constructs, see [Changing Constructs: Interactions with the Project](#) on page 304.

The construct must be closed in order to delete it.

NOTE Do not delete a construct from Windows Explorer. This might result in inconsistent project data.

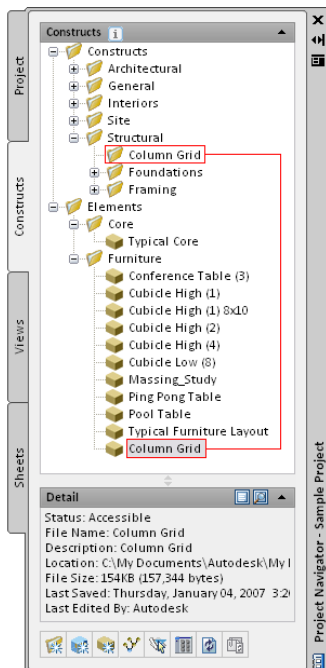

1 Click Window menu ► Project Navigator Palette.

2 On the Constructs tab, locate the construct to delete, right-click, and click Delete.

3 Click Yes in the subsequent message box.

Converting a Construct to an Element

Use this procedure to convert a construct to an element.

You may create a construct, and then realize that this is actually a repeating element. For example, you might create a column grid and then decide to use it on another floor. You can easily convert the construct to an element and reference it into multiple constructs.

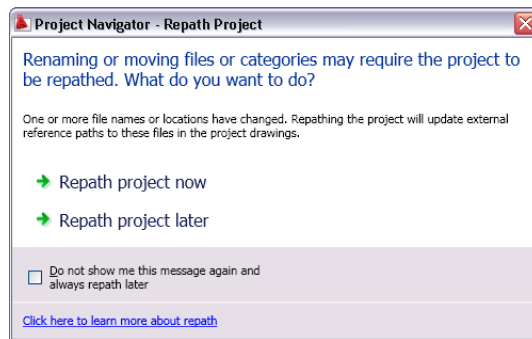

NOTE When you convert a construct to an element, the level and division information is lost. Should you later convert the element back to a construct, you must reassign to a level and division.

NOTE Do not drag a construct into the Elements folder within Windows Explorer. This will result in inconsistent project data.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the construct to convert to an element, and drag it into the Elements category or one of its subcategories.

NOTE If you want to convert the element back to a construct, drag the element to the Constructs category.

- 3 Specify the element properties, as described in [Creating an Element](#) on page 306. The Project Navigator - Repath Project dialog displays.

- 4 Update your project files:

If you want to...

Then...

update all project files now

click Repath project now.

update all project files later

click Repath project later. If you close the project before repathing, the drawing files remain in a queue for update and display in the Project Repath Queue dialog the next time you open it.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

For more information on updating files, see [Repath the Project](#) on page 372.

Changing Constructs: Interactions with the Project

Changes made to one part of a project frequently influence other parts of the project. The following information describes the changes you can make to a construct and the effects of the changes on other parts of the building project:

- **Adding a new construct:** When you add new constructs to a project, you must fill them with drawing objects or referenced elements. Also, you must create views in which to display them. For more information, see [Creating a New View Drawing](#) on page 323.
- **Changing the construct name and category (location):** Constructs are referenced into views. Therefore, any name and location changes to a construct need to be updated throughout the project. To update any xref paths to the construct, repath the project, as described in [Repath the Project](#) on page 372.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

- **Changing the level and division of a construct:** If you change the level and division you may need to regenerate views. For more information, see [Regenerating the View Drawings in a Project](#) on page 331.
- **Deleting a construct:** If you delete a construct you may need to regenerate views. For detailed information on deleting constructs, see [Deleting a Construct](#) on page 302. For detailed information on views, see [Views](#) on page 318.

Elements

Elements represent groups of objects that are used multiple times within a building, similar to blocks. For example, you can create an element for a repeating design object like a desk/chair combination to place in a number of cubicles. You can also create an element for a typical bathroom layout and reference it multiple times into one or more constructs. Because you can annotate individual instances of an external reference, you can use the same element and annotate it differently in different locations.

Element repeated in construct

For information on scheduling repeating elements, see [Attaching Property Sets to Objects from External References](#) on page 379.

Element Files

An element is a drawing (DWG) file. As opposed to non-project drawing files, an additional XML file with the same name is created. The accompanying XML file contains information to connect the drawing file to the project.

NOTE The XML file is created and updated automatically. You do not need to edit it, but be careful not to accidentally delete it in Windows Explorer.

Converting Drawings to Elements

You can convert a drawing file into an element within a project. You specify the subcategory into which to move or copy the source drawing.

When you convert a legacy drawing file into an element:

- The drawing file is moved, copied, or linked to the project category you specify.
- You can assign a different name and add a description to the file.

Element Templates

When you create a project, you specify a default template for new elements. For more information about project templates, see [Project Support Files](#) on page 228.

Constructs and Elements

An element is a generic building block for multiple use. If you create a bathroom layout as an element, you can use it on the second floor of the west wing just as well as on the first floor of the east wing. To place the element on a specific floor and wing, reference it into a construct. For example, you could create an element named Generic Bathroom Layout and reference it into constructs named First Floor, Second Floor, and Third Floor.

Referencing an element into a construct

Referencing Elements to Multiple Constructs

In multi-story buildings, levels may have identical elements. You can create an element once, and then reference it into multiple constructs in one single, convenient step. For detailed information, see [Referencing an Element into Multiple Constructs](#) on page 297.

When to Start with Elements

You would start creating elements when you can identify generic building blocks in your project.

Elements can be small units like a desk/chair combination or large units like an entire apartment layout or a generic furniture layout. You can also define an element that uses other elements as external references

in its content. A generic building core element, for example, could contain references for bathroom elements or staircase elements. You can nest elements that are external references multiple levels deep.

Keep in mind these points when creating elements:

- An element must be referenced into a construct before it can be used for views.
- An element can be referenced directly into a sheet. This might be done for title blocks or the documentation of a detail on the sheet.
- An element can be uniquely scheduled.
- An element is re-usable.

Processing Elements in the Building Project

After you have created and modified some elements in your project, decide how to use them in the project. The following list describes typical uses for elements and where to find additional information:

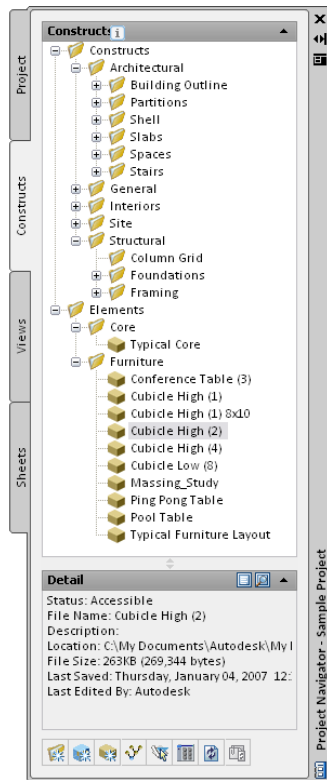

Use	Further Information
reference an element into a construct	This is the most frequent use case for an element. A generic element, like a bathroom layout, is referenced into a specific construct, like a floor plan. For more information, see Referencing Elements into Constructs on page 296 and Referencing an Element into Multiple Constructs on page 297.
reference an element into another element	For example, if you want to have different elements for single cubicles—a 4-cubicle group, you could create an element for one cubicle, and reference that 4 times into the 4-cubicle group element. For more information, see Referencing an Element into Another Element on page 314.
reference an element into a sheet	You can directly reference an element into a sheet. This can be useful for title block elements.

Creating an Element

Use this procedure to create an element.

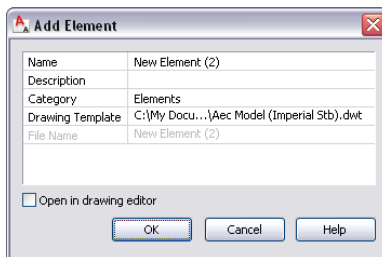

- 1 Click Window menu ► Project Navigator Palette.

2 On the Constructs tab, locate the Elements category or subcategory where you want to add the new element.

3 Open the Add Element dialog using one of the following methods:

- Right-click the category in which to place the new element, and click New ► Element.
- In the toolbar at the bottom of the Constructs tab, click . (You then specify the category in the dialog.)

4 Define the element properties:

If you want to...

Then...

name the new element

enter a name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see [Specifying Basic Project Properties](#) on page 239.

If you want to...	Then...
add a description for the element	click the setting for Description, enter a description of the element, and click OK.
change the category of the element	select a category from the Category list. By default, the category you chose in step 3 is suggested.
select a different template file	click  , and browse for a new template. By default, the default template for elements set in the project is used.

5 If you want to work in this element immediately, select Open in drawing editor.

For information about other methods of opening elements if you do not select this option, see [Opening and Closing an Element](#) on page 311.

6 Click OK.

7 Edit the element as necessary:

- Add objects to the element.
- Reference other elements into the element.
For more information, see [Referencing an Element into Another Element](#) on page 314.

8 Close the element using either of the following methods:

- Right-click the element in the Drawing Explorer, and click Close.
- Click File ► Close.

9 Click Yes to save the changes in the drawing if necessary.

Converting a Drawing to an Element

You may have drawing files in AutoCAD Architecture that you want to convert into elements. When you convert a drawing file into an element:

- The drawing file is either moved, copied, or connected via a link to the element category you specify.
- If necessary, a different name is given to the file and a description is added to it.

There are 2 ways to convert a drawing file into an element: you can open the drawing file in AutoCAD Architecture and save it as an element, or you can drag a drawing file from Windows Explorer to the Project Navigator.

Converting Drawing Files by Opening and Saving as an Element

Use this procedure to convert a drawing file to an element by opening it in AutoCAD Architecture and then saving it as an element.

- 1** On the File menu, click Open, and open the desired drawing file.
- 2** Click Window menu ► Project Navigator Palette.

3 On the Constructs tab, locate the Elements category, right-click, and click Save Current Dwg as Element.

4 Define the element properties:

If you want to...	Then...
change the name of the drawing file	enter a new name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see Specifying Basic Project Properties on page 239.
enter a description for the element	click the setting for Description, enter a description of the element, and click OK.
change the category of the element	select one from the Category list. By default, the category you chose in step 4 is suggested.

5 Click OK.

6 Close the element using either of the following methods:

- Right-click the element in the Drawing Explorer, and click Close.
- Click File ► Close.

7 Click Yes to save the changes in the drawing, if necessary.

Converting Drawing Files from Windows Explorer

Use this procedure to convert drawing files to elements by dragging and dropping them from Windows Explorer.

Windows Explorer offers 3 different modes of conversion:

- Converting a file to an element and moving it into a project folder
- Copying a file, and converting the copy to the element in a project folder
- Converting a file to an element and creating a link to its original location

1 Click Window menu ► Project Navigator Palette.

2 Click the Constructs tab.

3 Start Windows Explorer, and position it next to the Project Navigator.

4 In Windows Explorer, open the folder that contains the drawing.

5 Drag and drop the drawing in the Elements category or one of its subcategories:

If you want to...	Then...
move the drawing into the selected category, and convert it to an element	drag the drawing into the desired location in the Drawing Explorer.
move a copy of the drawing into the selected category, and convert it to an element	CTRL-drag the drawing into the desired location in the Drawing Explorer.

If you want to...**Then...**

create a link to the drawing in its original location, and convert it to an element

ALT-drag the drawing into the desired location in the Drawing Explorer.

NOTE You can also drag an entire folder into the project. The folder is converted into a category, and all drawings within are converted to elements. For instructions on converting folders to categories, see [Creating a Category from Windows Explorer](#) on page 282.

6 Define the element properties:

If you want to...**Then...**

change the name of the drawing file

enter a new name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see [Specifying Basic Project Properties](#) on page 239.

enter a description for the element

click the setting for Description, enter a description of the element, and click OK.

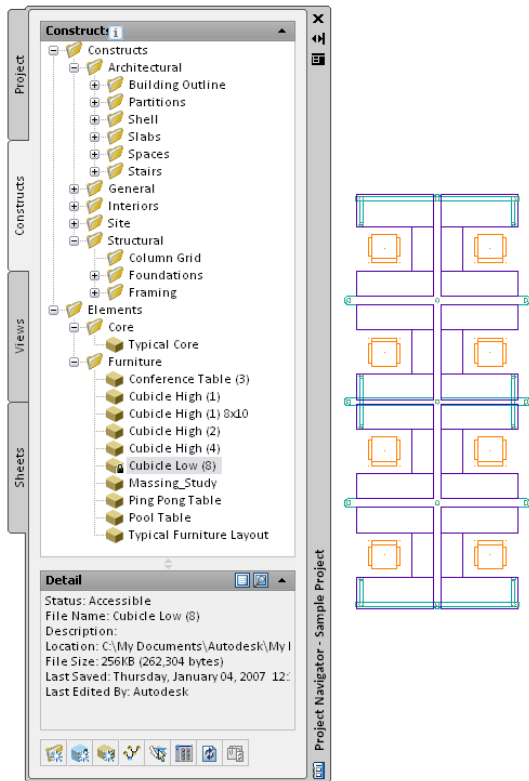

change the category of the element

select one from the Category list. By default, the category you chose in step 5 is suggested.

7 Click OK.

Opening and Closing an Element

Use this procedure to open and close an element. For information about additional commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.

When you open an element, the status line in the AutoCAD Architecture drawing area displays the name of the associated project.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the element you want to open.
- 3 Open the element using either of the following methods:
 - Select the element, right-click, and click Open.
 - Double-click the element.

The element is opened in the drawing area of AutoCAD Architecture. You can now edit it.

- 4 Close the element using either of the following methods:
 - Right-click the element in the Drawing Explorer, and click Close.
 - Click File ► Close.

5 Click Yes to save the changes in the drawing, if necessary.

- 6 To update the preview of the element in the Drawing Explorer, click  .

Dragging Objects into an Element

Use this procedure to drag and drop objects into an element.

When you create a new element, you may choose to add content to it in several ways. You can draw objects within the element, you can reference one element into another, or you can drag and drop objects from other drawing files into an element.

- 1 Open the drawing that contains the objects you want to drag and drop into an element.

NOTE The drawing containing the objects is not required to be a part of a project.

- 2 Click Window menu ► Project Navigator Palette.
- 3 On the Constructs tab, locate the element to which you want to add objects from another drawing file.
- 4 In the open drawing file, select the objects you want to drag and drop into the element.
- 5 Move or copy the objects into the element:

If you want to...	Then...
-------------------	---------

move the objects from the open drawing to the element	drag the objects from the drawing onto the desired element in the Drawing Explorer.
---	---

copy the objects from the open drawing to the element	CTRL-drag the objects from the drawing onto the desired element in the Drawing Explorer.
---	--

NOTE You can also drag the objects from the drawing onto a category in the Drawing Explorer to create an element.

Changing the Properties of an Element

Use this procedure to change the properties of an element.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the element you want to change, right-click, and click Properties.
- 3 Change the element properties:

If you want to...	Then...
-------------------	---------

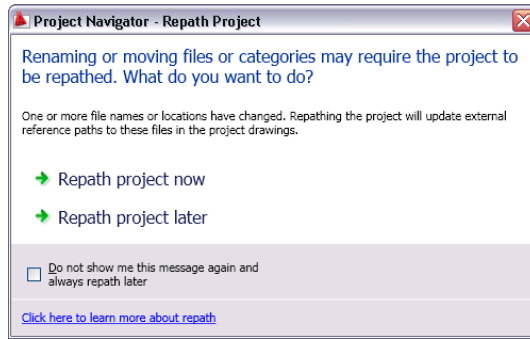

change the name of the element	enter a new name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see Specifying Basic Project Properties on page 239.
--------------------------------	--

change the description of the element	click the setting for Description, change the description of the element, and click OK.
---------------------------------------	---

change the category of the element	select one from the Category list. Changing the category of an element means changing its location in the project.
------------------------------------	--

4 Click OK.

The Project Navigator - Repath Project dialog displays.

5 Update your project files:

If you want to...

Then...

update all project files now

click Repath project now.

update all project files later

click Repath project later. If you close the project before repathing, the drawing files remain in a queue for update and display in the Project Repath Queue dialog the next time you open it.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

Electronically Transmitting an Element

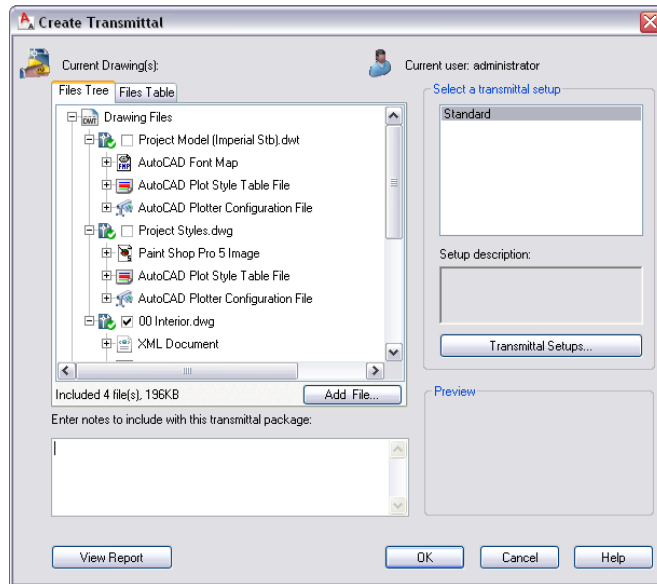

Use this procedure to electronically transmit an element drawing.

Electronically transmitting a drawing means that you package the drawing for delivery in electronic form. Drawing files in the transmittal package include all related dependent files such as external references and font files.

For more information about electronic transmittal, see “Package a Set of Files for Internet Transmission” in AutoCAD Help.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the element to transmit.
- 3 Select the element, right-click, and click eTransmit.

The Create Transmittal dialog is displayed.

4 On either the Files tree tab or the File Table tab, select the components to be included in the electronic package.

The Files Tree tab displays the included files sorted by type. The Files Table tab displays all files in a list view. You can sort the list by name, path, type, version, size, and date.

For detailed information about packaging project information for an electronic transmittal, see [Electronically Transmitting a Project](#) on page 252.

5 Click OK to start the electronic transmittal.

Deleting an Element

Use this procedure to delete an element.

The element must be closed in order to delete it.

NOTE Do not delete an element from Windows Explorer. This might result in inconsistent project data.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Constructs tab, locate the element to delete.
- 3 Select the element, right-click, and click Delete.
- 4 Click Yes in the subsequent message box.

Referencing an Element into Another Element

Use this procedure to reference an element into another element.

NOTE When you are working in a project environment, make sure that all files you are using belong to this project. Drawing files that do not belong to a project do not give access to the full functionality of Drawing Management. To reference a non-project drawing file into the project, convert the file into an element, and then reference it.

Cubicle element referenced 4 times into cubicle group

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Constructs tab.
- 3 In the Drawing Explorer, locate and open the element into which you want to reference another element.
- 4 On the Project Navigator palette, locate the element to reference into the open element.
- 5 Reference the element into the open element using one of the following methods:

If you want to...

Then...

attach the element as an external reference to the open element

select the element in the Drawing Explorer, right-click, and click Xref Attach, or select the element in the Drawing Explorer, and drag it into the open element in the AutoCAD Architecture drawing area.
When you attach an element as an external reference, you create a link from the referenced element to the current element; any changes to the referenced element are displayed in the current element when it is opened or refreshed.

overlay the element as an external reference on the open element

select the element in the Drawing Explorer, right-click, and click Xref Overlay.
When you overlay an external reference, you also create a link from the referenced element to the current element. Unlike an attached reference, an overlaid reference is not included when the element is itself attached or overlaid as a reference to another element or construct.

insert the element as a block into the open element

select the element in the Drawing Explorer, right-click, and click Insert as Block.
When you insert an element as a block reference into another element, the link between the referenced element and the current element is cut off. The inserted element is converted to a block and does not up-

If you want to...

Then...

date when the reference element is changed. You can, however, edit the block in the current element.

6 If necessary, edit the external reference in the open element.

For more information on external references, see “Attach External References” in AutoCAD Help.

For more information on blocks, see “Create and Insert Symbols (Blocks)” in AutoCAD Help.

Displaying External References Attached to an Element

Use this procedure to display a list of xrefs attached to an element and to access the functions available for each xref.

1 Click Window menu ► Project Navigator Palette.

2 Click the Constructs tab.

3 In the Drawing Explorer, locate the element for which to display xrefs.

4 Select the element.

5 Display the xrefs using either of the following methods:

- Right-click, and click External References.

- On the toolbar at the bottom of the Constructs tab, click  .

The External References dialog displays a list of xrefs in the element.

6 Expand or collapse the list by clicking individual items, and right-click to change the status of the xref, if necessary.

From the context menu, you can unload, reload, or detach the attached xref. For more information, see Reference Other Drawing Files in AutoCAD Help.

7 View the details of the xref:

- Saved Path displays the saved path, if any, that is used to locate the xref. This path can be a full (absolute) path or a relative (partially specified) path.

- Found At displays the path where the xref was found. If no path was saved for the xref, or if the xref is no longer located at the specified path, the program searches for the xref and displays the location here.

8 Click OK to close the dialog.

NOTE You can also display external references by opening the element in the AutoCAD Architecture drawing area and using the AutoCAD Xref Manager. For more information, see Reference Other Drawing Files in AutoCAD Help.

Converting an Element to a Construct

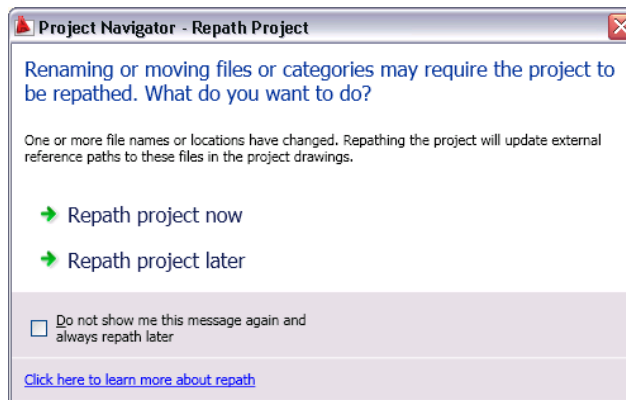

Use this procedure to convert an element to a construct.

If you create an element and realize later that you do not need this drawing as a repeating element, you can convert it into a construct.

NOTE Do not drag an element to the Constructs folder within Windows Explorer. This will result in inconsistent project data.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Constructs tab.
- 3 In the Drawing Explorer, locate the element to convert into a construct.
- 4 Select the element, and drag it into the Constructs category or one of its subcategories.
- 5 Specify the construct properties, as described in [Creating a New Construct](#) on page 290.
- 6 Click OK.

The Project Navigator - Repath Project dialog displays.

- 7 Update your project files:

If you want to...	Then...
update all project files now	click Repath project now.
update all project files later	click Repath project later. If you close the project before repathing, the drawing files remain in a queue for update and display in the Project Repath Queue dialog the next time you open it.

NOTE If you want to convert the construct back to an element, drag it back to the Elements category.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

Changing Elements: Interactions with the Project

Changes made to one part of a project frequently influence other parts of the project. The following information describes the changes you can make to an element, and the effects of the changes on other parts of the building project.

- **Adding new elements:** When you add new elements to a project, you may reference them into other elements, constructs, or sheets.
- **Changing the element name and category (location):** Elements are used as external references in other files. When you change the name and the location of an element, external reference paths to it no longer correct. To update the project, repath it, as described in [Repath the Project](#) on page 372.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

- **Deleting an element:** When you delete an element that has been referenced into another element or into a construct or a sheet, that drawing now has missing references. If a construct with deleted elements has been referenced into a view, and the view is updated, it also has missing references. Therefore, before deleting an element, check to see if it is still used elsewhere. For detailed information on deleting elements, see [Deleting an Element](#) on page 314.

Views

After the structure of the building project is defined, and constructs are assigned to levels and divisions, you can start to create view drawings. A view drawing references a number of constructs to present a specific view of the building project. To create a view drawing, you first decide which portion of the building you wish to look at and which type of view to generate. You could, for example, create a first-floor reflected ceiling plan or a second-floor framing plan, or create a composite view of all floors in the building. View drawings automatically reference the appropriate constructs according to their level/division assignments within the building. For example, to create a floor plan of the west wing of the second floor, you would create a view that references all constructs assigned to the second floor and the west wing. This would also include a curtain wall spanning the first through fifth floors.

3D view of entire building view

In a view drawing you also add data like annotation, dimensions, and schedule tables.

Types of View Drawings

There are 3 different types of view drawings in the Drawing Management feature:

- **General view drawing:** A general view drawing contains referenced constructs from the project, representing a specific view on the building model. General view drawings are based on the general view template defined in the project settings.

You can reference a view drawing in a sheet. When you reference the view drawing into a sheet, a sheet view is created that contains the view drawing reference.

Perspective view of building

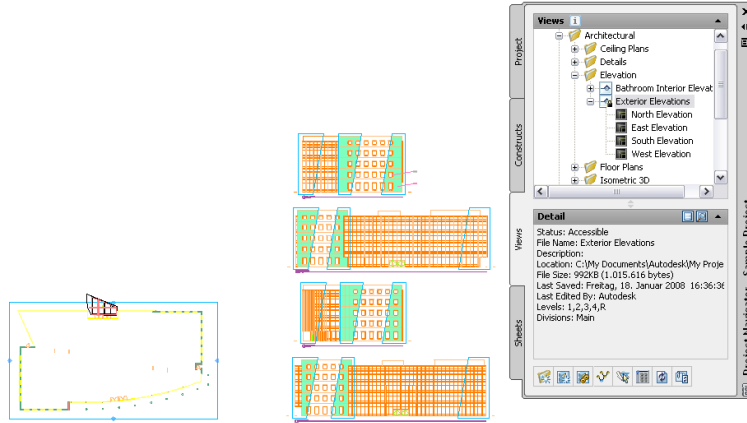

- **Detail view drawing:** A detail view drawing contains one or more model space views that show a defined portion of the detail drawing in the level of detail you specify. A model space view containing a detail can be associated with a callout. Detail view drawings are based on the detail view template defined in the project settings.

Detail view in callout

- **Section/Elevation view drawing:** A section/elevation view drawing contains one or more model space views, each showing a defined portion of the section/elevation view drawing. A model space view containing a section or elevation can be associated with a callout. Section/Elevation view drawings are based on the section/elevation view template defined in the project settings.

Elevation view drawing with 4 model space views

When you reference a view drawing into a sheet, a sheet view is created that contains the view drawing reference.

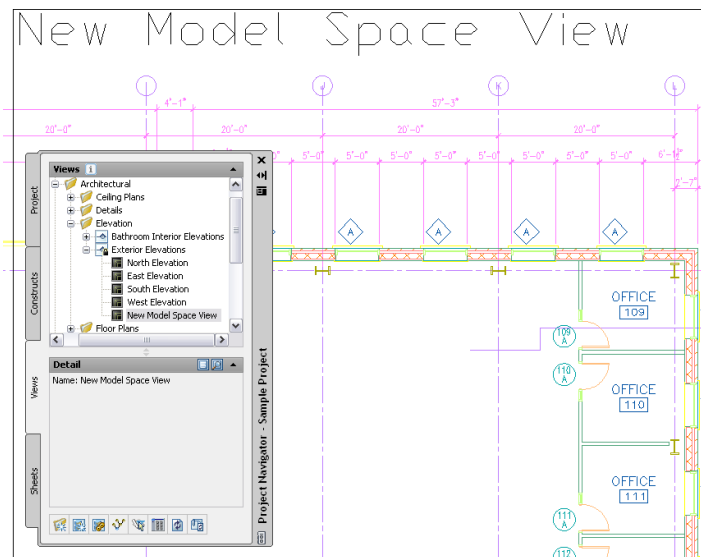

Model Space Views

A model space view is a portion of a view drawing that may be displayed in its own paper space viewport on a sheet. Model space views are an evolution of the Named Views concept of AutoCAD. Unlike Named Views, a model space view has a defined boundary. When a model space view is placed onto a sheet, a sheet view is created. A view drawing can contain any number of model space views.

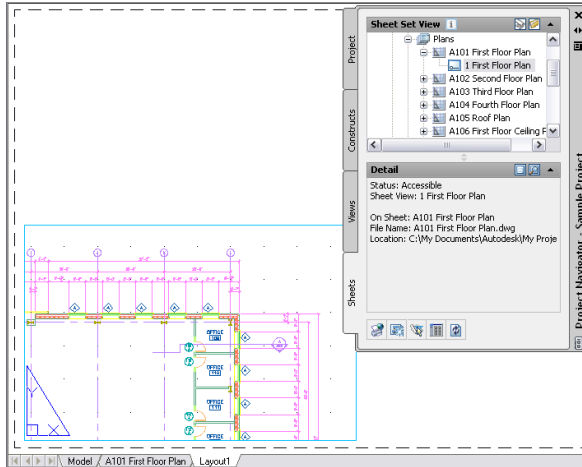

Sheet Views

A sheet view is a paper space viewport on the sheet that is created when you drag a view drawing or model space view from the Project Navigator palette onto a sheet.

Model space view of plan area

Sheet view placed on sheet

Sheet views can have viewport-specific layer overrides. When a view drawing or a model space view is referenced into a sheet view, these overrides will be retained, unless the project has been set up to synchronize views with sheets. In that case the layer settings of the view drawing will be reset in the sheet view when the sheet is opened, plotted, or published. For more information, see [Synchronizing View Drawing Layers with Sheet View Layers](#) on page 338.

For more information on viewport-specific layer overrides, see “Override Layer Properties in Viewports” in the AutoCAD help.

Views and Constructs

You create a view drawing by selecting constructs from the Project Navigator palette and referencing them into the view drawing. When you are creating multi-level views, each construct is referenced at its relative level height, with the lowest level inserted at $Z = 0$. For more information, see [Creating a New View Drawing](#) on page 323.

3D view of copied building core constructs at each building level

Views and Annotation

You can add annotation, dimensions, and schedule tables in a view drawing or on a sheet, depending on your specific workflow and needs. For more information on annotating a project, see [Annotating a Project](#) on page 374.

View drawing with annotation tags

Updating View Drawings

A view drawing can include either individual constructs or entire construct categories. For example, if you select the Architectural—First Floor construct category, all constructs within this category at the appropriate level or division are included in the view drawing. If you add constructs to that category later, the view drawing is automatically regenerated to include the new constructs as applicable. Using categories helps you keep your view drawings current throughout the project.

View Templates

When you create a project, you set a default template for new view drawings. There are separate templates for general view drawings, detail view drawings, and section/elevation view drawings.

The default view template should be saved so that it will create a drawing that opens to the Model tab. When you create a new view drawing, all constructs that you assign to it will be referenced into the view drawing. If the template does not open with model space active, the building will be referenced into paper space.

For more information about project templates, see [Project Support Files](#) on page 228.

When to Start with Views

Typically, you create view drawings and model space views after you have defined levels, divisions, and the basic constructs. For example, you could create the following series of views for individual floors: First Floor Plan, Second Floor Plan, Basement Plan, Roof Plan. You could also create a series of views based on plan type, such as: Plan View, Model View, Reflected View. Another approach could be by function; for example: Walls, Framing, Furniture. Only constructs can be referenced into a view drawing. To see elements in a view, they must be referenced by a construct.

3D view of first floor plan and framing plan

floor plan

framing plan

Working in a view, you add tags, dimension the building objects, and create a schedule table. Tags and schedule tables may contain a number of project properties, such as level and division assignments. For detailed information on annotating a project, see [Annotating a Project](#) on page 374.

After you have assembled a view drawing, you can create model space views in it. These model space views are later placed on sheets, creating sheet views.

Process Overview: Creating a View Drawing

Creating a view drawing involves the following main steps:

- 1 Select levels and divisions to include in the view drawing.
See [Creating a View Drawing: Assigning Levels and Divisions](#) on page 325.
- 2 Select the constructs to be contained in the view drawing.
See [Creating a View Drawing: Selecting the Constructs](#) on page 325.
- 3 If necessary, annotate and dimension the new view drawing.
See [Annotating a Project](#) on page 374.
- 4 Create model space views in the view drawing.
See [Creating a Model Space View](#) on page 334.

Creating a New View Drawing

A wizard leads you through the steps for creating a view drawing as described in the topics that follow.

NOTE View drawings are containers for constructs. Typically, you create a view drawing after you add the necessary constructs to the project. However, you can also create an empty view drawing first, and reference constructs into it later.

Creating a View Drawing: Defining General Properties

Use this procedure to specify the name, description, category, and template file for a new view drawing.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Views tab, and locate the Views category or subcategory where you want to add the new view drawing.

- 3 Add a new view drawing to the project using either of the following methods:
 - Right-click the category in which to place the new view drawing, click New View Dwg, and click the view type (General, Section/Elevation, or Detail).
 - On the toolbar at the bottom of the Views tab, click , and in the Add View dialog, click the view type (General, Section/Elevation, or Detail).

4 In the Add <View Type> View dialog, define the General properties for the view:

If you want to...

Then...

name the new view drawing

enter a name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see [Specifying Basic Project Properties](#) on page 239.

enter a description for the view drawing

click the value for Description, enter a description of the view, and click OK.

change the category of the view drawing

click the value for Category, and select a category from the list. The category you chose in step 3 is recommended.

select a different template file

click , and browse for a new template. The default template for view drawings set in the project is recommended.

5 Click Next, and continue with assigning levels and divisions. For more information, see [Creating a View Drawing: Assigning Levels and Divisions](#) on page 325.

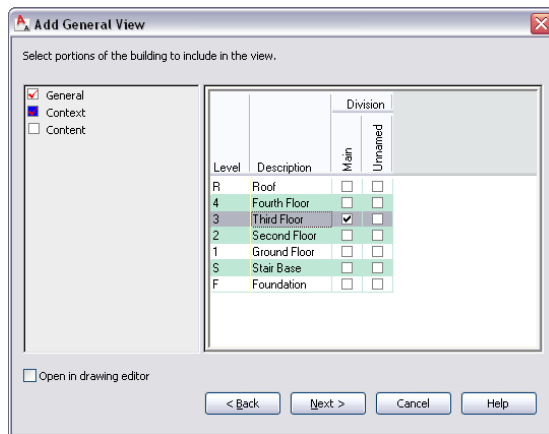

Creating a View Drawing: Assigning Levels and Divisions

Use this procedure to select portions of the building to include in the view by assigning levels and divisions. You can choose multiple levels and divisions for a view drawing; for example, to create a view of the entire building. This provides the context for the view drawing.

When you select one or more levels as a view context, all constructs that belong to the selected levels are referenced into the view drawing. The lowest level in the view is inserted at an elevation of 0' - 0". A spanning element would be referenced at the elevation of the lowest level to which it is assigned.

The levels and divisions you choose for the context serve as a preselection for selecting the constructs. For example, if you choose the first level and the south wing as the view context, all constructs belonging to that level and wing are selected as content in the next step by default. You can exclude constructs if you wish, but preselection saves time and effort.

- 1 Define the general properties of the view drawing, as described in [Creating a View Drawing: Defining General Properties](#) on page 324.

- 2 In the Add <View Type> View dialog, select the levels and divisions to include in the view drawing.
- 3 When you finish defining levels and divisions, click Next, and proceed to defining the view content. For more information, see [Creating a View Drawing: Selecting the Constructs](#) on page 325.

Creating a View Drawing: Selecting the Constructs

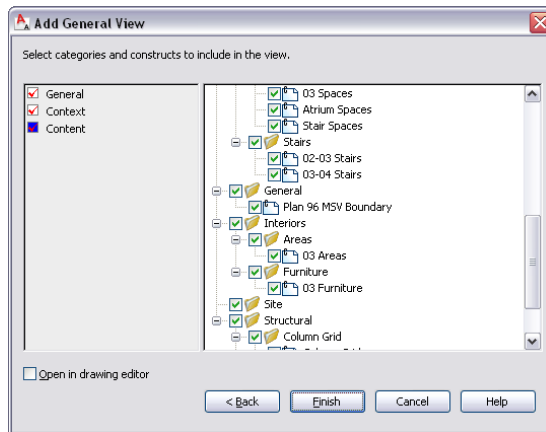

Use this procedure to select constructs to be referenced in the view drawing—the content. By default, each construct is attached as an external reference. For detailed information on attaching and overlaying external references, see “Reference Other Drawing Files” in AutoCAD Help.

Selecting constructs is the key to creating a view drawing. The view drawing consists mainly of referenced constructs.

There are several ways to make the selection of constructs easier:

- **Preselect levels and divisions:** Depending on the level and division you selected previously as the context, all constructs at that level and division are already checked.
- **Work with categories:** When you select a category, all constructs within that category are selected. When you add constructs to the category later, they are included in the view drawing.

1 Define the general properties and the context of the view drawing, as described in [Creating a View Drawing: Defining General Properties](#) on page 324 and [Creating a View Drawing: Assigning Levels and Divisions](#) on page 325.

2 Create the selection set of constructs for the view drawing:

If you want to...	Then...
select an entire category to include in the view drawing	select the category. All constructs in the category are selected automatically. When you add constructs to the category later, they are included in the view drawing.
select a construct to include in the view drawing	expand the categories as needed, and select the construct.
exclude a category from the view drawing	clear the category's box. All constructs in the category are cleared automatically.
exclude a construct from the view drawing	clear the construct.

3 Determine the referencing mode of the constructs in the view drawing:

If you want to...	Then...
attach the construct to the view drawing	select the construct, right-click, and click Set All to Attach. NOTE Attaching an external reference is the default insertion method for views. When the Set All to Attach command is unavailable, the construct has already been attached.
overlay the construct on the view drawing	select the construct, right-click, and click Set All to Overlay. NOTE When the Set All to Overlay command is unavailable, the construct has already been overlaid.

4 If you want to work in this view drawing immediately, select Open in drawing editor.

For information about other methods of opening views, see [Opening and Closing a View Drawing](#) on page 329.

5 Click Finish.

Displaying External References of a View Drawing

Use this procedure to display a list of xrefs attached to a view drawing and to access the functions available for each xref.

1 Click Window menu ► Project Navigator Palette.

2 Click the Views tab.

3 In the Drawing Explorer, locate the view drawing for which to display external references.

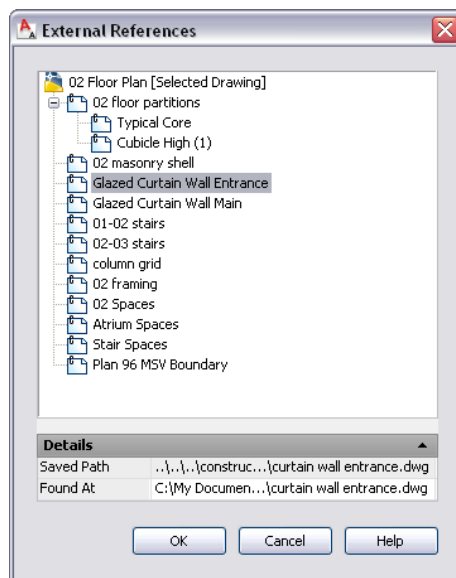

4 Select the view drawing.

5 Display the xrefs using either of the following methods:

■ Right-click, and click External References.

■ On the toolbar at the bottom of the Views tab, click  .

The External References dialog displays a list of xrefs in the view.

- 6 Expand or collapse the list by clicking individual items, and right-click to change the status of the xref, if necessary.

You can unload, reload, or detach the attached xref. For more information, see Reference Other Drawing Files in AutoCAD Help.

- 7 In the External References dialog, view the details of the xref:

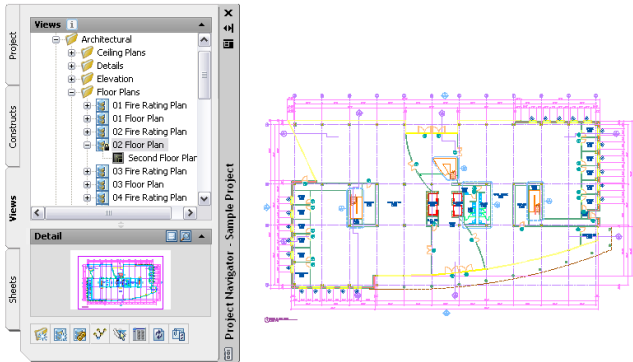

- Saved Path displays the saved path, if any, that is used to locate the xref. This path can be a full (absolute) path or a relative (partially specified) path.
- Found At displays the path where the xref was found. If no path was saved for the xref or if the xref is no longer located at the specified path, the program searches for the xref and displays the location here.

- 8 Click OK to close the dialog.

NOTE You can also display external references by opening the view drawing and using the AutoCAD Xref Manager. For more information, see “Overview of Referenced Drawings (Xrefs)” in AutoCAD Help.

Opening and Closing a View Drawing

Use this procedure to open and close a view drawing.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Views tab.
- 3 In the Drawing Explorer, locate the view drawing you want to open.
- 4 Open the view drawing using one of the following methods:
 - Select the view drawing, right-click, and click Open. (For information about additional commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.)
 - Double-click the view drawing.The view drawing opens in the drawing area of AutoCAD Architecture.
- 5 Close the view drawing using one of the following methods:
 - Right-click the view drawing in the Drawing Explorer on the Project Navigator, and click Close.
 - Click File ► Close.
- 6 Click Yes to save the changes in the drawing, if desired.

Creating a Model Space View Drawing from a Callout

In most cases, when you need a model space view containing a detail or a section/elevation, you will create it by using a callout tool. This method lets you specify whether the resulting model space view is placed in the view drawing you have created it from, in a different drawing, or in a new view drawing. For more information, see [Callouts](#) on page 2449.

NOTE You can still associate a callout symbol with the view later if you do not use a callout tool to create the model space view. For more information, see [Callouts](#) on page 2449.

On the Views tab of the Project Navigator palette, general, detail, and section/elevation view drawings are distinguished by different symbols:

View Drawing Type	Symbol
General view drawing	

View Drawing Type	Symbol
Detail view drawing	
Section/Elevation view drawing	

For more information, see [Creating a New View Drawing](#) on page 323.

Changing the Properties of a View Drawing

Use this procedure to change the general, context, or content properties of a view drawing.

If you change the name or the location (general properties) of constructs included in the view drawing, repath the project.

If you change the level or division assignment (context properties) of constructs included in the view drawing, reload the external references in the drawing. For information, see [Regenerating the View Drawings in a Project](#) on page 331.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Views tab.
- 3 In the Drawing Explorer, select the view drawing, right-click, and click Properties.
- 4 In the left pane of the Modify <View Type> View dialog, click the General category, and change the general view properties as needed:

If you want to...	Then...
change the name of the view drawing	enter a new name. If the project number is used as a prefix for project file names, you do not need to enter the prefix here. The complete name with prefix is displayed under File Name. For more information on prefixes, see Specifying Basic Project Properties on page 239. Changing the name prompts you to repath the project. For more information, see Repath the Project on page 372.
change the description of the view drawing	click the setting for Description, change the description of the view drawing, and click OK.
change the category of the view drawing	select one from the Category list. Changing the category prompts you to repath the project. For more information, see Repath the Project on page 372.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

- 5 In the left pane of the Modify <View Type> View dialog, click the Context category, and change the levels and divisions to include in the view drawing as needed.
- 6 In the left pane of the Modify <View Type> View dialog, click the Content category, and change the selected constructs for the view drawing as needed:

If you want to...	Then...
add a construct or category to the view drawing	select the construct or category.
remove a construct or category from the view drawing	select the construct or category.
change the referencing mode of a construct	right-click the construct, and select one of the following commands: <ul style="list-style-type: none"> ■ To attach a previously overlaid construct to a view, click Set All to Attach. ■ To overlay a previously attached construct to a view, click Set All to Overlay.

NOTE If one of these commands is unavailable, its mode is already selected.

- 7 Click OK.

Regenerating the View Drawings in a Project

Use this procedure to regenerate view drawings in the project when the content, levels, or divisions have changed. When you regenerate a view drawing, the external references used to generate it are attached, detached, or reloaded as needed.

- 1 On the Project Navigator palette, click the Views tab.
- 2 On the toolbar at the bottom of the tab, click the  button.
All view drawings in the project are updated with the changed constructs.

Placing a View Drawing onto a Sheet

When a view drawing is placed onto a sheet to create a sheet view, the model space settings (the viewport scale, layer settings, and display configuration) of the view drawing are used in the sheet view.

NOTE For information about placing a model space view, instead of a whole view drawing, onto a sheet, see [Placing a Model Space View onto a Sheet](#) on page 335.

When generating a model space view or a new view drawing from a callout tool, you define the drawing scale to be used. This scale is also used in any sheet views generated from the view.

Layer changes (including xref dependent layer changes) from the view drawing can be displayed and updated in the sheet view, if the project has been set up to synchronize sheets with views, as described in [Synchronizing View Drawing Layers with Sheet View Layers](#) on page 338.

If a project has been set up to synchronize view drawing layers with sheet view layers, viewport layer overrides in sheet views will be overwritten by the layer configuration of the view drawing when the external references are loaded or reloaded. If not, layers and xrefed layers in the sheet view will behave as normal.

1 Click Window menu ► Project Navigator Palette.

2 On the Sheets tab, click  (Sheet Set View) on the title bar.

3 In the Sheet Set view, locate the sheet into which you want to reference the view drawing.

4 Open the sheet using one of the following methods:

- Select the sheet, right-click, and click Open.
- Double-click the sheet.

The drawing containing the sheet opens in the drawing area. The sheet you selected is the active layout.

5 On the Project Navigator palette, click the Views tab.

6 Select the view drawing you want to place on the sheet, and drag it from the Drawing Explorer to the drawing area of the sheet.

TIP While inserting the view drawing on a sheet, you can change the scale of the resulting sheet view by right-clicking and selecting a different scale before defining the insertion point. After creating the sheet view, you can change its scale on the Properties palette.

NOTE Sheet views are inserted with their own layer key. By default, the sheet view layer is G-Anno-Nplt.

Electronically Transmitting a View Drawing

Use this procedure to electronically transmit a view drawing.

Electronically transmitting a drawing means that you package the drawing for delivery in electronic form. Drawing files in the transmittal package automatically include all related dependent files, such as external references and font files.

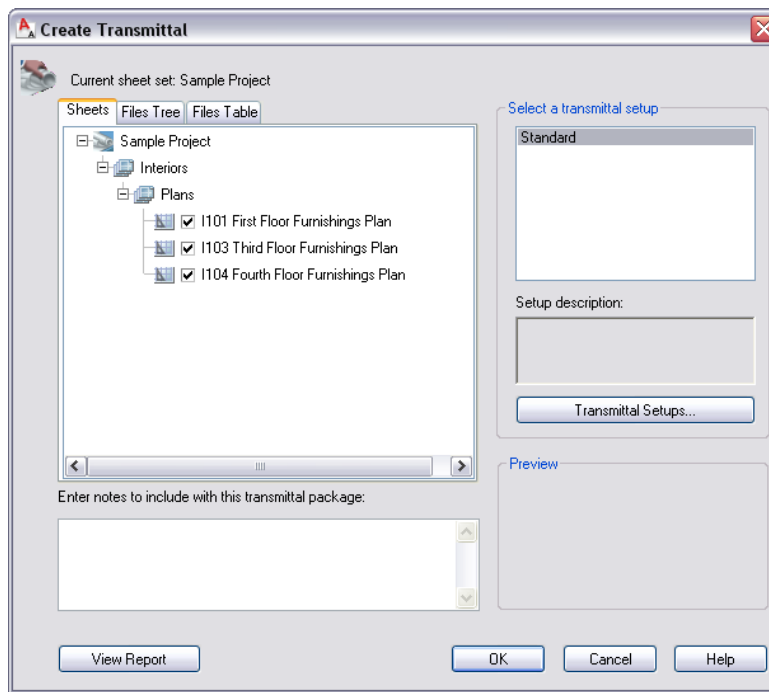

NOTE If the view contains multiple model space views, you are prompted to drop each in succession.

For more information about electronic transmittal, see “Package a Set of Files for Internet Transmission” in AutoCAD Help.

1 Click Window menu ► Project Navigator Palette.

2 Click the Views tab.

3 Select the view drawing you want to transmit, right-click, and click eTransmit.

- 4 In either the Files tree tab or the File Table tab, select the components to be included in the electronic package.
The Files Tree tab displays the included files sorted by type. The Files Table tab displays all files in a list view. You can sort the list by name, path, type, version, size, and date.
- 5 To include project information, double-click the setup under Select a transmittal setup, and in the Modify Transmittal Setup dialog, select Include project information under Include options.
For detailed information about packaging project information for an electronic transmittal, see [Electronically Transmitting a Project](#) on page 252.
- 6 Click OK to start the electronic transmittal.

Deleting a View Drawing

Use this procedure to delete a view drawing.

For information on the consequences of deleting view drawings, see [Changing Views: Interactions with the Project](#) on page 341.

The view drawing must be closed in order to delete it.

NOTE Do not delete a view drawing from Windows Explorer. This might result in inconsistent project data.

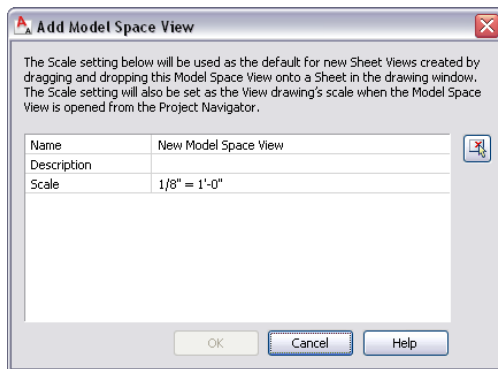

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Views tab.
- 3 In the Drawing Explorer, select the view drawing, right-click, and click Delete.
- 4 Click Yes in the subsequent message box.

Creating a Model Space View

A model space view is a named view that represents a view definition in model space. You can create multiple model space views in a view drawing, each with its own name, description, layer settings, and drawing scale.

When a model space view is placed onto a sheet, its own viewport scale, layer settings, and the display configuration of the view drawing are used in the sheet view created. The view direction, however, defaults to plan.

You can associate an AutoCAD layer snapshot with a model space view. If you then place the model space view on a sheet, the AutoCAD layer snapshot determines the On/Off and Freeze/Thaw settings of the model space layers. The layer settings from the layer snapshot will only be used if the project has not been set up to synchronize view drawing layers with sheet view layers. If that synchronization has been set up, the layer settings from the view drawing's model space are used, and any attached layer snapshots on the model space view are ignored.

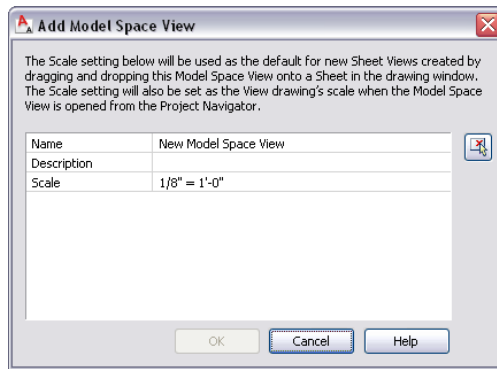

Defining a model space view

Displaying a model space view

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Views tab, select the view drawing in which you want to create a model space view, right-click, and click Open.
- 3 Select the view drawing again, right-click, and click New Model Space View.

4 In the Add Model Space View dialog, enter a name for the new model space view.

5 Define the settings for the new model space view:

If you want to...

Then...

enter a description for the model space view

click the setting for Description and add a description of the model space view.

change the scale of the model space view

select a scale from the list of those used in the current view drawing.

6 Click  to define the boundaries of the new model space view.

7 Specify the first boundary point of the desired view area.

8 Specify the second boundary point of the desired view area.

9 Click OK.

The new model space view is listed under the view drawing from which it was created.

10 To associate an AutoCAD layer snapshot with the new model space view, select the model space view in the Drawing Explorer, right-click, and click Save Layer State.

11 Open the model space view using either of the following methods:

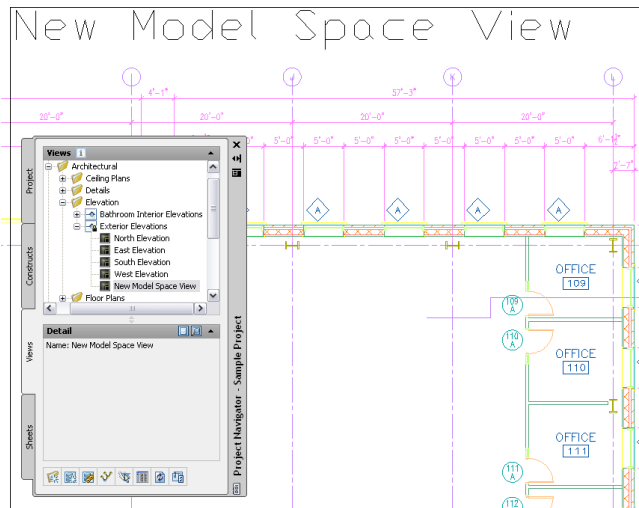

- double-click it in the Drawing Explorer.
- select the model space view in the Drawing Explorer, right-click, and click Open.

Placing a Model Space View onto a Sheet

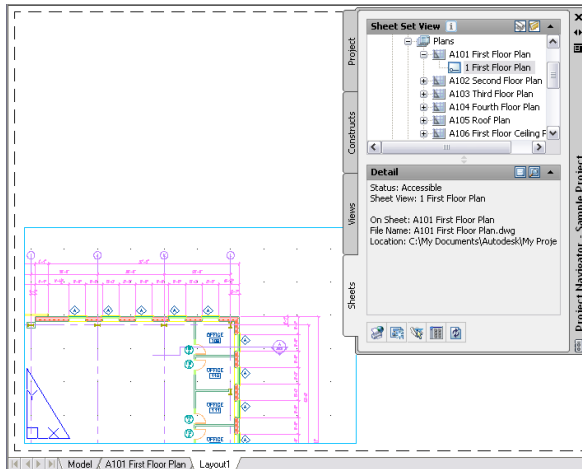

Use this procedure to place a model space view onto a sheet, creating a sheet view. A sheet can contain any number of sheet views.

When a model space view is placed on a sheet, it retains its own drawing scale and layer settings but uses the display configuration of the view drawing. The view direction of the sheet view is determined by the sheet.

Model space view of plan detail

Sheet view placed on sheet

- 1 Click Window menu ► Project Navigator Palette.
 - 2 On the Sheets tab, click  (Sheet Set View) on the title bar.
 - 3 In the Sheet Set view, locate the sheet into which you want to reference the model space view, and open it using one of the following methods:
 - Select the sheet, right-click, and click Open.
 - Double-click the sheet.
- The drawing containing the sheet opens in the drawing area with the selected sheet as the active layout.
- 4 On the Project Navigator palette, click the Views tab.
 - 5 Use one of the following methods to place the desired model space view on the sheet:
 - Select the model space view, right-click, and click Place on Sheet. Then, specify an insertion point on the sheet.
 - Select the model space view, and drag it from the Project Navigator to the drawing area of the sheet.

You can disable image previews to improve performance while dragging a view from the Project Navigator palette. For more information, see [Drawing Explorer Tooltips](#) on page 268.

You can change the scale of the resulting sheet view by right-clicking and selecting a different scale before defining the insertion point. After creating the sheet view, you can change its scale on the Properties palette.

NOTE Sheet views are inserted with their own layer key. By default, the sheet view layer is G-Anno-Nplt.

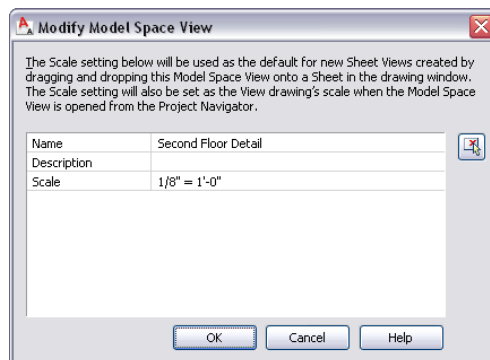

Changing the Properties of a Model Space View

Use this procedure to change the properties of a model space view.

NOTE If you change the properties of a model space view, instances of that view that have been placed as sheet views on a sheet are not updated. Only new instances of the model space view will have the new settings. For example, if a model space view named West Stairs is defined with a scale of $1/8'' = 1'-0''$, it is placed with that scale on a sheet. If the scale is later changed to $1/4'' = 1'-0''$, the new scale is not updated on existing sheet views, but will be used for new sheet views.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Views tab.
- 3 In the Drawing Explorer, select the view drawing that contains the model space view you want to change, and expand it.

NOTE To change the name, description, or scale of a model space view, the associated view drawing does not need to be open. To change the model space boundaries, the associated view drawing must be open.

- 4 Right-click, click Properties, and change the properties of the model space view as needed:

If you want to...

Then...

change the name of the model space view enter a new name.

change the description for the model space view click the setting for Description and change it.

change the scale of the model space view select a new scale from the list.

- 5 To change the model space boundary, click , and redefine the boundaries on screen.
- 6 Click OK.

Deleting Model Space Views

Use this procedure to delete a model space view.

When you delete a model space view, it is only deleted from the view drawing; existing sheet views based on a deleted model space view remain in their respective sheets.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Views tab.
- 3 Select the view drawing that contains the model space view you want to delete, and expand it.
- 4 Select the model space view to delete, right-click, and click Delete.

NOTE You can also delete model space views by the following method: Click View menu ► Named Views. Then, delete the model space view from the AutoCAD Named Views dialog.

Synchronizing View Drawing Layers with Sheet View Layers

You can set up your project so that the sheet view layer settings are updated from the layer settings in the model space of the view drawing. The synchronized layer settings include:

- the layer states (on/off, thawed/frozen).
- the layer properties (layer, color, linetype, plotstyle) of layers native to the view drawing.
- the layers in external references attached to the view drawing through constructs and elements.

View drawing with xref dependent layer changes

Sheet view with layer settings from view

Before you can use the layer settings of the view drawing in a sheet view, the following conditions must be met:

- In the Project Properties dialog, the setting for synchronizing view drawing layers with sheet view layers must be activated. For more information, see [Configuring an Existing Project to Synchronize View Drawing Layers with Sheet View Layers](#) on page 341.
- In both the view drawing and the sheet drawing, the VISRETAIN variable should be set to 1.
- The VPLAYEROVERRIDESMODE variable for the AutoCAD session must be set to 1.
- The project in which the view drawing and the sheet drawing reside must be the currently active project. If you open the sheet drawing outside of Project Navigator while its project is not current, the synchronization will not take place. The layer settings from the last successful synchronization will remain in effect.
- The layer synchronization takes place only if the view drawing and sheet drawing are located within the project context. If either the view drawing or the sheet drawing have been disconnected from the project, the standard AutoCAD VISRETAIN behavior controls how the externally referenced layer settings resolve. If you register both files back into the project, you can synchronize the view and sheet layers again.

Synchronization of view drawing layers with sheet view layers occurs in the following instances:

- Loading or reloading external references
- Background plotting and publishing of the sheet

When a project is set to synchronize view drawing layers with sheet view layers, the following behaviors will differ from standard AutoCAD behavior:

- If a layer is off or frozen in the model space of the view drawing, it will be frozen in synchronized sheet views.
- Plotting or publishing output will include synchronized sheet views except when you are foreground plotting the active sheet; in this case, the current display settings in the sheet view will be used. In all other cases, the output may display the updated, synchronized layer settings, even though the open sheet view remains out of synch.
- Synchronization of layer settings will never occur during electronic transmission of a sheet.

If you copy or cut and paste a sheet view, the new copies will not be linked to the original source view. To create multiple sheet views of a model space view, drag the model space view to the sheet again. This creates a new sheet view with the same model space view content.

When you drag a view drawing with multiple model space views onto a sheet, the sheet view layers will be synchronized with the view drawing after all sheet views are created.

When the project is set to synchronize view drawing layers with sheet view layers, any AutoCAD layer snapshots that are attached to model space views will be ignored. If the project is not set to synchronize view drawing layers with sheet view layers, then the layer snapshot settings will be retained. However, any layer that did not exist when the AutoCAD layer snapshot was created will be frozen in the sheet view, regardless of whether it is frozen or thawed in the view drawing. The new layer will also be listed as an unreconciled layer in Layer Manager. For more information, see [New Layer Notification](#) on page 505.

Display Configurations in Sheet Views

When a project is set to synchronize view drawing layers with sheet view layers, changes to the display configuration of the view drawing will not be updated in the sheet view. The display configuration initially used in the sheet view will be the same configuration that was active when the view drawing or model space

view was first referenced into the sheet drawing, unless changed in the sheet view. Use one of the following methods to update the display configuration of the view drawing in a sheet view:

- Edit the sheet view directly by double-clicking it and changing the display configuration in the sheet view.
- Create a new sheet drawing, and reference the view drawing that has the desired display configuration.

Viewport Layer Overrides in Sheet Views

Sheet views created in AutoCAD Architecture allow for layer overrides in paper space viewports. (For more information, see [Overriding Layer Properties in Layout Viewports](#) on page 494.) If the project has been set to synchronize view drawing layers with sheet view layers, any viewport-specific overrides in the sheet view will be overwritten when the view drawing xrefs are reloaded in the sheet view. Otherwise, sheet view specific overrides behave as normal viewport layer overrides. In this case, the xref-dependent layer changes from the view will be marked as viewport overrides in the sheet.

Process Overview: Synchronizing View Drawing Layers with Sheet View Layers

Synchronizing view drawing layers with sheet view layers entails the following basic steps:

- 1 Set up the project to synchronize view drawing layers with sheet view layers. See [Configuring an Existing Project to Synchronize View Drawing Layers with Sheet View Layers](#) on page 341.
- 2 Create view drawings to define layer settings, including xref dependent layers. See [Creating a New View Drawing](#) on page 323 and [Creating a Model Space View Drawing from a Callout](#) on page 329.
- 3 Verify that the VISRETAIN variable in the view drawing is set to 1 before saving and closing the view drawing. For more information, see [Override Layer Properties in Viewports in AutoCAD Help](#).
- 4 Create a sheet, as described in [Creating a Sheet](#) on page 345.
- 5 Verify that the VISRETAIN variable of the sheet drawing is set to 1.
- 6 Verify that the VPLAYEROVERRIDESMODE variable for the AutoCAD session is set to 1. For more information, see [Override Layer Properties in Viewports in AutoCAD Help](#).
- 7 Place view drawings or model space views on the sheet as described in [Placing a Model Space View onto a Sheet](#) on page 335 and [Placing a View Drawing onto a Sheet](#) on page 331.
- 8 If you have set the project to synchronize view drawing layers with sheet view layers after you created sheet views, close and reopen the existing sheet views, or reload their xrefs to perform the synchronization.
- 9 If you have set a legacy project from a previous version of the software to synchronize view drawing layers with sheet view layers, you may need to manually link the sheet views to the view drawing. If the sheet views need to be linked, they will display a warning icon  in the Drawing Explorer. In that case, follow the instruction in [Linking a Legacy View Drawing to a Sheet View](#) on page 340 to link the sheet view to the view drawing.

Linking a Legacy View Drawing to a Sheet View

In order to synchronize the view drawing layers with the sheet view layers, the sheet view and view drawing must be linked. In legacy projects created with a previous version of the software, where a view drawing

without model space views was placed on a sheet, this information does not exist and must be added by linking the sheet view to the view drawing.

When this happens, the sheet view icon on the sheet set tree displays a warning icon (). The sheet view must be linked to the view drawing to establish the link and allow synchronization.

NOTE In other cases where the link between a sheet view and its associated view drawing is broken, no warning icon will be displayed. In these cases, the sheet view must be recreated in the sheet by dragging the model space view or view drawing onto the sheet again. This creates a new sheet view with the correct connection. The connection between sheet view and view drawing or model space view can be broken by: renaming of the view drawing, renaming of the model space view, copying and pasting a sheet viewport, or creating a viewport by using the MVIEW command.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Sheets tab, open the sheet containing the sheet view to be linked.
- 3 Select the desired sheet view, and drag it onto a view drawing on the Views tab.
The sheet view node will be updated when you expand the containing sheet node, when you click Refresh  on the Project Navigator palette, or when the linking is complete.

Configuring an Existing Project to Synchronize View Drawing Layers with Sheet View Layers

At any time during a project, you can activate synchronization of view drawing layers with sheet view layers. Selecting this option does not update existing sheet views instantly; the update occurs the next time they are opened or their external references are reloaded.

- 1 At the bottom of the Project Navigator palette, click .
- 2 In the Project Browser, select the currently active project, right-click, and click Properties.
- 3 Under the Basic category, expand Drawing Settings.
- 4 For Match Sheet View Layers to View, select Yes.
- 5 Click OK to close the Project Properties dialog, and click Close to close Project Browser.
New sheet views you create will use the layer settings of the associated view drawing. Existing sheet views will be synchronized the next time they are opened or have their xrefs are reloaded.

Changing Views: Interactions with the Project

Changes made to one part of a project frequently influence other parts of the project. Listed below are the effects of some of the common changes you can make to a view.

- **Adding a new view drawing:** When you create a new view drawing, all or most of the referenced constructs should be present. For easy selection of constructs, place them in categories.
- **Changing the view name and category (location):** A view drawing has a number of constructs referenced into it, and the view drawing itself can be referenced into a sheet. Therefore, any name and location changes to a view drawing need to be updated throughout the project. To update the path, repath the project as described in [Repath the Project](#) on page 372.

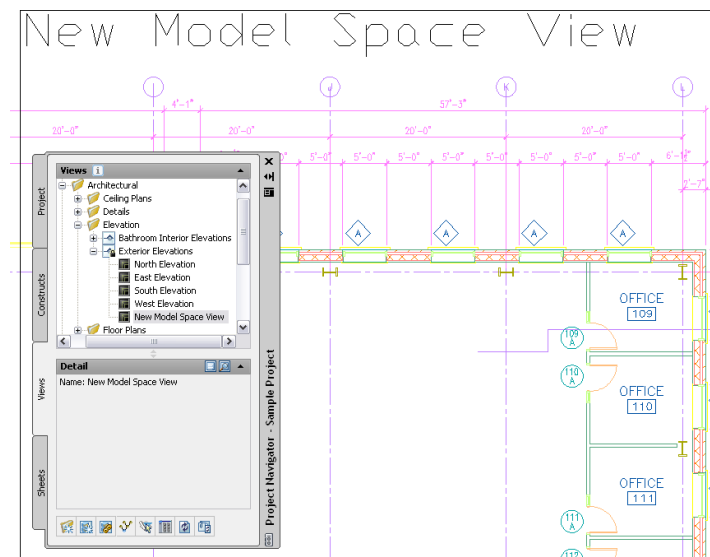

- **Changing the content of a view drawing:** Any changes made to the content of a view are also made to the sheets that reference that view. If you have created model space views and sheet views from the view drawings, they will be updated to reflect the changed content of the view drawing.
- **Deleting a view drawing:** If you delete a view drawing that has been referenced into a sheet, that sheet now has missing references. Check to see if the view is still used in a sheet before deleting it. If you delete a view drawing, all model space views associated with that view are deleted also. Any sheet views that reference these views will have missing references.
- **Changing a model space view:** Changes made to the boundaries or scale of an existing model space view are not updated in existing sheet views derived from this view. To change the sheet view, delete it and re-create it from the updated model space view. If the content of a model space view changes due to changes in the view drawing, these changes will be updated in the sheet view.
- **Deleting a model space view:** When you delete a model space view, all sheet views created from it remain intact. For definition, sheet views need only the building model in the view drawing.

Sheets

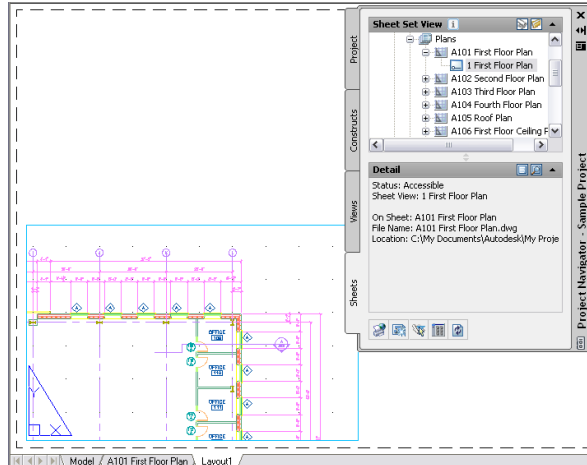

Sheets are used to plot drawings of your building project. The sheet system in AutoCAD Architecture consists of these components:

- **Sheet:** A sheet is a paper space layout that has been registered as a sheet. A sheet can contain one or more sheet views.
- **Sheet views:** A sheet view is a paper space viewport created by dragging and dropping a model space view from the Project Navigator onto a sheet.

Model space view of plan detail

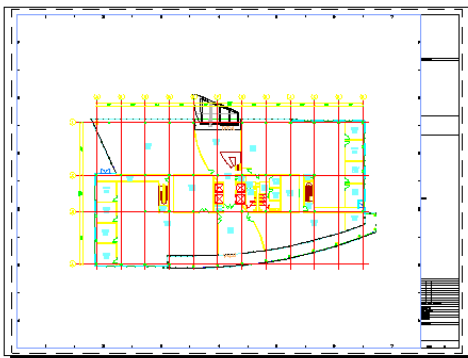

Sheet view placed on sheet

- Sheet sets: A sheet set is a collection of sheets. Within the sheet set, sheets are organized in sheet subsets.
- Sheet drawing: A sheet drawing is a drawing file containing one or more sheets.

Sheets, sheet subsets, sheet views, and sheet drawings are listed on the Sheets tabs of the Project Navigator.

Sheet with building plan view

Sheets and Sheet Drawings

The National CAD Standard (NCS) mandates that sheets should be stored in individual drawings, each with one sheet layout. The drawing name should be the sheet number in its sheet set. The AutoCAD Architecture Project Navigator follows this standard, so that each new sheet is placed in a new sheet drawing. You can, however, create multiple sheets in one sheet drawing, if necessary. For more information, see [Importing the Current Layout as a Sheet](#) on page 351.

Sheets and Annotation

Although it is recommended that annotation be placed in a view, you can add annotation, dimensions, and schedule tables in a view or a sheet, depending on your specific workflow and needs. Scheduling in AutoCAD Architecture makes it easy to add annotation in both views and sheets. For more information on annotating a project, see [Annotating a Project](#) on page 374.

Sheet Drawing Files

A sheet drawing is a DWG file. As opposed to other non-project drawing files, an XML file with the same name is created when you create a sheet drawing. The accompanying XML file contains information to connect the drawing file with the project.

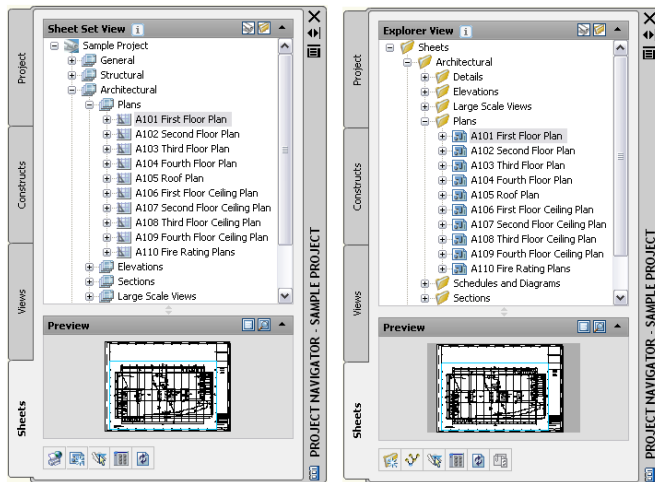

NOTE The XML file is created and updated automatically. You do not need to edit it but be careful not to accidentally delete it in Windows Explorer.

Sheets and sheet views are contained within sheet drawings. There are no corresponding XML files for individual sheets or sheet views.

Sheet Categories and Subsets

Sheets are organized in 2 different methods. In the Explorer View, sheet drawings are placed in category folders. When you create sheets or sheet views within a sheet drawing, they are placed in the host sheet drawing.

Sheet tab with Sheet Set View of project (left) and Explorer View (right)

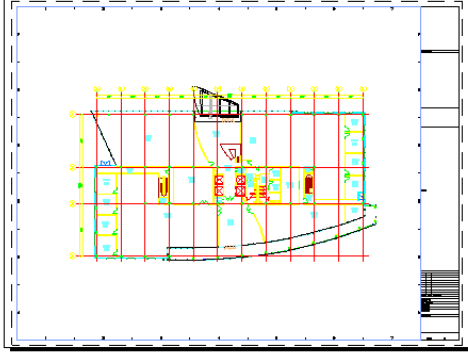

In the Sheet Set view, sheets are organized in sheet subsets. Sheet subsets are a logical structure rather than a physical one. This means that the sheet and subset organization may not reflect the drawing file organization on disk. You can logically rearrange sheets into a different subset within the Sheet Set View, but that will not change their physical location in the category or folder. The sheet category folder does not need to be identical to the sheet subset in which the sheet is placed. However, to avoid confusion, it is recommended to have parallel structures in the sheet set and the sheet categories. When you remove a sheet from a sheet subset in the Sheet Set view, only the reference to the sheet in the subset is removed; the layout itself and its containing sheet drawing are not deleted from the Sheets folder or subfolder. For more information, see [Sheets](#) on page 342.

When to Start with Sheets

Sheets are the final output of a building design. You create sheets after you have created constructs for all parts of the building model, along with the necessary model views, detail views, and section/elevation views. You then drag the views onto the sheets to create sheet views.

Designing a building is an iterative process. You will revisit planning stages and make changes to constructs, elements, and views. These changes are reflected in sheets.

Sheet with building plan

Keep these points in mind when creating sheets:

- The content of a sheet depends on the views that are referenced into it and the constructs referenced into the views.
- The viewport settings of a sheet view are defined in the model space view placed on the sheet from a view drawing. For more information, see [Creating a Model Space View](#) on page 334.
- A sheet contains all plotting-specific settings and title blocks.

Creating a Sheet

Use this procedure to create a new sheet. Each new sheet is created in a new sheet drawing.

1 Click Window menu ► Project Navigator Palette.

2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.

3 Add a new sheet to the project using one of the following methods:

- Right-click the subset in which to place the new sheet, and click New ► Sheet.

- In the toolbar at the bottom of the Sheets tab, click .

4 If you selected to be prompted for a template each time you create a new sheet, you are prompted now for a sheet template. Select a drawing template and a layout from a DWT, DWG or DWS file as a sheet template, and click OK.

If you selected not to be prompted for a sheet template when creating new sheets, the default template defined in the project sheet set or the sheet subset is used.

5 Define the sheet properties:

If you want to...

Then...

number the new sheet

enter a number. If you selected a project prefix in the project settings, the prefix is placed in front of the sheet number in the file

If you want to...**Then...**

name. For more information, see [Specifying Basic Project Properties](#) on page 239.

enter a title for the sheet

enter text under Sheet title. Commas, ampersands, and semicolons are allowed in sheet titles. The sheet title is used in these locations:

- As the display name of the sheet in the Drawing Explorer.
- As the display name of the sheet in a sheet list.
- As the sheet layout name in the sheet drawing.

enter a file name for the sheet

enter one under File name.

change the folder in which the sheet is saved

The folder path defined in Project Properties is displayed. This field is read only. For information about changing the Folder path, see [Specifying Basic Project Properties](#) on page 239.

select a new sheet template

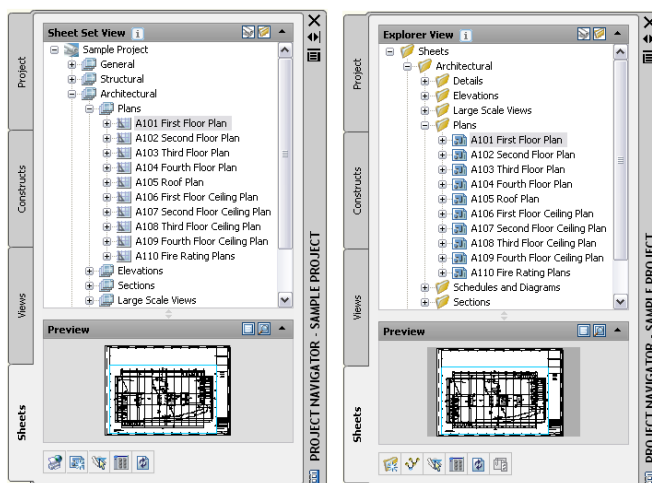

enter a template path.

NOTE If the settings for the storage folder and the sheet set template are read only, these settings are defined in the sheet subset. To change them, you must change the properties of the sheet subset.

6 Click OK.

You can access the new sheet from 2 locations:

- In the Sheet Set view, the new sheet is displayed under the sheet subset in which you created it.
- In the Explorer View, the sheet drawing and the sheet are displayed under the folder category in which you saved the sheet.

Sheet Set View on project (left) and Explorer View (right)

By default, these have the same organization, but depending on your project setup, these 2 locations can have different names and structures.

Setting the Properties of the Project Sheet Set

Use this procedure to set the properties of the project sheet set.

The properties of the project sheet set are initially defined by the sheet set template you assigned in [Creating a New Project](#) on page 235. However, you can change the settings for an individual project.

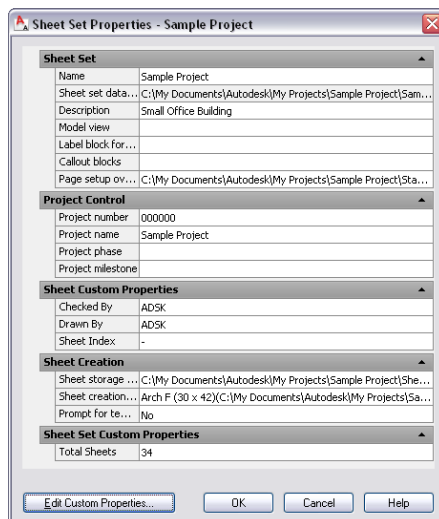

NOTE A number of settings apply only to sheet sets referenced in the AutoCAD Sheet Set Manager. For a sheet set that will be used in an AutoCAD Architecture project, most settings come from the project, and not from the sheet set template.

The following settings are ignored when you use a sheet set template in an AutoCAD Architecture project:

- Sheet set data file: The DST file is always stored in the root folder of the project.
- Model view: Model view drawing locations are not tracked in AutoCAD Architecture sheet sets. They are automatically taken from the project views.
- Label block for views: Label blocks are not recommended in an AutoCAD Architecture project. Use callout tools instead. For more information, see [Callout Tools in ProductName](#) on page 2451.
- Callout blocks: Callout blocks are not recommended in an AutoCAD Architecture project. Use callout tools instead. For more information, see [Callout Tools in ProductName](#) on page 2451.
- Sheet storage location: The sheets in a project are always stored in the Sheets folder of the project, or in one of its subfolders.

NOTE If you enter a project name and project number under Project Control that differs from the project name and number you have entered in [Creating a New Project](#) on page 235, you will get a message when editing the sheet set properties, and be prompted to consolidate the information.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the root node of the sheet set, right-click, and click Properties.

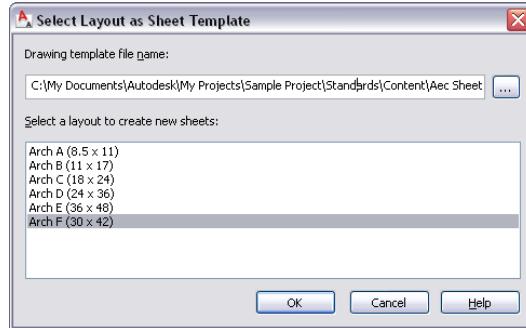

- 4 Expand Sheet Set.
- 5 To define page setup overrides in the project, click the setting for Page setup override files.
- 6 In the Select Template dialog, select a drawing template (DWT) file.

NOTE Select a template that contains named paper space layouts, and make sure that their plot areas have been set to Layout. Otherwise, you cannot use them as page setup overrides.

7 Expand Sheet Creation.

In this category, you define settings for the sheets you create within the sheet set.

8 To define a default template for new sheets, click the setting for Sheet creation template.

9 Click  to browse for a drawing (DWG) or template (DWT) file, and click Open.

10 Select the default layout you want to use to create new sheets. Then, click OK.

11 Specify if you want to be prompted for the sheet template each time you create a new sheet:

If you want to...

Then...

be prompted for a sheet template each time you create a new sheet select Yes.

always use the default sheet template select No.

12 To add, edit, or delete custom properties, click Edit Custom properties.

For information about Custom Properties, see “Include Information with Sheets and Sheet Sets” in AutoCAD Help.

NOTE When working in an AutoCAD Architecture project, you can also use the project properties. For more information, see [Adding Detailed Information to Project Properties](#) on page 242.

13 Click OK.

If you have entered a project name and project number in the sheet set properties that differs from the project number and name defined in [Creating a New Project](#) on page 235, a message appears informing you of the mismatch. For information about consolidating the inconsistent name and number, see [Consolidating Inconsistent Project and Sheet Set Information](#) on page 249.

Creating a Sheet Subset

Use this procedure to create a new sheet subset. You create sheet subsets in the Sheet Set view of the Sheets tab.

1 Click Window menu ► Project Navigator Palette.

2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.

3 Select the sheet subset under which you want to create a new subset, right-click, and click New ► Subset.

4 Define the properties of the new subset:

If you want to...	Then...
change the name of the sheet subset	enter a new name.
set a different default directory for new sheets created in this subset	under Store new sheet DWG files in, click  . Then, select a folder into which new sheets should be placed, and click Open.
set a different default template for new sheets created in this subset	under Sheet creation template for subset, click  . Then, use the default or select a DWG or DWT file, and select a layout of the file.
be prompted for a template each time you create a new sheet in this subset	select Prompt for template.

5 Click OK.

Setting the Properties of a Sheet Subset

Use this procedure to set the properties of a sheet subset.

A sheet subset is a logical grouping of sheets and subsets. Subsets help you organize your sheet by allowing you to create sheet subsets for plan sheets, detail sheets, elevation sheets, or other grouping criteria.

You can set the following parameters for a sheet subset:

- The default template for new sheets created in this subset
- Whether to be prompted for a sheet template each time you create a new sheet

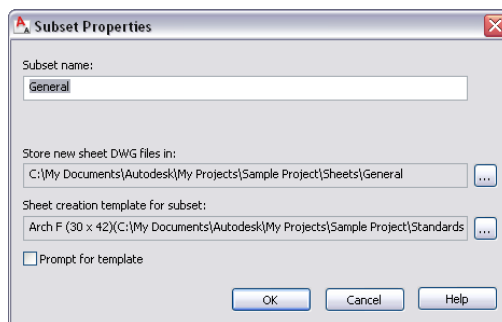

These parameters are set in sheet set properties., but you can override them for individual subsets. This would be useful if you want to use different sheet templates for plan sheets and detail sheets.

If you have no sheet subsets in your sheet set yet, see [Creating a Sheet Subset](#) on page 348.

1 Click Window menu ► Project Navigator Palette.

2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.

3 Select the sheet subset for which to change properties, right-click, and click Properties.

4 Change the properties of the sheet subset:

If you want to...	Then...
change the name of the sheet subset	enter a new name.
set a different default directory for new sheets created in this subset	under Store new sheet DWG files in, click  . Then, select a folder into which new sheets should be placed, and click Open.
set a different default template for new sheets created in this subset	under Sheet creation template for subset, click  . Then, select a DWG or DWT file, and select a layout of the file as the default sheet template.
be prompted for a template each time you create a new sheet in this subset	select Prompt for template.

5 Click OK.

Removing a Sheet Subset

Use this procedure to remove a sheet subset from the project sheet set. When you delete a sheet subset, no sheets or sheet drawings are deleted.

You can remove a sheet subset only if it contains no sheets.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet subset you want to delete, right-click, and click Delete.

Importing Sheets into the Sheet Set

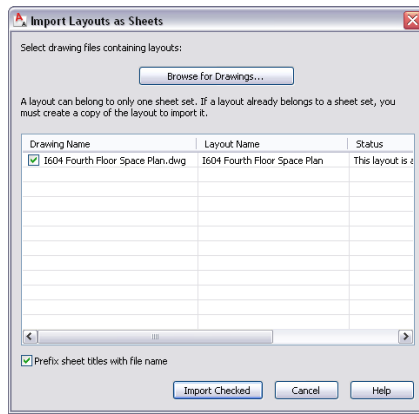

Use this procedure to import a sheet into the project sheet set.

When you import a layout as a sheet, the layout and its associated sheet drawing are physically not moved from their original location. For example, if you import a layout from the drawing C:\Additional Drawings\Example.dwg into the project sheet subset Architectural, the selected sheet is displayed under the Architectural subset; the Example.dwg file, however, is not moved into the Sheets folder of the project. This drawing remains in its original location under C:\Additional Drawings\Example.dwg.

If you switch to the Explorer View, the imported sheet drawing is listed if the drawing is located outside the folder. It is marked with a special icon .

A sheet can belong to only one sheet set. You cannot import a sheet that is already part of another sheet set.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet subset into which to import the sheet, right-click, and click Import Layout as Sheet.

- 4 Click Browse for Drawings.
- 5 Browse for the drawing file containing the sheet you want to import, and click Open.
- 6 Select the sheet layout to import.

NOTE You can select multiple layouts here.

- 7 If you want the sheet name to be prefixed with the sheet drawing's file name, select Prefix sheet titles with file name.
- 8 Click OK.

NOTE To import a layout that is currently open and displayed on the drawing screen, select the subset in which it should be displayed, right-click, and click Import Current Layout as Sheet.

Importing the Current Layout as a Sheet

Use this procedure to import the current layout as a sheet in the sheet set.

In some cases, you might have sheet drawings that do not conform to the NCS standard, and contain more than one sheet. When you create a sheet in the Drawing Explorer of AutoCAD Architecture, only the first sheet in the sheet drawing is registered. To register other sheets as well, you may import them while the sheet drawing is open and the layout is displayed.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Explorer View) in the title bar.
- 3 Locate the sheet drawing that has additional layouts you want to register as a set.
- 4 Double-click the sheet drawing.
- 5 On the drawing screen, click the layout you want to import to make it current.
- 6 On the Project Navigator palette, click .
- 7 Navigate to the sheet subset in which the additional sheet should be placed, right-click, and click Import Current Layout as Sheet.

The sheet is added to the sheet subset. When you change to the Sheet Set view, and expand the sheet drawing containing the sheet, you can see that the additional sheet is now listed under the sheet drawing.

Opening and Closing a Sheet

Use this procedure to open and close a sheet. For information about additional commands available on the context menu, see [The Drawing Explorer Context Menu](#) on page 264.

When you open a sheet, the sheet drawing containing the sheet opens with the correct sheet (layout) displayed.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Sheets tab, click  (Sheet Set View) in the title bar.

NOTE You can also open a sheet from the Explorer View of the Sheets tab.

- 3 Locate the sheet you want to open.
- 4 Open the sheet using one of the following methods:
 - Select the sheet, right-click, and click Open.
 - Double-click the sheet.

The drawing containing the sheet opens in the drawing area of AutoCAD Architecture. You can now edit it. To close the sheet, you must close the sheet drawing.

- 5 Close the sheet drawing using one of the following methods:
 - Right-click it in the Drawing Explorer, and click Close.
 - Click File ► Close.
- 6 Click Yes to save the changes in the drawing, if necessary.

- 7 To update the preview of the sheet in the Drawing Explorer, click  (Refresh Project).

Changing the Properties of a Sheet

Use this procedure to change the properties of a sheet.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet for which you want to change properties, right-click, and click Properties.
- 4 Change the sheet properties as necessary.
 - For more information, see “Include Information with Sheets and Sheet Sets” in AutoCAD Help.
- 5 Click OK.

Removing a Sheet

When you remove a sheet from the sheet set, the sheet drawing and its companion XML file are deleted unless other sheets exist in the sheet drawing. If other sheets exist in the sheet drawing, or the sheet drawing is located outside of the sheet folder, then only the reference to the sheet is removed. When only the reference is removed, the sheet drawing is still physically saved on disc.

You must be in the Sheet Set view on the Sheets tab of the Project Navigator to remove sheets.

Removing a sheet from the sheet set has the following consequences:

- The sheet cannot be selected for a sheet selection.
- The sheet will not be included in new sheet lists.
- The sheet will not be included in electronic packages of the sheet set.
- The sheet will not be included in archive packages of the sheet set.
- The sheet will not be included when you publish the sheet set to a plotter or to a DWF file.

To remove a sheet from the sheet set:

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet you want to remove from the sheet set, right-click, and click Delete.
- 4 In the Confirm Sheet Delete dialog, click Yes.

Deleting a Sheet Drawing

You must delete sheet drawings from the project using the Explorer View on the Sheets tab of the Project Navigator. When you delete a sheet drawing, all sheet layouts in the sheet drawing are deleted from this project.

To delete a sheet drawing from the project:

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Explorer View) in the title bar.
- 3 Select the sheet drawing you want to delete, right-click, and click Delete.
- 4 In the Confirm Sheet Delete dialog, click Yes.

Creating a Sheet View

Use this procedure to create a sheet view on a sheet.

A sheet view is a paper space viewport on a sheet that is created when a model space view or view drawing from the Project Navigator is dragged and dropped onto a sheet. For information on model space views, see [Creating a Model Space View](#) on page 334.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 In the Sheet Set view, locate the sheet on which you want to place a new sheet view.
- 4 Open the sheet using one of the following methods:
 - Select the sheet, right-click, and click Open.
 - Double-click the sheet.

The sheet opens in the drawing area of AutoCAD Architecture. The sheet you have selected is the active layout.

- 5 On the Project Navigator palette, click the Views tab.

6 Select the model space view, right-click, and click Place on Sheet. Then, select an insertion point on the sheet.

Alternatively, drag the model space view from the Project Navigator and drop it onto a sheet.

NOTE Sheet views are inserted with their own layer key. The layer key used for sheet views is G-Anno-Nplt.

Opening a Sheet View

Use this procedure to open a sheet view.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet containing the sheet view you want to open, and expand it.
- 4 Select the sheet view, right-click, and click Open.

Numbering Sheet Views

Use this procedure to number sheet views in a sheet set.

The number assigned to a sheet view is displayed as a prefix to the sheet set view name on the Project Navigator.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet that contains the sheet view you want to number, and expand it.
- 4 Select the sheet view, right-click, and click Rename and Renumber.

- 5 Enter a number for the sheet view.
- 6 If necessary, rename the sheet view.
- 7 Click Next to display the information for the next sheet view in the sheet.
- 8 When you finish changing the numbering of sheet views, click OK.

Deleting a Sheet View

Use this procedure to delete a sheet view from a sheet.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet containing the sheet view you want to delete, and expand it.
- 4 Select the sheet view, right-click, and click Open.
The sheet view opens in the drawing area.

5 Select the sheet view in the drawing area, and press *DELETE*.

NOTE The view xref is still attached in model space. To also detach the view from the sheet, right-click the sheet in the Drawing Explorer, and click External References. In the External References dialog, select the view, right-click, and click Detach.

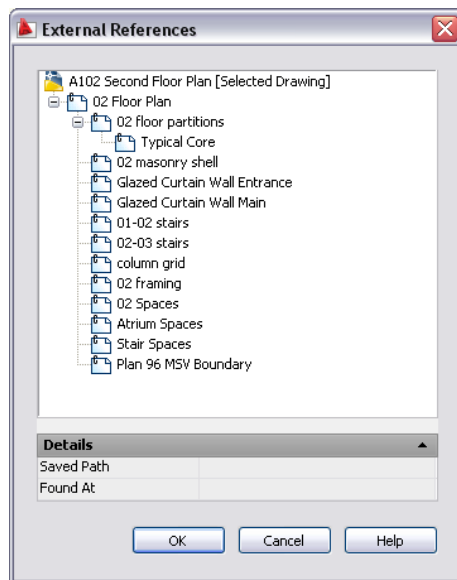

Displaying External References of a Sheet Drawing

Use this procedure to display the external references of a sheet drawing.

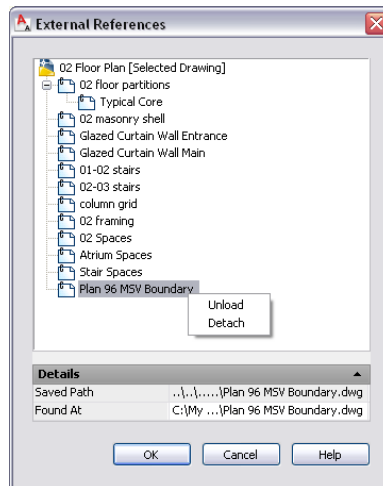

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Explorer View) in the title bar.
- 3 In the Drawing Explorer, locate the sheet drawing for which to display external references.
- 4 Select the sheet drawing.
- 5 Display the xrefs using either of the following methods:
 - Right-click, and click External References.

- On the toolbar at the bottom of the Sheets tab, click  .

The External References dialog displays a list of xrefs in the sheet.

- 6 Expand or collapse the list by clicking individual items, and right-click to change the status of the xref, if necessary.

From the context menu, you can unload, reload, or detach the attached xref. For more information, see Reference Other Drawing Files in AutoCAD Help.

- 7 On the External References dialog, view the details of the xref.

- Saved Path displays the saved path, if any, that is used to locate the xref. This path can be a full (absolute) path or a relative (partially specified) path.
- Found At displays the path where the xref was found. If no path was saved for the xref or if the xref is no longer located at the specified path, the program searches for the xref and displays the location her.

- 8 Click OK to close the dialog.

NOTE You can also display external references by opening the sheet drawing and using the AutoCAD Xref Manager. For more information, see “Reference Other Drawing Files (Xrefs)” in AutoCAD Help.

Inserting a Sheet List

Use this procedure to insert a sheet list on a sheet.

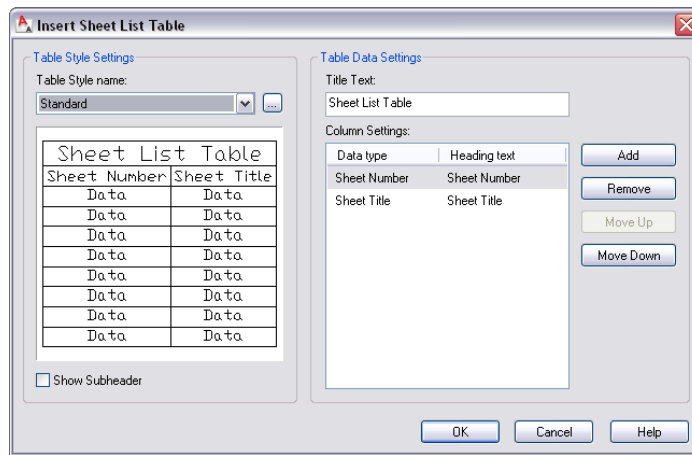

A sheet list is a table of contents for the sheets in a project. Normally, you place it on the cover sheet of your sheet set; however, you can place it on any sheet.

Sheet list on cover sheet

The sheet list is inserted as a table.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Open the sheet on which you want to place the sheet list.
- 4 Select the sheet set root node, right-click, and click Insert Sheet List.

- 5 Select the table style for the sheet list under Table Style name.

To create a new table style, click . For information on creating table styles, see “Work with Table Styles” in AutoCAD Help.

- 6 Enter the title of the sheet set under Title Text.
- 7 Under Column Settings, define the information to include in the sheet list.

Columns for sheet number and sheet title have already been defined; however, you can delete them.

If you want to...

Then...

add a column to the sheet list

click Add. Then, click the Data Type entry, and select the data you want to display in the list. You can choose subject, author, keywords, and more. To change the heading text for the entry, click the heading text and enter new text.

If you want to...	Then...
remove a column from the sheet list	select the column in the list, and click Remove.
rearrange a column in the sheet list	select the column in the list, and click Move Up or Move Down. The top entry in the list will be placed as the far left column in the sheet list. The next-lower entry will be placed next to the left column, and so on.

NOTE You can see a preview of the sheet list in the viewer on the left.

8 Click OK twice.

NOTE The sheet list is generated from the sheets contained in the sheet set. If you make manual changes to the sheet list after placing it on a sheet, these changes will be overwritten when you update the sheet list, as described in [Updating the Sheet List](#) on page 358.

9 Specify an insertion point for the sheet list on the current sheet.

The sheet list is placed on the sheet.

The sheet title and sheet number entries are hyperlinked to the files containing these sheets. If you CTRL-click the sheet title or sheet number, it will open the associated drawing file.

Changing the Sheet List Properties

Use this procedure to change the properties of a sheet list.

NOTE Changing the properties of a sheet list includes changing the table style, the number and arrangement of columns displayed, and the sheet list title. If you change the actual sheets in your list (for example if you rename sheets, add, or delete sheets), update the sheet list, as described in [Updating the Sheet List](#) on page 358.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Open the sheet that contains the sheet list.
- 4 Select the sheet list in the drawing, right-click, and click Edit Sheet List Table Settings.
- 5 Change the properties of the sheet list, as described in [Inserting a Sheet List](#) on page 356.

Updating the Sheet List

Use this procedure to update a sheet list.

If you add, remove, or rename sheets, update the sheet list when you change the sheet set; for example, if you add, remove, or rename sheets.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Open the sheet that contains the sheet list.
- 4 Select the sheet list in the drawing, right-click, and click Update Sheet List Table.

Refreshing the Sheet Set

Use this procedure to refresh the sheet set.

Refreshing a sheet set includes opening all sheets in the set, updating them with any changes that have occurred (for example, changed external references), saving them, and closing them. You cannot refresh sheets, if any of the following conditions are true:

- The associated sheet drawing is already open.
- The sheet drawing or its folder are set to read-only.
- The associated sheet drawing has been deleted.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the sheet set root node, right-click, and click Refresh Sheet Set.

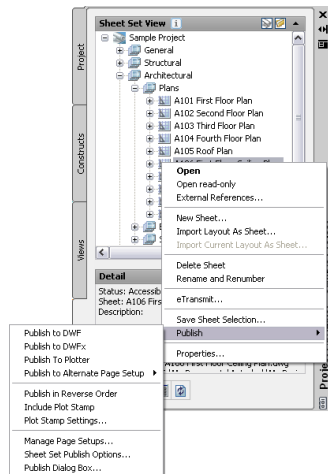

Refreshing the sheet set can take a moment or two. A progress bar shows how long the refresh will take. When the Refresh is complete, you are notified by a message. If there were been problems refreshing one or more sheets, they are listed. You can also view details of the refresh in a log file located in the root directory of the project folder.

Creating a Sheet Selection

Use this procedure to create a sheet selection.

If you regularly work with a specific group of sheets in the project sheet set, you can create a named selection of those sheets. You define the sheet selection by choosing its name in the Sheet Set view of the Project Navigator.

Ceiling plan sheet selection

You could use a sheet selection as a selection set for electronic transmissions or publishing.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 SHIFT-click or CTRL-click to select the sheets to include in the sheet selection.
- 4 When you finish selecting sheets, right-click, and click Save Sheet Selection.

5 Enter a name for the sheet selection, and click OK.

Activating a Sheet Selection

Use this procedure to activate a sheet selection.

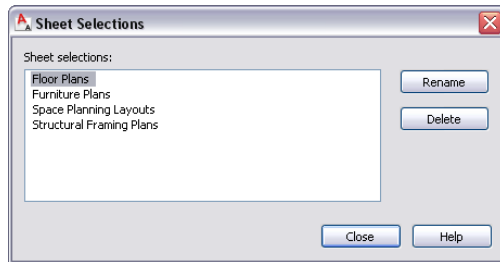

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the project sheet set root node, right-click, and click Sheet Selections.
- 4 Make your selection from the Sheet Selections submenu.

Removing a Sheet Selection

Use this procedure to delete a sheet selection.

NOTE Deleting a sheet selection does not delete any sheets included in that selection.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the Sheets tab, and click  (Sheet Set View) in the title bar.
- 3 Select the project sheet set root node, right-click, and click Sheet Selections ► Manage.

- 4 Select the sheet selection you want to delete, and click Delete.
- 5 Click OK.

Electronically Transmitting Sheets and Sheet Sets

Use this procedure to electronically transmit a sheet, a sheet subset or the project sheet set.

Electronically transmitting a file set means that you package the file set for delivering in electronic form. Drawing files in the transmittal package include all related dependent files, such as external references and font files.

You can select different components of the project sheet set for electronic transmittal:

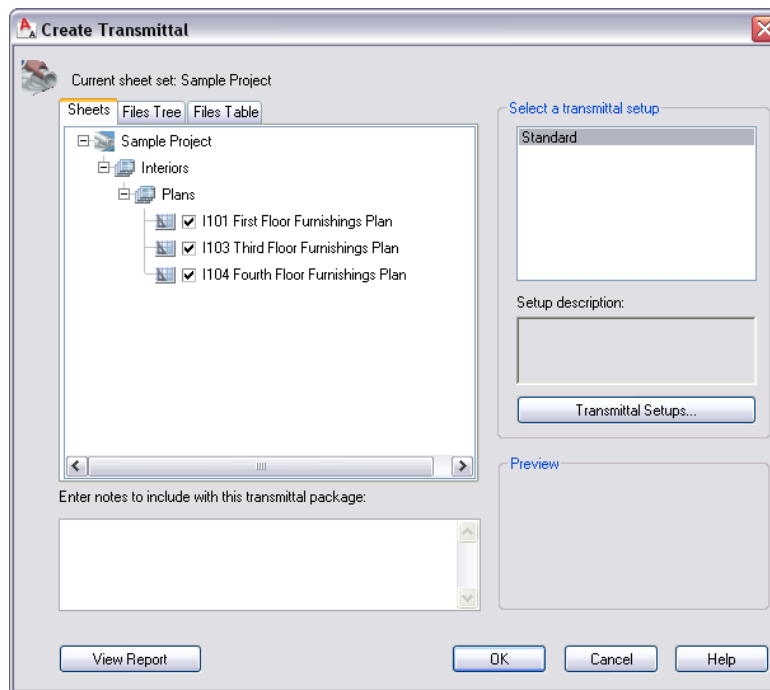

- The complete project sheet set: This includes all sheets in the project sheet set.
- A sheet subset: This includes all sheets from a specified sheet subset.
- A sheet: This includes the sheet.

For more information about electronic transmittal, see “Package a Set of Files for Internet Transmission” in AutoCAD Help.

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Sheets tab, click  (Sheet Set View) on the title bar.
- 3 Select the component you want to transmit electronically:

If you want to...	Then...
transmit the complete project sheet set	select the project sheet set.
transmit a sheet subset	select the desired subset.
transmit a sheet	select the desired sheet.

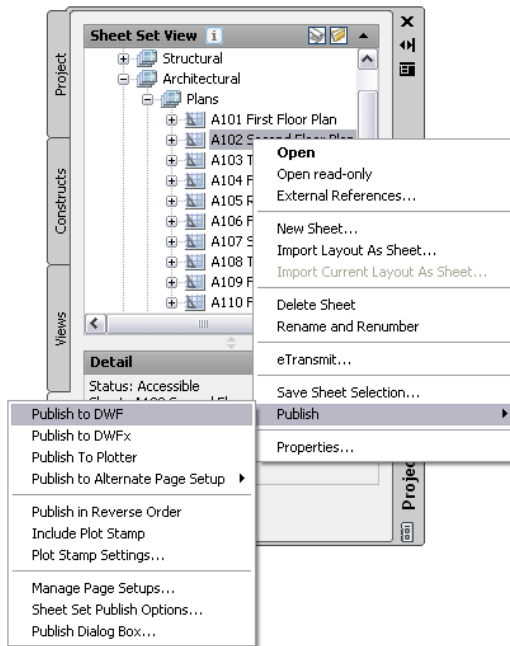

- 4 Right-click, and click eTransmit.
The Create Transmittal dialog is displayed.

- 5 In either the Files tree tab or the File Table tab, select the components to be included in the electronic package.
The Files Tree tab displays the included files sorted by type. The Files Table tab displays all files in a list view. You can sort the list by name, path, type, version, size, and date.
- 6 To include project information, double-click the setup under Select a transmittal setup, and in the Modify Transmittal Setup dialog, select Include project information under Include options.
For detailed information about packaging project information for an electronic transmittal, see [Electronically Transmitting a Project](#) on page 252.
- 7 Click OK to start the electronic transmittal.

Publishing Sheet Sets

In the Sheet Set view, you can publish sheets to a plotter, a DWF file, or a DWFx file. You can assign plot stamps to the sheet set, publish sheets to an alternate page setup, and specify DWF and DWFx publishing settings.

You publish from the following components:

- An individual sheet.
- A sheet subset. For information about creating sheet subsets, see [Creating a Sheet Subset](#) on page 348.
- A sheet selection. For information about creating sheet subsets, see [Creating a Sheet Selection](#) on page 359.
- The project sheet set.

For detailed information about plotting and publishing, see the following topics in AutoCAD Help:

- Set Options for Plotted Objects and Plot Stamp Dialog Box
- Overview of Page Setup Settings
- Publish, Transmit, and Archive Sheet Sets

Changing Sheets: Interactions with the Project

Changes made to one part of a project frequently influence other parts of the project. The following information describes the changes you can make to a sheet and the effects of the changes on other parts of the building project:

NOTE Because the sheet is the last stage of the project, it has fewer interactions with the project than the other components do. For example, deleting a sheet has no influence on other drawings, like views or constructs.

- Adding a new sheet: Normally, a sheet is created to reference a specific view. For example, if you create a view called First Floor Plan, create a sheet that contains this view.
- Changing the sheet name and subset: A sheet has one or more views referenced into it. Therefore, any name and location changes to a sheet need to be updated throughout the project. To update the path, repath the project as described in [Repath the Project](#) on page 372.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format. For more information, see [Repath the Project](#) on page 372.

- For detailed information on deleting views, see [Deleting a View Drawing](#) on page 333.

Creating a Sheet Set Template

When you create a new project, a project sheet set is automatically created. The project sheet set controls the settings relevant to sheets and the sheet set, such as page setups, the sheet template, and sheet subsets. The sheet set is based either on the sheet set template that you define in the project default options, or, if you base a new project on a project template, on the sheet set of this project template.

The easiest way to create a new sheet set template is to base it on an existing sheet set. You can also base your new sheet set template on existing drawing files, allowing you to add existing sheet layouts to the template.

NOTE A number of settings apply only to sheet sets referenced in the AutoCAD Sheet Set Manager. For a sheet set that will be used in an AutoCAD Architecture project, most settings come from the project, and not from the sheet set template. For more information, see [Adding Detailed Information to Project Properties](#) on page 242 and [Working with Project Properties](#) on page 239.

These fields on the Sheet Set Properties dialog are ignored when you use a sheet set template in an AutoCAD Architecture project for the following reasons:

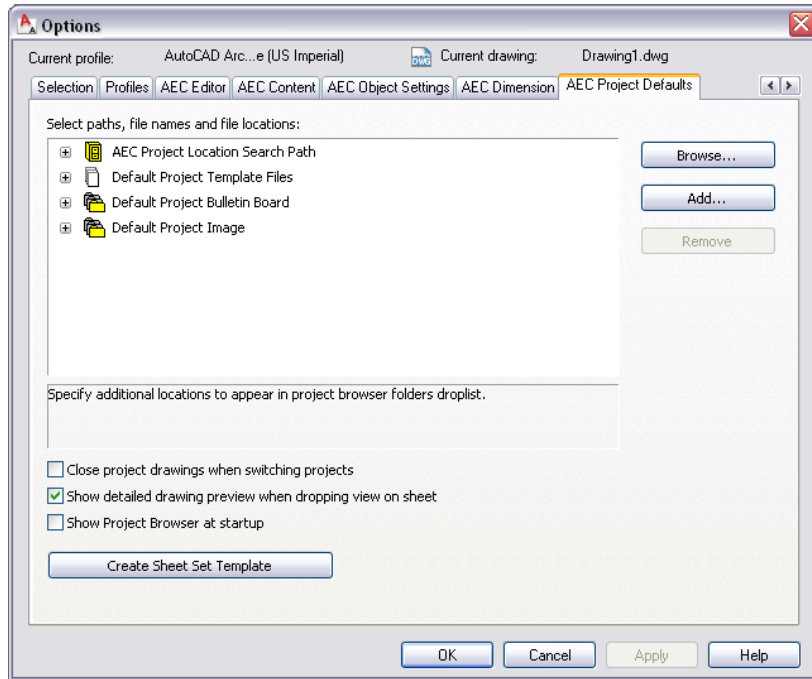

- Sheet set data file: The sheet set file (DST) is always stored in the root folder of the project.
- Model view: Model view drawing locations are not tracked in AutoCAD Architecture sheet sets. They are automatically taken from the project views.
- Label block for views: Label blocks are not recommended in AutoCAD Architecture projects. Use callout tools instead. For more information, see [Working with Callouts](#) on page 2449.
- Callout blocks: Callout blocks are not recommended in AutoCAD Architecture projects. Use callout tools instead. For more information, see [Callout Tools in ProductName](#) on page 2451.
- Sheet storage location: The sheets in a project are always stored in the Sheets folder of the project, or in one of its subfolders.

Creating a Sheet Set Template

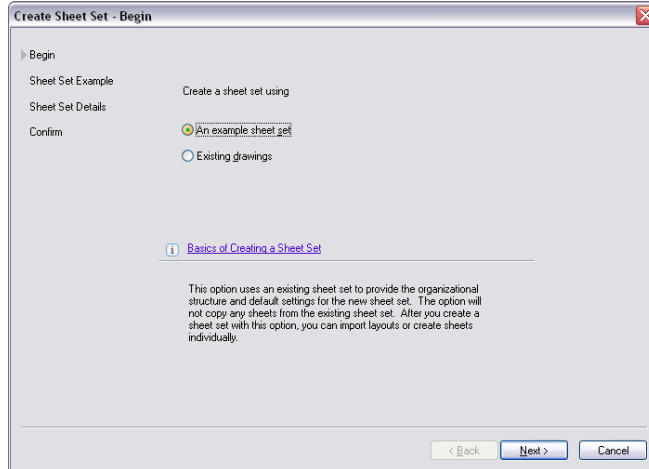

Use this procedure to create a sheet set template based on a sheet set in an existing project. Settings applied here are overridden if you redirect top-level categories on the Project Property dialog in the project in which

the sheet set is located. For more information, see [Specifying the Location of Top-Level Categories](#) on page 283.

- 1 Click Format menu ► Options.
- 2 Click the AEC Project Defaults tab, and click Create Sheet Set Template.

The Create Sheet Set wizard is displayed. It will help you create a new sheet set template.

- 3 In the Create Sheet Set - Begin dialog, under Create a sheet set using, select An example sheet set, and click Next.

- 4 In the Create Sheet Set - Sheet Set Example dialog, select a sheet set to use as an example:

If you want to...

Then...

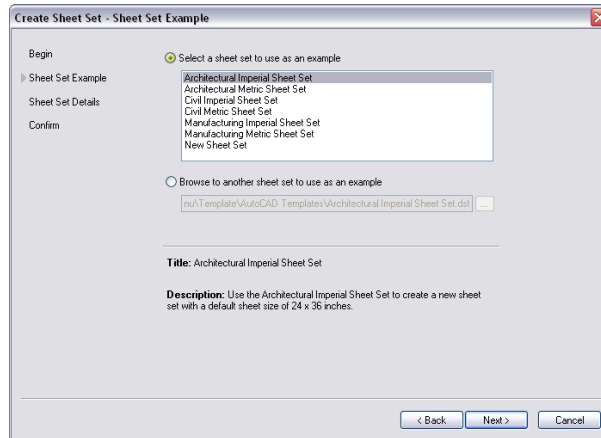

use a sample sheet set from the list

click Select a sheet set to use as an example, select a sheet set from the list, and then click Next.

If you want to...**Then...**

use a sheet set not listed

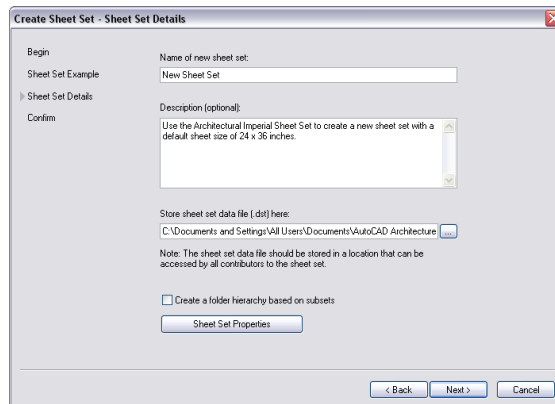

click Browse to another sheet set to use as an example, and click . In the Browse for Sheet Set dialog, select a sheet set (DST) file, click Open, and then click Next.

5 In the Create Sheet Set - Sheet Set Details dialog, enter a name for the new sheet set template.

6 Enter a description for the new sheet set template.

7 Select the folder location in which to save the new sheet set template.

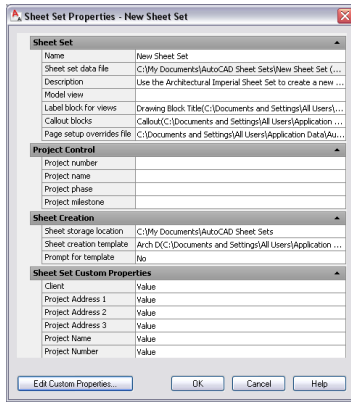

NOTE The location of a sheet set template (DST file) does not define the location of project sheet sets created from that template. A project sheet set is always stored in the root folder of the associated project.

If you are creating a sheet set template for an AutoCAD Architecture project, selecting Create a folder hierarchy based on subsets will have no impact because sheet subsets in the Drawing Explorer will have corresponding folders associated to them automatically. If you are creating a sheet set template for an AutoCAD sheet set, you can select this option. This will create a new subfolder in the sheet set every time you create a new sheet subset in the Sheet Set Manager.

8 To define the properties of the new sheet set template, click Sheet Set Properties.

The Sheet Set Properties dialog is displayed.

It is not necessary to complete the following fields when you use the sheet set template for an AutoCAD Architecture project:

Field	Reason
Sheet set data file	The DST file is always stored in the root folder of the project.
Model view	Model view drawing locations are not tracked in AutoCAD Architecture sheet sets. They are automatically taken from the project views. In an AutoCAD sheet set, this field displays the paths and names of folders that contain drawings used by the sheet set.
Label block for views	These are stored in the view templates.
Callout blocks	These are located on the Tools palette.
Name, Number, Phase, Milestone under Project Control	You associate project information with the project file (API), instead of the project sheet set, when you are working in an AutoCAD Architecture project. For information on associating information with a project, see Creating a New Project on page 235 and Working with Project Properties on page 239.
Sheet storage location	NOTE If you enter a project name and project number under Project Control in the Sheet Sets Properties dialog that differs from the project name and number you enter in Creating a New Project on page 235, you will get an error message when editing the project, and be prompted to consolidate the information. Therefore, it is strongly recommended to leave the Project Control fields in the sheet set template empty.
Sheet storage location	The sheets in a project are always stored in the Sheets folder of the project, or in one of its subfolders.

- 9 In the Sheet Set Properties dialog, under Sheet Set, click the setting for Page setup overrides file to define overrides for the project.
- 10 In the Select Template dialog, select a drawing template (DWT) file, and click Open.

NOTE Select a template that contains named paper space layouts, and make sure that their plot areas have been set to Layout. Otherwise, you cannot use them as page setup overrides.

None of the other settings under Sheet Set are applied when using the sheet set template for an AutoCAD Architecture project.

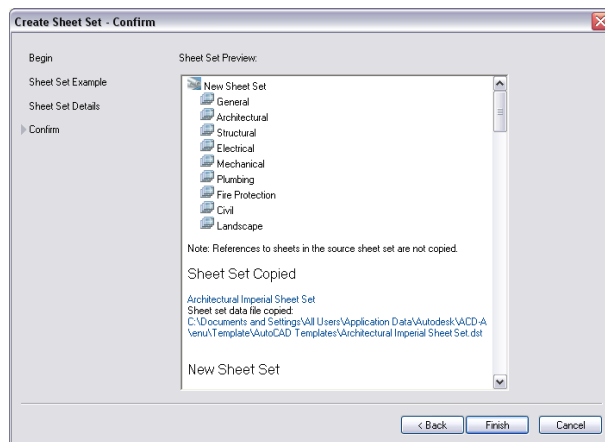

- 11 Under Sheet Creation, you define settings for the sheets you create within the sheet set.
- 12 To define a default layout for new sheets, click the setting for Sheet creation template.
- 13 In the Select Layout as Sheet Template, click  to browse for a drawing (DWG) or template (DWT) file, and click Open.
- 14 In the Select Drawing dialog, select the default layout to use to create new sheets, and click OK.
- 15 Specify if you want to be prompted for the sheet template each time you create a new sheet:

If you want to...	Then...
be prompted for a sheet template each time you create a new sheet	select Yes for Prompt for Template.
always use the specified template	select No for Prompt for Template.

- 16 To add, edit, or delete custom properties, click Edit Custom properties.
For information about Custom Properties, see “Include Information with Sheets and Sheet Sets” in AutoCAD Help.

NOTE When working in an AutoCAD Architecture project, normally you do not use custom properties. In most cases, you use the project details in the Project Browser. For more information, see [Adding Detailed Information to Project Properties](#) on page 242.

- 17 Click OK to close the Sheet Set Properties dialog. Then, click Next.
The Create Sheet Set - Confirm dialog displays.

18 Verify that all settings for the new sheet set are correct:

If you want to...	Then...
make changes to one or more settings	click Back.
finish creating the sheet set template	click Finish.

NOTE You can edit a project sheet set in the Sheet Set view of the Project Navigator, as described in [Setting the Properties of the Project Sheet Set](#) on page 347. You can edit a project sheet set template in the Sheet Set Manager of AutoCAD, as described in “Create and Manage a Sheet Set” in AutoCAD Help.

Creating a Template from Existing Drawings

Use this procedure to create a sheet set template that contains layouts from one or more existing drawings. You can also select options to prefix the sheet titles with the file name and create subsets based on the folder structure. Settings applied here are overridden if you redirect top-level categories in the Project Properties dialog in the project in which the sheet set is located. For more information, see [Specifying the Location of Top-Level Categories](#) on page 283.

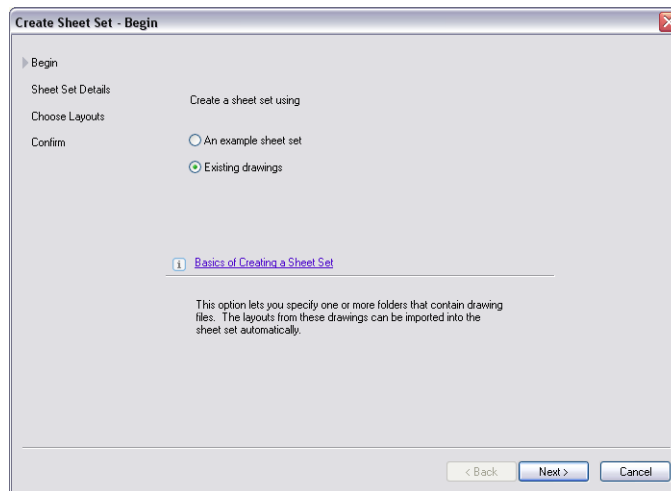

1 Click Format menu ► Options.

2 Click the AEC Project Defaults tab, and click Create Sheet Set Template.

The Create Sheet Set wizard is displayed. It will help you create a new sheet set template.

3 Under Sheet Set Template, click Create.

The sheet set wizard is displayed. It will help you to create a new sheet set template.

4 Under Create a sheet set using, select Existing drawings, and then click Next.

5 In the Create Sheet Set - Sheet Set Details, enter a name for the new sheet set.

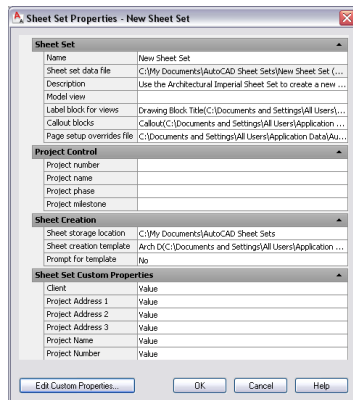

6 Enter a description for the new sheet set.

7 Select the folder location where the new sheet set template should be saved.

NOTE The location of a sheet set template (DST file) does not define the location of project sheet sets created from that template. A project sheet set is always stored in the root folder of the associated project.

8 To define the properties of the new sheet set template, click Sheet Set Properties.

The Sheet Set Properties dialog is displayed.

It is not necessary to complete the following fields when you use the sheet set template for an AutoCAD Architecture project:

Field	Reason
Sheet set data file	The DST file is always stored in the root folder of the project.
Model view	Model view drawing locations are not tracked in AutoCAD Architecture sheet sets. They are automatically taken from the project views. In an AutoCAD sheet

Field	Reason
	set, this field displays the paths and names of folders that contain drawings used by the sheet set.
Label block for views	These are stored in the view templates.
Callout blocks	These are located on the Tools palette.
Name, Number, Phase, Milestone under Project Control	<p>You associate project information with the project file (APJ), instead of the project sheet set, when you are working in an AutoCAD Architecture project. For information on associating information with a project, see Creating a New Project on page 235 and Working with Project Properties on page 239.</p> <hr/> <p>NOTE If you enter a project name and project number under Project Control in the Sheet Sets Properties dialog that differs from the project name and number you enter in Creating a New Project on page 235, you will get an error message when editing the project, and be prompted to consolidate the information. Therefore, it is strongly recommended to leave the Project Control fields in the sheet set template empty.</p>
Sheet storage location	The sheets in a project are always stored in the Sheets folder of the project, or in one of its subfolders.

9 In the Sheet Set Properties dialog, under Sheet Set, click the setting for Page setup overrides file to define overrides for the project.

10 In the Select Template dialog, select a drawing template (DWT) file, and click Open.

NOTE Select a template that contains named paper space layouts, and make sure that their plot areas have been set to Layout. Otherwise, you cannot use them as page setup overrides.

None of the other settings under Sheet Set are applied when using the sheet set template for an AutoCAD Architecture project.

11 Under Sheet Creation, you define settings for the sheets you create within the sheet set.

12 To define a default layout for new sheets, click the setting for Sheet creation template.

13 In the Select Layout as Sheet Template, click  to browse for a drawing (DWG) or template (DWT) file, and click Open.

14 In the Select Drawing dialog, select the default layout to use to create new sheets, and click OK.

15 Select the default layout you want to use to create new sheets. Then, click OK.

16 Specify if you want to be prompted for the sheet template each time you create a new sheet:

If you want to...	Then...
be prompted for a sheet template each time you create a new sheet	select Yes for Prompt for Template.

If you want to...

Then...

always use the specified template

select No for Prompt for Template.

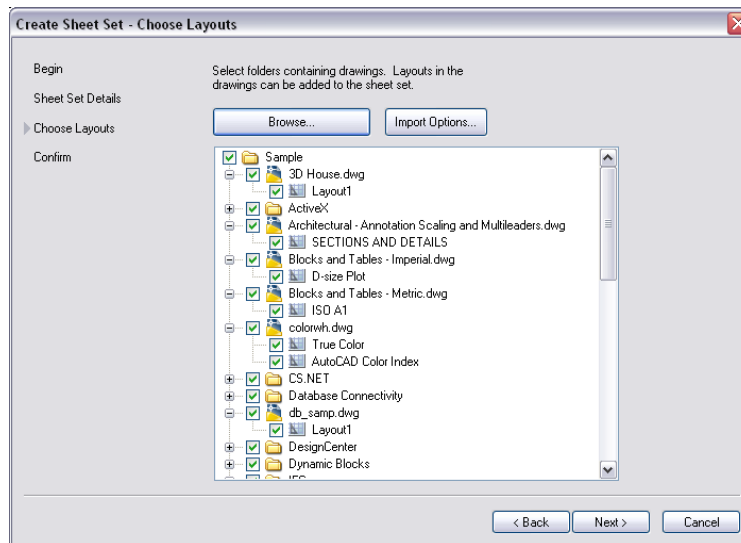

17 To add, edit, or delete custom properties, click Edit Custom properties.

For information about Custom Properties, see “Include Information with Sheets and Sheet Sets” in AutoCAD Help.

NOTE When working in an AutoCAD Architecture project, normally you do not use custom properties. In most cases, you use the project details in the Project Browser. For more information, see [Adding Detailed Information to Project Properties](#) on page 242.

18 Click OK to close the Sheet Set Properties dialog. Then, click Next.

The Create Sheet Set - Choose Layouts dialog is displayed.

In the Create Sheet Set - Choose Layouts dialog, you can select layouts from existing drawings and add them to the sheet set template as sheets. For example, you could do this to convert legacy sheets to project sheets.

19 To select one or more drawings from which to copy layouts to the sheet set template, click Browse.

20 In the Browse for Folder dialog, select the folder containing the drawings, and click OK.

21 Expand the folder and drawing name, and select the layouts to be included in the sheet set template.

22 To remove a drawing or folder, select it, right-click, and click Remove.

23 Repeat this step for drawings in other folders, if necessary.

24 To prefix sheet titles with the file name or create subsets of sheet sets based on the folder structure, click Import Options, select the options, and click OK.

25 Click Next.

26 Verify that all settings for the new sheet set are correct:

If you want to...	Then...
make changes to one or more settings	click Back.
finish creating the sheet set template	click Finish.

NOTE You can edit a project sheet set in the Sheet Set Explorer of the Project Navigator, as described in [Setting the Properties of the Project Sheet Set](#) on page 347. You can edit a project sheet set in the Sheet Set Manager of AutoCAD, as described in “Create and Manage a Sheet Set” in AutoCAD Help.

Repath the Project

Use this procedure to update the external reference paths within the project after making changes to the names or locations of elements, constructs, or views. For example, if you move a project file into another category, or rename it, you must update the file that references the changed drawing to reflect that change on the Project Navigator palette.

WARNING When you repath a project that was saved in a version of Architectural Desktop prior to 2007, the drawings are saved in the new file format. You will no longer be able to open these drawings in a version of Architectural Desktop prior to 2007. Synchronizing a project with the project standards will also save the project drawings in the new file format.

A repath is necessary after you make any of the following changes in the project:

- Move the project to a different location
- Move a project file to a different category
- Rename a project file
- Move a subcategory from one category to another

In addition to updating the project files, repathing will also update the paths of the following files:

- Paths to support files, folders, and templates stored within the project setup, such as drawing templates, tool content root path, or project standards drawings.
- Paths to images referenced in project drawings
- Paths for schedules referencing external drawings within project drawings

When you zip a project and send it to another user who unpacks the project to a different location on another computer, the project will be updated in its new location when it is set current for the first time on

the new computer. For example, if your project resides in C:\Project1\, and the user you are sending it to unpacks it to D:\Project1, the path information is updated when the new user sets the project current in AutoCAD Architecture. However, this will update only if all project paths were correct and current when you zipped them. If, for example, you have moved the project to another location on your computer before zipping it, and not repathed it before zipping, the repathing on the new user's machine will not work correctly. Before you zip and send a project, you must make sure that all external reference paths in the project are valid.

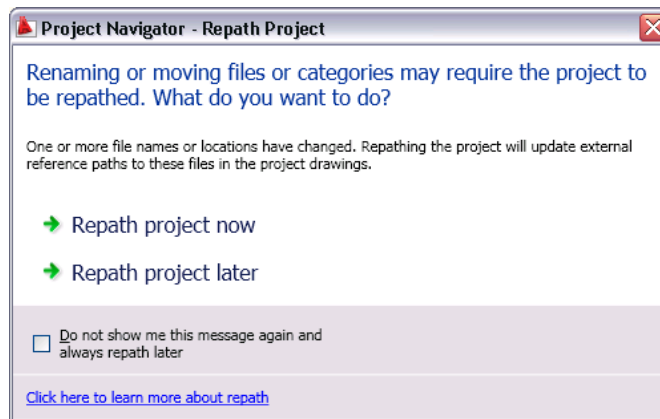

You have the choice of repathing:

- A single project file
- All files in a category
- All files in the project

1 Click Window menu ► Project Navigator Palette.

2 Change the name or the location of a project file or project folder in the Drawing Explorer.

The Project Navigator - Repath Project dialog displays.

3 Specify when you want the repathing to be done:

If you want to...	Then...
update all project files now	click Repath project now.
update all project files later	click Repath project later. If you close the project before repathing, the drawing files remain in a queue for update and will display in the Project Repath Queue dialog the next time you open it. The repath queue is shared by all users working on a project and it is saved from session to session.

4 Alternatively, click  to update all files in the project at any time.

Refreshing the Project Navigator

Use this procedure to refresh the project view on the Project Navigator palette.

When multiple people are working on the same project simultaneously, the situation can occur that one person's Drawing Explorer view on the Project Navigator palette becomes out of sync with the changes of another.

For example, user 1 is adding/moving/deleting constructs of a project. At the same time, user 2 is annotating sheets. User 2 is not automatically notified that user 1 has removed some constructs from the project. If user 2 tries to open a removed construct from the Project Navigator on their machine, an error message results.

To prevent this situation, refresh the Project Navigator by clicking  (Refresh Project) so that all items are updated to reflect the current project status.

- 1 Click Window menu ► Project Navigator Palette.
- 2 Click the tab for which you want to refresh the file tree.
- 3 Click .

NOTE It is recommended that you do this frequently during a project session when multiple people are working on the same project.

Object Display in External References

When you reference a project drawing into another project drawing—a construct into a view or a view into a sheet—the referenced drawing uses the display settings of the host drawing (the drawing into which it is referenced).

In some cases, however, you might want to change the display of an external reference for a specific view. For example, you may want to display a new walls construct with its regular display configuration, and an existing wall construct as a light gray background image, as displayed in a different display configuration.

To do this, you could define in a construct a display configuration called Existing Walls and assign a light gray color to it. When you reference the construct into a view during the first phase of the project, you use the regular display configuration for new walls. When you reference that construct into a view in a later phase, you can assign the Existing Walls display configuration. For more information, see [Specifying the Display Configurations Used in Xref Overlays](#) on page 568.

Annotating a Project

A number of annotation features of AutoCAD Architecture have been enhanced to work optimally with the Drawing Management feature.

The following sections summarize the enhancements of the Scheduling feature for annotating a building project.

Generating Spaces

Before you start creating annotation for the building objects, you might need to create spaces and space property information from your project. Spaces and space schedule properties help you report information on the rooms of a building, such as room numbers, room finishes, or physical information like net and gross areas, perimeters, and calculation modifiers. You can easily create spaces from walls and other building objects. For more information, see [Generating Associative Spaces](#) on page 1931, [Converting Objects, Profiles, and Polylines to Non-Associative Spaces](#) on page 1961, and [Basic Schedules](#) on page 2491.

Tagging in a Project

Use this procedure to tag objects in a project drawing.

One of the most frequent uses of annotation in a project is tagging the individual objects. It is recommended that you tag objects in view drawings. You can create project-specific tags that display project information or use the default project-based schedule tags that are in the Document tool palettes. The difference between a standard schedule tag and a project-based schedule tag is that a project-based schedule tag recognizes the level in the project in which the object is located. When you want this additional information captured, use a project-based schedule tag. For more information, see [Adding Tags Using Schedule Tag Tools](#) on page 2495.

For more information, see [Project Schedule Properties](#) on page 378, [Creating a Property Set Definition with Project Property Definitions](#) on page 379, and [Creating a Title Block for a Project](#) on page 382.

- 1 Open the view drawing in which to add your tags.
- 2 Open the tool palette that contains the tag you want to use, and select the tool.
Predefined project tag tools are located in the Documentation Catalog in the Content Browser. You can add these tools to any tool palette.
- 3 Select the object to which to attach the tag.

NOTE You can select an object within an external reference.

- 4 Specify the location of the tag.
- 5 If prompted, enter property set data for the object in the Edit Property Set Data dialog, and click OK.
For information about preventing the worksheet from displaying each time you add a tag, see [Turning Off the Edit Property Set Data Worksheet](#) on page 2499.
If property set data is not yet attached to the object, you can attach an appropriate property set from the current drawing or the Schedule Tables.dwg file in C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial or Metric. For more information about property sets, see [Property Set Definitions](#) on page 2542.
- 6 Enter m, press ENTER, and select multiple objects to tag.
- 7 Alternatively, press ENTER, and add schedule tags one at a time.

Property Set Data and Schedule Tables in Projects

Schedules are tables that list specific information about selected objects in your building model. You can create different types of schedules by attaching property set data to objects and object styles, and then extracting and displaying the data in a schedule table.

For detailed information on property sets and schedule tables, see [Schedules and Display Themes](#) on page 2485.

The existing scheduling features have been enhanced to work in a Drawing Management environment.

You can schedule each instance of each external reference individually. For example, if you have an element that contains a typical door, you can reference that door element five times into a construct. When you create a door schedule in the construct, all five instances of the door element are scheduled independently and can have unique data.

When you work in a non-project environment, you typically attach property data to objects directly in the drawing. When you use the Drawing Management feature, you work extensively with external references and often tag objects in xrefs.

- **Attach property set data to objects in external references:** You can, for example, reference a construct into a view, and attach property sets in the view to the objects from the referenced construct. Attaching property sets to external references works for any nested levels, but it is recommended that you attach data while in a view drawing.
- **Attach different property sets to individual instances of an external reference within a host drawing:** You can reference the same door multiple times into the same host drawing and attach different property sets to each instance of the door. That way, you can reference the same typical element multiple times in a building and schedule each one differently.
- **Access property sets from the source element or construct drawing as well as property sets from views or sheets:** You can create a property set with properties in the element drawing and another property set in the sheet and schedule both in the sheet.

Example: Numbering a Door in a Project

The following example shows how you can define property data that combines object properties with project properties. The example uses space information to show how you could use project and formula property definitions. The following diagram shows how a space number can be built up from information on the space and in the project.

Value	Property Set Definition	Property Definition	Description
2	Space	LevelNumber	A project property definition, getting the Level ID for the object for the current project
01	Space	BaseNumber	A manual auto-incrementing property definition
201	Space	RoomNumber	A formula property definition, with the formula [LevelNumber][BaseNumber]

Process Overview: Creating Property Sets and Schedule Tables in a Project

The main steps necessary to work with property set data and schedules in a project are as follows:

- 1 Create property set definitions and schedule table styles that contain the necessary project information. For more information, see [Project Schedule Properties](#) on page 378 and [Creating a Property Set Definition with Project Property Definitions](#) on page 379.

You can create property set definitions and schedule table styles at different locations in the project environment:

- In the AutoCAD Architecture Schedule Tables.dwg file
- In your own, user-defined property set definitions drawing
- In the drawing template
- In the drawing

NOTE To attach a property set definition to an external reference, import it into the object drawing. This is done automatically when you drag a tag from DesignCenter into the drawing.

NOTE The drawing that contains your property set definitions does not need to be a part of your project. You can import and use property set definitions from any drawing file accessible to you.

There are a number of guidelines that can help you decide in which property set definition to put property definitions:

- Non-manual property definitions—that is, Automatic, Formula, Classification, Material, and Project Property Definitions—can in many cases be defined in property set definitions that are applied to styles. If a property set definition is to be applied to objects that do not have styles, it does not matter where the property definition is defined.
- Manual property definitions containing data that does not change for each instance of a style should be defined in property set definitions that are applied to styles.
- Manual property definitions containing data that does change for each instance of a style should be defined in property set definitions that are applied to objects.

2 Attach the property set definition to an object or style in a project drawing.

You can attach a property set to an object at various stages of the project. You can attach property set data to an external reference and also override existing property sets from the external reference in the host drawing. For example, you can attach a property set definition to a door in an element and then override that property set with an extended one when referencing that door into a construct. You could also create an element without property sets, reference it into a construct and a view, and attach a property set there.

NOTE Overriding property set definitions works only for those property sets attached to objects. Property sets attached to styles cannot be overridden when referenced into another drawing.

For more information, see [Attaching Property Set Data to Objects](#) on page 2534 and [Attaching Property Sets to Objects from External References](#) on page 379.

The following guidelines help you to select the correct location for attaching property sets to objects within a project:

- Property set definitions that are applied to styles must be attached to styles in the drawing containing the style.
- Property set definitions that are applied to objects and that contain data that does not change for each instance of the object that is externally referenced should be attached to the object itself in the externally referenced drawing.
- Property Set Definitions that are applied to objects and that contain data that does change for each instance of the object that is externally referenced should be overridden at the external reference, typically at the project construct level.

These guidelines are recommendations. The location of property data also depends on the processes and workflow you have established in your work environment.

- 3 Open the project drawing in which to place the schedule table.
- 4 If necessary, attach property sets to objects to be scheduled from external references, or override property sets for those objects on the external references that contain them.
For more information, see [Attaching Property Sets to Objects from External References](#) on page 379.
- 5 Create schedule tables in the drawing.
For more information, see [Creating a Schedule Table in a Project](#) on page 381.

Project Schedule Properties

A project property definition can be defined in a property set definition so that an object has access to information about the project in which it is currently located.

These project properties are available:

Property	Description
Name	Name of the project
Description	Description of the project
Number	Number of the project
Location	File location of the project on the hard disk or network drive
Number of Levels	Total number of levels in your project
Level ID	ID of the level the object is on
Level Elevation	Elevation of the level the object is on
Level Height	Height of the level the object is on
Number of Divisions	Total number of divisions in your project
Division ID	ID of the division the object is in
Sheet Name	Name of the sheet drawing that contains the object
Sheet Description	Description of the sheet drawing that contains the object
Details of the project: Project Data, Proposed Improvements, Site Legal Description, Owner's Data, Site Information Sources, Public Services, Financial Data, and Method of Handling	Properties for all project details created in Adding Detailed Information to Project Properties on page 242.

For general information on creating property set definitions, see [Creating a Property Set Definition](#) on page 2554.

For a list of available project properties, see [Project Schedule Properties](#) on page 378.

Creating a Property Set Definition with Project Property Definitions

Use this procedure to create a property set definition containing project property definitions.

For a list of available project properties, see [Project Schedule Properties](#) on page 378.

For general information on creating property set definitions, see [Creating a Property Set Definition](#) on page 2554.

NOTE A property set definition can contain different types of property definitions such as automatic properties, project properties, formulas, and classifications.

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and click Property Set Definitions.
- 3 Right-click, and click New.
- 4 Enter a name for the new property set definition press *ENTER*.
- 5 Click the Applies to tab, and define if the property set definition should be applied to objects or to object styles.
- 6 Select the entities or styles to which the property set definition should apply.
Typically, you would attach project information to objects such as spaces, walls, doors, windows, and curtain walls.
- 7 Click the Definition tab.
- 8 Click  .
The general project properties are listed. If you have created project details, as described in [Project Schedule Properties](#) on page 378, they are listed too and can be selected for the property set definition.
- 9 Select a project property.
- 10 Enter a name, and click OK.
- 11 Repeat steps 8-10 for each project property you want to add to the property set definition.
- 12 If necessary, add other properties to the definition.
- 13 Click OK twice.

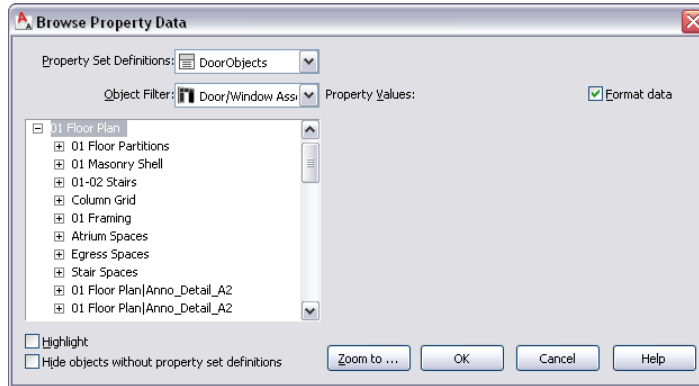

Attaching Property Sets to Objects from External References

Use this procedure to attach property sets to objects in external references.

This topic explains the following procedures:

- Attaching property sets to objects from external references.
 - Attaching different property sets to different instances of the same external reference. For example, you can reference the same floor plans onto multiple levels and schedule each level differently.
- 1 Reference a project drawing, such as an element or a construct, into another project drawing, such as a view or a plotting sheet.

2 Open the Scheduling tool palette, and select the Browse Property Data tool.

3 Under Property Set Definitions, select the property set definition from the host drawing with which you want to work.

4 Expand the desired external reference in the tree, until you can see the desired object.

5 Attach property set data to objects:

If you want to...

Then...

attach a property set from the host drawing to an object in an external reference

If no property set definition with the same name has been attached to the object, the row of boxes immediately next to it is empty. Select the box to check it. A property set is attached directly to the object. It is displayed on the right side, and can be edited.

override a property set from an external reference with a property set from the host drawing

If a property set with the same name has been attached at a lower level to the external reference, a read-only box is displayed at the appropriate level. Select the box at that level next to the object. The property set is attached to the external reference at the selected level as an override for the object. If a property set definition with the same name as that selected above exists in the external reference, it uses it, otherwise the property set definition in the host drawing is copied to the external reference. The property set is displayed on the right and is editable.

attach different property sets to different instances of an external reference

Expand the desired instance of the external reference in the tree. Select the box next to the object instance. To attach a different property set to another instance, select a different property set definition, expand a different instance of the external reference, and attach the property set to it.

remove a property set from the host drawing for an external reference

clear the box at the appropriate level next to the desired object.

6 If necessary, decrease the number of objects displayed in the tree:

If you want to...	Then...
show only one type of object in the tree	select the appropriate object under Object Filter.
show only those objects that already have the selected property set attached on some level	clear Hide Objects without Property Set Definitions.

- 7 If you are not sure whether you selected the correct object from the external reference, click Highlight to mark the object in the drawing area.
- 8 To display the correct object in the drawing area, click Zoom to.
- 9 If necessary, edit the property set data on the right.
- 10 To display properties with the correct data format style from the property set definition, select Format Data.
- 11 Click OK.

Creating a Schedule Table in a Project

Use this procedure to create a schedule table that contains property data from an external drawing such as a project drawing.

Schedule tables can contain information from external references and block references, which typically must exist in the same drawing as the schedule table. Schedule tables now optionally specify an external drawing, which is scheduled as if it were an external reference in the same drawing as the table. The advantage to this is that the graphics of the external drawing do not need to be generated in order to fill out the data in the table.

For general information on adding schedule tables, see [Overview of Schedules](#) on page 2485.

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

- 1 Open the sheet to contain the schedule table.
- 2 Open the tool palette that you want to use, and select a Schedule Table tool.
If necessary, scroll to display the tool that you want to use.
- 3 On the Properties palette, expand Basic, and expand General.
- 4 Select a style.
- 5 Instead of selecting objects in the drawing, press *ENTER*.
- 6 Specify the insertion point of the schedule table.
- 7 Specify the size of the schedule table.
A schedule table with no rows is inserted into the drawing.
- 8 Select the empty table, right-click, and click Properties.
- 9 On the Properties palette, expand Advanced, and expand External Source.
- 10 For Schedule External Drawing, select Yes.
The External Drawing settings are displayed, with a list containing all drawings in the Views directory of the current project. Each drawing should correspond to a view defined in the project. If no project is active, the list contains all drawings in the last directory browsed.
- 11 Select the view you want to schedule.

NOTE The setting for External Drawing Name is displayed only if you have selected Yes for Schedule External Drawing.

If the desired external view drawing is not displayed in the list, select Browse and find it.

Creating a Title Block for a Project

You can create title blocks that display information specific to the sheet set or the project. When the information changes, it is updated in the title block. A title block can be a multi-view block or a block and project sheet set fields that include project information from project attributes.

A title block would typically be placed in a sheet template or a sheet drawing. If it is in a sheet template, you can use it for all sheet drawings based on that template.

Process Overview: Creating a Multi-View Block Title Block

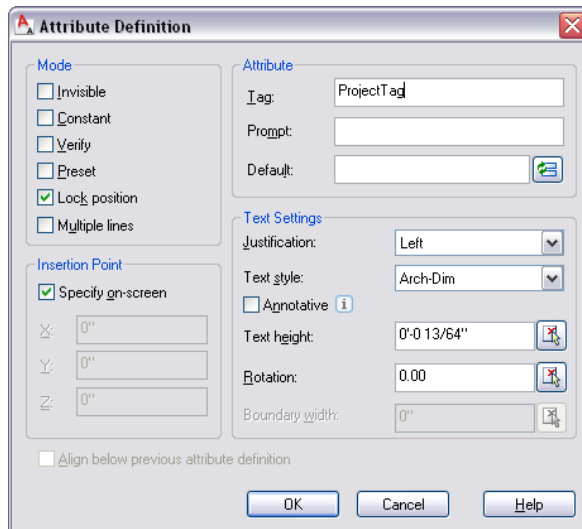

Creating a project title block consists of these basic steps:

- 1 Open the project drawing in which to add a title block. Typically, this is a sheet.
- 2 Add project attributes to the drawing.
For more information, see [Adding Project Attributes](#) on page 382.
- 3 Create a block from the attributes.
For more information, see [Creating a Project Block](#) on page 384 and [Create Annotative Blocks and Attributes in AutoCAD Help](#).
- 4 Create a multi-view block from the block.
For more information, see [Creating a New Multi-View Block Definition](#) on page 1898.
- 5 Insert the multi-view block as a title block in the sheet.
For more information, see [Adding Multi-View Blocks to a Drawing](#) on page 1904.

Adding Project Attributes

Use this procedure to create project attributes for a title block in the drawing.

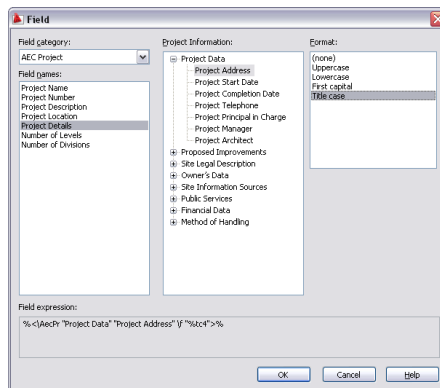

- 1 Click Format menu ► Blocks ► Define Attributes.

2 In the Attribute Definition dialog, enter a name for Tag.

3 Click  for Default.

The Field dialog is displayed.

4 In the Field dialog, select the field category you want to display in the title block.

For example, if you want to display details of the project, select AEC Project for Field category, and then select Project Details for Field names.

5 Select the text format for Format, and click OK.

6 Click OK to add the attribute.

For more information, see Attach Data to Blocks (Block Attributes) in AutoCAD Help.

7 Repeat steps 1–5 to add additional attributes to the project title block.

8 Complete the attribute block with lines and borders.

The result is a number of attributes and graphic elements in your drawing. Your attribute block might look like this:

MARK	DATE	DESCRIPTION
PROJECT NO:		PROJECT:NUMBER

Creating a Project Block

Use this procedure to create a block that contains the project attributes you want to display in a project title block. For information about adding attributes, see [Adding Project Attributes](#) on page 382.

- 1 Click Format menu ► Blocks ► Block Definition.
- 2 In the Block Definition dialog, enter a name for the block.
- 3 Click Select Objects, and select the attributes and additional graphics to include in the title block.
- 4 For Block unit, select Unitless.
- 5 Continue creating the block as described in Create Blocks Within a Drawing in AutoCAD Help.

Creating a Multi-View Block for a Title Block

Use this procedure to create a multi-view block that contains the blocks you want to display in the project title block. For information about creating blocks, see Create Blocks Within a Drawing in AutoCAD Help.

For detailed information about multi-view blocks, see [Creating Multi-View Block Definitions](#) on page 1896.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects.
- 3 Right-click Multi-View Block Definitions, and click New.
- 4 Enter a name for the new multi-view block definition, and press *ENTER*.
- 5 Select the new multi-view block definition, right-click, and select Edit.
- 6 Click the View Blocks tab.
- 7 Select a display representation for the title block.
Typically, you would display a title block in plan views and reflected views.
- 8 Click Add.
- 9 Select the block you defined in [Creating a Project Block](#) on page 384, and click OK.

- 10 Select the view directions for the block.
- 11 Repeat steps 6–10 for each display representation in which you want the title block to display.
- 12 Click OK twice.

Creating a Tool for a Title Block

Use this procedure to create a tool for inserting the title block in a drawing. It is assumed you have already defined the multi-view block, as described under [Creating a Multi-View Block for a Title Block](#) on page 384.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand Multi-View Block Definitions.
- 3 Locate the multi-view block definition you want to make into a tool, and drag it to the tool palette.
- 4 Click OK to close the Style Manager.

Inserting the Title Block in a Sheet

Use this procedure to insert a title block into a drawing using a tool you have created. See [Creating a Tool for a Title Block](#) on page 385.

Viewing title block attributes and data

title block detail
with project
number data

- 1 Click Window menu ► Project Navigator Palette.
- 2 On the Sheets tab, open the sheet on which you want to place the title block.
- 3 Open the tool palette that contains the title block tool you want to use.
- 4 Specify the insertion point for the title block.
- 5 If necessary, specify the scale and rotation of the title block.
- 6 Press *ENTER*.

Dimensioning a Project

Use this procedure to dimension objects in a project drawing.

In the documentation phase of a project, you create detailed dimensions of objects. AEC dimensions can be attached to objects in a drawing or to objects in an external reference. You can dimension objects in source drawings like elements or constructs, or you can dimension them in higher-level drawings like views or sheets.

For detailed information, see [AEC Dimensions](#) on page 2243.

1 Open the project drawing in which to add a dimension.

This may not be the drawing in which the object to be dimensioned is located. It may be a drawing that references the object. For more information, see [Associative Dimensions in External References](#) on page 2253.

2 Open the tool palette that you want to use, and select an AEC dimension tool.

If necessary, scroll to display the tool that you want to use.

3 On the Properties palette, expand Basic, and expand General.

4 Select a style.

5 In the drawing area, select the objects to dimension.

6 Press *ENTER*.

7 Specify the position of the new dimension:

If you want to...	Then...
insert the dimension group parallel to or perpendicular to the dimensioned object	drag the cursor in the desired direction, and click in the drawing at the desired insertion point. NOTE If your selection set contains objects with different directions, the direction of the first selected object defines the parallel and perpendicular directions.
insert the dimension group at a specified rotation	enter <i>r</i> (Rotation) on the command line, and press <i>ENTER</i> . Then, enter a rotation angle either by clicking in the drawing or by entering one on the command line. Press <i>ENTER</i> , and click in the drawing at the desired insertion point. NOTE If your selection set contains objects with different directions, the rotation is calculated with reference to the first selected object.
insert the dimension group aligned parallel to an object other than the dimensioned object	enter <i>a</i> (Align) on the command line, and press <i>ENTER</i> . Then, select the object to which to align the dimension group. Press <i>ENTER</i> , and click in the drawing at the desired insertion point. NOTE The direction of the dimension group is dependent on the rotation of the chosen object. The drawing direction of the object has no influence on the dimension group direction.

Working with Cut Planes in a Project

You can set a global cut plane for each display configuration in a drawing, and individual cut planes for objects like walls, curtain walls, and wall openings. For more information, see [Viewing Display Configurations](#) on page 554.

The Global Cut Plane

You can set a cut plane for a display configuration in a drawing. All objects included in that display configuration are cut at the height defined in the display configuration, unless they have an object-specific cut plane override. Each display configuration can have a different cut plane. For more information, see [Object-Specific Cut Planes](#) on page 394 and [Global Cut Planes](#) on page 388.

The Object-Specific Cut Plane

A number of objects can override the cut plane settings in the display configuration and use their own cut planes: for example, walls, curtain walls, and stairs. For more information, see [Object-Specific Cut Planes](#) on page 394.

Cut Plane Display Range

A cut plane is set to a specific height, for example, 1.4 meters. Objects above or below that level are by default not displayed in a plan view. You can, however, define a display range above and below the cut plane. Object components inside that range are displayed too. This would be useful if you want to display a window that lies above or below the cut plane but that should be included in the display.

Viewing plan view window cut plane options

You also use a display range to define clipped views, such as the model view of a second floor. In that case, the display range defines which levels to display and which levels to hide.

Clipped 3D view of second floor

For more information, see [Creating a Clipped Model View](#) on page 392.

Cut Planes and Levels

Levels are represented separately by one or more files and are assembled in a view or sheet to represent the entire building.

You set the cut plane individually for each level of a building. You create a drawing file—a construct or a view—that represents the level, and assign a cut plane to a display configuration within the drawing.

The following images illustrate a curtain wall that spans 3 levels. The images on the left indicate the cut plane for the associated level drawing. The plans to the right show how the curtain wall would be displayed in plan view at each level. Notice the different appearance of the doors and mullions on the various floor plans.

Specifying 3 cut plane levels

Global Cut Planes

The global cut plane cuts all objects in a drawing at the same height. It is defined separately for each of the display configurations that can be applied to a drawing, so you can have, for example, one cut plane height for a regular plan view and another cut plane height for a Reflected view.

The global cut plane is used on all objects that do not have an object-specific cut plane override. For more information, see [Object-Specific Cut Planes](#) on page 394.

Global Cut Plane Display Range

When you set a cut plane for a display configuration, you also set a display range above and below the cut plane. This is the range in which objects, even when they do not intersect the cut plane, are displayed. For example, if you set the cut plane to 1.4 meters and define the visible range above the cut plane at 2 meters and the visible range below the cut plane at 1 meter, then your objects are cut at 1.4 meters. Objects that lie between 1.4 meters and 2 meters as well as objects that lie between 1.4 meters and 1 meter are also displayed, but with different display for above and below the cut plane. Objects that lie outside the range—for example, a window that is inserted at 0.8 meter—are not displayed at all.

NOTE The values for the display range are calculated relative to the WCS, not relative to the global cut plane height.

Plan view of window cut planes

You also use a display range to define clipped views, such as the model view of a second floor. In that case, the display range defines which levels to display and which levels to hide.

Clipped 3D view of second level

For more information, see [Creating a Clipped Model View](#) on page 392.

Display Properties for the Cut Plane Display Range

Many objects have display components that you can set for display above and below the cut plane. For example, an object below the cut plane can be displayed with dashed lines and a different color. If you want to work with the display range, set the appropriate display components accordingly.

NOTE The Above and Below Cut Plane display components display in some plan-type display representations, such as Plan, Plan High Detail, Plan Low Detail, Plan Screened, Reflected, and Reflected Screened, as well as in user-defined display representations that are based on any of these display representations.

The following objects have display components for above and below the cut plane:

Object	Components that can be set for above and below cut plane
Curtain Walls/Curtain Wall Units	Curtain Wall/Curtain Wall Unit body
Doors	Frame/Panel/Stop/Swing/Threshold
Door/Window Assemblies	Door/Window Assembly body
Mass Elements	Mass Element body
Railings	Guard Rail/Hand Rail/Bottom Rail/Post
Slabs/Roof Slabs	Slab Body/Slab Outline

Object	Components that can be set for above and below cut plane
Stairs	Stringer/Stringer Facets/Riser/Riser Numbers/ Nosing/Path Outline
Structural Members	Beam/Brace/Column body
Walls	Wall Body
Windows	Glass/Frame/Sash/Sill

For more information on setting display properties for individual objects, see the appropriate procedures for the objects.

Setting the Global Cut Plane and the Display Range

Use this procedure to set the cut plane and the visible display range for a display configuration.

For information on the display system, see [Display Configurations](#) on page 549.

NOTE The values you enter for the Above and Below ranges are the absolute height values calculated from the WCS origin. They are not relative to the cut plane. For example, if you have set the global cut plane to 1.4 meters, set the visible range above the cut plane to a value higher than 1.4 meters; otherwise, you get an invalid display range.

1 Access the global cut plane controls using one of the following methods.

If you want to...

Then...

define the global cut plane height for the current display configuration

click the value for Cut Plane on the drawing window status bar.

define the global cut plane height for any display configuration

Click Format menu ► Display Manager. Then, select a display configuration in the left pane, and click the Cut Plane tab.

2 Define the cut plane and the visible ranges above and below the cut plane:

If you want to...

Then...

define the global cut plane height for the display configuration

enter the appropriate value for Cut Height.

define the visible range above the cut plane

enter the appropriate value for Display Above Range.

NOTE The value you enter here is calculated from the WCS origin and is not relative to the cut height.

If you want to...**Then...**

define the visible range below the cut plane

enter the appropriate value for Display Below Range.

NOTE The value you enter here is calculated from the WCS origin, and is not relative to the cut height.

3 Click OK.

Displaying the Cut Plane for a Specific Level

Use this procedure to display the cut plane for a specific level in a project.

Usually, you want to display the cut plane of the current level. However, in some cases, you might want to display a different level. For example, you may want to see how a curtain wall that spans several levels in a project will display at each level.

Specifying different cut planes results

result using first floor cut plane

result using second floor cut plane

- 1 On the Project Navigator, open a construct with a curtain wall.
- 2 If necessary, switch to a plan view.
- 3 Access the cut plane controls using one of the following methods.

If you want to...**Then...**

define the cut plane height for the current display configuration

click the value for Cut Plane on the drawing window status bar.

define the cut plane height for any display configuration

Click Format menu ► Display Manager. Then, select a display configuration in the left pane, and click the Cut Plane tab.

4 Click Calculate.

This button is only available when the drawing is part of a project. It uses the level information you entered in [Creating a New Level](#) on page 272.

5 In the Cut Plane Worksheet, select the level whose plan view you want to display in the current drawing.

For example, if you have created a view of the first floor but want to display the plan view of the second floor, select 2.

6 Select the cut plane height of the selected level.

For example, to display the second level at a cut height of 1.4 meters, enter 1.4 here.

7 Click OK.

The display range is adapted to display the height of the selected level.

For example, perhaps you have a 3-story building with a floor height of 2.75 meters for each floor. You have created a view of the first floor but want to display the second floor in it at a cut height of 1.4 meters. In the Cut Plane dialog, you enter 2 for level, and 1.4 for Cut Plane Height Above Level. When you click OK, the display range of the view now spans the second level. The following values are entered into the Cut Plane Tab of the display configuration:

Field Name	Value	Comment
Display Below Range	2.75 meters	This is where the second level starts.
Cut Height	4.15 meters (2.75 meters + 1.4 meters)	To display a cut height of 1.4 meters, add 1.4 meters to the start of the second level at 2.75 meters.
Display Above Range	5.5 meters	The second level starts at 2.75 meters, and has a base height of 2.75 meters. This results in an overall height of 5.5 meters.

8 Click OK.

Creating a Clipped Model View

Use this procedure to create a clipped Model view of a building level.

If a level is crossed by a spanning element like a curtain wall or an elevator shaft, you want to display only those parts of the spanning element that actually lie on that level. You can create a clipped Model view that displays only those objects and object ranges within the user-defined display range.

Clipped Model view

Some display settings for a clipped Model view are influenced by the materials assigned to the clipped objects:

- Display of object ranges outside the display range: You can display the parts of a spanning element that are outside the display range of the level. In some cases, you might want to display those parts of the object in a lighter color and thinner lineweight to imply the complete shape of the object.

3D view of spanning element in and out of display range

spanning element out of display range

spanning element in display range

How those parts are displayed is set in the Sectioned Body component of the object's materials. For information on setting the display of the Sectioned Body component, see [Sectioned Body and Sectioned Boundary](#) on page 614 and [Defining the Layer, Color and Linetype of a Material Definition](#) on page 626.

- Display of a section hatch and a section boundary where the display range cuts the spanning object: You might choose such a display to highlight the cut line. How the section hatch and boundary are displayed is defined in the Section Hatch component of the materials for the object. For information on setting the display of these components, see [Section Hatch Material Component](#) on page 613 [Sectioned Body and Sectioned Boundary](#) on page 614, and [Defining the Layer, Color and Linetype of a Material Definition](#) on page 626.

1 Create a view containing the desired level.

For more information, see [Creating a New View Drawing](#) on page 323.

2 If necessary, switch to a Model view: for example, SW Isometric.

3 Click Format menu ► Display Manager.

4 Expand Configurations.

5 Select the current display configuration.

It is displayed in bold text.

6 Click the Cut Plane tab.

7 Set the Above and Below display ranges to be identical to the level height.

For example, if your level is 2.75 meters high, set Display Below Range to 0.0 meters and Display Above Range to 2.75 meters.

NOTE For a clipped model view, it is not important how you set the cut plane, as the cut plane is displayed only in plan views. Either keep the original value, or enter any value within the display range: for example, 1.4 meters.

8 Expand Sets.

9 Select the current display set (displayed in bold text).

10 Click the Display Options tab.

11 Define the display of the clipped model view:

If you want to...	Then...
display the objects in the display range defined in step 7 with their regular display settings, and the objects outside of the display range as Sectioned Body	select Section AEC Objects by Display Range defined in Display Configuration.
show a section hatch and a section boundary where spanning objects are cut by the display range	select Show Materials where Display Range Intersects AEC Objects.
hide all parts of spanning objects outside of the display range	select Hide Sectioned Body Component.
suppress the surface hatch of objects within the display range	select Hide Surface Hatching.

12 Click OK.

Object-Specific Cut Planes

Many objects in AutoCAD Architecture have individual settings for cut planes that can override the cut plane setting of the display configuration. Object-specific cut planes are useful when you have objects of different heights in your plan view. This happens frequently when you are working with a window high in a wall.

An object-specific cut plane takes precedence over the global cut plane in the display configuration.

For more information on the global cut plane, see [Global Cut Planes](#) on page 388.

Example: Overriding the Cut Plane for a Wall

The object-specific cut plane is a part of the display properties of an object. You can set it for an individual object, an object style, or as the system default.

For detailed information on display properties, see [Display Representations](#) on page 544 and [Creating a Display Representation for an Object](#) on page 562.

TIP If you want to create a clipped model view, as described in [Creating a Clipped Model View](#) on page 392, or want to display the cut plane of a different level, as described in [Displaying the Cut Plane for a Specific Level](#) on page 391, make sure to turn off the object specific-cut plane of the included objects. The object-specific cut plane overrides the global cut plane, and so you might get unexpected display results.

The following is an example of how to set a cut plane for a wall style. The detailed steps for other objects may vary slightly. For more information, see the individual object chapters.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and then expand Wall Styles.
- 3 Select the wall style for which you want to set an individual cut plane, and click the Display Properties tab.
- 4 Select a Plan or Reflected display representation.
- 5 Click the Edit button.

- 6 Click the Cut Plane tab.
- 7 Select Override Display Configuration Cut Plane.
- 8 For Cut Plane Height, enter the desired cut plane.
- 9 Click OK 3 times.

Example: Using the Cut Plane of the Anchoring Object

Whether an anchored object uses the cut plane of its host object or the cut plane of the display configuration is set in the display properties of the object. You can define this for an individual object, an object style, or as the system default.

For detailed information about display properties, see [Display Representations](#) on page 544 and [Creating a Display Representation for an Object](#) on page 562.

The following example demonstrates how to set an anchored window to use the cut plane of the wall to which it is anchored. The detailed steps for other objects may vary slightly. For more information, see the individual object chapters.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and then expand Window Styles.
- 3 Select the window style for which you want to set the cut plane when anchored, and click the Display Properties tab.
- 4 Select a Plan or Reflected display representation.
- 5 Click the Edit button.
- 6 Click the Other tab.
- 7 Select Respect Cut Plane of Container Object When Anchored.

NOTE You should use this setting as the default. Even when the cut plane of the anchoring object does not differ from the global cut plane, this setting ensures a correct display of the anchored object in plan views.

- 8 Click OK 3 times.

Object-Specific Cut Plane Overrides

The following objects can have an object-specific cut plane:

- Curtain Walls
- Curtain Wall Units
- Door/Window Assembly
- Mass Elements
- Roof Slabs
- Slabs
- Stairs
- Walls

Cut Planes from the Anchoring Object

Objects like windows or doors usually are anchored into walls, curtain walls, and window assemblies. Normally, you want those anchored objects to have the same cut plane height as the object into which they are anchored. However, because the cut plane of the anchoring object can be set by either the display configuration or by the object itself, specify in the anchored object whether it should use the cut plane of the display configuration or of the object to which it is anchored.

The following objects can derive their own cut plane from the cut plane of the object to which they are anchored:

- Curtain Wall Units
- Doors
- Door/Window Assemblies
- Windows

Manual Cut Planes

You can define any number of manual cut planes for a wall or a curtain wall. Manual cut planes are only displayed when they are inside the display range.

For information on setting the manual cut plane, see:

- [Specifying the Cut Plane Display of a Curtain Wall](#) on page 1018
- [Specifying the Cut Plane Display of a Wall Style](#) on page 891
- [Specifying the Cut Plane Display of a Curtain Wall](#) on page 1018
- [Specifying the Cut Plane Display of a Curtain Wall Unit](#) on page 1104
- [Specifying the Cut Plane Display of a Door and Window Assembly](#) on page 1193

Drawing Management Commands

You can run certain Drawing Management commands from the command line. These commands are also available as toolbar buttons or context menu commands. In some cases, for example when creating LISP routines, you might want to initiate them via the command line.

Command Line: Opening the Project Browser

Use this procedure to open the Project Browser from the command line.

- On the command line, enter `AecProjectBrowser`.
The Project Browser is displayed.

NOTE Alternatively, you can click the  button on any of the Project Navigator tabs.

Command Line: Opening the Project Navigator

Use this procedure to open the Project Navigator palette from the command line.

- On the command line, enter **AecProjectNavigator**.
The Project Navigator palette is displayed.

NOTE Alternatively, you can click Project Navigator Palette on the Window menu.

Command Line: Refreshing the Project

Use this procedure to refresh the project on the Project Navigator palette from the command line.

- On the command line, enter **AecRefreshProject**.
The Project Navigator Palette is displayed, and all tabs are refreshed to display the current project state.

NOTE Alternatively, you can click the  button on each of the Project Navigator tabs.

Command Line: Regenerating Views

Use this procedure to regenerate all views in the current project from the command line. When you regenerate a view, you reload all of the external references used to generate the view.

- On the command line, enter **AecRegenerateProjectViews**.
All views in the current project are regenerated.

NOTE Alternatively, you can click the  button on the Views tab of the Project Navigator.

Command Line: Selecting a New Project Environment

Use this procedure to select a new project environment from the command line.

NOTE You can select only existing projects from the command line. To create a new project environment, go to the Project Browser and create a new project as described in [Setting a Project Current](#) on page 235.

- 1 On the command line, enter **AecSetCurrentProject**, and press *ENTER*.
- 2 Enter the project you want to set current on the command line.

NOTE Alternatively, you can click  on any of the Project Navigator tabs, and set the new project current in the Project Browser.

Command Line: Closing the Project Navigator

Use this procedure to close the Project Navigator from the command line.

- On the command line, enter **AecCloseProjectNavigator**.
The Project Navigator Palette is closed.

NOTE Alternatively, you can click the  button of the Project Navigator Palette.

Frequently Asked Questions about Drawing Management

This topic contains questions and answers that can help you to achieve the results you need when working with Drawing Management.

What do I have to consider when working with the XML files in the project?

The project data of a building model is contained in the APJ file, which contains information about the overall project, and in the XML files accompanying each DWG file. Both file types are well-formed XML. In most cases, you should not try to edit these files manually in an XML editor, as you might inadvertently corrupt the file. To make changes to your project, use the Project Browser and Project Navigator commands instead.

NOTE Do not delete any XML files generated by the Drawing Management feature. They are vital to the project.

I have added a lot of project details in the Project Browser. Can I export these to another application?

Yes. The project details you enter in the Project Browser are stored in the project's APJ file, which is a well-formed XML file. If you want to export these details, create a copy of the APJ file, and export it to any XML application or database. If you want to use the project detail categories and items in another project, use the existing APJ file as the template for the new project.

What should I do if my APJ file has been accidentally deleted or corrupted?

Deleting or corrupting the project's APJ files has no influence on the DWG files and XML files contained in the project. In the Project Browser, the project will not display anymore. To recreate the project with a new APJ file, go to the Project Browser, and create a new project of the same name in the same folder location as the previous APJ file. For instructions, see [Creating a New Project](#) on page 235. Then, go to the Project Navigator, and drag-and-drop the Elements, Constructs, Views, and Sheets folders of the project from Windows Explorer into the corresponding tabs of the Project Navigator. This re-inserts the files into the project.

What should I do if an XML file has been accidentally deleted or corrupted?

Each DWG file within a project has an accompanying XML file that contains the project-specific information. If the accompanying XML file is accidentally deleted or corrupted, the DWG file is no longer recognized as part of the project and will not display in the Drawing Explorer. To insert it into the project again, convert the DWG file into a project file. For instructions, see [Converting a Drawing to a Construct](#) on page 292 and [Converting a Drawing to an Element](#) on page 308.

Can I limit other users access to the project files?

You can limit other users ability to edit and delete project files by using the network permissions. You can limit the Delete rights for the entire project, so that users are not able to delete files from the project or move files around within the project. You might also consider just limiting the delete rights to the top project folder (containing the APJ file) and allow deleting in the subfolders.

How much additional file space will the project files need?

Working with a project does not require large additional amounts of file space on your computer or network folder. The XML files are less than 10K, most of them around 1-3K. The APJ file is slightly bigger, but in most cases will not exceed 10K either.

How can I best archive a project?

With AutoCAD Architecture, you can electronically transmit and archive a project. For more information, see [Electronically Transmitting a Project](#) on page 252.

Alternatively, you can copy and paste a project in Windows Explorer. All of the project files are contained in a folder structure within the top project folder, which also contains the APJ file. Just take the top project folder and move or copy it to the desired archive location on a folder, a CD, or streamer tape.

How would I best place Addenda, Alternates, or As-Built within the project?

How you organize these items would largely depend on your internal processes and workflow. One solution would be to draw the alternates as regular constructs and then create special views for them.

If you want to present completely different plans/elevations to represent Alternates, you could use divisions to represent them; when generating the view, you just need to include the appropriate division into the view.

In some cases you might also consider copying the project and putting the Alternates into the copied project. For instructions, see [Creating a New Project Based on a Template \(Copying a Project\)](#) on page 235. If you copy a project, however, you have 2 different file sets to maintain; the copied project does not retain any links to the original one.

How do I define the physical locations of constructs and elements in the building?

The location of the objects in a project file when referenced into another project file depends on the location in the original file. By default, project files are referenced at 0,0,0. When generating a view, the lowest level included in this view is placed at a Z axis of 0.

When referencing a project file into another project file, are basepoints other than 0,0,0 respected?

Yes. When referencing elements into constructs, and constructs into views, they are inserted at 0,0,0. A base point (INSBASE) other than 0,0,0 within the constructs and elements is respected.

Can I override the basepoints of project files when referencing them in other project files?

No. This is standard AutoCAD behavior.

Can I lock constructs and elements in their position to avoid accidentally moving them?

Yes. If you want to lock an element or construct within the building model, lock the layer the element or construct has been inserted on.

Is there an easy way to copy an element to multiple constructs at once?

Yes. Select the element in the Drawing Explorer, right-click, and click Attach Element to Constructs. For detailed instructions, see [Referencing an Element into Multiple Constructs](#) on page 297.

Is there an easy way to copy a construct to multiple levels at once?

Yes. There are 2 methods of achieving this, which are described in [Copying a Level with Assigned Constructs](#) on page 273 and [Copying Constructs to Levels](#) on page 291.

How do I move constructs from one level to another?

To move a construct to a different level, change its level assignment. Select the construct, right-click, and click Properties in the context menu. Then, choose a different level in the Assignments matrix. For detailed instructions, see [Changing the Properties of a Construct](#) on page 300.

Will wall cleanups work across walls from different divisions?

Yes. Walls do cleanup across external references, such as divisions. You just need to make sure that the wall baselines are at the same elevation.

Will AEC dimensions work with objects from external references?

Yes. AEC dimensions are capable of dimensioning objects from external references, even when they are nested. For detailed information, see [Dimensioning a Project](#) on page 386.

Will schedule tags and property sets work with objects from external references?

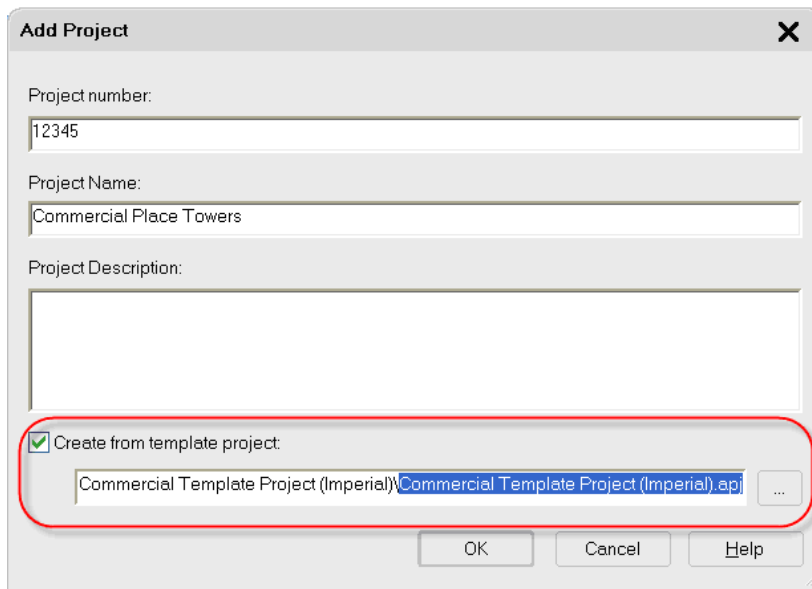

Yes. Schedule tags and property set definitions are capable of annotating objects from external references, even when they are nested. For detailed information, see [Tagging in a Project](#) on page 375 and [Property Set Data and Schedule Tables in Projects](#) on page 375.

Is the Project Navigator MDI compliant?

No. During a session of AutoCAD Architecture, only one project can be opened at a time. You can open files from different projects with the regular Open file command in the File menu. You do not, however, see the associated project on the Project Navigator palette.

Appendix I: Template Projects

A template project is an AutoCAD Architecture project that is used as the starting point for a new project. The files and folder structure of the existing project are used for the new project and are copied to the location you specify. You can access template projects when creating a new project in Project Browser.

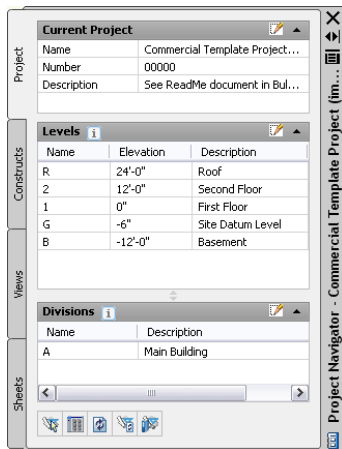

Once chosen, the template project is copied to the new location (selected in the Project Browser window before clicking the New Project icon) and then automatically repathed. A template project provides the equivalent benefits that DWT files provide for individual drawing files. Template projects help to speed project setup and ensure office standards and consistency.

Using the Commercial Template Project as template for a new project

- 1 Click File menu ► Project Browser.
- 2 In the Project Browser window, navigate to the location where you want to create the new project, and click .
- 3 Enter the project name and number, and then click Create from template project.
- 4 Navigate to the following project: C:\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Template\Commercial Template Project (Imperial)\Commercial Template Project (Imperial).apj. This includes United States-based constructs.
Alternatively, you can select the metric version.
- 5 Click OK and wait until the project has finished repathing.

Levels and Divisions

The Commercial Template Project includes 5 basic levels to get you started. For detailed information, see [Creating a New Level](#) on page 272.

If you are using divisions to divide the project laterally, set those up right away.

Project File Naming

Below is a summary of potential file names based on the recommendations of the US National CAD Standard as adapted to the Project Navigator and suggestions made here. For complete information and to purchase a copy of NCS visit: <http://www.nationalcadstandard.org/>.

An NCS Model file name is composed of a Discipline, plus a drawing type Code, followed by an enumeration (which typically corresponds to the floor number), though not always. (Elevations, for instance, would just be numbered sequentially in any logical order.)

For example:

- A-FP01 = Architectural First Floor Plan
- A-EL01 = Architectural Elevations (first group of elevations; there could be others named 02, 03, etc.)
The hyphen is used between discipline and code, but not between code and number.

NCS Recommends the following codes for Model files. Use these designations for View file names:

- FP = Floor Plan
- SP = Site Plan
- DP = Demolition Plan
- QP = eQuipment Plan
- XP = eXisting Plan
- EL = ELevation
- SC = SeCtion
- DT = DeTail
- SH = ScHedules
- 3D = isometrics/3D
- DG = DiaGrams

Technically, FP would be used for any type of plan and each would simply be enumerated. So, the first floor plan might be: A-FP01, while the first floor ceiling plan might be: A-FP02. However, A-FP02 for a ceiling plan on the first floor is confusing to most people and it is highly likely you would run out of codes with only 2 digits. Therefore, the following abbreviations are used almost universally by most firms:

- CP = reflected Ceiling Plan
- RP = furniture Plan
- EP = Enlarged Plan

While A-3D01 would technically be correct for the name of a composite model, the following is recommended:

- CM = Composite Model

So the file would be named A-CM01. (You could also use A-CM00 for the first composite model in a set. It is not that critical with which number you start.)

NCS knows nothing about constructs. Since their names indicate drawing type and function, they are best suited to use as View file names. Consider descriptive names for Constructs such as:

- 01 Walls
- 01 Shell and Core
- 01 Floor
- 01 Floor Plate (not Plan)
- Stair (for spanning Stairs)
- 00 Stair (alternative for stairs)
- Roof
- 01 Slab

For sheets, the NCS system is fine. They recommend the number of the sheet, which typically includes the discipline code as well. The number is in 2 parts: the first digit is a code indicating drawing type, and the remaining 2 are an enumeration.

- 1 = Plans (Horizontal Views)
- 2 = Elevations (Vertical Views)
- 3 = Sections (Sectional Views)
- 4 = Large Scale Views (Plans, Sections & Elevations that are not Details)
- 5 = Details
- 6 = Schedules and Diagrams
- 7 = User Defined
- 8 = User Defined
- 9 = 3D Representations (Isometrics, Perspectives and Photographs)

Examples:

- A-101 - (Architectural First Floor Plan)

- A-102 - (Architectural Second Floor Plan)
- A-103 - (Architectural First Floor Reflected Ceiling Plan)
- A-201 - (Architectural Building Elevations)
- A-301 - (Architectural Building Sections)

Constructs Included in the Commercial Template Project

All constructs included in the Commercial Template Project are suggestions of typical commercial project organization. Feel free to modify the arrangement to suit your specific project needs and add or delete files as needed. Some files may contain geometry; these are placeholders that are meant to be erased by project team members prior to beginning work. Simply erase the geometry, and draw actual project geometry in its place. For example, the Typical Toilet Room element file contains a rectangle, and many files include a Live Area Guide block insertion.

General Considerations for all Constructs

Typically there will be at least one construct for each level and/or division (if used). However, there will often be many more than that. Project and team member requirements will be a determining factor in shaping the exact quantity and makeup of the constructs on a per-project basis. Some projects will have many constructs per floor, while others might have only one per floor. Below is a brief description of each construct included in this Commercial Template Project. Feel free to add or delete them as required to meet your specific project and team needs. You can also make modifications to the Commercial Template Project and save it as a custom template project for use in later projects.

Terrain Construct

This construct is intended for a simple terrain model of the project's site conditions. The Terrain construct is referenced in the Site Plan, Composite Model, Section and Elevation View files.

Shell Construct

Several shell constructs have been included into the Commercial Template Project: one for each floor of the building. These constructs are intended for the exterior enclosure of the building. The various shell constructs are referenced in the Floor Plans, Composite Model, Section and Elevation View files.

Core Construct

This construct is intended for objects that are part of the building core (like walls, doors, etc.), excluding the stairs and possibly the toilet rooms. The stairs should be drawn in the separate stairs construct. Toilet rooms, if the layout is the same on all levels, can be drawn here and copied to each level. Otherwise, they can be created as an element file like the Typical Toilet Room element file (included in this Commercial Template Project), and then dragged into the Core construct file.

If you do not wish to have a separate core construct, core geometry can be drawn in either the Shell or Interior construct files instead. If you do this, delete the core construct(s) from the project.

The various Core constructs are referenced in the Floor Plans, Composite Model and Section View files.

Slab Construct

This construct is intended for slab objects and other objects that should display in sections and models but should not display in plans. The various slab constructs are referenced in the Composite Model and Section View files.

Interior Construct

This construct is intended for all geometry that is placed within the exterior shell of the building. This includes all partitions, doors, etc. on the interior of each floor. You can include space objects, ceiling grids, furniture and equipment in this construct as well. Or, if you wish, you can separate these other objects into their own spaces and grids and furniture constructs.

The various Interior constructs are referenced in the Floor Plans, Composite Model and Section View files.

Stairs Construct

This spanning construct is intended to contain the complete flight of stairs from the lowest level to the roof (if applicable). You can create separate constructs for each stair tower, or a single Stairs construct that contains all stairs for the entire project. If you view the properties of the construct on the Project Navigator palette, you will note that all levels are checked. This makes it spanning. To work with this construct, draw a single run of stairs at the lowest level, and add railings and any slabs needed for landings. Then use the Stair Tower Generate tool (on the Design Palette - Design Tool Palette Group) to copy the stairs, railings and slabs (if desired) to the upper levels. For more information, see [Stair Tower Generator](#) on page 1525.

To make the multi-story stair display correctly in view files, use the Medium Detail Intermediate Level display configuration as an external reference (xref) display override when referencing the stair into a view. Select the Medium Detail Intermediate Level display configuration for the intermediate levels, and the Medium Detail Top Level display configuration for the top level stair reference. For more information, see [Object Display in External References](#) on page 374

The Stairs construct is referenced in the Floor Plans, Composite Model and Section View files.

Roof Construct

This construct is intended for the roof of the building. You can create a separate roof construct for each discrete portion of the roof (lower roofs, wings, towers, etc.) or you can create all roofs in this file at their appropriate Z-heights relative to the roof level elevation. Parapets and other roof features can be included here or in other constructs as appropriate.

The roof construct is referenced in the Roof Plan, Composite Model, Elevation and Section View files.

Column Grid Construct

This construct is intended for structural column grids and their columns. Include column grids, columns, column grid bubbles and dimensions in this file. This file has been included in a Structural folder.

The various column grid constructs are referenced in the Floor Plans, Composite Model and Section View files.

The Element File Included in the Commercial Template Project

Elements are meant for typical conditions in the project and also are useful for miscellaneous project resources whose external referencing (xref) behavior you wish to control manually (not appearing automatically in views or sheets).

Typical Toilet Room Element

This element is intended for creating toilet room layouts that will occur more than once in the project. Rather than draw the same layout several times, or copy and paste it, only to have to redraw when changes occur, use an element to centralize edits to a single source file.

This element file contains a simple rectangle on a non-plotting layer as a way to alert you to its presence in the preconfigured files. Open this element and delete this rectangle and replace it with your actual toilet room geometry at the start of a project. The Typical Toilet Room Element is referenced into the various core constructs.

Views Included in the Template Project

A collection of starter views is included in this Template Project.

Consultant Backgrounds

This folder contains floor plan views that have been saved with the Screened display configuration active. For consultants that use AutoCAD Architecture or AutoCAD MEP, simply save and send these files. For consultants using AutoCAD, change the display configuration to Plan Only and then use the Export to AutoCAD command on the File menu to save a non-AutoCAD Architecture version of the file. For more information, see [Exporting a Drawing to AutoCAD](#) on page 173.

Detail Views

The only view in this folder simply provides a layout grid divided into a detail grid module. Draw details in this file on the detail grid. Create a new view for details at a different scale.

Enlarged Views

This folder is for interior elevations and enlarged plan views. Use the callout tools on the Callouts tab of the Tool Palettes to create such views. For more information see [Callout Tools in AutoCAD Architecture](#) on page 2451.

Floor Plan Views

Floor plan views are included here. Basic titemarks, elevation, and section markers are included in these files. You can use these, modify them, or erase and add them again as required.

3D Model Views

Composite Model views gather all the constructs together for visualization and/or coordination. Two are provided here, one of the entire model and another of just the shell constructs.

Reflected Ceiling Plan Views

Reflected ceiling plan views are included here. Basic titlemarks and elevation and section markers are included in these files.

Schedule Views

A composite Model is included in the Commercial Template Project for use in generating schedule tables. This view file is referenced directly by the schedule objects in the schedule sheet file included in the project (Sheet A601–Schedules). Reload external references and then update the schedule table periodically throughout the project to see the latest data. For more information, see [Updating a Schedule Manually](#) on page 2494.

Elevation and Section Views

These files are generated using the callout tools. They include 2D section/elevation objects of the overall building. Four elevations and 2 sections are included. As you add geometry to your constructs, you can move and resize the section and elevation lines as appropriate to capture the complete design and then refresh the sections and elevations. The constructs listed in this document are already included in the section and elevation objects' selection set. If you add new files, you will need to regenerate the section or elevation. For more information, see [Updating a 2D or 3D Section](#) on page 2177 and [Updating a 2D or 3D Elevation](#) on page 2225.

Sheets Included in the Template Project

Several basic sheets have been included in this Template Project. Some of the sheets already include viewports, such as the floor plans. Others are empty sheets ready to place views on. Drag a view file or named model space view within a View file from Project Navigator and drop it on the sheet. For more information, see [Placing a Model Space View onto a Sheet](#) on page 335 and [Creating a Sheet View](#) on page 353.

Sheets are organized in a sheet set and subsets. The list of sheets includes the following:

General	G-100, Cover Sheet
Architectural: General	A-100, Site Plan
Architectural: Plans	A-101, Floor Plans A-102, Floor Plans A-103, Floor Plans A-104, Floor Plans
Architectural: Elevations	A-201, Building Elevations A-202, Building Elevations
Architectural: Sections	A-301, Building Sections

Architectural: Large Scale Views	A-401, Enlarged Plans A-402, Interior Elevations
Architectural: Details	A-501, Details
Architectural: Schedules and Diagrams	A-601, Schedules
Architectural: 3D Representations	A-901, 3D Diagrams

Project Standards

Project Standards are a tool that allows project files to have their object styles and display settings synchronized to one or more Standards drawing files. The Template Project has been set up to only be synchronized with the standards when the user manually starts a synchronization. For more information, see [Setting up Synchronization of AEC Standards](#) on page 421.

In the project's Standards\Content folder, a file named Project Styles.dwg is included. Some sample styles have been included in this file. Tools in the Project's Tool Palette reference the styles in this file. The project is set to synchronize all types of styles to this drawing except layer key styles. The default AECLayerStd.dwg file has been set as a second Standards drawing to synchronize layer key styles.

In the Standards\Template folder, 2 additional drawing template files (DWT) have also been provided: one for constructs, elements and views and the other for sheets. The project is configured to synchronize display settings from the Model DWT file in this folder. All styles in the project have been versioned and synchronized to these files.

Project Standards

7

The Project Standards feature lets you establish, maintain and synchronize standards across all drawings in an AutoCAD Architecture project. Project standards include standard styles, display settings, and AutoCAD standards that are used across all project drawings. Standard styles and display settings are specified in one or more standards drawings associated with the project. Project drawings can then be synchronized with these standards throughout the project lifecycle, either automatically, or on demand. In addition, you can designate tool palettes and a Content Browser library that are associated with the project.

Project Standards Terminology

project drawing A drawing file belonging to an AutoCAD Architecture project. A drawing must be part of a project to access and be synchronized with project standards.

standards drawing A file (DWG, DWT, DWS) that contains standard styles and display settings associated with the project. Standards drawings can be placed in a folder within the project folder, if they contain project-specific standards, or outside the project folder if they contain department-specific or company-wide standards.

Standards drawings can be included in e-transmit and archiving packages.

standard style or display setting A style or display setting that has been defined as a standard for a certain project. To be defined as a standard style or display setting, it needs to be contained in a standards drawing. Standard style types and display settings include the following:

- object styles (for example, wall styles, door styles, and so on)
- property set definitions
- property data formats
- schedule table styles
- classification definitions
- display theme styles
- layer key styles
- mask block definitions
- material definitions

- multi-view block definitions
- profile definitions
- display properties
- display sets
- display configurations

Not standardized style or display setting A style or display setting in a project drawing for which no corresponding object can be found in the project standards drawings.

version The process of recording changes to project standard styles and display settings. Standard styles and display settings should be versioned when they are changed in a standards drawing. When a new version is created, the next synchronization recognizes the style or display setting as changed and lets you update the project drawing accordingly.

Nonstandard version of a standard style or display setting Standard styles and display settings in a project are versioned when they are changed either in a project drawing or a project standards drawing. A version of a standard style could for example have the date of July 14, 2006. The previous version could be a week earlier from July 7, 2006.

When the synchronization detects a version of the style or display setting in a project drawing that has a version date not found in the project standards drawing (for example, a version dated July 12, 2006), this version is labeled a “nonstandard version” of a project standard style or display setting.

older version of a standard style or display setting When the synchronization in the above example detects a version of the style or display setting dated July 7, 2006 in the project drawing, this is labeled as an “older version”, because the version exists in the project standards drawing, but has been updated by a newer one from July 14, 2006.

synchronization The process of checking a drawing or project against its associated standards to identify and remove version discrepancies between the standards and the project. Synchronization can be set up to run invisibly in the background, run automatically with user prompting, or can be manually initiated by the user.

project tool palette group A project tool palette group is associated automatically with the project. It can be referenced from a shared location or be copied to each user’s computer.

project tools Project tools are tools in the project tool palettes set for the project. In order to ensure that the current style definition is always used, project-specific tools should point directly to the styles within a standards drawing.

standards drawing location When standards drawings, catalogs, and libraries are located within the project folder, they are treated as project-specific. For example, if the project is used as a template for a new project, all files from the standards folder are copied to the new project, to enable changing and overwriting them in the new project. Standards files that are located outside the project folder are not copied when creating a new project; they are only referenced from their original location in both the existing and the new project. This would be appropriate for files containing company standards that should not be changed from project to project.

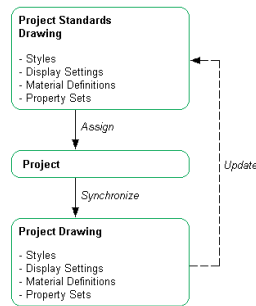

Project Standards Overview

Standard styles and display settings for a project are specified and stored in one or more standards drawings that are associated with the project. This allows you to organize your standards drawings in various ways. For example, you could have one standards drawing for styles, another for display settings, and a third for AutoCAD components such as layers, dimension styles, text styles, and linetypes. Or you could place all

your wall styles in one standards drawing and all of your property set definitions and data format styles into another.

Project standards can be accessed from a variety of AutoCAD file formats. They can be saved in one or more drawing files (DWG), drawing templates (DWT), or AutoCAD standards drawings (DWS). Each of these file types can be associated with a project as standards drawings.

The project can be compared to the project standards at any time during the project lifecycle, and if version discrepancies between the standards and the project drawings are detected, be synchronized with the standards. In addition, the standards can be updated from the project drawings if necessary.

AEC Standards

AEC standards for a project include all items from Style Manager and Display Manager. AEC standard objects are included in the synchronization and can be updated from a project drawing.

They include these items:

- object styles (for example, wall styles, door styles, and so on)
- property set definitions
- property data formats
- schedule table styles
- classification definitions
- display theme styles
- layer key styles
- mask block definitions
- material definitions
- multi-view block definitions
- profile definitions
- display properties
- display sets
- display configurations

Standard Scheduling Information

Project standards enable you to define and distribute a set of property set definitions, property data formats, schedule table styles, and object tags across a project. Property set definitions, property data formats, and

schedule table styles are created and accessed through Style Manager. Schedule tags are accessed through the project tool palettes.

Standard Material Definitions

Material definitions can be defined and distributed across the project. Materials are an integral part of object styles, and should be contained in the same standards drawing as the object styles that reference them.

Layer Key Styles

Layer key styles can be defined in a project standards drawing, and distributed across the project. Layer standards, however, are not set in the project standards. If you want to associate a layer standard with a project, you need to associate it with the drawing templates used for elements, constructs, views, and sheets.

Profiles

Profile definitions for a project are specified in one or more project standards drawings. Profiles can be used by many objects, for example mass element shapes or window styles.

Classification Definitions

A project may have a set of classification definitions in one or more standards drawings. Classifications are used as a reporting and display tool for building objects. Classifications are attached to object styles. If you want to use a classification in a project standard style, the classification needs to be stored in the same standards drawing as the object style to which it is referenced.

Display Settings

You can define standard display representations, display sets, and display configurations for a project. This will ensure consistent display of drawing objects in the project. Only one display standards drawing can be set for a project.

AutoCAD Standards

The Project Standards feature integrates the AutoCAD Standards checker, allowing the user to set up one or more DWS files for AutoCAD components. AutoCAD components that can be included in a standards check are:

- AutoCAD dimension styles
- AutoCAD layers
- Text styles
- Linetypes

When you set up AutoCAD standards, a CHX batch checker file is created for the project. The CHX file contains all project drawings as drawings to be checked, and all specified DWS files as drawings to check against. You can run this batch file for checking the whole project, or check individual project drawings manually. For more information, see [Synchronizing a Project with AutoCAD Standards](#) on page 452 and [Synchronizing a Project Drawing with AutoCAD Standards](#) on page 453.

Standard Tools

Standard styles can be organized and accessed through tools. You can define project tool palettes and a project library in Content Browser for quick and easy access. For detailed information, see [Setting up Standard Tools in a Project](#) on page 425.

Project Tool Palette Group

You can define a project tool palette group containing standard project styles. You can choose between defining a shared tool palette group on a network location, or a copy of the project tool palette group on the local users' machines.

Standard Content Browser Library

An icon now appears on the Project Navigator Palette to launch the Content Browser. You can set a custom Content Browser library that is opened by default when Content Browser is started from the Project Navigator. With the possibility of creating tool catalogs from existing drawings, as described in [Creating a Project Standards Tool Catalog](#) on page 427, it is now easy to create standard tools and catalogs for a project.

Synchronizing the Project

During the lifecycle of a project, project standards can change. For example, the hatching associated with a wall component can change its pattern, or a property set definition can have added properties. In cases such as these, the project must be synchronized with the modified standards. You can configure the project standards so that project drawings are automatically checked against the standards when opened, and automatically updated with the new edits. You can also manually start a synchronization for a project drawing or on the complete project at any time or you can configure standards for manual synchronization regardless of the overall project synchronization settings.

Process Overview: Using Standards in a Project

Setting up and using standards in a project entails the following actions:

- 1** Create standard styles, display settings, and AutoCAD components in one or more standards drawings.
Standards drawings can be drawing files (DWG), drawing templates (DWT), or AutoCAD standard files (DWS).
Optionally, you can create different project standards files for different styles, display settings, and AutoCAD components.
- 2** If desired, create a tool catalog that uses the styles from the standards drawings for their tool definitions.
- 3** Optionally, you can create a Content Browser library that should be used throughout the project.
- 4** Associate the standards drawings with the project.
- 5** If there are multiple standards drawings for styles, define which style type should be controlled by which standards drawing.
- 6** Set up the desired synchronization behavior of the project.
You can choose between different synchronization modes, depending on your project workflows. For example, you can specify that a project drawing is synchronized with the standards when it is opened, or you can specify that synchronization happens only manually.

- 7 Add standard styles and display settings to your project drawings by one of these methods:
 - Use tools from the standard palettes.
 - Use tools from the standard Content Browser library.
 - Copy styles and display settings from the standards drawings through Style Manager and Display Manager.
- 8 Synchronize project drawings with the project standards. Project drawings can be synchronized automatically on opening, or manually by the user.
- 9 Update any inconsistent objects.

Using Project Standards

Project standards help ensure consistency across a project.

The following workflows demonstrate how to use standards in a project:

- The user opens a project drawing, and the styles and display settings are synchronized with the associated project standards. Depending on the standard settings, the user can either be prompted to update out-of-synch objects, or they can be automatically updated by the software.
- The CAD manager makes changes to a style in a standards drawing, applies a version to the change, and saves and closes the standards drawing. The next time a project drawing is opened it can be synchronized with the changed style, making it match the version in the standards file.
- A user receives a project drawing from another user or a subcontractor, and performs a standards audit on it to determine if there are any not standardized styles or display settings, or if any of them are out-of-date. The user can decide whether to update out-of-date styles and display settings, or ignore them.
- The CAD manager sets up a default Content Browser library for the project. When a user starts Content Browser from the current project in Project Navigator, the project library is displayed. The user can then drag standard tools into a project drawing.
- To create a standard tool catalog based on an existing project, the CAD manager opens the AEC Tool Catalog Generator, browses to the project, and creates a tool catalog from the project drawings. He adds the new catalog to a Content Browser library and connects that library to a project. From there, the tools can be used either directly in the project or be used to build up a project-specific tool palette group.
- To transmit the project to an external subcontractor, the CAD manager creates an e-transmit package containing all project drawing files, standards drawings, and standard catalogs, as well as the standard Content Browser library. The subcontractor unzips the package to access these standard objects for use on the subcontracted design work.
- The CAD manager wants to create a hierarchical structure for standards. Some standards are specific to the project, whereas others are specific to a customer or general company standards. By placing different standards drawings in different locations, some can be copied and overwritten for a specific project, whereas others are referenced from a central location and are read-only.

Prerequisites for Working with Project Standards

The following points need to be taken into consideration to work efficiently with the project standards feature:

- Project standards can be used only with projects. A drawing must be part of a project to be synchronized with project standards. Project standards cannot be applied to standalone drawings. You can copy standard

styles and display settings into standalone drawings, but they will not be synchronized when the standards change.

- Project standards can be distributed among multiple standards drawings, if desired. However, there can be only one drawing that is designated for the display settings in a project.
- Project standards can be stored in DWG, DWT, and DWS files.
- AutoCAD standards for layers, text styles, linetypes, and AutoCAD dimension styles must be placed in DWS files.
- Demand loading needs to be enabled for working with project standards. The XLOADCTL system variable must be set to 2 (default value).

Setting up Standards in a Project

You can define one or more files to use as the source for standard styles and display settings. You can also specify options for synchronizing the styles and display settings with the standards. Additionally, you can set up DWS files for AutoCAD layers, dimension styles, text styles, and linetypes.

Creating a New Project with Predefined Standards

The quickest and easiest way to create a new project that already has standards associated with it, is to use an existing project with standards as a template. When you use an existing project as a template, the following files and structures are copied to the new project:

- All project DWG files and XML files
- AEC standards files
- AutoCAD standards files
- Project standards synchronization settings
- Sheet set template
- Project details
- Drawing template paths
- Keynote and detail component database paths
- Project tool palette group
- Tool content root path
- Project Content Browser library

NOTE Project standards files, tool palettes, and the project Content Browser library are copied to the new project only if they are located within the original project folder. Standard components located outside the project folder will be referenced by the new project, but not copied to it.

For information about creating a project with predefined standards, see [Creating a New Project Based on a Template \(Copying a Project\)](#) on page 235.

When you create a new project based on a template, all files that are in the project folder, will be copied, including the project drawings (DWG) and their associated XML files. If you want to copy only the standards

files and support files, as well as the structure of the project, you need to create a project with a copied structure, as described in [Creating a New Project with the Structure of an Existing Project](#) on page 237.

Configuring Project Standards

After setting up a project, you can configure the project standards. If you have created a project based on a template, the initial project standard settings come from the template. If you have not used a template, the settings are undefined or default settings.

Project standard settings include the following:

- Standard styles
- Standard display settings
- Synchronization settings
- AutoCAD standards (layers, dimension styles, text styles and linetypes)

NOTE To set up project standards, you must have one or more project standards drawings available. If you have created a new project based on a project with standards, the standards drawings of the original project are copied to the new project and are automatically associated with the new project. If you have created a new project not based on a template, or based on a project without standards, you first need to define one or more standards drawings. For more information, see [Creating a New Project Standards Drawing](#) on page 456.

Setting up Standard Styles and Display Settings

Use this procedure to set up standard styles and display settings for a project.

NOTE Standard styles include object styles, definitions, profiles, materials, property set definitions, and classifications.

To set up standard styles and display settings, you define one or more project standards drawings that contain the standards for styles and display settings. These drawings can be DWG, DWT, or DWS files and are added in the configuration dialog.

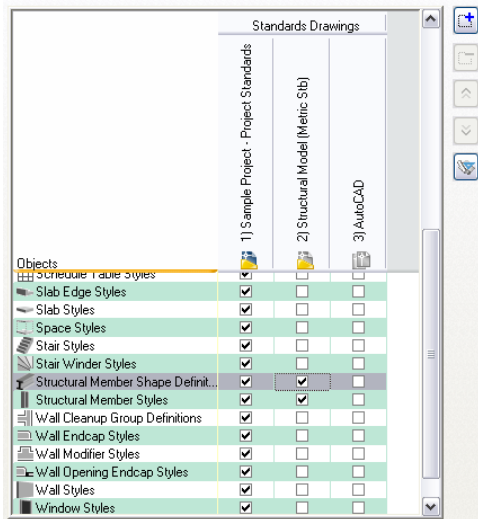

Standard files are marked by icons next to their name in the configuration setup.

Icon	Description
	Standards drawing (DWG)
	Standards template (DWT)
	AutoCAD Standards file (DWS)
	Missing standards file

Synchronization Order

If you have multiple standards drawings associated with a specific style type, then during synchronization the occurrence of the style in the first standards drawing is used as the style with which the style in the project drawing is synchronized. Further drawings containing the same standard style are ignored.

Order of standards drawings

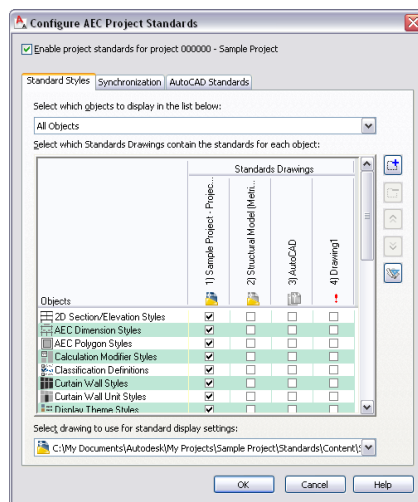

1 Click File menu ➤ Project Browser.

NOTE To access the standards configuration of the current project only, you can click AEC Project Standards ➤ Configure on the CAD Manager menu. If the CAD Manager menu does not appear on your menu bar, click Window ➤ Pulldowns ➤ CAD Manager Pulldown.

2 Select the project for which you want to configure standards, right-click, and click Project Properties.

3 Next to Project Standards, click Configure.

4 To add a new standards drawing for styles, click  .

5 In the Select Standards Drawing dialog box, select a DWG, DWT, or DWS file that contains standard styles, and click Open.

If you do not yet have standards drawings, see [Creating a New Project Standards Drawing](#) on page 456.

The new styles drawing is appended to the Standards Drawings list. The order of the columns, from left to right, defines the search order and precedence during synchronization. To change

the order of the drawings, select the drawing name in the column header, and click  to

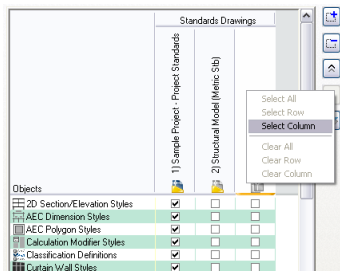

move the drawing up in the drawing order, and click  to move the drawing down in the drawing order.

After you have added styles drawings to the project standards setup, you need to define for which style types each drawing should be the standard. To do this, you associate each style type with a standards drawing. The style types are listed under Objects in the Standard Styles tab. You can find all style types from Style Manager here.

6 To display only style types of one style category, select the category under Select which objects to display in the list below. If you want to see all style categories, select All Objects.

7 To define that a specific style type should be controlled by a specific standards drawing, click the style type's check box in the appropriate drawing column.

TIP If you want to select one drawing for all style types, right-click in the header, and click Select Column.

If a style type has not been associated with a standards drawing, these styles are not controlled by the standards. For example, if the standards drawing “Standard Styles 1.dwg” has not been associated with the Wall Styles type, then even if wall styles from this standards drawing exist in a project drawing, they will be interpreted as “not standardized” by the synchronization.

If you select multiple standards drawings for one style type, then during synchronization, each drawing is searched for that style type in the order of the drawings. This means that you can distribute standard styles for a style type among different drawings. For example, you could store your concrete wall styles in the standards drawing “Wall Styles - Concrete (Imperial)”, and your brick wall styles in the drawing “Wall Styles - Brick (Imperial)”.

NOTE If two standards drawings contain a style of the same name and type, the style in the first standards drawing will be used for synchronization. Further instances of that style will be ignored. The order of standards drawings is determined by their position from left to right in the table.

re-order the drawings, use the Up  and Down  buttons.

8 To remove a standard styles drawing from the project, click on its name in the Standards Drawings list, and click .

Removing a standards drawing from the list only removes the reference of this drawing to the project. The drawing is not deleted from the file system.

Next, you need to define a standards drawings for the display settings in the project. You can assign only one standards drawing for display settings. The standard display settings drawing can be one already assigned as a styles standards drawing.

- 9 Under Select drawing to use for standard display settings, select a file. If necessary, select Browse to browse for a file.

NOTE If you are using a display standards drawing that is different from the styles standards drawing, or if you have multiple styles standards drawings, you need to make sure that the styles standard drawings are in synch with the display standards drawing. For more information, see [Synchronizing Project Standards with Each Other](#) on page 468.

- 10 Click the Synchronization tab.

If you have added a standards drawing to the project, and the drawing is located in the project folder, the drawing will automatically have initial version information added to all styles and display settings. If the new standards drawing is located outside the project folder, and has not yet been versioned, you need to version it as described in [Versioning a Project Standards Drawing](#) on page 466. For more information about versioning, see [Versioning Standards](#) on page 459.

- 11 If necessary, enter a universal comment to all versioned styles and display settings.

For instance, you might want to add a comment to indicate what has changed in the style as of this version.

- 12 Click OK.

NOTE If some of the standards drawings have been set to read-only, they cannot be automatically versioned. In this case, they need to be versioned manually by a user with read-write access.

Synchronization Options

When a project uses standards, it needs to be synchronized with the standards in regular intervals to make sure the standards are observed. During synchronization with its standards, the styles and display settings in the project or project drawing are compared with the project standards, to find version discrepancies between them, and fix them.

You can set different synchronization options. Before deciding on settings, you should review your desired workflow to find the optimal choice. Keep in mind that the option you select will be in effect for all users of the project.

Automatic Synchronization

If you select automatic synchronization, the following behavior is defined for the synchronization:

- Project drawings are compared with the project standards when they are opened.

- In case of version discrepancies between a project drawing and the project standards, the styles and display settings in the project drawing are overwritten by the styles and display settings from the project standards without prompting. The user cannot prevent the update.
- No notification of not standardized styles and display settings in the project drawing is displayed during the automatic synchronization. If not standardized styles and display settings exist, they are ignored.

TIP To display not standardized styles and display settings, you can audit the drawing, as described in [Auditing a Project or a Drawing](#) on page 454.

- When users make changes to a standard style or display setting in a project drawing, they will not be prompted to upload the styles or display settings to the projects standards drawings accordingly. Unless a user uploads the changed objects to the standards drawing manually, they will not be copied into the standards drawing.

Semi-Automatic Synchronization

If you select semi-automatic synchronization, the following behavior is defined for the synchronization:

- Project drawings are compared with the project standards when they are opened.
- In case of version discrepancies between a project drawing and the project standards, a notification dialog is displayed where the user can decide whether the styles and display settings in the project drawings should be overwritten with the standards. The user has the option to ignore inconsistent styles and display settings.
- Not standardized styles and display settings in the project drawing are displayed in a list.
- When users make changes to a standard style or display setting in a project drawing, they will be prompted to upload the styles or display settings to the projects standards drawings.

Manual Synchronization

If you select manual synchronization, the following behavior is defined for the synchronization:

- Project drawings are *not* compared and synchronized with the project standards when opening the project drawing. To perform a synchronization, the user needs to manually initiate it. For more information, see [Synchronizing a Project with the Standards](#) on page 440.
- In case of version discrepancies between a project drawing and the project standards, a notification dialog is displayed where the user can decide whether the styles and display settings in the project drawings should be overwritten with the project standards. The user has the option to ignore inconsistent standard styles or display settings.
- Not standardized styles and display settings in the project drawing are displayed in a list.
- When users make changes to a standard style or display setting in a project drawing, they will *not* be prompted to upload the changes to the projects standards. Unless a user uploads the changed standards in the standards drawing manually, they will not be copied into the standards drawing.

The synchronization settings are valid for all users of the project. So the synchronization method selected should reflect the workflow needs of the majority of users. For example, if you want all users to be in synch with all project standards at all times, you should choose automatic synchronization. If you want greater transparency and user control, you could choose semi-automatic or manual synchronization.

If you have selected automatic synchronization, the synchronization of project drawings will run “invisible” in the background. On opening, each drawing will automatically be synchronized with the standards without notification to the user. If you have selected semi-automatic or manual synchronization, you have more

control and information about the synchronization process; you can display lists of not standardized styles and display settings, nonstandard versions, or older versions, and individually decide if you want to update or ignore them.

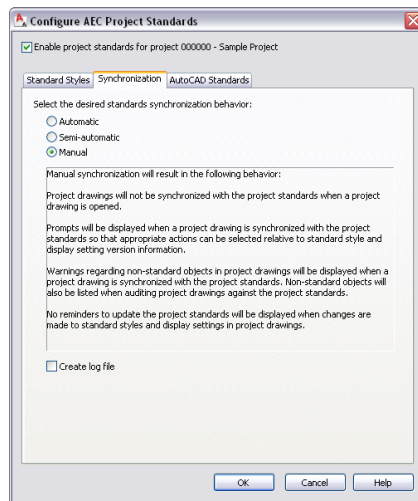

Setting up Synchronization of AEC Standards

Use this procedure to set up the synchronization options for the AEC standards in a project.

NOTE The synchronization settings you define are relevant only for the synchronization of the AEC standard styles and display settings in a project, as specified in [Setting up Standard Styles and Display Settings](#) on page 416. They do not affect the synchronization of AutoCAD standards in a project, as defined in [Setting up AutoCAD Standards](#) on page 422. For more information about synchronization, see [Synchronizing a Project with the Standards](#) on page 440.

NOTE The settings in this dialog box control only how project drawings are synchronized with project standards drawings. They do not specify how project standards drawings are synchronized with each other. For information on synchronizing project standards drawings, see [Synchronizing Project Standards with Each Other](#) on page 468.

- 1 Click File menu ► Project Browser.
- 2 Select the project for which you want to set the AEC standards synchronization, right-click, and click Project Properties.
- 3 Next to Project Standards, click Configure.
- 4 Click the Synchronization tab.

- 5 Select the synchronization method for your project.
For information about the available methods, see [Synchronization Options](#) on page 419.
- 6 To create a log file of the synchronization, select Create log file.
When the log file is created, you can choose between a report in XML or HTML format. The log file contains information about the drawings synchronized, the standards drawings used, and the changes made to standard styles and display settings in the course of synchronization.
- 7 Click OK or click the AutoCAD Standards tab.

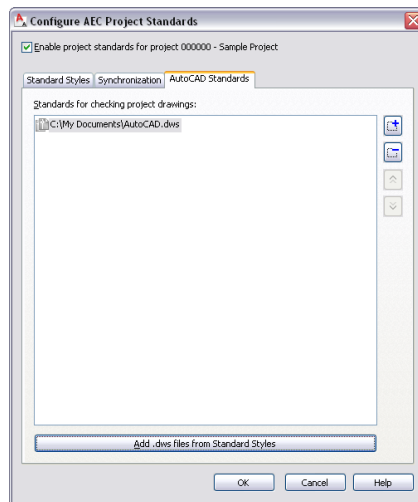

Setting up AutoCAD Standards

Use this procedure to set up AutoCAD standards for the project.

AutoCAD standards include AutoCAD layers, AutoCAD dimension styles, text styles, and linetypes, and are contained in DWS files. You cannot define different DWS files for different components; for example, you cannot define one DWS file for dimension styles, and another one for linetypes. Each setting from each DWS file is processed. If there is conflicting information in different DWS files, then the first one in the list is used. If necessary, you can change the order of the DWS files to change the precedence. For more information, see “Define Standards” in AutoCAD Help.

When you set up AutoCAD standards, a CHX batch checker file with the same name as the project file is created in the project folder. The CHX file contains all project drawings as drawings to be checked, and all specified DWS files as drawings to check against. You can run this batch file for checking the whole project, or check individual project drawings manually. For more information, see [Synchronizing a Project with AutoCAD Standards](#) on page 452 and [Synchronizing a Project Drawing with AutoCAD Standards](#) on page 453.

- 1 Click File menu ► Project Browser.
- 2 Select the project for which you want to set up AutoCAD standards, right-click, and click Project Properties.
- 3 Next to Project Standards, click Configure.
- 4 Click the AutoCAD Standards tab.

- 5 To add a new DWS file, click .

By default, the new DWS file is appended to the end of the list. That means that will be processed last, and settings from higher listed DWS files will take precedence.

- 6 To change the order of the DWS files in the list, use the Up  and Down  buttons.

- 7 To remove a DWS file from the list, click on its name in the list, and click .

Removing a DWS file from the list only removes the reference of this file to the project. The file is not deleted from the file system.

- 8 If you have set up DWS files as AEC standards drawings in [Setting up Standard Styles and Display Settings](#) on page 416, you can re-use them for the AutoCAD standards by clicking Add .dws files

from Standard Styles. This will copy the AEC standards files to the AutoCAD Standards tab, and use them as AutoCAD standard files in the project.

Copying Project Standards from Another Project

Use this procedure to copy the project standard settings from an existing project.

Copying the project standards copies the following standards settings:

- Copy or reference the style and display standards drawings to the new project
- Copy or reference AutoCAD standards drawings to the new project
- Duplicate the association of standards drawings to style types in the new project
- Duplicate the synchronization settings in the new project

When you copy the standards of an existing project to a new project, standards drawings can be either referenced from their original location in the new project, or be copied to the new project.

- If the project standards drawings of the copied project are located within the original project folder, then the drawings are copied to the new project. You would do this if you wanted to have a separate set of project standards drawings for each project you create. That way, you can make project-specific changes for each set of project standards.
- If the standards drawings of the copied project are outside the original project folder, they will not be copied to the new project, but will be referenced from their original location. You could do this if your project standards are not specific to one project, but are rather department-specific or company-wide standards. If you make changes to a project standards drawing referenced by several projects, all projects will be able to be synchronized with the changes.

1 Click File menu ► Project Browser.

2 Select the project into which you want to copy standards, right-click, and click Project Properties.

3 In the Modify Project dialog box, click Configure next to Project Standards.

4 Click the Standard Styles tab.

5 Click .

6 In the Select Project dialog box, select the project file (APJ) from which you want to copy project standards, and then click Open.

7 Select the copy settings.

If you want to...

Then...

overwrite the existing project standards with the copied project standards	click Remove existing settings.
--	---------------------------------

If you want to...**Then...**

add the project standards from the selected project to any existing project standards

click Append copied settings to existing settings. Existing settings that are inconsistent with the copied settings will be replaced with the copied settings.

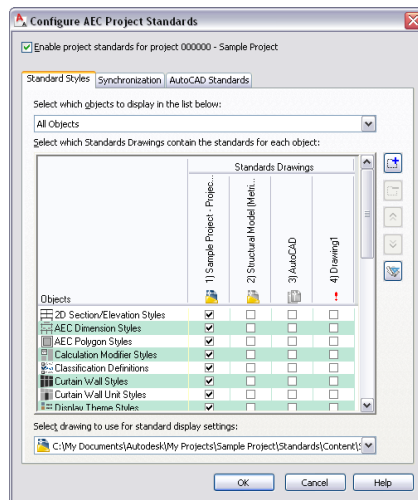

8 Click OK twice.

Enabling Project Standards for a Project

After defining the standards for a project, you need to enable them to make them active within the project.

While you are still working on setting up the standards for a project, you might not want the standards to be activated in the project right away, as standards styles might still be added, removed, or changed. Once the setup is complete, however, you must enable the standards for the project.

- 1 Select the project for which you want to enable project standards, right-click, and click Project Properties.
- 2 In the Modify Project dialog box, click Configure next to Project Standards.

3 Select Enable project standards for project <Project Name>.

4 Click OK twice.

The selected synchronization behavior (automatic, semi-automatic, or manual) is now activated.

NOTE Enabling the standards in a project does not mean that standard styles and display settings are copied to project drawings. To add standard styles and display settings to project drawings, see [Adding Standards to a Project Drawing](#) on page 437.

Generating a Project Standards Setup Report

Use this procedure to create an HTML or XML report that lists the project's standard drawings, and standard styles and display settings, along with their version history.

- 1 Verify that the project for which you want to create a standards setup report is set as the current project.

For information on setting a project current, see [Setting a Project Current](#) on page 235.

2 Click CAD Manager menu ► AEC Project Standards ► Project Standards Setup Report.

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

3 In the Save Setup Report dialog box, select a file name, location, and format for the generated report.

4 Click Save.

The report is saved in the specified location and can be displayed with a Web Browser or XML editor.

Setting up Standard Tools in a Project

Every project has a project tool palette group associated with it. If you are using project standards, the tools should point to standard styles from a project standards drawing. To make working with project tools easier, a project-specific library can be created in Content Browser.

Setting up standard tool palettes is usually a task for a CAD manager or project owner. Depending on the requirements of the project, different steps can be taken to achieve the desired results. The main considerations for creating the project tool palettes are the following:

Per User Workspace Catalog and Shared Workspace Catalog

The CAD manager can decide whether to create a group of tools and palettes that are shared by all users of a project and accessed from a single location, or to define a project catalog and Content Browser library, and maybe create a starter set of palettes for copying to individual users' computers. For more information, see [Before You Begin: Working in a Network Environment](#) on page 227.

AutoCAD Architecture loads the tool palettes found in the paths specified in the Files tab of the Options dialog box. Projects allow you to specify an additional location path for a tool palettes file that contains project-specific tool palettes. This path is appended to the current profile when the project is made current, and removed when the project is closed or when another project is set current.

Projects support two workflows for working with project palettes:

Per user workspace catalog: This is the recommended option. Use the Per user workspace catalog option in conjunction with project tool catalogs in Content Browser. In this mode, users can access the tools and tool palettes they need for the job from tool catalogs in Content Browser on a per-user basis. By utilizing the refresh/linking behavior of Content Browser, you can make changes to the original tools and tool palettes in project catalogs, and your team can refresh their tools and palettes to get the latest versions. Thus, each user's workspace is maintained by the application uniquely, but linked palettes allow for global updates.

You can optionally provide your project team with a starter set of tool palettes, including the initial layout and tool ordering. To do this, you would create the project palettes in your own workspace, and then use Windows Explorer to copy the files to the location specified for the tool palette file location in the project properties. For detailed instructions, see the workflow examples below.

Shared workspace catalog: This option is recommended if you wish to mandate a set collection of project tool palettes for everyone on the project. In this case you do not want users going to Content Browser to customize project tools or tool palettes. To create a shared workspace, you specify a shared network location and assign it to the tool palette file location of the project. As this path will be appended to every project team member's profile when the project is set current, the path should be read-only. Otherwise changes made by one user would affect every user, and the last change would be the final form of the tool.

NOTE If you make changes to the shared tool palettes, they are not copied to disk until you close the project to close AutoCAD Architecture. Similarly, other users will not see your updates until the next time the project is set current or AutoCAD Architecture is closed and re-opened with the project still current.

Using Content Browser or Style Manager

You can create standard catalogs in Content Browser and define a standard Content Browser library for a project. You can use the catalog and library to drag tools and palettes to the workspace or to the project tool palettes. This would likely be the case if you set up the project using the Per user workspace catalog option. If you do not want to give users access to a Content Browser library with standard tools, do not set a library for the project. In that case, you need to build the project tool palettes from standard styles in Style Manager. You would typically do this if you are using the Shared workspace catalog option.

Using Linked or Unlinked Tools

When you build your project palettes from a project catalog in Content Browser, you can either link the palettes and tools from Content Browser, or create an unlinked copy in the project palettes. If you want to be able to make frequent updates in Content Browser, linking tools and palettes is recommended.

Following are two suggested workflows for setting up standard tools. The first one is based on a per user workspace catalog, giving more freedom to the individual users of the project. The second one is based on a shared workspace catalog, and puts greater emphasis on adhering to a given structure.

Workflow 1: Using a Per User Workspace Catalog

- 1 Create standard styles in standards drawings and associate them with the project. For more information, see [Creating a New Project Standards Drawing](#) on page 456 and [Setting up Standard Styles and Display Settings](#) on page 416.
- 2 Create one or more tool catalogs from the standards drawings. For more information, see [Creating a Tool Catalog for a Project](#) on page 427.
- 3 Create a project library in Content Browser, and add the standard catalogs. For more information, see [Adding a Project Catalog to a Content Browser Library](#) on page 431.

TIP By default, tool catalogs are set to be linking. This makes it easier to update them once they have been copied to the workspace tool palettes.

- 4 Define the tool palette file location for the project. For more information, see [Adding a Project Library and Tool Palette Group](#) on page 431.

TIP If you are using one of the project templates provide with the software, the tool palette file location is by default set to `\<Project Folder>\WorkspaceToolPalettes`.

- 5 For Tool palette storage type, select Per user workspace catalog.
- 6 Associate the Content Browser library you have created with the project. For more information, see [Adding a Project Library and Tool Palette Group](#) on page 431.
- 7 Build up the project tool palette group. For more information, see [Building the Tool Palette Group](#) on page 435.
- 8 If you want your project users to start out with the same tools you have in your workspace, copy the palettes to the location specified in the tool palette file location path. For more information, see [Copying the Project Tool Palettes to the Tool Palette File Location](#) on page 436.
- 9 If you want your project users to have the same palette groupings, icon size, and ordering as you have, copy the project profile (AWS) to the location specified in the tool palette file location path. That way,

new project users will have the profile installed in their Documents and Settings folder. For more information, see [Adding the Project Profile to the Tool Palette File Location](#) on page 437.

Workflow 2: Using a Shared Workspace Catalog

- 1 Create standard styles in standards drawings and associate them with the project. For more information, see [Creating a New Project Standards Drawing](#) on page 456 and [Setting up Standard Styles and Display Settings](#) on page 416.
- 2 Define the tool palette file location for the project. For more information, see [Adding a Project Library and Tool Palette Group](#) on page 431.

TIP If you are working with a shared workspace catalog, it is highly recommended that you point the tool palette file location to a read-only folder.

- 3 For Tool palette storage type, select Shared workspace catalog.
- 4 Build up the project tool palette group. For more information, see [Building the Tool Palette Group](#) on page 435.
- 5 If you want your project users to have the same palette groupings, icon size, and ordering as you have, copy the project profile (AWS) to the location specified in the tool palette file location path. That way, new project users will have the profile installed in their Documents and Settings folder. For more information, see [Adding the Project Profile to the Tool Palette File Location](#) on page 437.

Creating a Tool Catalog for a Project

A tool catalog for a project should contain tools from project standards drawings. The easiest way to generate a tool catalog from standards drawings is to either create a new tool catalog based on one or more project standards drawings, or to add tools from a project standards drawing to an existing tool catalog.

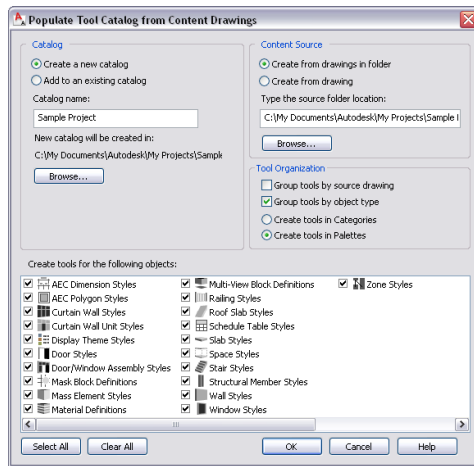

The tool catalog can then be added to the Content Browser library that is associated with the project. This makes it easy to use the tools either in the drawing or add them to the project tool palettes.

Creating a Project Standards Tool Catalog

Use this procedure to create a new tool catalog based on existing standards drawings. You specify the styles from which tools will be created and whether the new tools are organized in categories or palettes.

- 1 Click CAD Manager menu ► Tool Catalog Generator.

NOTE If the CAD Manager menu is not visible on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

- 2 Under Catalog, select Create a new catalog.
- 3 Enter a name for the new catalog.
- 4 Click Browse to define the location of the catalog.
- 5 Under Content Source, specify whether you want the new catalog to be created from multiple drawings in a folder or from a single drawing. Then, enter the path for the folder or drawing.

NOTE When you specify a folder as the catalog source, any nested folders are included in the new tool catalog.

- 6 Specify how you want the tools organized in the new catalog:
 - To organize the new tools by their source drawing, select Group tools by source drawing. This option is well suited for a tool catalog that is generated from a number of styles drawings. The resulting tools could be placed in categories or palettes named “Wall Styles - Concrete (Imperial)”, “Wall Styles - Brick (Imperial),” and so on.
 - To organize the new tools by their object type, select Group tools by object type. This option is well suited if you want to merge styles from various drawings into palettes or categories. The resulting tools will be placed in categories or palettes named “Walls”, “Doors,” and so on.

NOTE If both options are enabled, the catalog is first grouped by the drawings and then by the object type, generating categories from the drawings, and palettes from the object types. This is implemented because palettes cannot be nested. In this case the radio buttons for categories and palettes are disabled, and the Create tools in palettes option is selected for the catalog.

NOTE If neither of the two options is enabled, all new tools will be generated in the top category of the catalog.

- To organize the new tools in categories, select Create Tools in Categories. If you selected Group tools by source drawing, a category will be created for each source drawing. If you selected Group tools by object type, a category will be created for each object type.
- To organize the new tools in palettes, select Create Tools in Palettes. If you selected Group tools by source drawing, a palette will be created for each source drawing. If you selected Group tools by object type, a palette will be created for each object type.

7 Under Create tools for the following objects, select the object styles you want to appear as tools in the new catalog.

By default, all available style types are selected. Use the Select All and Clear All buttons as necessary.

8 Click OK.

A progress bar in the application status bar informs you of the progress of the catalog generation. This can take a few moments for a large catalog.

NOTE Each category and each palette is created in its own ATC file. The category and palette ATC files are stored in the Palettes or Categories subfolders within the folder where the new catalog is created.

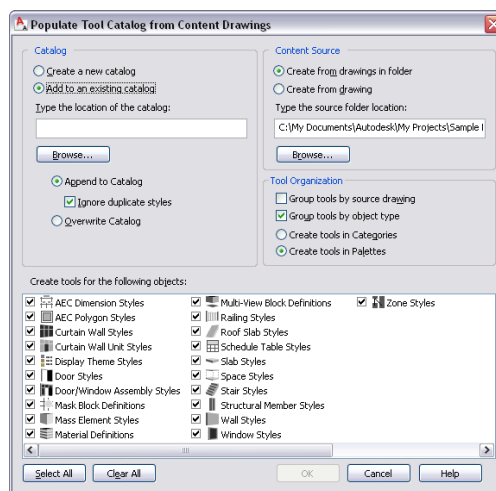

For information about associating a tool catalog to a project library, see [Adding a Project Catalog to a Content Browser Library](#) on page 431.

Adding Standard Tools to a Tool Catalog

Use this procedure to add project standard tools to an existing tool catalog.

1 Click CAD Manager menu ► Tool Catalog Generator.

NOTE If the CAD Manager menu is not visible on your menu bar, click Window menu ► Pulldowns ► CAD Manager Pulldown.

2 Under Catalog, select Add to an existing catalog.

3 Enter the name and the path of the catalog.

4 Click Append to Catalog and select Ignore Duplicate Styles if you want to prevent existing styles from being overwritten by styles with the same name and file path from the appended drawing. If you clear Ignore Duplicate Styles, existing styles are overwritten with styles from the appended drawing if they have the same name and file path.

5 If you want to overwrite the existing catalog, click Overwrite Catalog.

This deletes the whole catalog and replaces it with the palettes, categories, and tools from the source drawing(s).

WARNING You should use that option with great caution, as it will delete the complete existing catalog. If you just want to overwrite tools with their up-to-date versions from a content drawing, select Append to Catalog instead, and verify that Ignore Duplicate Styles is cleared.

6 Under Content Source, select a project standards drawing or standards folder to use as source for the new tools.

If you want to...	Then...
add tools from multiple drawings in a folder	select Create from drawings in folder, and then enter the path and folder name under Type the source folder location.
add tools from a single drawing	select Create from drawing, and then enter the path and drawing name under Type the source drawing.

7 Specify how the tools should be ordered in the catalog.

- To order the resulting tools by their source drawing, select Group tools by source drawing. This option is well suited for a tool catalog that is generated from a number of styles drawings. The resulting tools could be placed in categories or palettes named “Wall Styles - Concrete (Imperial)”, “Wall Styles - CMU (Imperial)” and so on.
- To order the resulting tools by their object type, select Group tools by object type. This option is well suited if you want to merge styles from various drawings into the catalog. The resulting tools will be placed in categories or palettes named after the style type, for example “Walls”, “Doors,” and so on.

NOTE If both options are enabled, then the tools are first grouped by the drawings and then by the object type, generating categories from the drawings, and palettes from the object types. This is implemented because palettes cannot be nested. In this case the radio buttons below are disabled and the Create tools in palettes option is selected for the tools.

NOTE If neither of the two options are enabled, all new tools will be generated in the top category of the catalog.

- To place the new tools in categories, select Create Tools in Categories. If you selected to group tools by their source drawing, then for each source drawing a category will be created. If you selected to group tools by their object type, then for each object type a category will be created.
- To place the new tools in palettes, select Create Tools in Palettes. If you selected to group tools by their source drawing, then for each source drawing a palette will be created. If you selected to group tools by their object type, then for each object type a palette will be created.

8 Under Create tools for the following objects, select which object styles should appear as tools in the catalog.

By default, all available style types are selected. Use the Select All and Clear All buttons as needed to make your selections.

9 Click OK.

A progress bar in the application status bar indicates the progress of the tool generation. When a large number of tools are being added, the process can take a few moments.

NOTE Each category and each palette is created in its own ATC file. The category and palette ATC files are stored in the Palettes or Categories subfolders in the folder in which the new catalog is created.

For information about associating a tool catalog to a project library, see [Adding a Project Catalog to a Content Browser Library](#) on page 431.

Adding a Project Catalog to a Content Browser Library

Tool catalogs are placed in catalog libraries. If you have created a tool catalog with standard tools, you need to add it to a catalog library. A Content Browser library can be set up on a shared network volume to be accessed by all project users. The CAD manager or project owner can point the project to that Content Browser library to have quick access to standard tools. For more information, see [Adding a Project Library and Tool Palette Group](#) on page 431.

1 Click Window menu ► Content Browser.

2 Click  to display the catalog library.

3 Click  to create a catalog.

4 In the Add Catalog dialog box, select Add an existing catalog or website.

5 Enter the location of the standards tool catalog created in [Creating a Project Standards Tool Catalog](#) on page 427, or click Browse a to navigate to the catalog.

6

7 Click OK.

NOTE Alternatively, you can drag and drop an ATC file from Windows Explorer to the Content Browser library pane.

Adding a Project Library and Tool Palette Group

If you have created a project library in Content Browser, you can associate it to a project. When you open the Content Browser from Project Navigator, the project library is automatically displayed.

The project library can be used to drag tools in project drawings, or to fill the project tool palettes with standard tools.

Project Tool Palette Group

Each project has a specific tool palette group (ATC) associated with it. Depending on how you created the project, the tool palette group can be created and displayed in different ways.

For a new project, the project tool palette group is by default empty, unless the project settings are pointing to an existing palette group.

Selecting the project tool palette group

Tool Content Root Path

Setting a tool content root path can help you keep your tools consistent with standards if the project or the standards drawings are moved during the project lifecycle.

When tools on the project tool palettes point to the tool content root path specified in the project settings, the content root path is created as a variable (%AECPROJECT_DIR%) in the XML definition of the tool. When the tool content root path in the project settings is changed, the path of the tools is changed accordingly.

For example, if all project tools point to content stored under *<Project Root Folder>\Standards\Content\Content 1*, you can move the content to *<Project Root Folder>\Standards\Content\Content 2*, adjust the tool content root path in the project setup accordingly, and all tools will now point correctly to *<Project Root Folder>\Standards\Content\Content 2*.

Another use case for changing the tool content root path would be if a user wants to work offline, and for that purpose creates an e-transmit package of the project and its tool content files. When the e-transmit package is unpacked on the local computer, the path to the content files will have changes. If it was *P:\<Project Root Folder>\Standards\Content\Content*, it could now be *C:\<Project Root Folder>\Standards\Content\Content*. If the tool content root path is redirected to the user's C drive, and all content will remain valid.

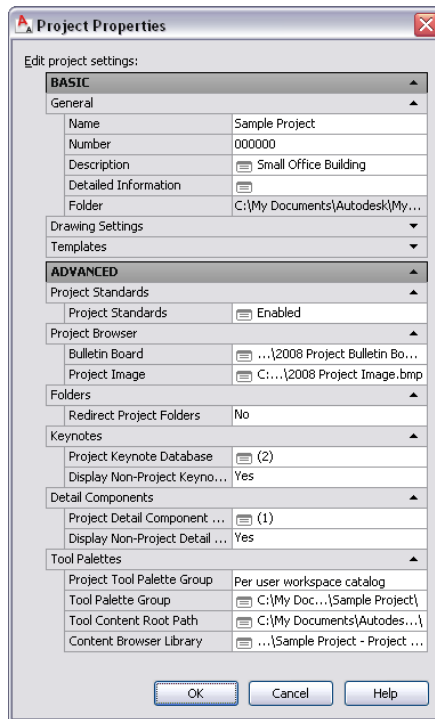

Later, when the drawings the user modified offline are copied back to the main project on the P server, the content root path will automatically change back to *P:\<Project Root Folder>\Standards\Content\Content*, as this is the path in the main APJ file.

Project Library

A Content Browser library can be set up on a shared network volume to be accessed by all project users. The CAD manager or project owner can associate the library with the project to have quick access to standard tools. This can be especially useful on a large project. For more information, see [Before You Begin: Working in a Network Environment](#) on page 227.

When Content Browser is opened from the Project Navigator, it will automatically open the library associated with the project.

- 1 Click File menu ► Project Browser.
- 2 Select the project for which you want to specify the tool palette group and the Content Browser library, right-click, and click Project Properties.

3 Under Tool Palette File Location, specify the location of the project tool palette group. You can select a local folder or a network folder here.

If you do not explicitly set a location here, the following default behavior is selected depending on how you created your project:

Project Type	Tool Palette File Location	Project Tool Palette Group
Legacy project from Autodesk Architectural Desktop 2005	pointing to new empty ATC file under <code>\<ProjectName>\Standards\ WorkspaceToolPalettes\ <ProjectName>.atc</code>	Created, but not displayed. To display the tool palette group in the tool palettes set and add tools to it, see Displaying the Project Tool Palette Group on page 434 and Building the Tool Palette Group on page 435.
New project not based on a template	pointing to new empty ATC file under <code>\<ProjectName>\Standards\ WorkspaceToolPalettes\ <ProjectName>.atc</code>	Created, but not displayed. To display the tool palette group in the tool palettes set and add tools to it, see Displaying the Project Tool Palette Group on page 434 and Building the Tool Palette Group on page 435.
New project based on default AutoCAD Architecture template project	pointing to new ATC file under <code>\<ProjectName>\Standards\ WorkspaceToolPalettes\ <ProjectName>.atc</code> . By default, one empty tool palette is already inserted in ATC.	Created and displayed with empty default tool palette. To add tools and palettes, see Building the Tool Palette Group on page 435.
New project based on user-defined existing template project	If the tool palette group of the template project is located within the template project folder, it will be copied with all	Displayed as either copied tool palette group or referenced tool palette group

Project Type	Tool Palette File Location	Project Tool Palette Group
		<p>contained palettes to the corresponding folder of the new project. The tool palette file location of the new project will point to the copied tool palette group.</p> <p>If the tool palette group of the template project is located outside the template project folder, the tool palette file location of the new project will point to the same location, sharing the tool palette group with the template project.</p>

4 For Tool Palette Storage Type, select Shared Workspace Catalog or Per User Workspace Catalog. If you select Shared Workspace Catalog, the path selected under Tool Palette File Location is added to the user's project profile (AWS), and the tool catalog is used from the specified location. If you select Per User Workspace Catalog, a folder is created under *\\Documents and Settings\<User Name>* and the tool palettes are copied to that folder.

5 Under Tool Content Root Path, you can set a root path for the tools used in the project tool palette group. When tools on project palettes are created with the tool content root path specified in the project setup, the content root path is created as a variable (%AECPROJECT_DIR%). When the tool content root path in the project setup is changed, and the referenced style drawings are moved to the new location, the path of the project tools is changed accordingly.

NOTE When a project is re-pathed, and the content root path is within the project folder, then it will be re-pathed accordingly.

6 Under Tool Catalog Library, select the default Content Browser library (CBL) to be displayed when opening Content Browser from the Project Navigator.

7 Click OK.

Displaying the Project Tool Palette Group

Use this procedure to display the project tool palette group in the tool palettes set.

Depending on the setting of the tool palette file location in [Adding a Project Content Browser Library and Tool Palette Group](#) on page 246, the project tool palette group can be displayed automatically after setting a project current and closing Project Browser, or it can be empty and not be displayed on the tool palettes set. The project tool palette group is displayed automatically when it contains at least one palette.

Tool palette groups that are not automatically displayed can appear in the following cases:

- A new project that is not based on a template, and does not point to an existing tool palette group
- A legacy project from Autodesk Architectural Desktop 2005 that is not manually re-pointed to an existing tool palette group
- A project that is based on a template project without project tool palettes

If an empty tool palette group is created for a project, it is not displayed in the tool palettes set after the project is set current. To display it, you need to add at least one tool palette to it.

1 Click Window menu ► Tool Palettes.

2 In the title bar of the tool palettes set, click .

- If the project tool palette group contains at least one palette, it is displayed in the list of available tool palette groups, and can be selected.

Selecting the project tool palette group

- If the tool palette group of the current project is empty, it is not displayed.

3 To display the project tool palette group, click , and click Customize.

On the left, all available palettes are listed. On the right, all palette groups are listed. The empty project tool palette group is listed there.

4 Right-click in the palettes list on the left, and click New Palette.

5 Enter a name for the new palette.

6 Select the palette, and drag it on the project palette group on the right.

7 Click Close, and click  again.

The project tool palette group is listed under the available palette groups and can be selected.

Building the Tool Palette Group

When a new project is created, its associated tool palette group is empty, unless the new project is explicitly pointing to an existing tool palette group. You can add and remove palettes, add, remove, and rearrange tools to suit the needs of the current project.

TIP To make sure that the changes you make here are distributed to all project collaborators, you should define the tool palette storage type as a shared workspace catalog.

IMPORTANT All new palettes you add to the tool palettes set while a project is current are added to the current project's tool palette group. This happens regardless of whether the project tool palette group is active or not. In order to add new palettes to the global tool palettes associated with your user profile, you must first close any project that is current.

You can add standard tools to the project palette group in these ways:

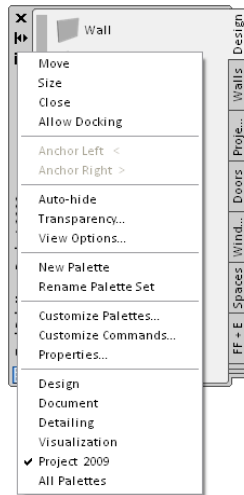

- Add standard tools from the project library
- Add standard tools from the from standards drawings in Style Manager

1 Set the desired project current.

2 Click Window menu ► Tool Palettes.

3 In the title bar of the tool palettes set, click  , and then select the project tool palette group.

Selecting the project palette group

4 Add and rename palettes as necessary.

For detailed information, see [Creating a New Tool Palette](#) on page 71.

5 To add standard tools from the project library, click  in the Project Navigator toolbar.

The Content Browser is opened with the project library displayed.

6 Drag tools or palettes from the project library to the project palette group.

7 To add standard tools from the standards drawings, open a project drawing. Click Format menu ► Style Manager.

The project standards drawings are displayed under the project node. You can drag-and-drop styles from the Style Manager to the project palettes.

The next time you open the project, the new palettes and tools will be present in the project tool palettes.

Copying the Project Tool Palettes to the Tool Palette File Location

If you are working with a per user workspace catalog, you can create a starter set of palettes and tools for the project users by copying your palettes to the project tool palette file location. The first time a user opens the project, the tool palettes from the tool palette file location will be copied to the local users' machines.

1 Set up project standards tools as described in [Adding a Project Library and Tool Palette Group](#) on page 431 and [Building the Tool Palette Group](#) on page 435.

2 Close AutoCAD Architecture.

3 In Windows Explorer, navigate to *C:\Documents and Settings\<username>\Application Data\Autodesk\ACD-A 2009\enu\Support\Profiles\ProjectCatalogs*.

4 Select the project catalog folder.

If you have just closed AutoCAD Architecture, the current project folder is the one with the latest date. In addition, the folder is named with the project GUID, which you can also find in the project APJ file.

5 Copy the project catalog folder and paste it to the folder specified as the tool palette file location for the project.

Adding the Project Profile to the Tool Palette File Location

After setting up the project tool palette group, the CAD manager or project owner needs to ensure that new users of the project will all have an identical set of tools and palettes when they are working with the project. To do this, the project profile needs to be copied to the folder specified as the tool palette file location.

1 Set up project standards tools as described in [Adding a Project Library and Tool Palette Group](#) on page 431 and [Building the Tool Palette Group](#) on page 435.

2 Close AutoCAD Architecture.

3 In Windows Explorer, navigate to *C:\Documents and Settings\<username>\Application Data\Autodesk\ACD-A 2009\enu\Support\Profiles\ProjectProfiles*.

4 Select the project AWS file.

If you have just closed AutoCAD Architecture, the current project profile is the one with the latest date. In addition, the AWS contains the project GUID which you can also find in the project APJ file.

5 Copy the project AWS file and paste it to the folder specified as the tool palette file location of the project.

Adding Standards to a Project Drawing

If you set up standards for a new project, or add new drawings to an existing project, standard styles and display settings do not yet exist in these drawings and need to be copied there.

If you have configured project standard tools as described in [Setting up Standard Tools in a Project](#) on page 425, you can drag-and-drop them from the project library or the project standards palettes to project drawings.

If you want to use standard styles and display settings in a project drawing without using tools, you need to copy them through Style Manager and Display Manager.

WARNING Project standard styles and display settings can be used only in project drawings. You can copy standard styles and display settings into standalone drawings as well; however, they will not be synchronized or versioned and maintain no link to the project standards.

There are different methods of copying standard styles and display settings to a drawing:

- Project tool palettes can be defined, as described in [Building the Tool Palette Group](#) on page 435. If the tools reference styles from standards drawings, the associated standard style is copied to the project drawing when the tool is executed.
- A Content Browser library for the project can be defined, as described in [Adding a Project Library and Tool Palette Group](#) on page 431. You can drag-and-drop tools from Content Browser to a project drawing.
- Standards drawings are displayed in the Style Manager and Display Manager under the project node. You can drag-and-drop styles and display settings into a project drawing from a project standards drawing.

Project Tool Palette Group

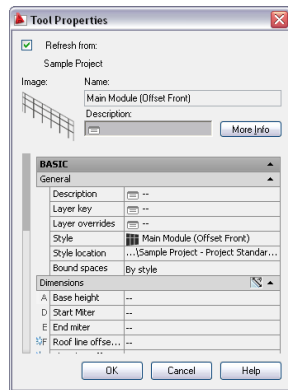

When you create a project, a project palette group is associated with it. The project palette group is displayed in the tool palettes set when the project is set current. For information about creating a project tool palette group, see [Setting up Standard Tools in a Project](#) on page 425.

Adding Standard Styles from the Project Tool Palettes

If you want to copy a standard style from a project palette into the current drawing, you can either insert the tool into the drawing, or import the associated style from the tool palette into the drawing.

- 1 Right-click the tool, and click Properties.

Verifying the style location

Under Style location, the associated style drawing is listed.

- 2 Verify that the tool points to a project standards drawing.
- 3 Click OK.
- 4 To add the standard style into the drawing, do one of the following:
 - Select the tool, right-click, and click Import <Style Name> <Object> Style. For example, if you want to add the wall style CMU-190 into the drawing, click Import CMU-190 Wall Style.
 - Click the tool to execute its function which will automatically use the referenced style.

Both of these options add the style to the drawing.

Adding Standard Styles from Content Browser

The CAD manager can set up a library in Content Browser that contains standard tools. Standard tools can be dragged from Content Browser directly to a drawing or to a tool palette.

For information about associating a library for a project, see [Adding a Project Library and Tool Palette Group](#) on page 431.

- 1 Set the project current, as described in [Setting a Project Current](#) on page 235, and close the Project Browser.
- 2 Click Window menu ► Project Navigator.
- 3 In the Project Navigator toolbar, click  .

The Content Browser is opened with the project library displayed.

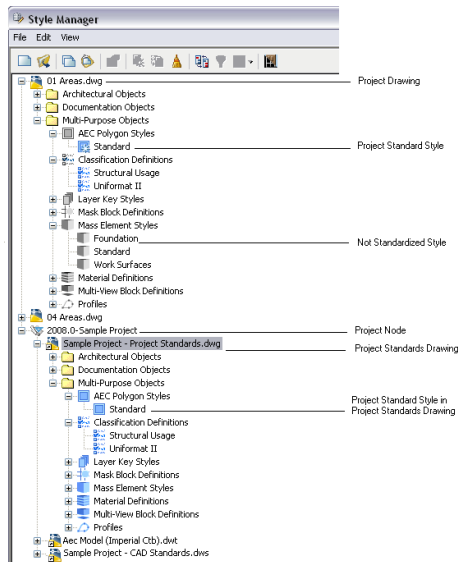

- 4 Select a standard tool by its eyedropper tool, and drag it either to the drawing area of AutoCAD Architecture, or to one of the tool palettes.

NOTE Be sure to hold down the mouse button until the eyedropper appears to “fill up” before dragging it to the drawing or tool palette.

Adding Standard Styles from Style Manager

You can add standard styles to project drawings in Style Manager. When standards drawings are specified in the project standards configuration, they are displayed in Style Manager when you open a project drawing. Styles can be dragged from the project node to the project drawing node here.

Standard styles in Style Manager

- 1 Open the project drawing to which you want to add standard styles.
- 2 Click Format menu ► Style Manager.

The standards drawings specified in the standards configuration are listed under the project node.

- 3 Expand the node for the project standards drawing containing the style you want to add, and expand subnodes as necessary to locate the style.
- 4 Drag the style from the project standards drawing node to the project drawing node in the tree view.

The standard style is copied to the project drawing node.

NOTE For the synchronization of the standard style to work, the style needs to come from a standards drawing that has been selected as a standards drawing for this style type in the configuration setup. For example, if the standards drawing “Wall Styles.dwg” has been configured as the standard for wall styles, and the standards drawing “Door Styles.dwg” has been configured as the standards drawing for door styles, you should not copy any wall styles from the “Door Styles.dwg” to the project drawing. Because that drawing has not been defined as the standards drawing for wall styles, the copied styles will display as not standardized in the synchronization. For information on configuring standards drawings, see [Setting up Standard Styles and Display Settings](#) on page 416.

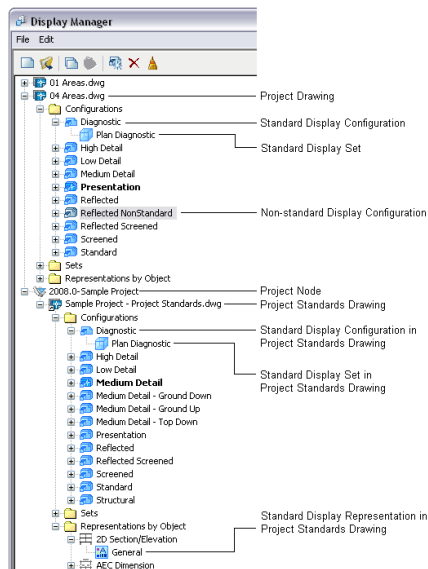

5 Click OK.

You can also drag styles from a project standards drawing into a drawing that is not part of the current project. If the drawing is not part of any project, no synchronization will happen to that style in the future. If the drawing is part of a different project, the style will display as not standardized in future synchronizations of that project, unless that project references the same standards drawing from which the style was dragged.

Adding Standard Display Settings from Display Manager

You can add standard display settings to project drawings in the Display Manager. When a standard display drawing is specified in the project standards configuration, it is displayed in Display Manager under the project node. From there, display configurations, display sets, and display representations can be dragged to the project drawing nodes.

Adding standard display settings from Display Manager

1 Open the project drawing to which you want to add standard display settings.

2 Click Format menu ► Display Manager.

The drawing that has been defined as display standards drawings in the project standards configuration is listed under the project node.

3 Expand the standards drawing node and navigate to the desired type nodes for Configurations, Sets, and Representations by object.

4 Drag the component to the project drawing node in the tree view.

5 Click OK.

Synchronizing a Project with the Standards

When a project or project drawing is synchronized with its standards, the styles and display settings in it are compared with the project standards to find version discrepancies between them, and fix them.

Synchronization can become necessary in these cases:

- A style or display setting in a project drawing has changed and needs to be updated with the correct version from the project standards.

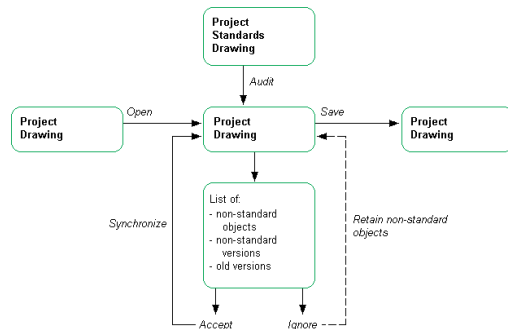

- A style or display setting in the project standards has changed and needs to be updated in the project drawings.
- Not standardized styles and display settings have been introduced in a project drawing.

Depending on the synchronization settings specified in [Setting up Synchronization of AEC Standards](#) on page 421, outdated standards in the project drawings are either automatically updated with the latest version from the project standards drawings, or you are presented with a list of objects that need to be updated. You can select individual objects to update, while ignoring others. If you select to update a style with the associated standard, the selected style is copied from the project standards drawing into the project drawing, overwriting the existing style definition.

NOTE Automatic synchronization of standard styles and display settings does not happen during background plot/publish.

WARNING You should always synchronize the display settings in your project. Version discrepancies between the display settings in the project drawings can result in objects in project drawings not being displayed consistently. You also need to make sure to synchronize all project standards drawings with the current standard display settings, as described in [Synchronizing Project Standards with Each Other](#) on page 468, to ensure consistent display in the standards drawings.

Synchronizing a project with standards

Versioning Styles and Display Settings

To determine whether a standard style or display setting in a project drawing is identical to the corresponding object in the project standards drawing, styles and display settings in a project are versioned. The version information includes a unique GUID (Global Unique Identifier), the date and time of the last modification, the windows login name of who last modified the object, and an optional comment.

A new version of a standard style or display setting in a project drawing is created each time the style or display setting is changed in Style Manager or Display Manager, and saved.

In a project standards drawing, a new version of a standard style or display setting must be manually created after the style or display setting has been changed in Style Manager or Display Manager. For information about versioning standard styles and display settings, see [Versioning Standards](#) on page 459. In project standards drawings, a version history is also stored. The version history will be used to determine if styles or display settings in project drawings are identical to the version in the project standards drawing, or newer or older versions.

An older version of a style or display setting in a project drawing is a version that exists in the project standards drawing, but is not the latest version. A newer version of a style or display setting in a project drawing is a style or display setting that exists in the project standards drawing, but has no corresponding version in its version history.

A special case occurs if a standard style or display setting in a standards drawing has no version information. This can happen if the version information has been purged, as described in [Purging the Version Information](#)

from a [Project Standards Drawing](#) on page 467. In this case, the standard style or display setting still participates in the synchronization and is considered the “latest version” when comparing with versions of the object in project drawings. No attempt is made during synchronization to automatically create a version GUID or history list. If you want to add version information to the standard style or display setting, you need to manually version the object as described in [Updating Standard Objects in a Project Standards Drawing](#) on page 461.

Synchronization Conditions

Two styles or display settings are considered identical if the following are identical:

- Object type (e.g. wall style, display set)
- Name
- Version GUID

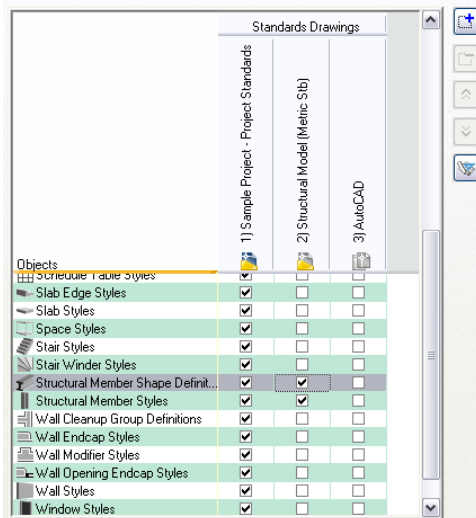

If the synchronization process finds a style or display setting in a project drawing that has the same type, name, and version GUID as the corresponding style or display setting in the project standards, it concludes that the style or display setting is up-to-date with the project standards. In that case, no change is necessary.

NOTE A synchronization does not perform a property-by-property comparison between the versions. The reason for this is that such a comparison would slow down the software considerably, and that the GUID, date and time stamp in the version information provides sufficient information to identify changes.

Synchronization Order

If you have multiple standards drawings containing the same standard styles associated with a specific style type, then the instance of the style in the first standards drawing is used as the style to which the style in the project drawing is synchronized. The first standards drawing is the one listed on the left in the standards configuration table. Further drawings containing the same standard style are ignored.

Order of standards drawings

NOTE The order of the synchronization is observed in all cases, even if a later project standards drawing contains a newer version of a standard style than the one contained in the preceding standards drawing.

Dependent Styles

Some styles have dependent styles or definitions used to create them. This could be, for example, door and window styles that are used within window assembly or curtain wall styles. In a case like that, it is recommended that all dependent styles and definitions are placed in the same standards drawing.

Synchronization Granularity

You can synchronize different parts of a project. You can synchronize a complete project, an individual project drawing, or an individual style or display setting.

Synchronizing only one drawing or style will take considerably less time, and may often be sufficient.

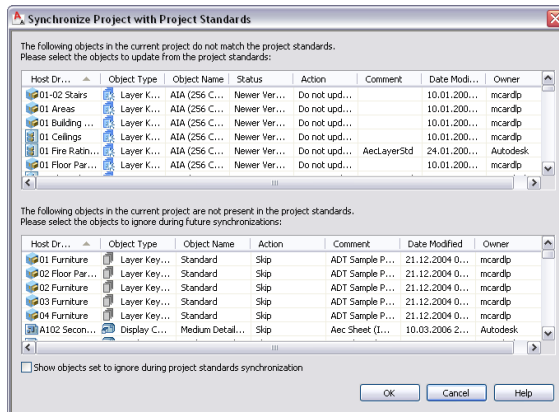

Synchronizing AutoCAD Standards

Synchronizing the AutoCAD standards (DWS) of a project is a separate process from synchronizing the AEC standards of a project. While you can set the AEC standards in a project to be automatically synchronized every time a drawing is opened, synchronization of the AutoCAD standards has to be initiated manually by the user. When AutoCAD standards are set up in a project, a CHX file is automatically created containing the project drawings and the associated AutoCAD project standards drawings. The batch standards checker can be used to open the project's CHX file and batch check the entire project.

Synchronization Status

When you synchronize a project or a drawing with its AEC project standards, the styles and display settings in the project drawings are compared with the versions in the standards drawings. If the version of the style or display setting in the project drawing is not identical to the version in the standards drawing, you can choose from several possible actions regarding the style or display setting.

Synchronization dialog

Status	Description	Action
Current standard version	The style or display setting in the project drawing is identical to the version in the project standards drawing.	No action required. The object is in synch with the standard.
Older version of standard style or display setting	The style or display setting in a project drawing is an older version than	You can choose from these actions: <ul style="list-style-type: none"> Update from Standard: this copies the version from the project standards drawing to the pro-

Status	Description	Action
	<p>the style in the project standards drawing.</p> <hr/> <p>NOTE The version GUID is used to determine which version is more current.</p> <hr/>	<p>ject drawing. The object in the project drawing is overwritten.</p> <ul style="list-style-type: none"> ■ Do not Update: The style or display setting is skipped for this synchronization. The next time the drawing is synchronized, it will display as inconsistent with the standards again. ■ Ignore: The style or display settings is skipped now and for future synchronizations. <hr/> <p>NOTE If you choose this option, you may choose to display ignored objects during each synchronization.</p> <hr/>
Nonstandard (Newer) Version of standard style or display setting	The style or display setting in the project drawing is a version not found in the project standards drawing's version history.	
Not standardized style or display setting	The style or display setting in the project drawing is not present in the project standards drawings.	<ul style="list-style-type: none"> ■ Skip: The not standardized object is skipped for this synchronization. The next time the project is synchronized, it will display as not standardized again. ■ Ignore: The not standardized object is skipped now and for future synchronizations. <hr/> <p>NOTE If you choose this option, you may choose to display ignored objects during each synchronization.</p> <hr/>

Synchronizing a Project with AEC Standards

When you have set up AEC project standards and enabled them, you can synchronize the project with the standards.

For information about setting up AEC standards, see [Setting up Standard Styles and Display Settings](#) on page 416.

Synchronizing a project will synchronize all drawings contained within. Depending on your system setup and project size, this might take some time. Also, project drawings that are open during the synchronization might not be correctly synchronized because they will not be able to be saved after the synchronization. In that case, the drawings need to be closed, and the synchronization repeated.

NOTE Synchronizing a project will not synchronize the project standards drawings with each other, even if they are located within the project folder. To synchronize project standards drawings with each other, see [Synchronizing Project Standards with Each Other](#) on page 468.

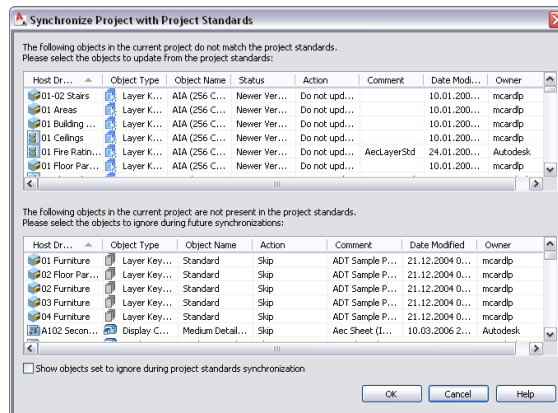

1 Verify that the project you want to synchronize is the current project.

For information about setting a project current, see [Setting a Project Current](#) on page 235.

2 Click CAD Manager menu ➤ AEC Project Standards ➤ Synchronize Project with Standards.

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

Synchronizing a project with AEC standards

The synchronization dialog is displayed with two lists. The top list shows styles and display settings that are either older versions of standard styles or display settings, or nonstandard (newer) versions. The bottom list shows a list of not standardized styles and display settings. For a definition of terms, see [Project Standards Terminology](#) on page 409.

- 3 To synchronize a style or display setting that is either an older version or a nonstandard (newer) version, select Update from Standards from the Action drop-down list.
- 4 To skip over a style or display setting that is either an older version or a nonstandard (newer) version, select Do not Update from the Action drop-down list.

In this case, the nonstandard version remains in the project drawing for now, and is not updated with the standard. The next time the drawing is synchronized, the style or display setting will be listed again as inconsistent with the standard.

- 5 To ignore a style or display setting that is inconsistent with the standard, select Ignore from the Action drop-down list.

In this case, the inconsistent object will not be listed again in future synchronizations, except if you select Show objects set to ignore during project standards synchronization, or remove the Ignore flag from the style or display setting in Style Manager or Display Manager, as described in [Excluding Styles and Display Settings from Synchronization](#) on page 451.

WARNING You should use the Ignore option only in clearly defined exception cases where you are sure that a style or display setting does not need to conform to the project standards.

- 6 To skip over a not standardized style or display setting, select Skip from the Action drop-down list.

The next time the drawing is synchronized, the style or display setting will be listed again as not standardized.

NOTE You cannot promote not standardized styles and display settings to standard ones here. To do this, you need to add the not standardized style to the project standards, as described in [Adding Standard Objects from a Project Drawing to a Project Standards Drawing](#) on page 464.

- 7 To ignore a not standardized style or display setting, select Ignore from the Action drop-down list.

In this case, the not standardized object will not be listed again in future synchronizations, except if you select Show objects set to ignore during project standards synchronization, or

remove the Ignore flag from the style or display setting in Style Manager or Display Manager, as described in [Excluding Styles and Display Settings from Synchronization](#) on page 451.

8 Click OK.

Synchronization Exceptions

When you synchronize a complete project, drawings that are currently opened by another user or are read-only will be excluded from the synchronization. Before the synchronization of the project is started, the program runs an internal check to see if there are drawings that cannot be synchronized at the time. If such drawings are found, the Synchronization Warning worksheet is displayed.

NOTE If a project drawing is opened by the same user who is trying to synchronize the project, no error warning is displayed. The program will detect that the drawing is open and will be able to make the synchronization changes to the open drawing.

If you get a warning message like this, you can either wait until all project drawings are available to you, or you can synchronize the project now, accepting that there are drawings that cannot be included.

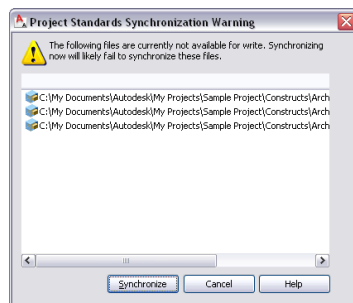

1 Verify that the project you want to synchronize is the current project.

For information on setting a project current, see [Setting a Project Current](#) on page 235.

2 Click CAD Manager menu ► AEC Project Standards ► Synchronize Project with Standards.

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

If there are project drawings that are currently unavailable for synchronization, you will receive the following warning message:

3 Click Synchronize to synchronize all project drawings *not* listed in the warning worksheet.

4 When the Synchronization dialog is opened, follow the instructions in [Synchronizing a Project with AEC Standards](#) on page 444.

Synchronizing a Project Drawing with AEC Standards

Use this procedure to synchronize a project drawing with the AEC project standards.

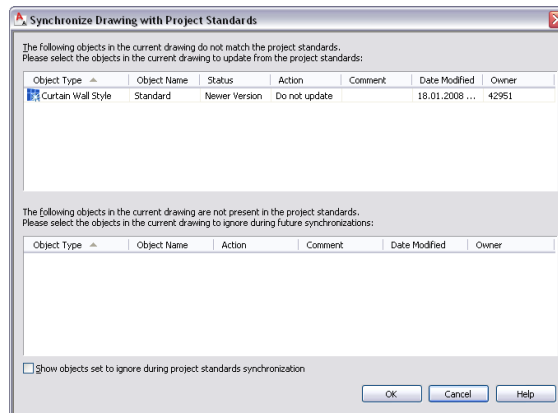

NOTE If you have selected automatic or semi-automatic synchronization in your standards configuration, the synchronization is automatically started every time you open the project drawing. For information on setting the synchronization mode, see [Synchronization Options](#) on page 419.

1 Open the project drawing you want to synchronize.

2 Click CAD Manager menu ► AEC Project Standards ► Synchronize Drawing with Standards

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

Synchronizing a project drawing with AEC standards

Two lists are displayed. The top list shows styles and display settings that have corresponding styles or display settings in the project standards, but are either an older version of a standard style or display setting, or a nonstandard (newer) version. The bottom list shows a list of styles and display settings that do not have corresponding styles or display settings in the standards (not standardized styles and display settings). For a definition of the terms, see [Project Standards Terminology](#) on page 409.

3 To synchronize a style or display setting that is either an older version or a nonstandard (newer) version, select Update from Standards from the Action drop-down list.

4 To skip over a style or display setting that is either an older version or a nonstandard (newer) version, select Do not Update from the Action drop-down list.

In this case, the nonstandard version remains in the project drawing for now, and is not updated with the standard version. The next time the drawing is synchronized, the style or display settings will be listed again as older version or nonstandard version.

5 To ignore a style or display setting that is either an older version or a nonstandard version, select Ignore from the Action drop-down list.

In this case, the nonstandard version will not be listed again in future synchronizations, except if you select Show objects set to ignore during project standards synchronization, or remove the Ignore flag from the style or display setting in Style Manager or Display Manager, as described in [Excluding Styles and Display Settings from Synchronization](#) on page 451.

You should use the Ignore option only in clearly defined exception cases where you are sure that a style or display setting does not need to conform to the project standards.

6 To skip over a not standardized style or display setting, select Skip from the Action drop-down list.

The next time the drawing is synchronized, the style or display setting will be listed again as not standardized.

NOTE You cannot promote not standardized styles and display settings to standard ones here. To do this, you need to add the not standardized style to the project standards, as described in [Adding Standard Objects from a Project Drawing to a Project Standards Drawing](#) on page 464.

7 To ignore a not standardized style or display setting, select Ignore from the Action drop-down list.

In this case, the not standardized object will not be listed again in future synchronizations, except if you select Show objects set to ignore during project standards synchronization, or

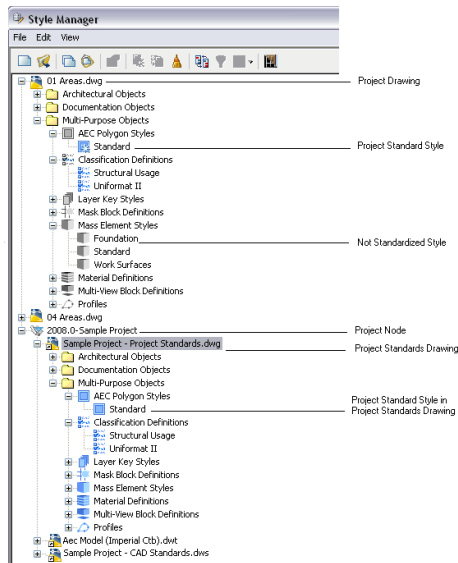

remove the Ignore flag from the style or display setting in Style Manager or Display Manager, as described in [Excluding Styles and Display Settings from Synchronization](#) on page 451.

8 Click OK.

Synchronizing Selected Styles and Display Settings with AEC Standards

You can synchronize individual styles and display settings in Style Manager and Display Manager. You could do this if you have accidentally changed a style in the project drawing, and want to restore the correct version from the project standards. Synchronizing an individual style or display setting will take less time than synchronizing a drawing or the project.

Standard styles in Style Manager

This process only synchronizes styles and display settings in a project drawing with the standards. It does not synchronize styles and display settings in different standards drawings with each other. For information on synchronizing standards drawings among themselves, see [Synchronizing Project Standards with Each Other](#) on page 468.

Standard Icons

Standard styles and display settings are displayed in Style Manager and Display Manager. Depending on their status with regards to the project standards, there are a number of different icons to differentiate them.

Icon	Description
	Standard style or display setting When a blue icon appears on a style or display setting in a project drawing or project standards drawing, the style or display setting is a standard one and is in synch with the standard. No update or synchronization is necessary.
	Standard style or display setting that is outdated When this icon appears on a style or display setting in a project drawing, the style or display setting is a standard one, but is out of date. This means that the corresponding style or display setting in the project standards drawing has a newer GUID than the one in the project drawing. To update the style or display setting in the project drawing, see Synchronizing Individual Styles with AEC

Icon	Description
	<p>Standards on page 450 and Synchronizing Individual Display Settings with AEC Standards on page 451.</p>
	<p>Standard style or display setting that is excluded from synchronization When this icon appears on a style or display setting, the object is excluded from synchronization. For more information, see Excluding Styles and Display Settings from Synchronization on page 451.</p>
	<p>Standard style or display setting that has no version information When this icon appears on a style or display setting in a project standards drawing, the style or display setting has no version information. Version information can be deleted, as described in Purging the Version Information from a Project Standards Drawing on page 467. To add version information to a style or display setting, see Updating Standard Objects in a Project Standards Drawing on page 461.</p>
	<p>Standard style or display setting that has been changed, but not versioned When this icon appears on a style or display setting in a project standards drawing, the object has been modified, but not versioned yet. In order for the changes to be included in the synchronization, the object must be versioned, as described in Updating Standard Objects in a Project Standards Drawing on page 461. This icon appears only in project standards drawings. Changes in project drawings are versioned automatically when you click Apply or OK in Style Manager or Display Manager.</p>
	<p>Not standardized style or display setting When a gray icon appears on a style or display setting in a project drawing, this object has no equivalent in the project standards, or (in the case of styles) the equivalent style in the project standards has not been associated with that style type in the project standards configuration. When this icon appears on a style in a project standards drawing, the style type it belongs to has not been associated with the corresponding standard style type in the project configuration setup. For example, if the Wall style type in the standards configuration has been associated with the Standards Drawing “Wall Styles 1.dwg” then the wall styles in “Wall Styles 1.dwg” will be displayed as standard styles in the Style Manager. The wall styles in “Wall Styles 2.dwg” will be displayed as not standardized styles.</p>

Overview: Styles in Project Drawings

You can synchronize individual styles in a project drawing.

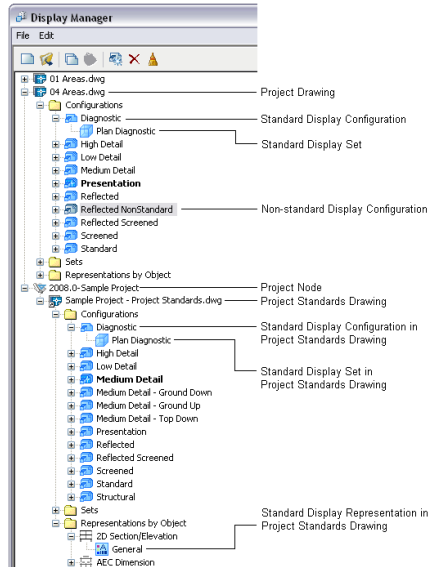

- All styles in a project drawing
- Style Categories: You can synchronize all styles contained in a style category. For example, you can synchronize all styles contained in Documentation Objects, if you have made changes to property set definitions, table styles, and data formats.

- **Style types:** You can synchronize all styles belonging to a style type. For example, you can synchronize all wall styles or all door styles.
- **Styles:** You can synchronize individual styles. You could do this if you have made a single change to a standard style, and do not want to start a complete synchronization of the drawing.

Overview: Display Settings in Project Drawings

You can synchronize individual components of the display system in a project drawing.

Display Manager tree

- **All display settings in a project drawing:** You can synchronize all display settings in a project drawing. This includes display configurations, display sets, and display representations.
- **Display configurations:** You can synchronize either an individual display configuration or all display configurations in the drawing.

NOTE A change to the cut plane is not a versionable change. If you change the cut plane, and synchronize the display configuration with the project standards, the changed cut plane will not be overwritten with the project standard.

- **Display Sets:** You can either synchronize an individual display set or all display sets in the drawing,

NOTE Changes to the Live Section settings are not a versionable change. If you change the Live Section settings, and synchronize the display set with the project standards, the changed Live Section settings will not be overwritten with the project standard.

- **Display representations:** You can either synchronize an individual display representation, all display representations of an object type, or all display representations in the drawing.

Synchronizing Individual Styles with AEC Standards

Use this procedure to synchronize styles in a project drawing.

- 1 Click Format menu ► Style Manager.

- 2 In the Style Manager tree, navigate to the style, style type, or style category you want to synchronize.
- 3 Select the object in the tree, right-click, and click Synchronize with Project Standards.
- 4 In the Synchronize Drawing with Project Standards dialog box, select Update from Standard from the Action drop-down list for each object that should be synchronized.
- 5 Click OK.

Synchronizing Individual Display Settings with AEC Standards

Use this procedure to synchronize display settings in a project drawing.

NOTE Display settings should always be synchronized with the latest standard settings. Out-of-synch display settings in a project can cause objects to be displayed inconsistently.

- 1 Click Format menu ► Display Manager.
- 2 In the Display Manager tree, navigate to the object you want to synchronize.
You can synchronize the following objects:
 - All display settings in a drawing
 - all display configurations
 - single display configuration
 - all display sets
 - single display set
 - all display representations
 - all display representations of an object type
 - a single display representation on an object type
- 3 Select the object in the tree, right-click, and click Synchronize with Project Standards.
- 4 In the Synchronize Drawing with Project Standards dialog box, select Update from Standard from the Action drop-down list for each object that should be synchronized.
- 5 Click OK.

Excluding Styles and Display Settings from Synchronization

Use this procedure to specify individual styles and display settings that you want to be ignored during synchronization.

Specified styles and display settings will not be overwritten with standards during automatic synchronization and will not be displayed as version mismatches during semi-automatic or manual synchronization, unless you select the Show objects set to ignore during project standards synchronization check box in the Synchronization dialog box.

- 1 Click Format menu ► Style Manager or Display Manager.
- 2 Navigate to the style or display setting to be excluded, right-click, and click Ignore During Synchronization.
Note that the Ignore During Synchronization option now has a check mark next to it. If you click the option again, the check mark disappears and the selected style or display setting is removed from the list of components to be ignored.

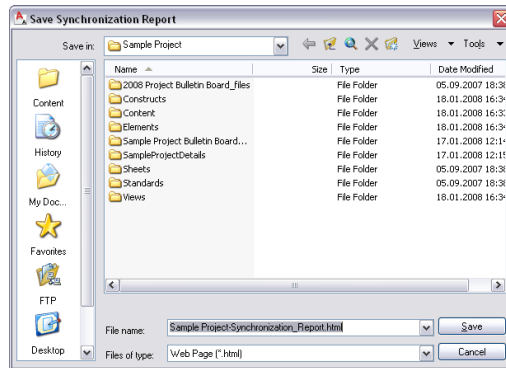

Generating a Synchronization Report

When you synchronize a project or a project drawing, you can save a synchronization report in HTML or XML format.

You can define in the project setup whether a synchronization report should be generated when synchronizing a project.

- 1 Verify that the creation of synchronization log files has been activated in the project configuration, as described in [Setting up Synchronization of AEC Standards](#) on page 421.
- 2 Synchronize a project or a drawing with its standards, as described in [Synchronizing a Project with AEC Standards](#) on page 444 or [Synchronizing a Project Drawing with AEC Standards](#) on page 446.

When the synchronization is finished, the Save Project Standards Report dialog box is displayed.

- 3 Select a file location and enter a name for the synchronization report.
- 4 Click Save.

The report is saved as an HTML or XML document in the specified location. You can open it with a Web Browser or an XML editor.

The report offers you various ways to display synchronization results; for example, you can view the synchronization results by drawing, by standard objects, or by problems encountered.

Synchronizing a Project with AutoCAD Standards

Use this procedure to synchronize a project with its AutoCAD standards. For information on defining AutoCAD standards for a project, see [Setting up AutoCAD Standards](#) on page 422.

When you set up AutoCAD standards for a project, a CHX batch checker file with the project name is created in the project folder. The CHX file contains a list of all project drawings as drawings to be checked, and a list of all specified AutoCAD standards files (DWS) as files to check against. If you want to synchronize a whole project against the AutoCAD standards, you need to run this batch file using the AutoCAD Batch Standards Checker.

The AutoCAD Batch Standards Checker runs independently from AutoCAD Architecture.

Before you start the AutoCAD Batch Standards Checker, you should update the project CHX file to make sure the CHX contains the current list of AutoCAD standard files and project files.

- 1 Verify that the project you want to check is the current project.
For information on setting a project current, see [Setting a Project Current](#) on page 235.
- 2 Click CAD Manager menu ► AEC Project Standards ► Update Project AutoCAD CAD Standards.

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

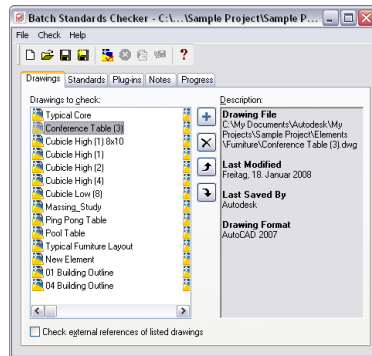

A progress bar indicates the progress of the CHX update.

3 Click Start (Windows) menu ► All Programs (or Programs) ► Autodesk ► AutoCAD Architecture 2009 ► Batch Standards Checker.

4 Click File menu ► Open Check File.

5 In the File Open dialog box, select the project CHX file.

Batch Standards Checker

6 Click Check menu ► Start Check.

For more information about AutoCAD standards, see “Maintain Standards in Drawings” in AutoCAD help.

Synchronizing a Project Drawing with AutoCAD Standards

Use this procedure to synchronize a project drawing with its associated AutoCAD standards. AutoCAD standards include AutoCAD layer settings, AutoCAD dimension styles, linetypes, and text styles.

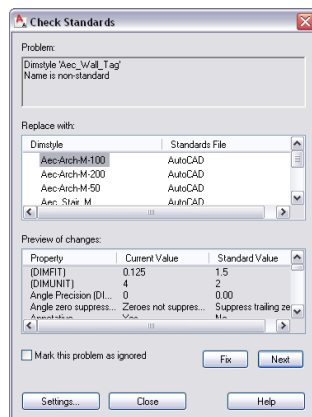

1 Open the drawing you want to synchronize with AutoCAD standards.

2 Click CAD Manager menu ► AEC Project Standards ► Update Project AutoCAD CAD Standards.

A progress bar indicates the progress of the CHX update.

3 Click CAD Manager menu ► CAD Standard ► Check.

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

Under Problem, the first AutoCAD dimension style, text style, layer, or linetype style that is inconsistent with the AutoCAD standards of the project is listed.

4 To synchronize the component with the project standards, select one of the styles listed under Replace with, and click Fix.

5 To retain the not standardized component in the drawing, click Mark this Problem as ignored.

6 Click Next to display the next not standardized component.

When all problem components have been processed, a message displays with a summary of the problems.

7 Click OK, and then click Close.

Auditing a Project or a Drawing

When a project or a drawing is audited, the styles and display settings in the project drawing are compared with those of the project standards, and any out-of-synch standards will be reported.

Out-of-synch standards can appear in these cases:

- A style or display setting in a project drawing has changed and needs to be updated with the correct version from the project standards.
- A style or display setting in the project standards has changed and needs to be updated in the project drawings.
- Not standardized styles and display settings have been introduced in a project drawing.

You could for example run an audit on drawings that come from contractors, or from other outside sources. Before you synchronize the drawings with the project standards, you first want to look at what actually is different between the drawings and the standards. For information on synchronizing standards, see [Synchronizing a Project Drawing with AEC Standards](#) on page 446.

NOTE A drawing needs to be part of a project to be audited against project standards. You cannot audit standalone drawings. If a drawing had been outsourced, it needs to be copied back into the project before it can be audited. For more information, see [Converting a Drawing to a Construct](#) on page 292.

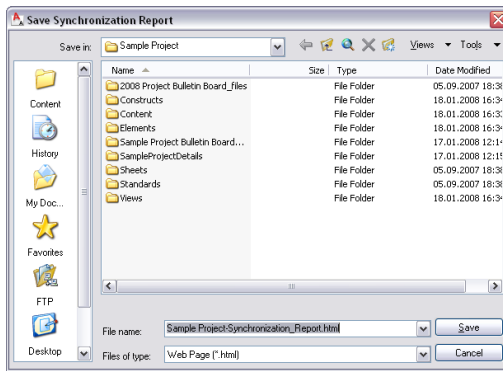

The result of the audit is placed in an HTML or XML audit report.

1 If you want to run an audit of the complete project, click CAD Manager menu ► AEC Project Standards ► Audit Project.

If you want to create an audit report of the current project drawing, click CAD Manager menu ► AEC Project Standards ► Audit Drawing.

If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

When the audit is finished, the Save Project Standards Report dialog box is displayed.

- 2 Select a file location and enter a name for the synchronization report.
- 3 Click Save.

The report is saved as an HTML or XML document in the specified location. You can open it with a Web Browser or an XML editor.

The report offers you various ways to display audit results; for example, you can view the audit results by drawing, by standard objects, or by problems encountered.

Showing Display Overrides in Project Drawings

To keep project drawings synchronized, it is important to control the properties and display properties of building objects by style, to be able to update the objects when the project standards change. Introducing object-level overrides makes it impossible for the overridden objects to be updated through the synchronization process when project standards change.

Use this procedure to detect object-level overrides on style-based objects in the current drawing.

- 1 Click CAD Manager menu ► AEC Project Standards ► Show Display Overrides.
If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

- 2 On the command line, enter a display option:

If you want to...

Then...

highlight the overridden objects in the drawing area.	enter O (byObject).
---	----------------------------

display a list of overridden objects in the AutoCAD command window	enter S (byStyle)
--	--------------------------

highlight the objects and display a list in the AutoCAD command window	enter B (Both).
--	------------------------

- 3 Remove any object-level overrides.

Editing Project Drawings Outside the Project

You need to work on a project drawing outside of a project in any of the following cases:

- A drawing is edited by an outside contractor.
- A user wants to work on a drawing offline without access to the project.
- A drawing has been created outside the project and is integrated into the project later.

When you are working with a project drawing outside of a project, you can use the drawing's standard styles and display settings, but they cannot be updated with changes that are made to the project standards during that time. So it is important to synchronize the drawing after it has been re-integrated into the project.

If you have made changes to standard styles and display settings in the project drawing during working outside the project, a new version of the styles and display settings is created automatically to track the changes when synchronizing the drawing with the project standards. You can select to either overwrite the new version with the current version from the project standards, or you can update the project standards with the version from the project drawing. For more information, see [Synchronizing a Project Drawing with AEC Standards](#) on page 446 and [Updating Standard Objects in a Project Standards Drawing from a Project Drawing](#) on page 463.

Creating a New Project Standards Drawing

Project standards drawings are assigned to a project, but are not project drawings like elements, constructs, views, and sheets. The styles and display settings in project drawings are compared with the standards and updated as necessary during the synchronization process.

To create a project standards drawing, you need to create a drawing file or a drawing template containing styles and display settings that should be used in the project.

For example, you can create one drawing that contains the standard wall styles, and another one that contains the standard door styles, or mask block definitions.

Project standard files can be of the file format DWG, DWT, or DWS. If you select the DWS format for your standards drawings, you can simultaneously use them as your AutoCAD standards drawings.

A project standards drawing is a regular drawing file. The definition of the drawing as a project standards drawing is created when the drawing is added as a project standards drawing to the standards configuration of a project, as described in [Setting up Standard Styles and Display Settings](#) on page 416.

Styles vs. Display Settings

You can assign multiple standards drawings for project styles. During synchronization, project drawings are compared against the project standards drawings in the order you establish in the project standards configuration. If a style is located in multiple standards drawings, the first instance in the search order is used as the standard.

For display settings, you can assign only a single standards drawing. It must contain all standard display settings for the project. Note, however, that the same standards drawing can be used for both styles and display settings.

File Location of Project Standards Drawings

You can choose two different options for storing project standards drawings:

Project Folder

If the project standards drawings are located within the project, they are treated as project specific. Typically, drawings containing project-specific standards are stored inside the project folder. For example, if you create styles for only one building project, you would place them in a project-specific standards drawing within the project folder. Placing standards drawings under the project folder has the following implications:

- When you use the project as a template for a new project, the project standards drawings are copied to the new project, and repathed to their new location.
- If you copy the standards of the project to another project, the project standards drawings are copied to that project.
- If you synchronize project standards drawings with each other, only standards drawings within the project will be included in the synchronization. For more information, see [Synchronizing Project Standards with Each Other](#) on page 468.
- The standards drawings are included in e-transmit and archiving packages created of the project.

You would place your standards drawings within the project if you want to keep the standards drawings specific to that project. You can copy the standards drawings to a new project, but any changes you make to one set of the standards drawings will not be propagated to the other one.

A Folder Outside the Project

If project standards drawings are located outside the project, they are referenced from that location. You would do this typically for standards that are not specific to a project, but rather to the department or the company. In that case, copying the standards to individual projects would create a risk of version discrepancies being introduced in the multiple copies. Also, a change made to a company-wide standards file would not be automatically propagated to all projects using that standards file. Placing a standards drawing outside the project has the following implications:

- When you use the project as a template for a new project, the project standards drawings are not copied to the new project. They are referenced from their original location.
- If you copy the standards of the project to another project, the project standards drawings are referenced from their original location in the other project.
- If you synchronize project standards drawings with each other, standards drawings outside the project will not be included in the synchronization. For more information, see [Synchronizing Project Standards with Each Other](#) on page 468.
- The standards drawings outside the project folder are not included in e-transmit and archiving packages created of the project. For more information, see [Electronically Transmitting a Project](#) on page 252.

1 Open a new drawing file.

2 Add the standard styles and display settings you need in this project.

For more information, see [Style Manager](#) on page 589, [Display System](#) on page 537, and the relevant object chapters.

3 Save the drawing as DWG, DWT, or DWS format.

If you want to...

Then...

make the standards drawing specific to a project

save it within the project folder.

NOTE You can create subfolders for standards drawings.

If you want to...

Then...

make the standards drawing available for general use within the company or team

save it outside the project folder.

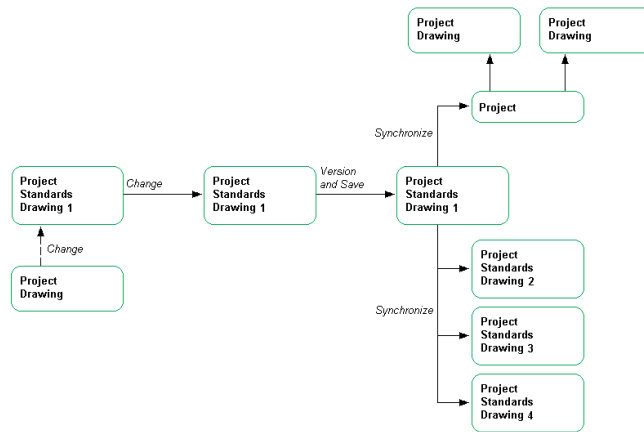

- 4 Associate the standards drawing with a project, as described in [Setting up Standard Styles and Display Settings](#) on page 416.

Updating Project Standards Drawings

When a standard style or display setting changes during the lifecycle of a project, it needs to be versioned, saved, and then updated in the project drawings and the other project standards drawings.

A standard component can be either changed directly in the standards drawing, or be updated from a project drawing. For more information, see [Updating Standard Objects in a Project Standards Drawing](#) on page 461 and [Updating Standard Objects in a Project Standards Drawing from a Project Drawing](#) on page 463.

Updating AEC project standards drawings

Process Overview: Updating AEC Standards in a Project

When a change is made to an AEC project standard, the following high-level steps need to be performed throughout the project:

- 1 Make a change to a standard style or display setting in a project standards drawing.
- 2 Version the changed style or display setting in Style Manager or Display Manager, and save or close the standards drawing. For more information, see [Versioning Standards](#) on page 459.
- 3 Synchronize the project, individual project drawings, or individual styles or display settings with the changed standard. For more information, see [Synchronizing a Project with the Standards](#) on page 440.
- 4 It is recommended that you synchronize all other project standards drawings with the change. For more information, see [Synchronizing Project Standards with Each Other](#) on page 468.

Versioning Standards

Styles and display settings in project standards drawings and project drawings have a version. The version is used to determine whether a style or display setting needs to be synchronized. The version information includes a unique GUID (Global Unique Identifier), the date and time of the last modification, the Windows login name of the user who last modified the object, and an optional comment.

Version Comparison

When a project is audited or synchronized with its standards, the comparison of the versions determines whether styles and display settings in the project are identical, older, or newer than the project standard.

Styles or display settings are considered identical to the project standards if the following are identical:

- Object type (such as Wall style or display set)
- Name
- Version GUID

For determining whether a style in a project drawing is identical to a project standard style, the GUIDs of both are compared. The GUID is a unique string that is newly created for each version of a standard object. In the project standards drawing, a list of previous GUIDs is kept as a version history to enable comparison with objects in a project drawing.

If the synchronization process finds a style or display setting in a project drawing that has the same type, name, and version GUID as the corresponding style or display setting in the project standards drawing, it concludes that the style or display setting is a standard one, and in synch with the object in the project standards drawing. In that case, no change is necessary.

If the comparison finds that the GUID in the project drawing does not match the GUID of the style in the project standards drawing, but matches a previous GUID from the standard style version list, it labels the style in the project drawing an “older version of a standard style.”

If the comparison finds a style or display setting that matches a standard object in name and object type, but has a GUID not appearing in the version history of the standard style or display setting, the style or display setting in the project drawing is labeled “nonstandard (newer) version of standard object.”

NOTE Synchronization does not perform a property-by-property comparison between the versions. The reason for this is that such a comparison would slow down the software considerably, and that the GUID, date and time stamp in the version information provides sufficient information to identify changes.

Creating Versions

A new version of a standard style or display setting in a project drawing is created automatically each time the style or display setting is changed in Style Manager or Display Manager.

A new version of a standard style or display setting in a project standards drawing must be created manually when the style or display setting is changed in Style Manager or Display Manager. In project standards drawings, a version history for each standard style and display setting is also stored. The version history is used during synchronization to determine if styles or display settings in project drawings match the versions in the project standards drawing, or are newer or older versions.

Versioning Exceptions for Display Settings in Project Standards Drawings

There are a few cases where modifications to the display settings will not be automatically versioned, as this will in most use cases not be a desirable effect. Some settings will routinely vary from the standards drawing, so these settings will not be included in the automatic versioning process.

- Display Configuration: Cut Plane
- Display Set: Surface Hatch on/off
- Display Set: Live Section on/off
- Wall display: wall graph toggle on/off

Version History

Standard styles and display settings in project standards drawings contain a version history for changes made to them during the project. You cannot roll back to a previous version of a standard object. The version history is only used to determine the current state of standard styles and display settings.

Change Types in Project Standards Drawings

Different types of changes you can make to project standards require different actions to be applied throughout the project.

Change Type	Actions required
Modifying a standard style or display setting	<ul style="list-style-type: none">■ Version style or display setting■ Save project standards drawing■ Synchronize project drawings■ Synchronize other project standards drawings (optional)
Renaming a standard style or display setting	<ul style="list-style-type: none">■ Rename style or display setting■ Save project standards drawing■ Copy style or display setting to project drawings■ Assign style or display settings in project drawing■ Remove older name version from project drawings <p>NOTE Renaming a style is not considered a modification to the style and cannot be synchronized.</p>
Adding a new standard style or display setting	<ul style="list-style-type: none">■ Create new style or display setting■ Save project standards drawing■ Copy style or display setting to project drawings■ Copy style or display setting to other project standards drawings (optional)
Deleting a standard style or display setting	<ul style="list-style-type: none">■ Verify that the style or display setting is not needed anymore in the project

Change Type	Actions required
	<ul style="list-style-type: none"> ■ Delete style or display setting ■ Save project standards drawing ■ Remove style or display setting from project drawings
<p>Modifying a standard style or display setting: When you make a modification to a standard style or display setting (except for renaming), you need to synchronize the project drawings that use the style or display setting. If the standard style or display setting is used in other project standards drawings, they need to be synchronized, too.</p>	
<p>Renaming a standard style or display setting: Renaming a style or display setting is similar to creating a new style. The previous version history of the renamed style remains. If you want to use the renamed object in a project drawing or in another project standards drawing, you need to copy it there. Any instances of the older name in a project drawing or a project standards drawing should be deleted.</p>	
<p>Adding a new standard style or display setting: If you have added a new standard style or display setting to a standards drawing and want to use the style in a project drawing or in another project standards drawing, you need to copy it through Style Manager and Display Manager or through tool palettes to these drawings. For information on copying styles and display settings to project drawings, see Adding Standards to a Project Drawing on page 437. Once it has been copied, the new style or display setting will be included in future synchronizations.</p>	
<p>Deleting a standard style or display setting: When you remove a standard style or display setting from a standards drawing, instances of that style in project drawings will be identified as not standardized in subsequent synchronizations. The not standardized instances should be removed from these drawings, as well.</p>	
<p>NOTE Standard styles and display settings can only be deleted in their standards drawings. The synchronization does not delete unused standard styles or display settings.</p>	

Updating Standard Objects in a Project Standards Drawing

You can change a standard style or display setting in a project standards drawing. When a change has been made, you must version it and then synchronize the project with the change.

When you change a standard style or display setting directly in the standards drawing, you do not need to version every single change. Many changes may be necessary to create a standard style or display setting in its final form; to create a version for every intermediate stage would slow down the process unnecessarily.

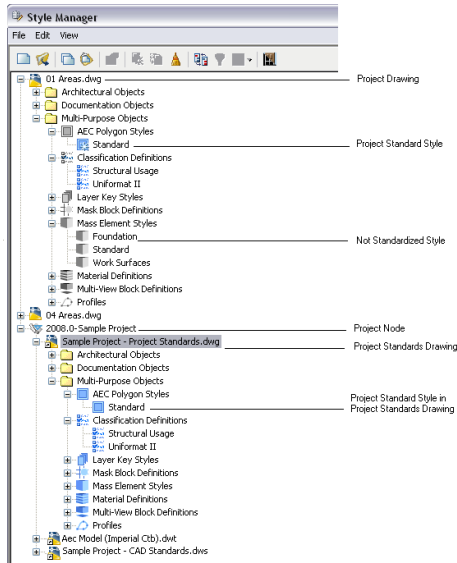

You can make multiple changes, save and close the drawing, reopen it, and then version the style or display setting when it is ready for propagating in the project. As long as the changes are saved to the project standards drawing, no edits will be lost, even without versioning in between.

WARNING As long as your changes are saved, but not versioned, any synchronizations taking place during that time will not recognize the styles and display settings as changed, since the object comparison is performed on the version GUID, and not the actual object properties. As a consequence, changed but unversioned styles and display settings in the project standards will not be updated in the project drawings. To have the changes synchronized with the project, you need to version the styles or display settings first.

To make changes to a project standards drawing, you must have write access to the drawing. If a standards

drawing is read-only, it is marked with a Lock icon () in Style Manager or Display Manager. You can make changes to that drawing, but you cannot save them. If you need to make changes to a locked drawing, contact the drawing owner or CAD manager.

Standards drawings and standard styles under the project node

Changing a standard style or display setting

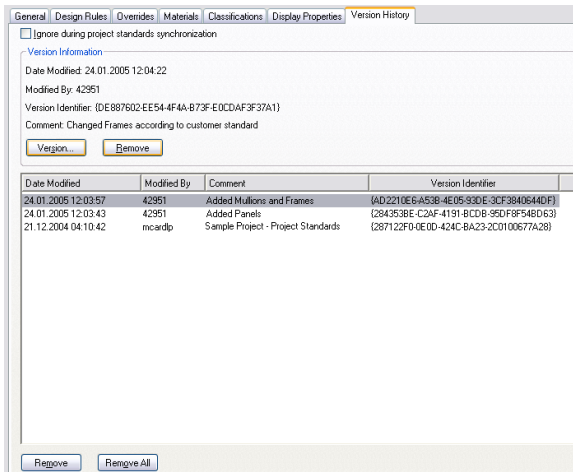

- 1 Open a project standards drawing.
- 2 Click Format menu ► Style Manager or Display Manager.

TIP All standards drawings are listed under the project node in Style Manager and Display Manager.

- 3 Select the style or display setting you want to edit, and make your changes.

Versioning changed styles and display settings

- 4 Click the Version History tab of the changed style or display setting.

- 5 Click Version.

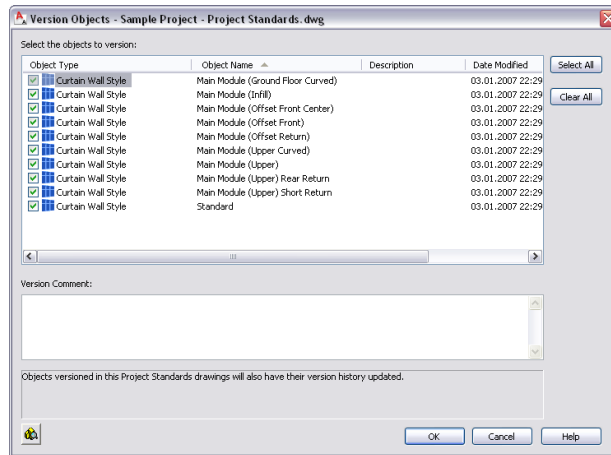

6 If necessary, enter a comment for the new version.

7 Click OK.

The new version is appended to the Version History tab.

8 To version multiple styles or display settings in a project standards drawing, select a group of objects and version them:

9 Select the styles or display settings that should be versioned.

10 If desired, enter a comment.

The comment will be applied to all objects selected for versioning.

11 Click OK.

NOTE To version all styles and display settings in a drawing, click AEC Project Standards ► Version Modified Objects on the CAD Manager menu. If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

Updating Standard Objects in a Project Standards Drawing from a Project Drawing

You can change a standard style or display setting in a project standards drawing by overwriting it with the corresponding style or display setting from a project drawing. When you have updated the project standard from a project drawing, the project needs to be synchronized to use the updated styles and display settings. For information, see [Synchronizing a Project with the Standards](#) on page 440.

NOTE Before you change a project standard from a project drawing, you should verify that this is the correct procedure. Once the project standard has been changed, the style or display setting will be updated in all project drawings during the next project synchronization, if automatic synchronization is selected.

To make changes to a standards drawing, you must have write access to the drawing. If a standards drawing

is read-only, it is marked with a Lock icon () in Style Manager or Display Manager. You can make changes to that drawing, but you cannot save them. If you need to make changes to a locked drawing, contact the drawing owner or CAD manager.

1 Open a project drawing from Project Navigator.

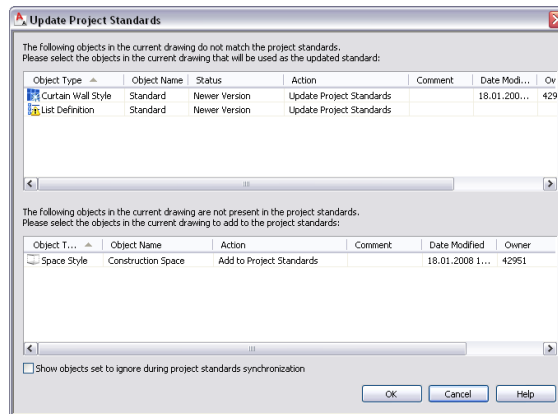

2 Click Format menu ► Style Manager or Display Manager.

- 3 Expand the node of the project drawing, and select the standard style or display setting with which you want to update the project standards.

NOTE A standard style or display setting in a project drawing is marked with a blue icon. If a style or display setting is displayed with a gray icon, it is not a standard style or display setting. In that case, you can add it to the project standards, as described in [Adding Standard Objects from a Project Drawing to a Project Standards Drawing](#) on page 464.

- 4 Right-click, and click Update Standards from Drawing.

NOTE You can select multiple objects here.

The selected style or display setting is listed in the top panel.

- 5 To update the project standards from a style or display setting in the project drawing, select Update Project Standards from the Action drop-down list of the style or display setting.
- 6 To not update the project standards from a style or display setting in the project drawing, select Do not Update Project Standards from the Action drop-down list of the style or display setting. In this case, the version in the project standards is not overwritten with the version in the project drawing. During the next synchronization of the project drawing, the style or display setting will be displayed as out of synch with the project standards.
- 7 To ignore the out of synch version of the style or display setting, select Ignore from the Action drop-down list. In this case, the style or display setting will not be displayed in future updates, except when you select Show objects set to ignore during project standards synchronization or remove the Ignore flag from the style or display setting in Style Manager or Display Manager, as described in [Excluding Styles and Display Settings from Synchronization](#) on page 451.
- 8 Click OK.
- 9 In Style Manager or Display Manager, click OK or Apply.
- 10 Click Yes to save the updated project standards drawing.

Adding Standard Objects from a Project Drawing to a Project Standards Drawing

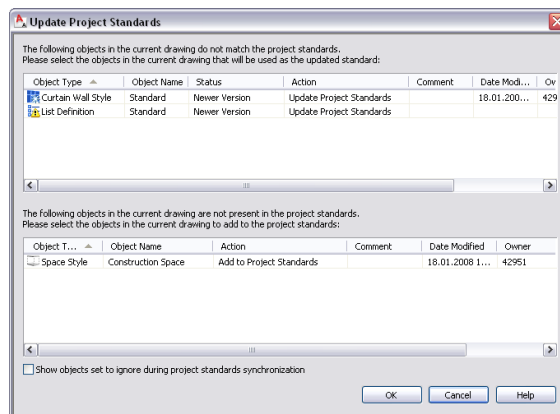

You can add not standardized styles or display settings from the current project drawing to the project standards. You can do this, for example, if you have created a complex style in a project drawing and want to include that in your standards.

If you want to add a style to the project standards in this way, in addition to copying the style to the standards drawing you need to verify that the style type in question has been selected for that standards drawing in the project configuration. Otherwise, it will not be used as a standard. For example, if you copy a wall style from a project drawing to the standards drawing “Standards 1.dwg,” you need to make sure that in the project configuration the Wall Style type has been checked for “Standards 1.dwg.” For more information, see [Setting up Standard Styles and Display Settings](#) on page 416.

After copying a style or display setting to the project standards, you need to synchronize the project to use the new standard object.

- 1 Open a project drawing from Project Navigator.
- 2 Click Format menu ► Style Manager or Display Manager.
- 3 Add a new style or display setting to the current project drawing.
- 4 Select the new style or display setting, right-click, and click Update Standards from Drawing.

NOTE You can select multiple items here.

The new style or display setting is listed in the lower panel, which displays styles and display settings in the project drawing that do not exist in the project standards.

- 5 To add the style or display setting to a project standards drawing, and thereby make it a standard style or display setting, select Add to Project Standards in the Action drop-down list.

NOTE If you are adding a display setting to the project standards, it is added to the display standards drawing. If you are adding a style to the project standards, it is added to the first project standards drawing in the search order that has been associated with that style type in the project standards configuration, as described in [Setting up Standard Styles and Display Settings](#) on page 416.

- 6 To skip over the not standardized style or display setting select Skip from the Action drop-down list.

In this case, the not standardized object remains in the project drawing, and is not entered in the standards.

- 7 To ignore the style or display setting, select Ignore from the Action drop-down list.

In this case, the not standardized object will not be listed again in future updates, except if you select Show objects set to ignore during project standards synchronization or remove the Ignore flag from the style or display setting in Style Manager or Display Manager, as described in [Excluding Styles and Display Settings from Synchronization](#) on page 451.

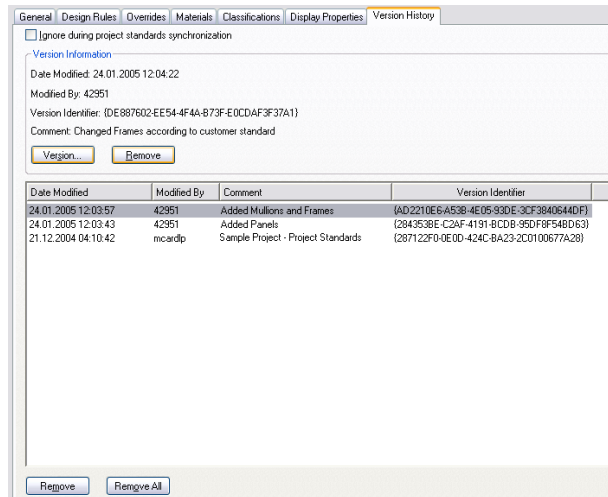

- 8 Click OK.
- 9 In Style Manager or Display Manager, click OK or Apply.
- 10 Click Yes to save the updated project standards drawing.

Editing the Version History of a Standard Object

Each style and display setting in a project standards drawing has a version history. The version history displays the unique version identifier (GUID), date and time of the modification, user name and any additional comments entered by the user.

You can edit the history by selectively removing individual versions, or removing all versions.

- 1 Open a project standards drawing.
- 2 Click Format menu ► Style Manager or Display Manager.
- 3 Select the standard style from the project standards node of the tree.
- 4 Click the Version History tab.

- 5 To add a new version, click Version, and enter the versioning information.
- 6 To remove an existing version, select the version from the Version History list, and click Remove.
To remove all versions in one step, click Remove All.
- 7 If you want the style or display setting to be ignored during synchronization of standards, select Ignore during project standards synchronization.
- 8 Click OK.

Versioning a Project Standards Drawing

You can version all styles and display settings in a project standards drawing in a one step.

- 1 Open a project standards drawing.
- 2 Click CAD Manager menu ► AEC Project Standards ► Version Modified Objects.

NOTE If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

- 3 Select the styles or display settings that should be versioned.
- 4 If desired, enter a comment.
The comment will be applied to all objects selected for versioning.
- 5 Click OK.

Purging the Version History from a Project Standards Drawing

You can remove the version history from all standard styles and display settings in a project standards drawing with one command. Purging the version history will remove all versions except the current one from the standard styles and display settings. You can do that to avoid cluttering your styles and display settings.

When you purge the version history, no version GUID except for the current one remains. That means that the synchronization can no longer distinguish between an older version of a standard style and a non standard version of a style. Each style in a project drawing that does not have the current GUID of the corresponding standard style, will be labeled a “non-standard,” or newer version.

- 1 Verify that the project with which the project standards drawing is associated is the current project.
- 2 Open the Project Standards drawing from which you want to purge the version history.

NOTE Project standards drawings do not appear on the Project Navigator. You need to open them with the standard File ► Open command.

- 3 On the command line, enter **AecClearVersionHistory**.
The version history is removed from all standard styles and display settings in the drawing.

Purging the Version Information from a Project Standards Drawing

You can remove the version information from all standard styles and display settings in a project standards drawing. When you remove the version information, the version history and the current version information is deleted.

When you run a synchronization, the standard style or display setting still participates in the synchronization and is considered the latest version when comparing with versions of the object in project drawings. No attempt is made during synchronization to automatically create a version GUID or history list. If you want to add version information to the standard style or display setting, you need to manually version the object as described in [Updating Standard Objects in a Project Standards Drawing](#) on page 461.

- 1 Verify that the project with which the project standards drawing is associated is set current.
- 2 Open the project standards drawing from which you want to remove the version information.

NOTE Project standards drawings do not appear on the Project Navigator. You need to open them with the standard File ► Open command.

- 3 On the command line, enter **AecPurgeVersion**.

The version information is removed from all standard styles and display settings in the drawing.

NOTE To re-add a version to all styles or display settings in the drawing, open Style Manager or Display Manager, select the drawing in the tree, right-click, and click Version Drawing.

Synchronizing Project Standards with Each Other

Project standard styles and display settings can be distributed among multiple standards drawings, and depend on each other. For example, the styles in a styles drawing should use the display settings from the standard display drawing. If display changes are introduced in a standard styles drawing, and not synchronized with the standard display drawing, styles can display inconsistently across the project. Therefore, you should synchronize project standards drawings with each other when changes have been made to individual standards drawings.

You can synchronize project standards drawings among themselves either from the project standards node in Style Manager and Display Manager, or from the CAD Manager menu.

When project standards drawings are synchronized among themselves, the following criteria are used to determine how the objects are updated:

- Standards drawing type: The display settings in the Standards display drawing update the display settings in all standard styles drawings.
- Assigned style types: When a drawing has been associated with a style type in the standards configuration setup, the styles in this drawing will update all other standards drawings that may contain standard styles of that type. For example, if the standards drawing “Door Styles.dwg” has been associated with the Door style type, the styles in that drawing will overwrite any existing door standard styles in all of the other standards drawings. Note that in most cases, you will not place standard styles anywhere but in the designated standards drawing for that style type.
- Search order: When more than one standards drawings in the standards configuration setup have been associated with a style type, the first standards drawing in the search order will update all other drawings associated with that style type.

Synchronizing project standards drawings among themselves is an automatic synchronization process, where no user interaction is possible. That means that no styles or display settings can be excluded from the synchronization process.

- 1 Verify that the project of which you want to synchronize the standards is the current project.
- 2 Click Format menu ► Style Manager or Display Manager.
- 3 Select the project node in the tree view, right-click, and click Synchronize Project Standards Drawings.

4 When the synchronization is finished, click OK to exit Style Manager or Display Manager.

NOTE Alternatively, you can click AEC Project Standards ► Synchronize Project Standards on the CAD Manager menu. If the CAD Manager menu does not appear on your menu bar, click Window ► Pulldowns ► CAD Manager Pulldown.

Editing Project Standards Drawings Outside the Project

You can edit project standards drawings outside the current project. This could happen, if you need to work offline, without access to the project, or if you want to work on a project standards drawing that is not part of the current project.

The following high-level steps are necessary to edit a project standards drawing outside of a project:

- 1 If necessary, copy the project standards drawing to an offline location outside the project.
- 2 Open the project standards drawing, and open Style Manager or Display Manager.
- 3 Edit the styles or display settings as necessary.

NOTE If the style or display setting you are editing already has a version history within the project, the version history is displayed in Style Manager or Display Manager.

- 4 Upon closing Style Manager or Display Manager, you are prompted to version changed styles or display settings. Version them just like you would within the project.
- 5 Save and close the project standards drawing.
- 6 If necessary, copy the project standards drawing back to the project.
- 7 Set the project current, and start a synchronization to propagate the changed styles and display settings to the project.

Scripting Project Standards Commands

Commands can help you automate the standards in your project by scripting your workflows and processes. The following commands are available for the project standards feature:

Command	Description
AecProjectStandards	Launches the Configure AEC Project Standards dialog box for the current project. For more information, see Configuring Project Standards on page 416.
AecSynchronizeProjectDrawing	Synchronizes the current drawing with the project standards. TIP To run this command without user interaction, make sure the automatic synchronization option is selected, as described in Setting up Synchronization of AEC Standards on page 421.
AecSynchronizeProject	Synchronizes the current project with the project standards. TIP To run this command without user interaction, make sure the automatic synchronization option is selected, as described in Setting up Synchronization of AEC Standards on page 421.

Command	Description
AecAuditProjectDrawing	Audits the current drawing against the project standards. For more information, see Auditing a Project or a Drawing on page 454
AecAuditProject	Audits the current project against the project standards. For more information, see Auditing a Project or a Drawing on page 454
AecShowObjectDisplayOverrides	Identifies objects in the current drawing that have their display properties overridden at the object level. For more information, see Showing Display Overrides in Project Drawings on page 455.
AecVersionModifiedObjects	Versions all modified styles and display settings in the current drawing. For more information, see Updating Standard Objects in a Project Standards Drawing on page 461. NOTE This command works only with project standards drawings.
AecProjectStandardsSetupReport	Generates a tracking report for the project standards setup. For more information, see Generating a Project Standards Setup Report on page 424.
AecUpdateStandards	Updates the project standards with the styles and display settings from the current drawing. For more information, see Updating Standard Objects in a Project Standards Drawing from a Project Drawing on page 463.
AecPurgeVersion	Purges the version information from all styles and display settings in the current drawing. For more information, see Purging the Version Information from a Project Standards Drawing on page 467. NOTE This command works only with project standards drawings.
AecClearVersionHistory	Purges the version history from all styles and display settings in the current drawing, except for the current version. For more information, see Purging the Version History from a Project Standards Drawing on page 467. NOTE This command works only with project standards drawings.
AecSynchronizeStandards	Synchronizes the project standards drawings of the current project among themselves. For more information, see Synchronizing Project Standards with Each Other on page 468.
AecUpdateProjectCADStandards	Updates the project's CAD Standards Batch Standards Checker CHX file. It also updates the CAD Standards file associations with each drawing in the current project.
NOTE The commands for the Drawing Management feature can also be useful for creating scripts for project standards. For more information, see Drawing Management Commands on page 396.	

Drawing Compare

8

An efficient review of drawings and revisions is key as you move through the design, development, and construction phases of a project. The Drawing Compare feature makes it easier and faster to compare versions of drawings visually and review proposed changes. In addition to AutoCAD Architecture, Drawing Compare also allows you to compare drawings from AutoCAD®, Revit MEP, Revit Architecture, and Revit Structure.

Overview of Drawing Compare

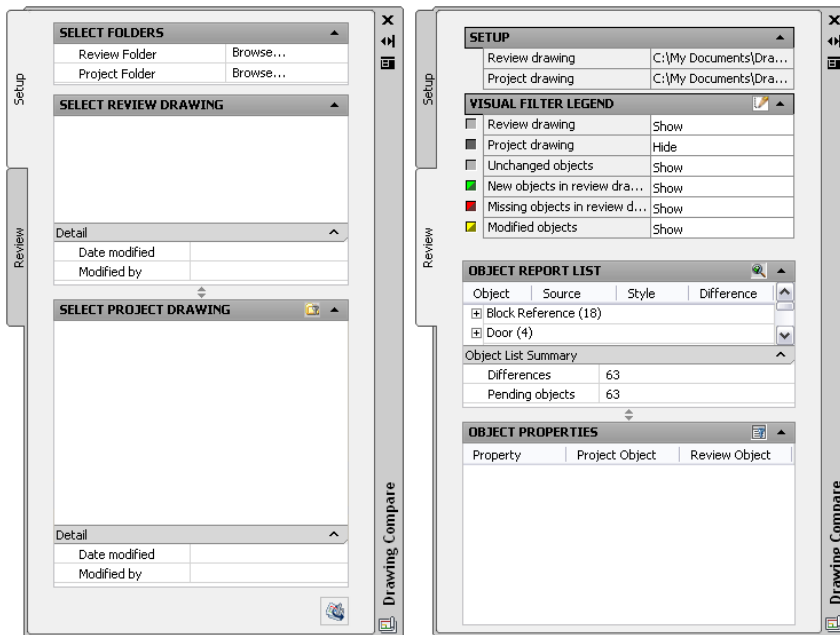

A typical project requires multiple reviews as you produce drawings and add supplemental information. Drawing Compare compares review drawings to project drawings. The original drawings are the project drawings. The drawings that are revised and ready for evaluation are the review drawings.

The comparison process is like how drawings were compared when they were received on tracing paper or Mylar sheets and then overlaid on the original project drawings. Drawing Compare displays informational data about the objects in your drawing as well as displaying the graphical changes on the drawing screen.

NOTE Drawing Compare is a subscription-only feature, available to participants in the Autodesk Subscription Program. Log on to the Subscription Center and download the “Drawing Compare Module.”

You select the review drawings and compare each to its corresponding project drawing on the Setup tab of the Drawing Compare palette. After the comparison, you view the results on the Review tab of the Drawing Compare palette and in the drawing area.

Drawing Compare identifies objects that have been modified, added, or removed in the review drawings. Based on the status of the objects (modified, new, or missing), colors are assigned, and a list of the changes is generated.

Drawing Compare palette

In the following example, a simple floor plan was modified to show what information Drawing Compare displays during a comparison session. The review drawing shows that changes to the project drawing include moving the lower vertical interior wall segment to the left (resulting in a shorter horizontal interior wall segment), adding an exterior door to the right exterior wall segment, and removing a window from the upper exterior wall segment.

project floor plan drawing

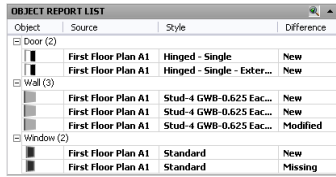

review floor plan drawing

When the drawings are compared, color-coded changes are displayed, based on the type of change.

Information about changes is also displayed in the Object Report List on the Review tab.

Object	Source	Style	Difference
Door (2)			
First Floor Plan A1		Hinged - Single	New
First Floor Plan A1		Hinged - Single - Exter...	New
Wall (3)			
First Floor Plan A1		Stud-4 GWB-0.625 Eac...	New
First Floor Plan A1		Stud-4 GWB-0.625 Eac...	New
First Floor Plan A1		Stud-4 GWB-0.625 Eac...	Modified
Window (2)			
First Floor Plan A1		Standard	New
First Floor Plan A1		Standard	Missing

File Organization for Drawing Compare

AutoCAD Architecture projects (the drawing management feature) provide automated tools to aid in the management, viewing, and construction of a building. Although it is not necessary for your drawings to be in a structured project, Drawing Compare works best when they are. When you are working in a project environment, Drawing Compare recognizes the Autodesk Project Information (APJ) file that identifies the collection of drawing files as being organized in a project. For more information about managing drawings in projects, see [Process Overview: Working in a Project Environment](#) on page 217. Different people on the team can access, share, and redirect project and review drawings in top-level folders in a project setting. For more information, see [Working with Design Teams Located Remotely](#) on page 231.

If you are not working with a structured project in AutoCAD Architecture, organize original drawings in project folders, and organize the revised drawings for review in review folders. The project drawings must all be contained within the same top-level folder to provide the correct context to perform the comparison. You specify these source folders for both Project and Review folders when you start Drawing Compare. Your drawings may be loosely organized as plans, elevations, and sections and look like this:

General Guidelines for Comparing Drawings

Drawing Compare only works in model space. If a drawing selected for comparison was saved in paper space, Drawing Compare automatically switches to the model tab. Because the content of sheets is exclusive to paper space, Drawing Compare does not display sheets in the list of project drawings in the Select Project Drawing pane.

Drawing Compare creates a snapshot of current drawing conditions. If you make changes, such as modifying project entities or changing the annotation scale while the review process is active, the results of the changes do not display until you run a new comparison.

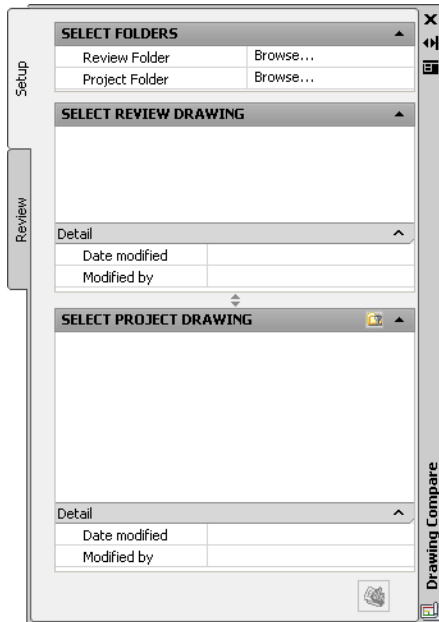

During a Drawing Compare session, the drawing open on your screen is the project drawing with a screened image of the review drawing overlaid. Any changes you make are made in the project drawing. You can save changes you make to this project drawing, but you cannot merge review drawings with project drawings or modify review drawings.

Drawing Compare is not an integration tool. After the Drawing Compare process is complete and differences between the drawings are compiled, review drawings are not automatically integrated into your project. You are responsible for manually integrating and copying review drawings and all of their associated files (xref and image files, for example) to their appropriate locations.

IMPORTANT The data collected from the comparison is not saved. When you exit Drawing Compare, the results of the comparison are discarded.

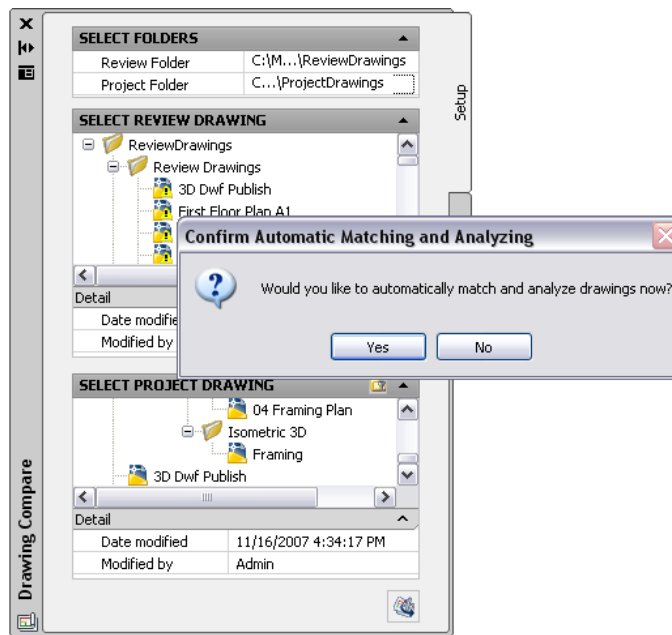

Starting a Drawing Compare Session

The Setup tab of the Drawing Compare palette is where you specify the context in which drawings are matched and analyzed. Under Select Folders, the review folder contains updated or revised drawings, and the project folder contains the original version of the drawing files. All the project drawings must be contained within the same top-level folder to provide the correct context. For more information, see [File Organization for Drawing Compare](#) on page 473.

The matching and analyzing process looks at each review drawing to verify whether it is a modified version of a project drawing. If so, the 2 drawing files are matched. For more information, see [General Guidelines for Comparing Drawings](#) on page 473.

- 1 Click Window menu ► Drawing Compare Palette.
- 2 On the Setup tab for Review Folder, click Browse, navigate to the folder containing project drawings, and select it.
Drawing files in this folder are displayed alphabetically in the Select Review Drawing pane. These files include host drawings and any drawings nested within them as external references (xrefs).
- 3 For Project Folder, click Browse, navigate to the folder containing project drawings, and select it.
The Confirm Automatic Matching and Analyzing dialog displays.

NOTE The automatic matching and analyzing option is strongly recommended for most use cases. Match drawings manually only when a review drawing has been renamed, or if you want to compare a smaller set of drawings.

4 Match review drawings to project drawings.

If you want to...

Then...

let Drawing Compare automatically match all the review drawings against all of the project drawings in these folders

click Yes.
The Automatically Matching and Analyzing Drawings progress bar displays. The software matches drawings by file name.

select a different project folder for Project Folder before automatically matching

click No, and under Select Folders, browse to the folder that contains project drawings for Project Folder. Click Yes when the Confirm Automatic Matching and Analyzing dialog displays.

You can also selectively match drawings:

If you want to...

Then...

select specific drawings/folder for automatic matching

click No, and in the Select Review Drawing pane, right-click the drawings or drawing folder to be matched, and select Automatically Match.

match drawings manually

click No, and in the Select Review Drawing pane, select a drawing, and drag it onto a drawing in the Select Project Drawing pane. When you manually match drawings with different names, a relationship is established between the drawings. This affects what displays when you use the filter mode for the Project folder.

If you want to...	Then...
exclude specific drawings from matching	<p>click No. In the Select Review Drawing pane, right-click the drawings or drawing folder to be excluded, and clear Include in Comparison.</p> <p>NOTE If you choose to exclude drawings from a comparison, objects in excluded drawings will appear as unmodified after the comparison. This allows you to focus on a smaller, more manageable set of modifications.</p> <p>A file excluded from a comparison will act as if it, and all its xrefs, are exact copies of the originals. Objects in excluded files (or xrefed by excluded files) will appear as unmodified. You should exclude files that you do not want to include in a comparison.</p>

NOTE Architectural Desktop R14 drawings or earlier versions may not match automatically, but they can still be compared. You can either update the older drawings by saving them in the 2007 format, or you can match them manually.

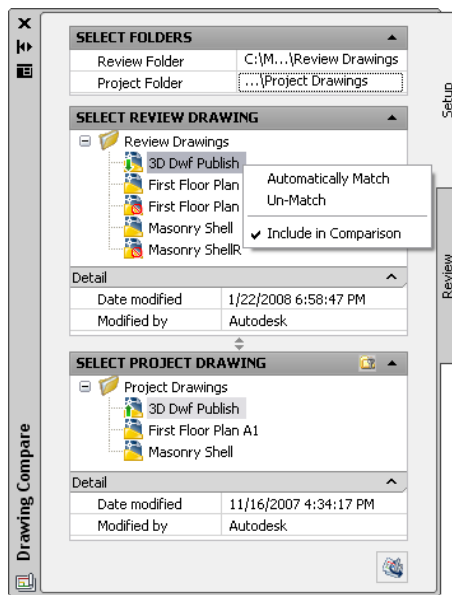

After project and review drawings have been matched, icons next to the drawing name indicate status of the drawings as follows:

Icon	Description
	No match attempted yet. This is the initial state of all review drawings.
	A review drawing is matched but is not selected.
	A review drawing that is matched and selected.
	A project drawing for which a matched review drawing is selected.
	No match for a review drawing is found.
	A review drawing that was specifically excluded from comparison by the user.

The date the selected drawing file was modified and the name of the person who made the modifications displays when you select a drawing from the review or project folder.

Detail	
Date modified	11/16/2007 4:34:17 PM
Modified by	Admin

5 If desired, the drawings in the Review folder can be reset from matched to unmatched. This undoes an incorrect or inadvertent match, removing the match relationship.

- You can un-match all review drawings at once by selecting the top-level folder in the Select Review Drawing pane, right-clicking, and clicking Un-Match All.
- You can un-match a single review drawing by selecting the drawing, right-clicking, and clicking Un-Match.

6 If you want to set up a filter for results, select any drawing in the Select Review Drawing pane, and click  on the Select Project Drawing title bar.

With the filter on, drawings in the project folder are filtered to display only those drawings that were matched to the drawing selected in the review folder and any project drawings into which the selected review drawing is xrefed. When you turn the filter mode off, all of the drawings in the project folder are listed.

7 Begin a comparison using one of the following methods.

- Select a review drawing from the Select Review Drawing pane, select a project drawing from the Select Project Drawing pane, right-click, and click Begin comparison from this drawing.
- Select a review drawing from the Select Review Drawing pane, select a project drawing from the Select Project Drawing pane, then click  (Start Drawing Comparison) at the bottom of the tab.
- Select a review drawing from the Select Review Drawing pane, double-click the project drawing from the Select Project Drawing pane.

The Object Comparison progress bar displays the number of objects being compared as they are processed. For results to be generated, always allow the Drawing Compare process to finish. For more information, see [Reviewing the Results of a Drawing Compare Session](#) on page 478.

IMPORTANT Although you can use the AutoCAD Undo command while working in a drawing, you cannot use it to undo any actions specific to Drawing Compare.

After the comparison is complete, the Review tab of the Drawing Compare palette displays along with a separate Drawing Compare Mode toolbar. For more information, see [Reviewing the Results of a Drawing Compare Session](#) on page 478.

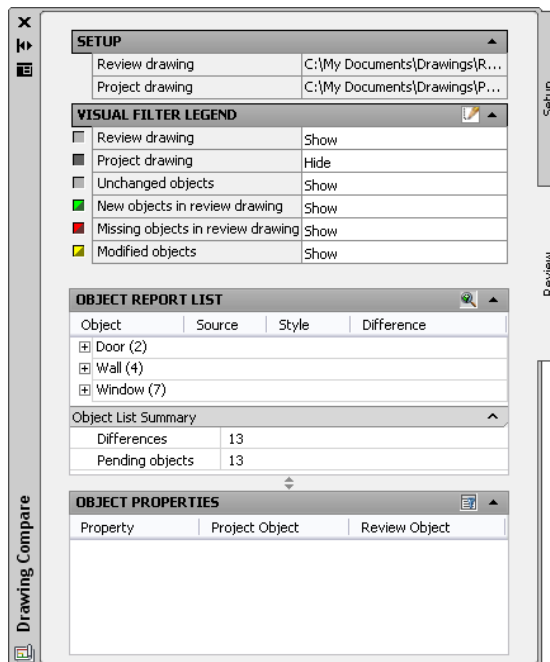

Reviewing the Results of a Drawing Compare Session

After you begin a comparison between a review drawing and a project drawing (see [Starting a Drawing Compare Session](#) on page 474), the Object Comparison progress indicator displays as shown.

When all objects in the drawings have been compared, the following events occur:

- The Review tab of the Drawing Compare palette becomes active. This tab has a legend for the colors used in the drawing area and lists all objects for which differences were found. Select an object in the list to view a comparative list of its properties in both drawings (and optionally zoom in on the object in the drawing area).

- Comparison results are shown graphically in the drawing area, with review drawing geometry overlaid on the project drawing. Objects for which differences were found display in color according to the Visual Filter Legend on the Review tab. For more information, see [Creating a Visual Filter](#) on page 482.
- The Drawing Compare Mode toolbar displays, providing a set of tools for reviewing comparison results.

Icon	Description
	Ends a Drawing Compare session. There is no Undo option for exiting Drawing Compare, and the compiled data is not saved. There is no way to recapture the information you were reviewing without beginning a new comparison.
	Plots a Drawing Compare session. You can publish the current comparison results (based on the current display system, layers, and filter settings) of the review drawing to 2D DWF or plot with foreground plotting. For more information, see Publishing Drawings to DWF and DWFx on page 204 and “Plot and Publish Drawings” in AutoCAD Help. NOTE Foreground plotting is used by default; background plotting is disabled when the plot button is selected. If you choose to plot or publish using background plotting, your comparison results will not be plotted, and you will lose the themed results.
	Selects the previous or next object in the Object Report List, and zooms in on the object in the drawing area if the Zoom to option is activated.
	Selects an object in the drawing area and highlights it in the Object Report List.
	Activates/deactivates the Zoom to option. Activate this option to move forward and back through objects in the Object Report List.
	Hides/displays the Drawing Compare palette. You can minimize the Drawing Compare palette and use the Drawing Compare Mode toolbar to navigate when viewing objects. Expand the palette when necessary to review information about objects and properties.

Using the Review Tab

The Review tab of the Drawing Compare palette lets you review the results of a Drawing Compare session on an object-by-object basis. It also provides a mechanism for filtering the display in the drawing area to show/hide certain categories of objects or an entire drawing. The tab includes the following sections.

- **Setup:** This section displays the full paths for the review and project drawings that are being compared. If multiple comparisons are active, this information updates as you switch between drawings.

SETUP	
Review drawing	C:\My Documents\Drawings...
Project drawing	C:\My Documents\Drawings...

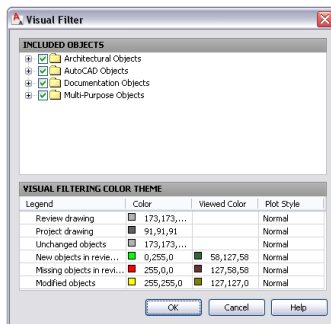

- **Visual Filter Legend:** The Visual Filter Legend identifies the colors used to indicate different categories of drawings and objects. You can switch the Hide/Show settings to control what will be visible in the drawing area. The icons for new, missing, and modified objects show 2 colors: the color in the upper-left corner of the icon is used for objects that have not been viewed; the color at the lower right is used for objects that have been viewed.

When you start a Drawing Compare session, the last used filter from the previous session is still in effect. To change the colors or plot styles for any of the categories in the legend, click the Edit Visual Filter icon () on the Visual Filter Legend title bar to open the Visual Filter dialog. For more information, see [Creating a Visual Filter](#) on page 482.

VISUAL FILTER LEGEND	
<input type="checkbox"/> Review drawing	Show
<input type="checkbox"/> Project drawing	Hide
<input type="checkbox"/> Unchanged objects	Show
<input checked="" type="checkbox"/> New objects in review drawing	Show
<input checked="" type="checkbox"/> Missing objects in review drawing	Show
<input checked="" type="checkbox"/> Modified objects	Show

- **Visual Filter:** The Visual Filter dialog displays after you click the Edit Visual Filter icon () on the Visual Filter Legend title bar. It allows you to specify filters that affect how objects display during your Drawing Compare session.

Select which objects will be compared under Included Objects. For example, you can set up a visual filter to include only modified windows to be included in the comparison. All other objects would display as unchanged. Under Visual Filtering Color Theme, you can adjust the color schemes and assign plot styles to different groups of objects, such as all modified windows. The Color column lists the colors for pending objects before they are selected. The Viewed Color column lists the colors for objects after they are selected. For more information, see [Creating a Visual Filter](#) on page 482.

- **Object Report List:** Objects that changed in the selected review drawing are listed alphabetically by categories, such as Circle, Door, Multi-View Block, and Polyline. All the information is in bold text initially, indicating objects as pending (not yet viewed). After an object is viewed, the associated information displays as normal text.

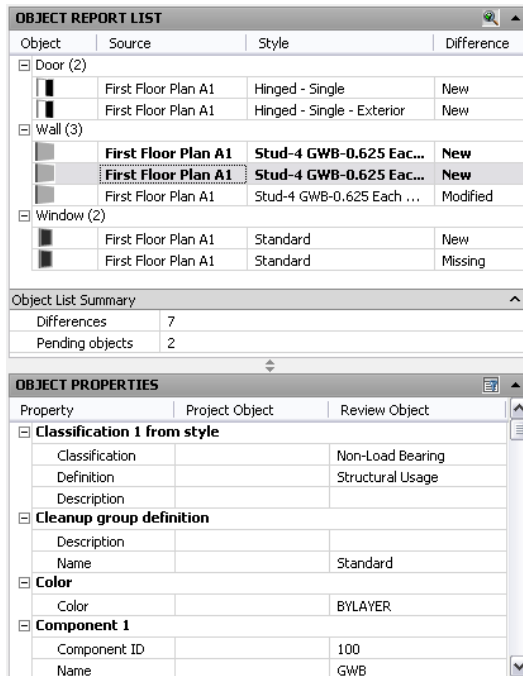

OBJECT REPORT LIST			
Object	Source	Style	Difference
[-] Door (2)			
	First Floor Plan A1	Hinged - Single	New
	First Floor Plan A1	Hinged - Single - Exter...	New
[-] Wall (3)			
	First Floor Plan A1	Stud-4 GWB-0.625 Eac...	New
	First Floor Plan A1	Stud-4 GWB-0.625 Eac...	New
	First Floor Plan A1	Stud-4 GWB-0.625 Eac...	Modified
[-] Window (2)			
	First Floor Plan A1	Standard	New
	First Floor Plan A1	Standard	Missing

Select objects from the list to reset their status to pending or to viewed. Use the *SHIFT* key to select multiple objects and the *CTRL* key to select objects one at a time, right-clicking, and clicking Reset to pending or Mark as viewed. Resetting the objects changes the text style on the Object Report List and updates values in the Object List Summary.

The option to zoom in on an object turns on and off when you click the Activate/Deactivate Zoom to icon () on the Object Report List title bar or on the Drawing Compare Mode toolbar. The software zooms into an object automatically after you select it in the Object Report List when this option is turned on.

When you select changed objects in the drawing area, the object is highlighted in the Object Report List. When you hold the cursor over new or modified objects in the drawing, a lock icon indicates that these objects cannot be changed.

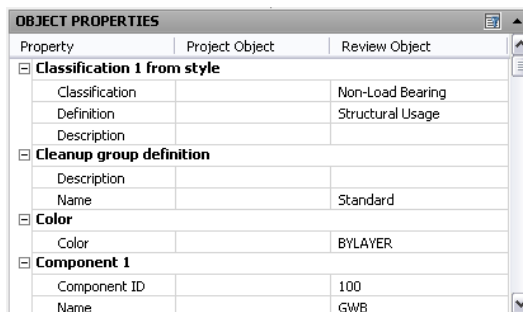

The Object Report List works hand-in-hand with the Object List Summary and the Object Properties. When you select an object from the Report List, the number of Pending objects changes, and the properties of the object display under Object Properties.

- Object List Summary:** This summary displays the total number of objects changed and the total number of objects waiting to be viewed. In the following example, a total of 209 objects changed in the review drawing in some way, and 7 of these were reviewed, leaving 202 objects still pending; that is, not yet selected in the Object Report List. As you change the status of objects in the Object Report List, the number of Pending objects decreases or increases accordingly.

- Object Properties:** This option is on by default and displays properties that have changed for the object that is selected in the Object Report List. If you want to view all properties of the selected object, click the Display properties for reviewed objects icon () on the Object Properties title bar to turn it off. If the object is missing, data is listed in the Project Object column only. If the object is new, data is listed in the Review Object column only. For modified objects, both project and review properties display.

Creating a Visual Filter

Use this procedure when you want to create a filter that controls which objects display and how they display during a review session. The changes you make on the worksheet are applied to the drawing and the Visual Filter Legend after you click OK.

- 1 On the Review tab, click the Edit Visual Filter button ().
- 2 On the Visual Filter dialog, in the Included Objects pane, select or clear the objects as needed to specify which ones will display.

TIP The context menu includes options to Clear All or Select All objects.

- 3 Specify settings for the visual filtering color theme:

If you want to...

Then click the  **...**

change the primary color of object groups pending review

under Color to display the Select Color dialog box, select the primary color to appear on the icon, and click OK.

change the secondary color of object groups after they are selected and viewed

under Viewed Color to display the Select Color dialog box, select the secondary color to appear on the icon, and click OK.

select a plot style

under Plot Style to display the Select Plot Style dialog box, select the plot style for the object group, and click OK.

NOTE No options are listed for drawings that use the CTB plot style. If the STB style is used, you can change the color and pen thickness for this group of objects. For more information about plot styles, see “Change Plot Style Settings” in AutoCAD Help.

- 4 Click OK.

Drawing Compare Commands

You can run certain Drawing Compare commands from the command line. These commands are also available as toolbar buttons.

- To open the Drawing Compare palette, enter DwgCompare at the command line, or click  (Drawing Compare) on the Navigation toolbar.
- To open the Visual Filter dialog (when the Review tab is current), enter VisualFilter, or click  (Visual Filter) on the Visual Filter Legend title bar.

Frequently Asked Questions about Drawing Compare

Question: When I copy an object from a project drawing to a review drawing and then start a Drawing Compare session, I would expect that the copied object would be identified as unchanged. However, the copied object is identified as new and missing. Why is this?

Answer: Drawing Compare uses object handles to match objects in review drawings to objects in the project drawings. When an object is copied from one drawing to another, it is assigned a new object handle and is identified as a new version of the object. This results in the object being identified as missing in the project drawing and new in the review drawing.

Question: When I run a Drawing Compare session, objects that I know have been altered are not identified as modified. What causes this situation?

Answer: Check the Visual Filter worksheet and verify that the objects in question are not excluded from the Drawing Compare review. In the Included Objects section, expand each list of objects and select the appropriate objects for inclusion in the Drawing Compare review if necessary. If the properties that have been modified are annotation scale-dependent, they may not have been modified at the current annotation scale.

Drawing Compare uses the current model space annotation scale from the project drawing when comparing drawings. Annotative entities that do not support the current scale are still compared, but properties that can vary by scale representation will be identified as "Missing scale representation." Properties that never vary by scale representation are always identified with their actual values. For any specific annotative entity, Drawing Compare will compare all its non-annotative properties as well as those scale-specific properties that are associated with the current annotation scale.

Non-annotative entities will always appear at the same size and rotation and will have the same property values regardless of the current annotation scale.

Question: I expect the Drawing Compare feature to zoom to each object that I select in the Object Report List, but this is not happening. Why?

Answer: The following reasons may apply:

- You may have clicked the Zoom to button and toggled off the option.
- You may be in the middle of a command. Click the Zoom to button again to toggle the option on, or end the command that you started to return to your Drawing Compare session.
- The selected object is not currently visible because of layer or display system settings. A message displays on the command line when a non-visible object is selected from the Object Report List.

Question: My Drawing Comparison results identify xrefs that are new and missing, but I expect these xrefs to be identified as unchanged or modified. Why is this?

Answer: Drawing Compare uses object handles to match objects in review drawings to objects in the project drawings. If the xref has been detached, then reattached, the xref is assigned a different object handle and is identified as a new version of the xref. This results in the xref being identified as new in the review drawing and missing in the project drawing.

Question: After drawings from review and project folders are matched automatically, some of the drawings are still identified as unmatched even though these drawings in question share the same name. How can this be?

Answer: The drawing names may be the same, but the individual drawing internal IDs are different. This can occur, for example, when a drawing is W-blocked into a new drawing. Different drawing internal IDs are also assigned to AutoCAD Architecture or Revit Architecture drawings when they are exported to AutoCAD.

NOTE Using the Save or Save As commands does not alter a drawing's internal ID.

Question: Why is my Select Project Drawing list empty after I select a project folder?

Answer: This occurs when the Project Drawing filter is toggled on and either no review drawing has been selected or the selected review drawing is not matched with a project drawing.

Question: Why do I not see the drawings that have been recently added to the project or review folder?

Answer: Folder contents are not automatically updated when drawings are added or removed. To update folder contents after they have been changed, reselect the appropriate folder.

Question: I see an external block reference identified in the Object Report List as new, modified, or missing, yet this external block reference does not appear graphically with any color assigned by the Visual Filter settings. What causes this problem?

Answer: External block references cannot have Visual Filter settings assigned to them. This is to ensure that the modifications to underlying objects within the external block reference are assigned colors according to the Visual Filter settings.

Question: Objects that have had their display settings modified are not identified in the Object Report List as modified. Why is this?

Answer: The Drawing Compare process does not review display settings for objects. Only the property and style settings of objects are reviewed.

Question: When comparing drawings exported from Revit Architecture or Revit Structure, I notice that a simple modification that I made to an object in these drawings results in numerous differences in associated objects. Why?

Answer: Each Revit object may be exported as separate objects, each of which may show up as a separate modification.

Question: Why do I have to always manually match drawings exported from Revit Architecture?

Answer: A new internal drawing ID is automatically assigned to each drawing file exported from Revit Architecture.

Layer Management

9

Enhanced layer management helps you to create, view, and modify the numerous and diverse elements of architectural plans. Use the Layer Manager in AutoCAD Architecture to effectively organize and manage conceptual groupings in a drawing.

Layer Management

Layer Manager

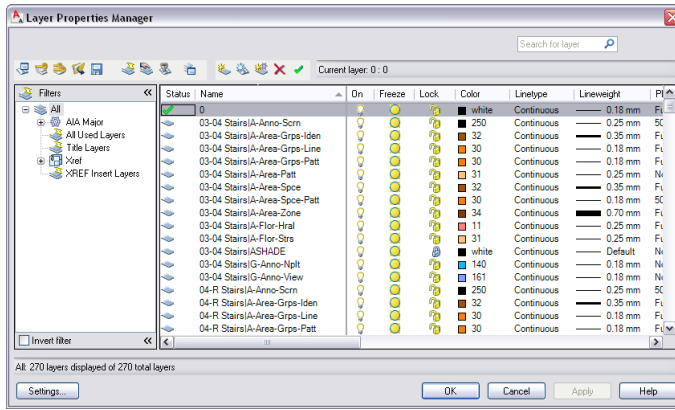

The Layer Manager helps you organize, sort, and group layers, and allows you to work with layer standards, layer key styles, layer filters, layer overrides, and saved layer states.

IMPORTANT In AutoCAD 2009 the Layer Properties Manager has changed from a modal dialog to a non-modal palette layout. This non-modal palette however does not contain any AutoCAD Architecture-specific functionality, such as Layer Key Styles or Layer Standards. When working with AutoCAD Architecture you will by default access the existing modal Layer Manager dialog. If you want to work with the non-modal AutoCAD Layer Palette, enter **LayerPalette** on the command line. If you want to switch back to the modal AutoCAD Architecture Layer Manager dialog, enter **ClassicLayer**.

In the Layer Manager you can perform all activities related to layers:

- Create, rename, and delete layers
- Set and change layer properties
- Make a layer current
- Work with layer standards and layer key styles
- Create layer groups and layer filters
- Create layer overrides for layout viewports
- Get notified about new layers in the drawing and its xrefs
- Save and restore layer states

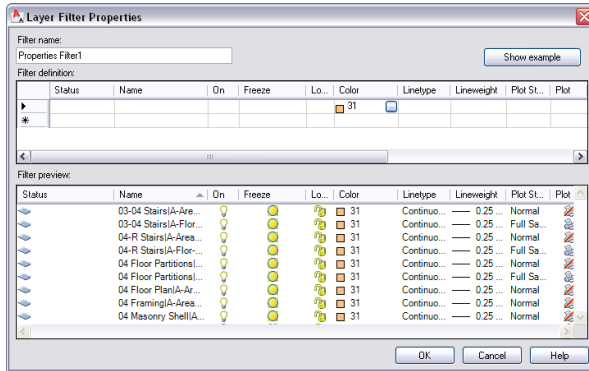

When you display the Layer Manager, all the layers in the current drawing are displayed in the All layer group. If there are any external reference files linked to the drawing, the layers are listed in a separate layer group, listed by referenced drawing.

Layer Filters

You can create layer filters to manage large sets of layers. The Layer Manager allows you to create three types of layer filters: group filters, property filters, and layer standards filters. Property filters group layers based on layer properties and states, like for example visibility or color. Group filters contain any layers that you put in them. Standards filters contain layers associated with a specified layer standards category.

Creating a layer properties filter

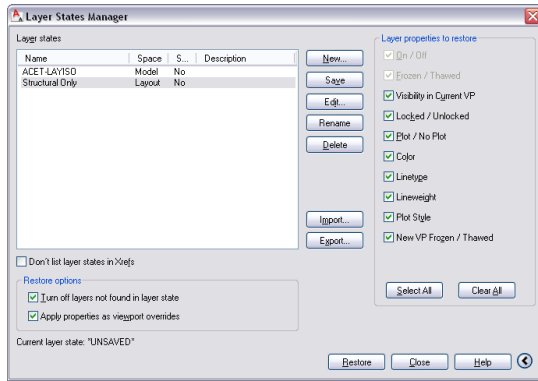

Layer States

You can save the current layer settings in a drawing as a layer state and restore this layer configuration later. Saving layer states is convenient if you need to return to particular settings for all layers during different stages in completing a drawing or for plotting.

Layer settings include layer states, such as on or locked, and layer properties, such as color or linetype. In a saved layer state, you can choose which layer states and layer properties you want to restore later. For example, you can choose to restore only the Frozen/Thawed setting of the layers in a drawing, ignoring all other settings. When you restore that named layer state, all settings remain as they are currently set except whether each layer is frozen or thawed.

Restoring a saved layer state

Viewport Layer Overrides

You can now apply overrides for color, linetype, lineweight, and plot style to layers in individual layout viewports. This is an efficient way to display objects with different property settings in individual viewports without changing their ByLayer or ByBlock properties. Because layer property overrides do not change the layer's global properties, you can have objects display differently in various viewports without having to create duplicate geometry or use xrefs that have different layer settings. When the Layer Manager is accessed from a layout tab, 4 additional columns for viewport-specific layer property overrides are displayed for VP Color, VP Lineweight, VP Linetype, and VP Plot Style.

Overriding layer properties for a viewport

S.	Name	On	Fr.	Lo.	Color	Linetype	Lineweight	Plot Style	VP Co.	VP Linetype	VP Lineweight	VP Plot Style	Ne.
0	0												
1	01-02 Stairs(A-A...)				250	Continuous	0.25	50 Percent	250	Continuous	0.25 mm	50 Percent	
2	01-02 stairs(A-A...)				32	Continuous	0.35	Full Satura...	32	Continuous	0.35 mm	Full Saturation	
3	01-02 stairs(A-A...)				30	Continuous	0.18	Full Satura...	30	Continuous	0.18 mm	Full Saturation	
4	01-02 stairs(A-A...)				30	Continuous	0.18	Full Satura...	30	Continuous	0.18 mm	Full Saturation	
5	01-02 stairs(A-A...)				31	Continuous	0.25	50 Percent	31	Continuous	0.25 mm	50 Percent	
6	01-02 stairs(A-A...)				32	Continuous	0.35	Full Satura...	32	Continuous	0.35 mm	50 Percent	
7	01-02 stairs(A-A...)				30	Continuous	0.18	Full Satura...	30	Continuous	0.18 mm	Full Saturation	
8	01-02 Stairs(A-F...)				34	Continuous	0.70	Full Satura...	34	Continuous	0.70 mm	Full Saturation	
9	01-02 Stairs(A-F...)				11	Continuous	0.25	Full Satura...	11	Continuous	0.25 mm	Full Saturation

17	01 floor partition...				30	Continuous	0.18	Full Satura...	30	Continuous	0.18 mm	Full Saturation	
18	01 floor partition...				31	Continuous	0.25	50 Percent	31	Continuous	0.25 mm	50 Percent	
19	01 floor partition...				32	Continuous	0.35	Full Satura...	32	Continuous	0.35 mm	Full Saturation	

New Layer Notification

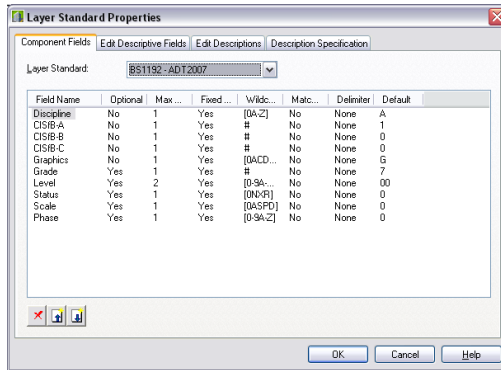

You can be notified when new layers are added to the current drawing or one of its attached xrefs before certain tasks, such as plotting, saving, or restoring a layer state. This way you can avoid potential problems such as plotting objects that were added to the drawing by the addition of a new layer. You can control when a drawing is evaluated for new layers, if at all. You can specify which commands, such as SAVE or PLOT, trigger the software to check the layer list and alert you of new layers. This can be limited to new layers that have been added to attached xrefs or include layers in the current drawing and attached xrefs.

Layer Standards

Layer standards establish naming conventions for layers in your drawings. A layer standard contains a set of rules that determines the structure of the layer names in a drawing. When you install the software, you can select from a number of layer standards that you can use. You can change or edit each of the layer standards later, if needed.

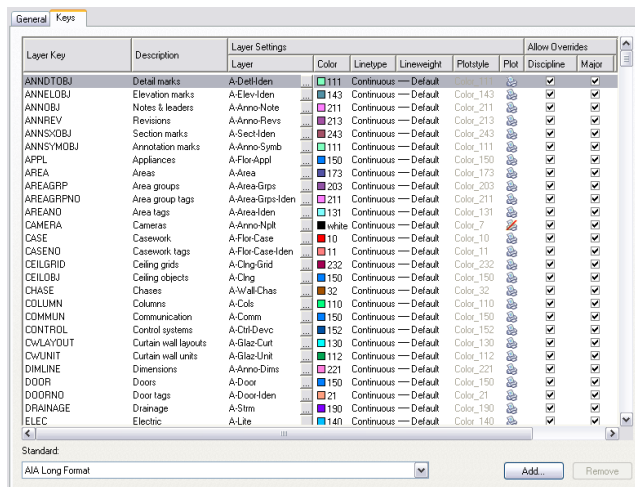

Defining a layer standard

Layer Keys and Layer Key Styles

Each layer standard has a corresponding layer key style. The layer keys in the layer key style assign objects to predefined layers with names that conform to the layer standard. When you add an object, the object is automatically drawn on the layer assigned to it in the current layer key style. This process is called *layer keying*.

Viewing a layer key style

You can change any part of the layer name structure using layer key overrides within the layer key style. You can override the layer names for all the layer keys in a layer key style, or you can override individual layer key styles.

Managing Drawing Layers

The Layer Manager helps you organize, sort, and group layers, as well as save and coordinate layer states. You can also use layer standards with the Layer Manager to better name the layers in multiple drawings.

When you open the Layer Manager, all the layers in the current drawing are displayed in the right pane. You can work with individual layers to:

- Create, rename, and delete layers
- Change layer properties
- Make a layer current

- Add and remove viewport layer overrides
- Get notified of new layers and reconcile them in the drawing
- Filter and group layers

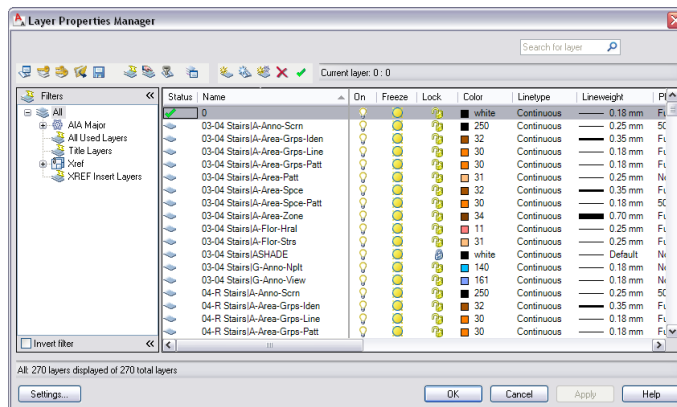

NOTE Additional AutoCAD layer functionalities are available from the Format ► Layer Tools menu. For more information about AutoCAD layer functionalities, see “Work with Layers” in the AutoCAD help.

Opening the Layer Manager

Use this procedure to open the Layer Manager. When you open the Layer Manager, all the layers in the current drawing are displayed in the right pane while the layer groups are displayed in the left pane.

IMPORTANT In AutoCAD 2009 the Layer Properties Manager has changed from a modal dialog to a non-modal palette layout. This non-modal palette however does not contain any AutoCAD Architecture-specific functionality, such as Layer Key Styles or Layer Standards. When working with AutoCAD Architecture you will by default access the existing modal Layer Manager dialog. If you want to work with the non-modal AutoCAD Layer Palette, enter **LayerPalette** on the command line. If you want to switch back to the modal AutoCAD Architecture Layer Manager dialog, enter **ClassicLayer**.

- 1 Click Format menu ► Layer Management ► Layer Manager.

- 2 To close the Layer Manager, click .

Making a Layer Current

Use this procedure to make a specific layer the current layer in the drawing. You must select an individual layer to make current. You cannot make multiple layers or layer groups current.

When you make a layer current, new objects you create are drawn on that layer, unless they have their own layer assignment. For example, if you make **A-Wall** the current layer, any lines, polylines, and other linework objects without layer assignment will be drawn on that layer until you select another layer to be current.

NOTE AutoCAD Architecture objects have their own layer assignment through layer key styles and layer standard, so they are not affected by the current layer setting.

- 1 Click Format menu ► Layer Management ► Layer Manager.

2 In the right pane, double-click the layer that you want to make current.

You can also select the layer that you want to make current and click .

The selected layer is now the current layer and is marked with a green check in the Layer Manager. The layer name is displayed next to the Current Layer button near the top of the Layer Manager.

3 Click OK.

Creating a Layer with a Layer Standard

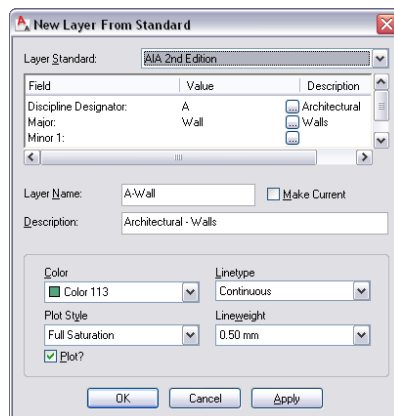

Use this procedure to create a layer that conforms to the layer standard selected for the drawing. Layer standards define the naming of new layers according to the structure defined in the standard. AutoCAD Architecture creates layers as needed according to the current layer standard. For example, when you add a wall to a drawing, the software creates the necessary wall layers if they do not yet exist.

Layer standards can be based on architectural standards like AIA or BS1192, or they can be user-defined and represent a company or other standard. AutoCAD Architecture ships with a number of predefined layer standards and matching layer key styles.

For information on selecting a layer standard and layer key style for a drawing, see [Specifying a Layer Standard and a Layer Key Style](#) on page 162. For information about creating your own layer standard, see [Creating a Layer Standard](#) on page 532.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Select the layer standard that you want to use for Layer Standard.

4 Specify the layer standard information.

Depending on the layer standard you are using, different fields are available here.

To select a value for one of the available fields, click the [...] button, and select one of the values.

You can also enter a new value, provided you follow the parameters specified for the layer standard components.

When you are finished, the Layer Name and Description fields display the combination of values you have selected. If you have, for example, created a new layer for storage shelves according to the BS1192 layer standard, it is named A746G.

NOTE If the name of the new layer is the same as an existing layer in the current layer key style, the properties of the new layer are automatically updated with the properties of the existing layer.

- 5 Select Make Current if you want to make the new layer the current immediately.
- 6 Select a color for the layer from the list.
If the desired color is not available on the list, select Select Color, and select a color from the Color Picker.
- 7 Select a linetype.
If the desired linetype is not available on the list, select Other, and select a linetype from the Select Linetype dialog box.
- 8 Select a lineweight.
- 9 Select a Plot Style.
Clear Plot if you do not want the new layer to be plotted.
- 10 Click OK twice.

Creating a Nonstandard Layer

Use this procedure to create a nonstandard layer. A nonstandard layer is a layer that does not need to conform to the layer standard. You might want to use nonstandard layers for elements like architect's comments or construction lines, blocks you do not want to insert on their original layer, or walls that you want to display partially.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 Click .
- 3 Select Non Standard for Layer Standard.
- 4 Enter a name for the new layer.
- 5 Select Make Current if you want to make the layer the current layer.
- 6 Enter a description for the new layer.
- 7 Select a color for the layer from the list.
If the desired color is not available on the list, select Select Color, and select a color from the Color Picker.
- 8 Select a linetype.
If the desired linetype is not available on the list, select Other, and select a linetype from the Select Linetype dialog box.
- 9 Select a lineweight.
- 10 Select a Plot Style.
Clear Plot if you do not want the new layer to be plotted.
- 11 When you finish specifying the properties of the layer, click OK twice.

Renaming a Layer

Use this procedure to specify a new name for a layer.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 Select the layer that you want to rename, and click the layer name.
- 3 Enter a new name for the layer, and press *ENTER*.
- 4 Click OK.

Deleting a Layer

Use this procedure to delete a layer from a drawing.

Keep the following points in mind when you delete layers:

- If you try to delete a layer that still has objects on it, you receive an error message. To delete this layer, you must first erase all objects on it in the drawing.
- If the layer you try to delete is the current layer, you receive an error message. To delete this layer, make another layer current and then delete the layer.
- Some layers may be assigned to the components of another object, or even to other object styles. These layers cannot be deleted.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Right-click the layer that you want to delete, and click Delete Layer.

The layer you have deleted is marked with a red "X." It is permanently deleted when you click Apply or OK.

NOTE If Apply Changes Immediately is selected, the layer is automatically deleted.

3 Click OK.

Changing the Layer Standard of a Layer

Use this procedure to assign a specific layer to a different layer standard.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Right-click the layer that you want to change, and point to Change Layer Standard.

3 Select the layer standard that you want to use for Layer Standard.

The layer you selected is now assigned to the specified layer standard.

NOTE If a layer standard is unavailable on the shortcut menu, the layer that you selected is not valid for that standard.

4 Click OK.

Defining the Properties of a Layer

A layer has a number of states and properties that define its display and behavior in the drawing.

A state is a condition of a layer that can have one of two values, like On/Off or Freeze/Thaw. The following layer states can be set in the Layer Manager:

Icon	Layer state value	Description
	On	Objects on the layer are displayed, plotted, and regenerated and hide other objects when you use HIDE.

Icon	Layer state value	Description
	Off	Objects on the layer are not displayed and not plotted but do hide other objects when you use HIDE. The drawing is not regenerated when you turn the layer on.
	Thawed	Objects on the layer are displayed and plotted and hide other objects when you use HIDE.
	Frozen	Objects on the layer are not displayed and not plotted but do hide other objects when you use HIDE. The drawing is regenerated when you thaw the layer.
	Unlocked	Objects on the layer can be modified.
	Locked	Objects on the layer cannot be modified. You can still apply object snaps to objects on a locked layer and perform other operations that do not modify those objects.
	Plot	The selected layer is plotted.
	Non Plot	The selected layer is not plotted. If you turn off plotting for a layer, the objects on that layer are still displayed. Layers that are off or frozen are not plotted, regardless of the Plot/Non Plot setting.
	New Viewport Thawed	Thaws the selected layer in new layout viewports.
	New Viewport Freeze (New VP Freeze)	Freezes selected layers in new layout viewports. For example, freezing the DIMENSIONS layer in all new viewports restricts the display of dimensions on that layer in any newly created layout viewports but does not affect the DIMENSIONS layer in existing viewports. If you later create a viewport that requires dimensions, you can override the default setting by changing the Current Viewport Freeze/Thaw setting.
	Current Viewport Thawed	Thaws the selected layer in the current layout viewport.
	Current Viewport Freeze (VP Freeze)	Freezes selected layers in the current layout viewport. You can freeze or thaw layers in the current viewport without affecting layer visibility in other viewports. Current Viewport Freeze is an override to the Thaw setting in the overall drawing. You can freeze a layer in the current viewport if it is thawed in the drawing, but you cannot thaw a layer in the current viewport if it is frozen or off in the drawing. A layer is not visible when it is set to Off or Frozen in the drawing.

Layer properties are settings that can have a list of different values for a display characteristic. The following properties can be set for a layer in the Layer Manager:

- **Color:** Changes the color of objects on the layer. Clicking the color name displays the Select Color dialog box.
- **Linetype:** Changes the linetype of objects on the layer. Clicking the linetype name displays the Select Linetype dialog box.
- **Lineweight:** Changes the lineweight of objects on the layer. Clicking the lineweight name displays the Lineweight dialog box.
- **Plot style:** If you are working with color-dependent plot styles (PSTYLEPOLICY = 1), you cannot change the plot style associated with a layer. Clicking the plot style displays the Select Plot Style dialog box.
- **Description:** You can add a description to the layer. If your layers are created with a layer standard, the description is filled in automatically. In that case, it is recommended to not overwrite it.

NOTE AutoCAD Architecture 2009 introduces the possibility of overriding layer properties for individual viewports. For more information, see [Overriding Layer Properties in Layout Viewports](#) on page 494.

Changing the Visibility of Object Subcomponents

You can place different components of an AEC object on different layers. This is accomplished via the object's display properties. For example, the current layer key style might place a wall on the layer named *A-Wall*, while the wall's material definitions might place its internal boundaries on the layer named *A-Wall-Comp*. Turning off the layer *A-Wall* would typically make the entire wall (including its internal boundaries) invisible, even though those components were assigned to a different layer. You can define that the subcomponents of an object remain visible, even though the primary object's layer (*A-Wall* in this case) is turned off. For information on setting this option, see [Specifying a Layer Standard and a Layer Key Style](#) on page 162.

NOTE Freezing the primary object's layer would make the entire object including its internal subcomponents invisible regardless of the value of this setting. You must turn the layer off if you want subcomponents to be visible without the main component.

To change the properties of a layer

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 To change one of the layer states On/Off, Freeze/Thaw, Lock/Unlock, Plot/Non Plot, Current Viewport Freeze/Thaw, or New Viewport Freeze/Thaw, click the layer state icon for the state to switch its value.
- 3 To change one of the layer properties Color, Linetype, Lineweight, Plot Style, or Description, click the current setting for the property. Then, use the subsequent dialog box to select a different value.
- 4 Click OK.

Overriding Layer Properties in Layout Viewports

You can now apply overrides for color, linetype, lineweight, and plot style to layers in individual layout viewports. This is an efficient way to display objects with different property settings in individual viewports without changing their ByLayer or ByBlock properties. Because layer property overrides do not change the layer's global properties, you can have objects display differently in various viewports without having to create duplicate geometry or use xrefs that have different layer settings. When the Layer Manager is accessed from a layout tab, 4 additional columns for viewport-specific layer property overrides are displayed for VP

Color, VP Lineweight, VP Linetype, and VP Plot Style (available only in named-plot style drawings; PSTYLEMODE=1.)

Viewport layer overrides in Layer Manager

S.	Name	On	Fr.	Lo.	Color	Linetype	Lineweight	Plot Style	VP Co.	VP Linetype	VP Lineweight	VP Plot Style	Ne...

	01 floor partition...				32	Continuous	0.35	Full Satura...	32	Continuous	0.35 mm	Full Saturation	

If you want to temporarily not display or plot property overrides, set VPLAYEROVERRIDESMODE to 0. Objects will display and plot with their global layer properties. Property overrides can still be set even when VPLAYEROVERRIDESMODE is set to 0.

NOTE Property overrides that are on xref layers are not retained when VISRETAIN system variable is set to 0.

Layer Property Overrides in Previous Releases

When a drawing containing layer overrides is opened in a previous release of the software, overrides are not visible and the layer displays its global properties. The override settings are retained however when the drawing is saved in a previous release, and are visible again when the drawing is re-opened in the current release.

If a viewport containing layer overrides is deleted when the drawing is opened in a previous release, the override settings are not retained and are not available when the drawing is re-opened in the current release.

When VISRETAIN is set to 0 when the drawing is opened in a previous release, viewport overrides in xref layers are not retained.

To override layer properties in a layout viewport

- 1 Make the layout viewport active for which you want to create viewport layer overrides.
- 2 Click Format menu ► Layer Management ► Layer Manager.
- 3 Scroll until you have the viewport overrides columns visible in the Layer Manager dialog box.

The following viewport overrides are available for layout viewports:

- VP Color
- VP Linetype
- VP Lineweight
- VP Plot Style

- 4 Click the desired setting to change the property value.

A layer value that is overridden in the viewport is marked by a different background color (light blue by default) on the override property and on the global property.

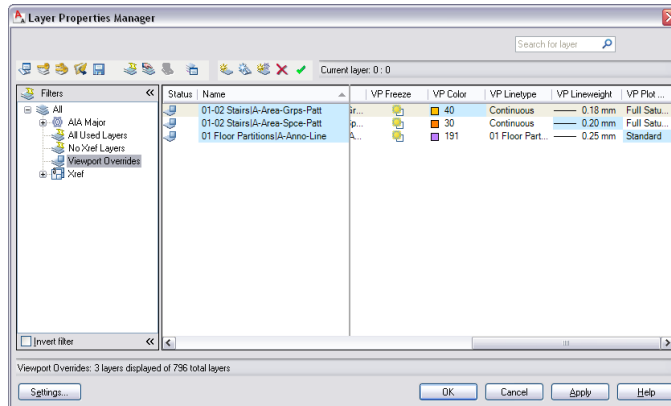

- 5 Click OK.

Identifying Viewport Layer Overrides

There are a number of ways to identify layers containing overrides.

In the Layer Manager:

- A background color displays for each override and for each corresponding global property setting. By default, it is set to light blue, but you can change that to another color. For information on changing the background color, see “Override Layer Properties in Viewports” in the AutoCAD help.
- A different icon () displays in the Status column of the layer.
- A tooltip displays property override information when the cursor is placed over the Status icon for the layer containing overrides.
- A predefined filter named Viewport Overrides is displayed in the tree view where all layers with viewport overrides are listed.

In the drawing workspace:

- A Viewport Overrides icon is displayed on the status bar () when the current viewport in paperspace has layer property overrides. If the drawing status bar is not displayed, the icon is displayed on the application status bar instead.
- On the command line, enter VPLAYEROVERRIDES to check if the current viewport contains layer property overrides. When VPLAYEROVERRIDES is equal to 1, the viewport contains overrides.

Removing Viewport Layer Overrides

You can remove layer overrides from layout viewports.

There are different options to make removing viewport overrides efficient and intuitive:

- You can remove overrides in the active viewport only, or for all viewports.
- You can remove overrides for selected layers only, or for all layers.
- You can remove individual overrides from a selected layer.

To remove a single override from a selected layer

- 1 Make the layout viewport active that has viewport layer override you want to remove.
- 2 Click Format menu ► Layer Management ► Layer Manager.

3 In the list of layers, right-click the overridden setting you want to remove (for information about identifying overrides, see [Identifying Viewport Layer Overrides](#) on page 495), and click Remove Viewport Overrides for.

Depending on the setting you have right-clicked, a submenu displays for the setting:

- Color
- Linetype
- Lineweight
- Plot Style

4 Click the desired submenu, and click one of these commands:

- In Current Viewport only: This will remove the override from the selected layer in the current viewport only. For example if you have clicked Remove Viewport Overrides for ► Color ► In Current Viewport only, then only the overridden color in the currently active viewport for the selected layer will be reset to the global color.
- In All Viewports: This will remove the selected override from the selected layer in all layout viewports. For example if you have clicked Remove Viewport Overrides for ► Color ► In All Viewports, then any color overrides for the selected layer in any layout viewport in the drawing will be reset to the global color.

To remove all overrides from a selected layer

5 Make the layout viewport active in which you want to remove all viewport overrides from a layer.

6 Click Format menu ► Layer Management ► Layer Manager.

7 In the list of layers, right-click the layer from which you want to remove all overrides, and click Remove Viewport Overrides for ► Selected Layers.

8 Click one of these two commands:

- In Current Viewport only: This will remove all overrides from the selected layer in the current viewport only.
- In All Viewports: This will remove all overrides from the selected layer in all layout viewports, and reset them to their global properties.

To remove all overrides from all overridden layers

9 Make the layout viewport active in which you want to remove all viewport layer overrides.

10 Click Format menu ► Layer Management ► Layer Manager.

11 In the list of layers, right-click any layer, and click Remove Viewport Overrides for ► All Layers.

12 Click one of these two commands:

- In Current Viewport only: This will remove all overrides from all layers in the current viewport only.
- In All Viewports: This will remove all overrides from all layers in all layout viewports, and reset them to their global properties.

13 Click OK.

Working with Layer Groups

With the Layer Manager, you can create different layer groups to produce working views and backgrounds from large building data sets. Layer groups help you work more efficiently in drawings that have many

layers. You can change the settings of a layer group to apply the changes to all layers in the group at one time. For example, you can lock a layer group to lock all the layers in the filter.

Types of Layer Groups

There are five types of layer groups:

Type	Description
All	Is always present and lists all the layers and other layer groups in the drawing.
Xref	Lists any layers in external reference files linked with the current drawing. This group is automatically created when you xref a drawing into the current drawing.
group filters	Contain layers that you have assigned to them.
property filters	Contain layers based on a filter that you specify for the group. You can base filters on layer names and other layer properties.
layer standards filters	Contain layers associated with a specified standards category.

Rules for Layer Groups

The following group rules apply when you are creating and working with layer groups:

- You can list a layer in more than one layer group.
- Multiple listings of the same layer must always have identical property settings. For example, a layer that is a member of two groups cannot be a different color in each group.
- You cannot list a layer twice in a group.
- You can delete layer groups without affecting the layers in the group.
- Changing one of the properties of a layer group changes that property for all the layers in that group, except where the change would be invalid. For example, it is not possible to freeze the current layer.
- Layer group names need not be unique.
- There is no naming convention for layer groups. Group names can include spaces, non-alphanumeric characters, and both uppercase and lowercase letters.
- Xref layer groups cannot contain other filter groups.

Managing Layer Groups

You can add and subtract layers from layer groups. You can change the standard AutoCAD properties for the layers in groups, rename layer groups, delete layer groups, and change the filters in filter groups.

Types of Layer Filters

With the Layer Manager, you can create three types of layer filters: group filters, property filters, and layer standards filters.

Group filters can contain any layers in the current drawing. You can manually add layers to, and remove layers from, group filters by dragging layers within the Layer Manager into the group filter or by selecting an object in the drawing on the layer that you want to add to the group filter.

Group filters are considered static because they are not automatically updated. They include only the layers that were assigned when the group was created. You can manually add layers to, and remove layers from, group filters.

Property filters contain layers that meet filter criteria that you specify for the group. Filter criteria can select layers according to layer states (on/off, frozen/thawed, locked/unlocked), properties, or names. For example, you can create a property filter that includes all of the red layers in the current drawing.

Property groups are considered dynamic because they are automatically updated when you change the properties of layers that are part of the group. Property filters are also updated when you add or modify layers that meet the criteria specified in the filter. You cannot manually add layers to, or remove layers from property filters.

The layer groups named Xrefs and All are created automatically.

Creating a Group Filter

Use this procedure to create a group filter. Group filters can contain any layers currently listed in the Layer Manager. You can manually add layers to, and remove layers from, group filters by dragging layers within the Layer Manager into the group filter or by selecting an object in the drawing on the layer that you want to add to the group filter.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the left pane of the Layer Manager, select a layer group that you want to create the new group under, right-click, and select New Group Filter, or click  in the Layer Manager.
- 3 Enter a name for the new group filter, and press *ENTER*.
- 4 Edit the new group filter:

If you want to...	Then...
add layers to the group filter	see Adding Layers to Layer Groups on page 503.
specify properties for the group filter	see Changing the Properties of a Layer Group on page 504.

- 5 Click OK.

Creating a Property Filter

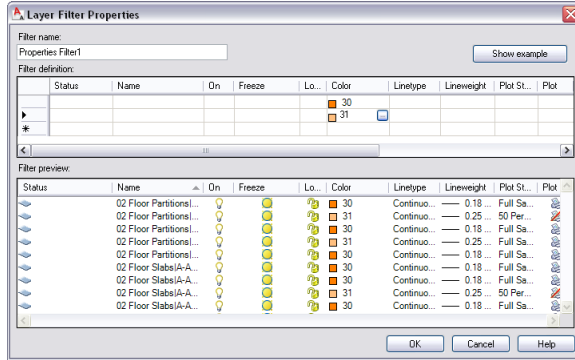

A property filter contains layers that meet filter criteria that you specify for the group. Filter criteria can include layers according to layer states (on/off, frozen/thawed, locked/unlocked), properties, or names. For example, you can create a property filter that includes all of the red layers in the current drawing.

Creating Property Filters

Use this procedure to create property filters. You can specify more than one filter for a group. For example, you can filter by both layer name and status in order to group all frozen walls layers.

You can also specify more than one set of criteria for a property filter. For example, you can create a filter that will include all frozen red layers and all frozen blue layers. Boolean AND/OR logic is applied to the filter definitions to determine which layers to include. A layer must meet all the criteria in a single row in order to be included in the filter. Continuing with the example, a layer must be frozen *and* red to be in the filter. Multiple rows offer alternative criteria. In the example below, a layer must be overridden with the color 30 or it must be overridden with the color 31.

Example of a property filter with multiple criteria

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the left pane of the Layer Manager, select a layer group that you want to create the new group under, right-click, and select New Property Filter, or click  in the Layer Manager.
- 3 Enter a name for Filter Name.
- 4 Specify the filter criteria:

If you want to...	Then...
filter layers by visibility state	see Specifying a Filter for Layer State on page 501.
filter layers by layer color	see Specifying a Filter for Layer Color on page 502.
filter layers by layer linetype	see Specifying a Filter for Layer Linetype or Lineweight on page 502.
filter layers by wildcard characters	see Specifying a Filter for Layer Name on page 502.

- 5 Once a row of criteria is configured, you can copy or delete the row:

If you want to...	Then...
copy a row of criteria	right-click in the row you want to copy, and select Duplicate Row.
delete a row	right-click in the row, and select Delete Row.

- 6 Click OK twice.

Specifying a Filter for Layer State

Use this procedure to specify a filter that includes layers based on the following layer states:

- In use/not in use
- On/off
- Frozen/thawed
- Locked/unlocked

A layer must meet all the specified filter criteria to be included. For example, if you select Off and Frozen for the filter, a layer that is turned off but is not frozen will not be included.

1 Click Format menu ► Layer Management ► Layer Manager.

2 In the left pane of the Layer Manager, select a layer group that you want to create the new group under, right-click, and select New Property Filter.

3 Enter a name for Filter Name.

4 Specify the In use/not in use layer criteria for the filter:

If you want to...	Then...
include all the layers in the drawing that are in use	click in the Status field, and select  .
include all the layers in the drawing that are not in use	click in the Status field, and select  .

5 Specify the On/Off layer state criteria for the filter:

If you want to...	Then...
include all the layers in the drawing that are turned on	click in the On field, and select  .
include all the layers in the drawing that are turned off	click in the On field, and select  .

6 Specify the Freeze/Thaw layer state criteria for the filter:

If you want to...	Then...
include all the layers in the drawing that are thawed	click in the Freeze field, and select  .
include all the layers in the drawing that are frozen	click in the Freeze field, and select  .

7 Specify the Locked/Unlocked layer state criteria for the filter:

If you want to...	Then...
include all the layers in the drawing that are unlocked	click in the Lock field, and select  .
include all the layers in the drawing that are locked	select Locked.  .

8 Click OK.

Specifying a Filter for Layer Color

Use this procedure to specify a filter that includes layers based on layer colors.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the left pane of the Layer Manager, select a layer group that you want to create the new group under, right-click, and click New Property Filter.
- 3 Enter a name for Filter Name.
- 4 Under Filter definition, click the Color field.
- 5 Click the [...] button.
- 6 Select a color from the Select Color dialog box.
- 7 Click OK.

Specifying a Filter for Layer Linetype or Lineweight

Use this procedure to specify a filter that includes layers based on linetype or lineweight.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the left pane of the Layer Manager, select a layer group that you want to create the new group under, right-click, and click New Property Filter.
- 3 Enter a name for Filter Name.
- 4 Specify the filter criteria for linetypes or lineweights:

If you want to...	then...
specify a linetype to include in the filter	click in the Linetype field, and click the [...] button. Select a linetype from the Select Linetype dialog box.
specify a lineweight to include in the filter	click in the Lineweight field, and click the [...] button. Select a lineweight from the Lineweight dialog box.

- 5 Click OK.

Specifying a Filter for Layer Name

Use this procedure to specify a filter that includes layers based on wildcard strings in a layer name. The wildcard string is not case sensitive.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the left pane of the Layer Manager, select a layer group, right-click, and click New Property Filter.
- 3 Enter a name for Filter Name.
- 4 Under Filter definitions, click the Name field.

5 Specify the wildcard filter criteria:

If you want to...	Then...
include all layers that start with a particular string	enter a wildcard string and an asterisk (*) for Name. Example: <i>wall*</i>
include all layers that end with a particular string	enter an asterisk (*) and the wildcard string for Name. Example: <i>*view</i>
include all layers where a particular string can occur anywhere within the layer name	enter an asterisk (*), the wildcard string, then another (*) for Name. Example: <i>*anno*</i>

For more information about working with wildcards, see “Filter Selection Sets” in AutoCAD help.

6 Click OK.

Creating a Layer Standards Filter

A layer standards filter contains layers that are associated with a particular category of a standard. For example, if you create a layer standards filter for the AIA 2nd Edition standard, and you specify the Major category as the one to include in the filter, you create a filter that contains all of the drawing annotation layers.

Creating Layer Standards Filters

Use this procedure to create standards filters. You can specify more than one standard category for a filter.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the left pane of the Layer Manager, select a layer group that you want to create the new group under, right-click, and select New Standards Filter, or click  in the Layer Manager.
- 3 Enter a name for Filter Names.
- 4 Select a standard for Layering Standard.
- 5 The categories in the Available Category(s) column will differ depending on the standard being used. Select a category to include in the filter, and click the Add >> button to move it to the Selected Category(s) column.
You can include multiple categories in one standards filter. All layers associated with the Selected Category(s) will be included in the filter.
- 6 Click OK twice.

Adding Layers to Layer Groups

Use this procedure to add layers to a layer group. You can manually add layers to a group filter. You can either drag them from the list of layers in the right pane of the Layer Manager to the group in the left pane or add the layer to the group by selecting an object in the current drawing that is on the layer that you want to add.

You can also replace all layers in an existing group by selecting objects in the current drawing that are on the layers that you want to use as replacements for the existing layers.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Add layers to a layer group:

If you want to...	Then...
add layers to a layer group by dragging	in the left pane of the Layer Manager, select the All layer group. In the right pane of the Layer Manager, drag a layer to the user layer group or static filter group in the left pane.
add layers to a layer group by selecting drawing objects	select the layer group, right-click, and click Select Layers ► Add. In the current drawing, select an object on each layer that you want to add to the group. Press <i>ENTER</i> to return to the Layer Manager.
replace layers from groups by selecting drawing objects	select the layer group whose layers you want to replace, right-click, and click Select Layers ► Replace. Select an object on each layer that you want to replace the layers in the group. Press <i>ENTER</i> to return to the Layer Manager.

3 Click OK.

Changing the Properties of a Layer Group

Use this procedure to change the properties of all layers in a layer group. If a layer is in more than one group, the changes apply to that layer in all groups in which it is included. For example, if you freeze a group that includes the layer A-Wall, that layer is frozen in any other group in which A-Wall appears.

NOTE Because you cannot freeze the current layer, you do not have the option to freeze a group in the active viewport if the current layer is included in the group. You also cannot freeze the active viewport on the Model layout tab.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click the layer group whose properties you want to change, and specify properties:

If you want to...	Then...
specify whether the group is locked	right-click, select Lock, and select Lock or Unlock Off.
specify whether the group is frozen	right-click, select Visibility, and select Thawed or Frozen.
specify the visibility of the group	right-click, select Visibility, and select On or Off.
freeze all layers in the drawing except those in the selected layer group	right-click, select Isolate Group, and select All Viewports or Active Viewport Only.

3 Click OK.

Renaming and Deleting Layer Groups

Use this procedure to rename or delete layer groups. The layer group is deleted from the Layer Manager, but the layers listed in the group are not deleted.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Rename or delete a layer group:

If you want to...	Then...
rename the layer group	right-click the layer group, and click Rename. Enter a new name, and press <i>ENTER</i> .
delete the layer group	right-click the layer group, and click Delete.

3 Click OK.

Converting a Property Filter to a Group Filter

Use this procedure to convert property filters to group filters. Note that dynamic property filters are converted to static group filters. You manually add, replace, and delete layers from group filters.

1 Click Format menu ► Layer Management ► Layer Manager.

2 On the left pane, select the property filter you want to convert.

3 Right-click, and select Convert to Group Filter.

4 Click OK.

New Layer Notification

You can be notified when new layers are added to the drawing before certain tasks, such as plotting, saving, or restoring a layer state. It is important to be aware of new layers that have been added to a drawing or to an attached xref without your knowledge. You can avoid potential problems such as plotting objects that were added to the drawing by the addition of a new layer.

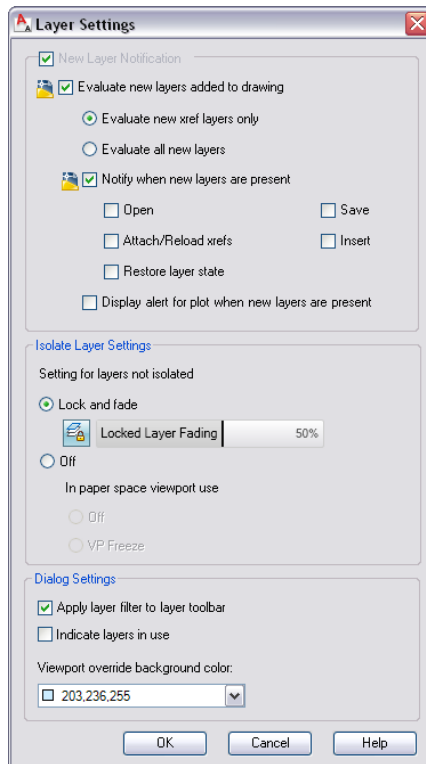

You can control when a drawing is evaluated for new layers, if at all. You can specify which commands, such as *SAVE* or *PLOT*, trigger the program to check the layer list and alert you of new layers. This can include new layers that have been added to attached xrefs.

Setting up the Notification for New Layers

Use this procedure to be notified when new layers are introduced into the drawing or any xrefs referenced to it.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click Settings.

3 To set up the new layers notification in the drawing, select Evaluate new layers in the drawing.

4 Determine if you want to be notified only of new layers added to xrefed drawings, or of new layers in xrefed drawings and in the current drawing:

To be notified only of new layers in xref drawings, click Evaluate new xref layers only.

To be notified of new layers in xref drawings and in the current drawing, click Evaluate all new layers.

5 Click Notify when new layers are present to define the actions that should trigger an evaluation for new layers. Each time one of the specified actions is performed in the drawing, a comparison is made between the last time a specified action was performed (the layer baseline) and the present time. If new layers have been added in the meantime, the new layers notification is displayed.

In new drawings, the layer baseline is created when the drawing is saved or plotted for the first time. For example, when layers are added to a new drawing, and then it is saved, the layer baseline is created. Layers that have been added since the drawing was saved are considered new unreconciled layers.

- Open: Checks for new layers on opening the drawing.

- Attach/Reload Xrefs: Checks for new layers when an xref is attached or reloaded.

- Restore Layer state: Checks for new layers when you restore a saved layer state. For more information, see [Working with Layer States](#) on page 508.

- Save: Checks for new layers when the drawing is saved.

- Insert: Checks for new layers when a block is inserted.

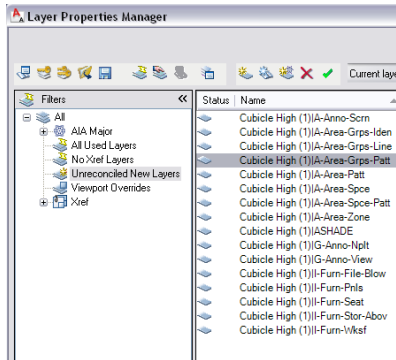

6 Click Display alert for plot when new layers are present to check for new layers when plotting a drawing.

Identifying New Layers in the Drawing

When notification is turned on, a New Layer Notification bubble displays on the status bar every time one of the specified actions is performed, and new layers are detected in the process. You can choose to view the new layers by clicking the View Unreconciled New Layers link.

When you click the link, the Layer Manager opens, and the Unreconciled New Layers filter is automatically selected. All new layers that have been added to the drawing or attached xrefs are displayed in the list view.

You can turn off layer notification but still have the layer list evaluated for new layers. Although the notification bubble does not display, you can still check for new layers by right-clicking the alert icon () on the status bar.

Reconciling New Layers in the Drawing

Unreconciled layers are layers that have been added to the drawing or to attached xrefs since the layer list was last evaluated. The layer list is checked for new layers when one of the commands selected in [Setting up the Notification for New Layers](#) on page 505 is used.

To reconcile a layer in the drawing you have to manually select it and mark it as reconciled.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 In the tree view on the left, select the Unreconciled Layers group.
All layers that have been added to the drawing or its xrefs since the last user-specified action (for example reloading an xref), are listed.
- 3 To reconcile a new layer, select the layer, right-click, and click Reconcile Layer.
This will add the layer to the layer baseline and not display it as new anymore in the drawing.
- 4 Click OK.

Working with Layer States

NOTE In AutoCAD Architecture 2009 the Layer Snapshot functionality is discontinued in favor of the Layer State functionality. Existing layer snapshots (LAY) files are automatically converted to layer states (LAS) when the Layer States Manager is invoked in a legacy drawing with layer snapshots. The layer snapshot is deleted after the conversion.

You can save the current layer settings in a drawing as a saved layer state and restore them later. Saving layer states is convenient if you need to return to particular settings for all layers during different stages in completing a drawing or for plotting.

For example, a facilities manager might save a layer state of individual floor plans and furniture, cable, and HVAC layouts to separate this information from a complete building layout.

Layer settings you can save and restore include layer states, such as on or locked, and layer properties, such as color or linetype. You can choose which layer states and layer properties you want to restore later.

You can modify the properties of a saved layer state. All layer properties other than the layer name can be edited. You can also add new layers to a layer state if new layers were added since the later state was saved.

NOTE To be notified when new layers are added to the drawing, see [Setting up the Notification for New Layers](#) on page 505.

Layer States in Xrefs

When an xref containing saved layer states is inserted in the host drawing, the xref layer states are listed by name and can be viewed in the Layer States Manager. Although they can be restored, they cannot be edited. Xref layer states are identifiable because the layer state name is preceded by the xref drawing's name and separated by a double underscore symbol. (Example: Xref Name__Layer State Name.) When the xref is bound to the host drawing, layer states are identifiable by \$0\$ that displays between the xref name and layer state name. (Example: Xref Name\$0\$Layer State Name.)

Layer states from nested xrefs are also included. Layer states from xrefs are removed from the host drawing when the xref is detached or unloaded.

Creating a Saved Layer State

You can save any set of currently existing layers and their properties as a layer state, with the purpose of either restoring that layer state later in the current drawing or exporting it to another drawing and restore it there.

The following lists the layer states and properties that are saved in a layer state:

Saving a Layer State in Model Space:

- Layer name
- On/Off
- Freeze/Thaw
- Lock/Unlock
- Color
- Linetype
- Lineweight

- Plot style

IMPORTANT When a layer state is saved from the model space, the global layer properties for color, linetype, lineweight, and plot style are saved in the layer state. When the layer state is restored to the model space, the global layer properties will be restored as the global layer properties of the drawing. If the layer state is restored to a layout viewport, you can choose if the settings from the saved layer state are restored either as the global layer properties for the drawing, or as viewport overrides for that specific viewport.

- Plot/Non Plot
- New VP Freeze

Saving a Layer State in a Layout Viewport:

- Layer name
- On/Off
- Freeze/Thaw
- Lock
- Color
- Linetype
- Lineweight
- Plot style

IMPORTANT When a layer state is saved from a layout viewport, and the viewport has overrides for color, linetype, lineweight, or plot style, the override settings are saved as the viewport properties. When the layer state is restored to a layout viewport, you can choose if the settings from the saved layer state are restored either as the global layer properties for the drawing, or as viewport overrides for that specific viewport. When the layer state is restored to the model space of a drawing, the saved layer settings will be restored as global layer properties to the model space.

- Plot/Non Plot
- New VP Freeze

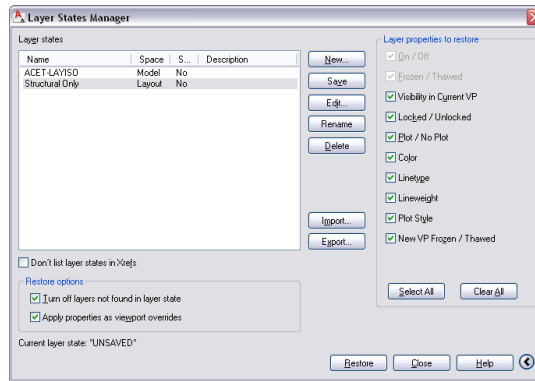

1 Verify that you are in the viewport - either model space or a layout - which you want to save as a layer state.

2 Click Format menu ► Layer Management ► Layer Manager.

3 Verify that all layers have the desired states and properties you want to save in a layer state. If necessary, make adjustments, and click Apply.

4 Click  to open the Layer States Manager.

Saving a layer state

5 Click New, and enter a name and description for the layer state. Then, click OK.

The current settings in Layer Manager are saved in the layer state.

When a layer state has been created, the following information about the layer state is displayed in the Layer States Manager:

- Name: name of the layer state.
- Space: displays whether the layer state has been saved from the model space or from a layout viewport.
- Same as DWG: If the layer configuration in the drawing is identical to the one saved in the layer state, it is listed as Yes. Otherwise, it is No. Typically, the layer state should be identical to the drawing layer configuration when it is created and when it just has been restored.

NOTE The layer state will also be reported to be Same as DWG=Yes if the drawing contains new layers not in the layer state, but these layers are turned off in the drawing.

- Description: optional description of the layer state.

TIP To view the saved layer state settings, click Edit.

6 To define which layer settings should be restored when later restoring the layer state, click , and select the appropriate properties under Layer properties to restore.

NOTE Selecting settings to restore has no influence over which settings are saved. All settings listed in the Edit window are saved; but you can control which of these settings to restore.

You cannot change the settings for On/Off and Freeze/Thaw if you are restoring a layer state to a layout viewport. When a layer state is restored to a layout viewport, the layers in it will be On and Thawed.

You cannot change the setting for Visibility in Current VP if you are restoring a layer state to the model space. In model space, you can only control the global visibility of the layer.

7 Click Save.

8 If new layers have been added to the drawing since the layer state was saved, and you have not added these layers to the layer state you can turn them off in the drawing when restoring the layer state. To do so, click Turn off layers not found in layer state.

9 If you want to restore the saved layer state to a layout viewport, determine if the saved layer properties for color, linetype, lineweight, and plot style should be restored to the viewport as global layer properties or as viewport overrides:

Select Apply properties as viewport overrides if you want to restore the saved layer state properties as viewport overrides.

Clear Apply properties as viewport overrides if you want to restore the saved layer state properties as global layer properties.

NOTE If you restore a saved layer state to the model space, the saved properties are always restored as global layer properties.

Editing a Saved Layer State

When a layer state is saved, it uses the current viewport layer settings. You can make changes to the saved layer state.

Changes to a saved layer state can be these 3 change types:

- adding layers that have been added to the drawing since the layer state was saved
- removing layers from the layer state
- modifying layer settings

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click  to open the Layer States Manager.

3 Select the layer state that you want to edit, and click Edit.

4 Edit the selected layer state:

If you want to...

Then...

add layers from the drawing to the layer state

click , select the layer that you want to add, and click OK.

delete a layer from the layer state

select the layer that you want to delete, and click .

edit the settings of the individual layers in the layer state

click the appropriate state or property icon and make the desired change. This affects only the layer state. The layers in the drawing are not affected until you restore the layer state.

5 Click OK twice.

Restoring a Layer State

You can restore a saved layer state in a drawing. When you restore a layer state, you can specify which of the saved settings you want to restore. The layer settings you have not selected remain unchanged in the drawing. For example, if you select only the Color property to be restored from the layer state, then the linetype, lineweight, and plot style of the drawing remain unchanged, even if they are different in the layer state than in the drawing. If the drawing contains layers that were added since the layer state was saved, those layers are not deleted when restoring the layer state. You can, however, select to turn them off when restoring a layer state that does not have these layers. For more information, see [Creating a Saved Layer State](#) on page 508.

When restoring a layer state, the layer that was current when the layer state was saved is made current. If that layer no longer exists, the current layer does not change.

IMPORTANT When you save a layer state in the current drawing and then delete any layers in the drawing that are in the layer state, these layers are deleted from the layer state without notification. To retain layers in a layer state that are deleted in the drawing, you must export the layer state before deleting the layers in the drawing. Later, you can re-import the exported LAS file and restore the deleted layers.

Restore Options for Different Viewports

In most cases it is recommended to restore layer states that have been saved from a layout viewport to a layout viewport and layer states that have been saved from the model space to the model space of the drawing. If you want to restore layer states between different workspaces, note the following behaviors:

When a layer state is saved from the model space, the global layer properties for color, linetype, lineweight, and plot style are saved to the state. When the layer state is later restored to the model space, the global layer properties will be restored as the global layer properties of the drawing. If the layer state is restored to a layout viewport, you can choose if the settings from the saved layer state are restored either as the global layer properties for the drawing, or as viewport overrides for that specific viewport.

NOTE Layers that were turned off or frozen in model space are set to VP Freeze in the Layer Manager if they are restored to a layout viewport.

When a layer state is saved from a layout viewport, and the viewport has overrides for color, linetype, lineweight, or plot style, the override settings are saved as the viewport properties. When the layer state is later restored to the model space of a drawing, the saved layer settings will be restored as global layer properties to the model space. If the layer state is later restored to a layout viewport, you can choose if the settings from the saved layer state are restored either as the global layer properties for the drawing, or as viewport overrides for that specific viewport.

- 1 Verify that the viewport in which you want to restore a saved layer state is active.
- 2 Click Format menu ► Layer Management ► Layer Manager.

3 Click  to open the Layer States Manager.

4 Select the saved layer state to restore.

If the setting for Same as DWG is set to Yes, the layer configuration in the drawing is already identical to the one saved in the layer state, or the drawing contains new layers not in the layer state, but these layers are turned off in the drawing. In this case, the layer state will also be reported to be Same as DWG.

5 Expand the Layer States Manager by clicking .

6 To define which layer settings should be restored, select the appropriate properties under Layer properties to restore.

You cannot change the settings for On/Off and Freeze/Thaw if you are restoring a layer state to a layout viewport. When a layer state is restored to a layout viewport, the layers in it will be On and Thawed.

You cannot change the setting for Visibility in Current VP if you are restoring a layer state to the model space. In model space, you can only control the global visibility of the layer.

7 Click Save.

8 If new layers have been added to the drawing since the layer state was saved, and you have not added these layers to the layer state you can turn them off in the drawing when restoring the layer state. To do so, click Turn off layers not found in layer state.

9 If you want to restore the saved layer state to a layout viewport, determine if the saved layer properties for color, linetype, lineweight, and plot style should be restored to the viewport as global layer properties or as viewport overrides:

Select Apply properties as viewport overrides if you want to restore the saved layer state properties as viewport overrides.

Clear Apply properties as viewport overrides if you want to restore the saved layer state properties as global layer properties.

NOTE If you restore a saved layer state to the model space, the saved properties are always restored as global layer properties.

10 Click Restore.

Deleting a Layer State

When you delete a saved layer state, you do not delete the layers from the drawing. You delete only the layer state.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click  to open the Layer States Manager.

3 Select the saved layer state to delete.

4 Click Delete, and click Yes in the subsequent dialog.

5 Click Close.

Importing Layer States to the Current Drawing

You can import layer states that are saved in drawing files (DWG, DWS, and DWT) or directly in a layer state (LAS) file.

If the layer state is imported from a drawing that contains layers not present in the current drawing, these layers are imported into the current drawing.

If the layer state is imported from a drawing and it contains a layer property, such as a linetype or plot style that is not loaded or available in the current drawing, that property is automatically imported from the source drawing.

If the layer state is imported from a LAS file, and it contains linetype or plot style properties that do not exist in the current drawing, that property cannot be restored.

When importing a layer state that is a duplicate of a layer state in the current drawing, you can choose to overwrite the existing layer state or not import it.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click  to open the Layer States Manager.

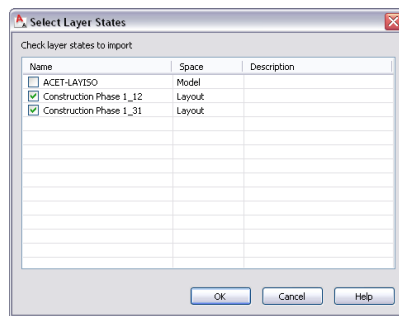

3 Click Import.

4 In the Import layer states dialog box, select the file format of the file from which you want to import a layer state:

- DWG: Imports layer states from a drawing file
- DWS: Imports layer states from a drawing standards file
- DWT: imports layer states from a drawing template
- LAS: Imports a saved and exported layer state directly

5 Select the desired file, and click Open.

6 If you have selected a DWG, DWS, or DWT file with multiple saved layer states, select the desired state in the Select Layer States dialog, and click OK.

7 If you have selected a LAS file, you are prompted upon successful import whether you want to immediately restore the layer state in the current drawing. Click Yes to restore or No to import without restoring.

Exporting a Layer State from the Current Drawing

You can export a saved layer state from the current drawing. Saved layer states are saved as LAS files and can be imported into drawing files.

When you export a layer state, all layers and their settings are saved in an external file and can be re-imported into a drawing. Exporting a layer state is useful for saving layer configurations you need across multiple drawings.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click  to open the Layer States Manager.

3 Select the layer state you want to export, and click Export.

4 In the Export Layer States dialog, select a name and location for the LAS file, and click Save.

5 Click Close.

Working with Layer Keys

A layer key maps an object that you draw to a defined layer. Layer keys also specify the default properties of each layer.

Layer Keys and Layer Keying

When you create an object, the layer key that is associated with the object automatically places that object on the layer to which it is mapped. Using layer keys to automatically place objects on predefined layers is called *layer keying*. Usually, you key objects to layers that conform to a layer standard. Each layer standard names layers according to a set of rules that you can modify. For more information, see [Creating and Editing Layer Standards](#) on page 526.

Layer Key Styles

You can create different sets of layer keys, called layer key styles, that you can use to place objects on defined layers in your drawings. Each layer key style contains a set of layer keys. Both the AIA and BS1192 layer key styles contain layer keys and layer properties, including layer name, description, color, linetype, linewidth, plot style, and plot settings for all of the AEC objects. You can import the AIA and BS1192 layer standards and layer key styles that are provided with AutoCAD Architecture 2009 from the *AecLayerStd.dwg* in the `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Layers` folder. You can modify these styles, if needed, or create new layer key styles. You can also create layer key styles from LY files.

Properties of Layer Key Styles

You can add and remove layer keys from layer key styles. Default layer keys cannot be removed. The properties of any layer in an existing layer key style can also be edited. You can change the layer name, description, color, linetype, linewidth, plot style, and plot settings for the layer that each layer key maps to. If the layer key style is based on a layer standard, you can use overrides on all or some of the layer keys within the layer key style. For more information about overrides, see [Layer Key Overrides](#) on page 524.

NOTE The default Standard layer key style is not based on a layer standard. It contains the default set of layer keys.

LY Files and Layer Key Styles

If you have LY files from S8 or Release 1 of Architectural Desktop that you want to use, you can create a new layer key style from an LY file. For more information see [Creating a Layer Key Style from an LY File](#) on page 521.

Overrides to Layer Key Styles

Whether you create an original layer key style or one from an existing LY file, if you want to use overrides, you must base the layer key style on a layer standard in the current drawing. If you create a nonstandard layer key style, the Overrides On/Off command is unavailable. If you copy a layer key style, you can use layer key overrides only if the layer key style that you copied is based on a layer standard. For more information about using layer key overrides, see [Layer Key Overrides](#) on page 524.

Managing Layer Key Styles

To create, edit, copy, or purge layer key styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture, where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Default Layer Keys

AutoCAD Architecture uses the following default layer keys when you create AEC objects.

Default layer keys for creating AEC objects

Layer Key	Description
ANNDTOBJ	Detail marks
ANNELKEY	Elevation marks
ANNELOBJ	Elevation objects
ANNMASK	AutoCAD Architecture masking objects
ANNMATCH	Match lines
ANNOBJ	Notes, leaders, etc.
ANNREV	Revisions
ANNSXKEY	Section marks
ANNSXOBJ	Section lines
ANNSYMOBJ	Annotation marks
APPL	Appliances
CAMERA	Cameras
CASE	Casework
CASENO	Casework tags
CEILGRID	Ceiling grids
CEILOBJ	Ceiling objects
CHASE	Chases
COGO	Control points
COLUMN	Columns
COMMUN	Communication

Default layer keys for creating AEC objects

CONTROL	Control systems
---------	-----------------

CWLAYOUT	Curtain walls
----------	---------------

CWUNIT	Curtain wall units
--------	--------------------

DIMLINE	Dimensions
---------	------------

DIMMAN	Dimensions (AutoCAD points)
--------	-----------------------------

DOOR	Doors
------	-------

DOORNO	Door tags
--------	-----------

DRAINAGE	Drainage
----------	----------

ELEC	Electric
------	----------

ELECNO	Electrical tags
--------	-----------------

ELEV	Elevations
------	------------

ELEVAT	Elevators
--------	-----------

ELEVHIDE	Elevations (2D)
----------	-----------------

EQUIP	Equipment
-------	-----------

EQUIPNO	Equipment tags
---------	----------------

FINCEIL	Ceiling tags
---------	--------------

FINE	Details - fine lines
------	----------------------

FINFLOOR	Finish tags
----------	-------------

FIRE	Fire system equipment
------	-----------------------

FURN	Furniture
------	-----------

FURNNO	Furniture tags
--------	----------------

GRIDBUB	Plan grid bubbles
---------	-------------------

GRIDLINE	Column grids
----------	--------------

Default layer keys for creating AEC objects

HATCH	Details - hatching
HIDDEN	Hidden lines
LAYGRID	Layout grids
LIGHTCLG	Ceiling lighting
LIGHTW	Wall lighting
MASSELEM	Massing elements
MASSGRPS	Massing groups
MASSSLCE	Massing slices
MED	Details - medium lines
OPENING	Wall openings
PEOPLE	People
PFIXT	Plumbing fixtures
PLANTS	Plants - outdoor
PLANTSI	Plants - indoor
POLYGON	AEC Polygons
POWER	Electrical power
PRCL	Property
PRK-SYM	Parking symbols
ROOF	Rooflines
ROOFSLAB	Roof slabs
ROOMNO	Room tags
SCHEDOBJ	Schedule tables
SEATNO	Seating tags

Default layer keys for creating AEC objects

SECT	Miscellaneous sections
SECTHIDE	Sections (2D)
SITE	Site
SLAB	Slabs
SPACENO	Space tags
SPACEOBJ	Space objects
STAIR	Stairs
STAIRH	Stair handrails
STRUCTBEAM	Structural beams
STRUCTBEAMIDEN	Structural beam tags
STRUCTBRACE	Structural braces
STRUCTBRACEIDEN	Structural brace tags
STRUCTCOLS	Structural columns
STRUCTCOLSIDEN	Structural column tags
SWITCH	Electrical switches
THIN	Details - thin lines
TINN	Triangulated irregular network
TITSCALE	Graphical Scales
TITTEXT	Border and title block
TITTEXT-DWG	Drawing title text
TOILACC	Architectural specialties
TOILNO	Toilet tags
TOPO	Topography

Default layer keys for creating AEC objects

UTIL	Site utilities
VEHICLES	Vehicles
VIEWPORT	Sheet View viewports
WALL	Walls
WALLFIRE	Fire wall patterning
WALLNO	Wall tags
WIDE	Details - wide lines
WIND	Windows
WINDASSEM	Window assemblies
WINDNO	Window tags
XLINE	Construction line
ZONE	Zones
ZONENO	Zone tags

Default Layer Key Values

The following default values are assigned to new layer keys.

Default values for layer keys

Layer name	Same as layer key name. Assigned to appropriate layer root name.
Description	Blank
Color	7 (white/black)
Linetype	Continuous
Lineweight	Default
Plot style	Normal

Default values for layer keys

Plot Yes

Creating a Layer Key Style

Use this procedure to create a layer key style. You can create a layer key style by using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

If you want to use layer key overrides, you must base the layer key style you create on a layer standard in the current drawing. If you create a nonstandard layer key style, you cannot attach layer key overrides to that layer key style.

- 1 Click Format menu ► Layer Management ► Layer Key Styles. Alternatively, you can click  in the Layer Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Create a new layer key style:

If you want to...	Then...
create a style with default properties	right-click Layer Key Styles, and click New.
create a style from an existing style	right-click the layer key style you want to copy, and click Copy. Right-click Layer Key Styles, and click Paste.

- 3 Right-click the new layer key style and click Rename.

- 4 Enter a name for the new layer key style, and press *ENTER*.

- 5 Edit the new layer key style:

If you want to...	Then...
specify properties for layer keys	see Editing Layer Key Styles on page 522.
add notes and files to the style	see Attaching Notes and Files to a Layer Key Style on page 523.

- 6 When you finish specifying the properties of the layer key style, click OK twice.

Creating a Layer Key Style from an LY File

Use this procedure to create a new layer key style from an existing LY file from S8 or Release 1 of Architectural Desktop. If the LY file that you are using does not contain the default layer keys required by the software, they are added to the new layer key style by default and mapped to default layers based on the key name. For example, the layer key ANNOBJ maps to the layer ANNOBJ.

If you want to use layer key overrides, you must base the new layer key style on a layer standard. If you create a nonstandard layer key style, you cannot attach layer key overrides to that layer key style. When you create an original layer key style from an existing LY file, you can choose which sections of the LY file you want to include in your layer key style.

You must first import an existing LY file.

- 1 On the command line, enter **-AECLYImport**.
- 2 Enter the file name to import, or enter **?** and browse for a file.
- 3 Select a file, and click Open.
- 4 Enter the name for the new layer key style.
- 5 Select the sections of the LY file you want to include in the new layer key style.
- 6 Click OK.

A new layer key style is created. It is not associated with a layer standard until you assign the new layer key style to a layer standard. For more information about changing style properties, see [Editing Layer Key Styles](#) on page 522.

Editing Layer Key Styles

Use this procedure to edit a layer key style.

- You can change the layer standard that a layer key style is based on, or you can specify a layer standard for a nonstandard layer key style.
- You can add layer keys to the layer key style.
- You can remove any layer keys except the default layer keys.
- You can edit the layer properties of the layers to which the layer keys map.
- You can specify whether layer key overrides can be used with the layer key style.

- 1 Click Format menu ► Layer Management ► Layer Key Styles. Alternatively, you can click  in the Layer Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Select the layer key style that you want to change.
- 3 Click the Keys tab.
- 4 Specify the layer standard:

If you want to...	Then...
specify a different layer standard on which to base the layer key style	select a new layer standard for Standard.
specify that the layer key style is not based on a layer standard	select Non Standard for Standard.

NOTE You can base more than one layer key style on the same layer standard so that each layer key style can be used with different color, linetype, and override settings.

- 5 To add a new layer key, click Add.
New keys are added with default values.
- 6 To delete a layer key, select a layer key, and click Remove.
You cannot delete the default layer keys.

TIP To change the properties of more than one layer key at a time, hold down *CTRL* and select the additional layer keys.

7 Select a layer key, and specify the layer key properties:

If you want to...	Then...
modify the description for a layer key	double-click the text that you want to change for Description, and enter new text.
modify the layer name	under Layer, click the [...] button. Specify the appropriate values for layer fields, and click OK.
modify the color for a layer key	under Color, click the current value. Select a new color, and click OK.
modify the linetype for a layer key	under Linetype, click the current value. Select a new linetype, and click OK.
modify the lineweight for a layer key	under Lineweight, click the current value. Select a new lineweight, and click OK.
specify whether a layer key will plot	under Plot, click the printer icon to turn plotting on or off.
specify whether to allow layer field overrides	under Allow Overrides, clear the options for which overrides are not allowed.

TIP When you first add a new layer key by default the name generated for the layer is not yet based on the layer standard used. This is why the layer overrides are inactive. Modify first the layer name associated to the key by clicking the [...] button. Once the name is based on the layer standard, you can allow overrides to the standard.

8 Click OK twice.

Attaching Notes and Files to a Layer Key Style

Use this procedure to enter notes and attach reference files to a layer key style. You can also edit notes and edit or detach reference files from a layer key style.

1 Click Format menu ► Layer Management ► Layer Key Styles. Alternatively, you can click  in the Layer Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Select the layer key style that you want to change.

3 Click the General tab.

4 To add a description to the layer key style, enter it for Description.

5 Click Notes.

6 To add a note, click the Notes tab, and enter the note.

7 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

8 Click OK three times.

Layer Key Overrides

A layer key override enables you to change the default layer names specified by one or more layer keys. The structure of layer names is determined by the descriptive fields in the layer standard definition. You can allow overrides on all the layer keys within a layer key style, or you can select individual layer keys that you want to override. You can override all descriptive fields that make up the layer name, or you can specify which descriptive fields to override. You can apply overrides to any layer keys in a layer key style that is based on a layer standard.

For example, in the AIA 2nd Edition layer standard definition, the Discipline Designator field assigns a description and the Major field assigns a name by default. By using layer key overrides, you can change the values specified in these fields and add values in the unused fields, Minor Code and Status.

The information that you enter to create layer key overrides must conform to the field width and value types specified by the layer standard definition. For example, you cannot specify a four-letter override in the Discipline Designator field in the AIA 2nd Edition Layer Standard, because the maximum width for the Discipline Designator field as specified in the AIA layer standard definition is 1. To modify the descriptive fields, you must edit the layer standard definition. For more information, see [Creating and Editing Layer Standards](#) on page 526.

After you add overrides to a layer key style, you can turn the overrides on and off in your current drawing. When the layer key overrides are on, objects that you create are placed on layers defined by the layer standard definitions and overridden with the values that you specify. When the layer key overrides are off, objects that you create are placed on the layers defined only by the layer keys. You can start using the layer key overrides immediately after you specify them, or you can use the Overrides On/Off command to switch them on later.

Layer key overrides do not change the layer assignments of existing objects. Only objects added after an override is enabled are affected by the override.

Specifying Layer Key Overrides

Use this procedure to specify layer key overrides. The layer key overrides that you specify apply only to the layer keys that have any or all descriptive field overrides selected in the Layer Key Properties dialog box. For more information, see [Editing Layer Key Styles](#) on page 522.

To specify layer key overrides, you must have a layer key style that is based on a layer standard. If you base your layer key standard on a nonstandard style, you cannot specify layer key overrides.

If you do not have all overrides enabled in the Layer Key Overrides dialog box, objects that you draw after you exit the dialog box are placed on the layer defined by the layer standard. You can use the Overrides On/Off command to turn on the layer overrides later.

NOTE Individual layer keys that do not allow overrides as specified in the Layer Key Properties dialog box are not overridden when you select Enable All Overrides.

1 Click Format menu ► Layer Management ► Layer Key Overrides.

2 Under Current Layer Key Style, select the layer key style that you want to override.

The layer standard that the layer key style is based on is displayed under Based on Standard and is not editable.

3 Enter values for Override or click the [...] button to specify values to override the information in the descriptive fields.

The fields in this dialog box depend on the layer standard your layer key style is based on. For example, if you are using the AIA 2nd Edition layer standard, you can enter override values for the Discipline Designator, Major, Minor 1, Minor 2, and Status descriptive fields.

4 To begin using the layer overrides immediately, select Enable All Overrides.

5 Click OK.

If you turned on the layer key overrides, any objects that you create now use the layer key overrides according to the override values that you have specified and whether you allowed overrides for the layer keys in the layer key style. If you did not turn on the layer key overrides, objects that you create are placed on layers defined by the layer standard.

Turning Layer Key Overrides On and Off

You can use the Overrides On/Off command to turn layer key overrides on and off for the current layer key style in your drawing. This command is available only if your current layer key style is based on a layer standard and if you have specified layer key overrides. If the layer key overrides are on in the current drawing, a check mark is displayed next to the command name on the menu.

■ Click Format menu ► Layer Management ► Overrides On/Off.

If you turned the layer key overrides on, objects that you create are placed on layers defined by the layer standard definitions and are overridden with the values that you specified. If you turned the layer key overrides off, objects that you create are placed on layers defined by the layer standard.

Remapping Objects to Different Layers

Use this procedure to change the layer an object is drawn on by remapping it from the current layer key to a different layer key.

1 Click Format menu ► Layer Management ► Remap Object Layers. Alternatively, click  in the Layer Manager toolbar.

2 Select the object or objects that you want to change, and press *ENTER*.

3 To view the list of available layer keys, enter ?.

4 Press *F2* to view the list of layer keys.

5 Select the layer key that you want to map the object to, right-click, and click Paste To CmdLine.

6 Press *F2* to close the text window, and press *ENTER*.

The object is mapped to a different layer in your drawing, respecting any current layer key overrides.

Restoring Objects to Default Layer Key Layers

Use this procedure to restore the default layer key assignment to an object after you remap the object to a different layer by assigning it to a different layer key.

1 Click Format menu ► Layer Management ► Remap Object Layers.

2 Select the object or objects that you want to change, and press *ENTER*.

3 Enter *o* (byObject).

This applies the layer assigned to the default layer key of each object in the selection set, respecting any current layer key overrides.

4 Press *ENTER*.

Creating and Editing Layer Standards

A layer standard contains predefined layer names and a set of rules that determines the names of new layers that you create using that layer standard. You can use layer standards to establish individual, project, or office layering conventions that provide consistent and informative layer names. AutoCAD Architecture provides a number of layer standards that you can use in drawings. You can also create your own layer standards by customizing an existing layer standard.

How Layer Standards Determine Layer Name

When you create a new layer using a layer standard, the layer name has a number of parts separated by delimiters (for example, hyphens). Each part of the layer name is determined by rules specified in a corresponding field of the layer standard.

For example, the AIA 2nd Edition layer standard includes four fields that form each new layer name: Discipline Designator, Major, Minor 1, Minor 2, and Status. Each field is separated by a hyphen (?) delimiter, as in the following example:

(Discipline Designator) - (Major) - (Minor 1) - (Minor 2) - (Status)

A layer in your drawing with a Discipline value of "A," a Major value of "Wall," a Minor 1 value of "Full," a Minor 2 value of "Abov" and a Status value of "D," to denote a demolition layer, would be named A-WALL-FULL-ABOV-D.

You can edit the layer standard definition to change these rules. For more information, see [Editing Component Fields](#) on page 532.

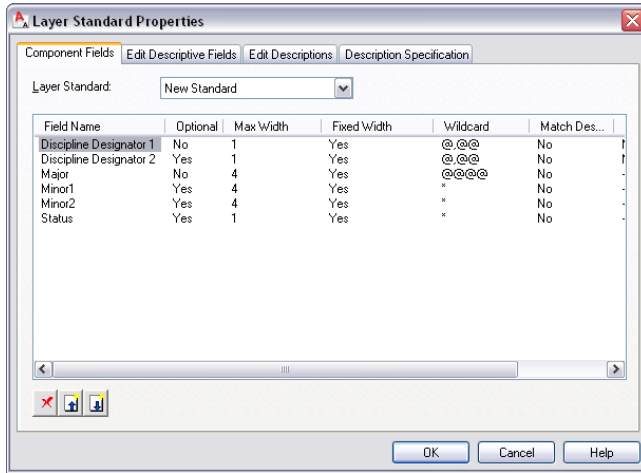

You can override the information in each field to change the way a layer standard creates a layer name by specifying layer key overrides. For more information, see [Layer Key Overrides](#) on page 524.

Layer Standards Included with the Layer Manager

AutoCAD Architecture provides industry-standard layering conventions including: AIA 2nd Edition, BS1192 Descriptive, and BS1192 - AUG Version 2. Additional international layer conventions are also provided including: DIN 276, ISYBAU Long Format, ISYBAU Short Format, and STL. Each layer standard contains specific information organized in fields. You can specify how the information appears in each field by changing the values in the layer standard fields. For more information, see [Editing Component Fields](#) on page 532.

Component Fields in Layer Standards

Each layer standard defines the number of component fields that make up a layer name and specifies the rules for the content allowed in each field. If you create or edit a layer standard, you access the layer standard properties to edit the component fields.

Component Field Descriptions

Each layer standard contains the following component fields.

Value	Description
Field Name	Identifies the field. Field names should be as consistent as possible across layering systems to aid in translation.
Optional	When Yes, allows the field to be omitted from the end of the layer name. Optional layer fields cannot precede a required layer field unless the match option is Yes so that the fields can be identified according to a match against specific descriptions.
Max Width	Represents the maximum width in characters that can be used.
Fixed Width	When Yes, prevents a field from being shortened from the max width setting.
Wildcard	An AutoCAD wildcard pattern that the field must match.
Match Description	When Yes, recognizes the field only if it exactly matches a description. You can omit fields from the middle of layer names. For example, an AIA layer may be made up of <discipline> <major> <minor>, or <discipline> <major> <status>, or <discipline> <major> <minor> <status>, as the <minor> field may not precede the <status> field and can be determ-

Value	Description
	<p>ined only by matching the field value against valid <minor> field descriptions.</p> <hr/> <p>NOTE When omitting fields from layer names, verify that the omitted field Match Description property is No. This ensures that the layer name specified can be created.</p>
Delimiter	Specifies the character used to separate fields with no fixed width. Delimiters are often also used in fixed-width fields for clarity.
Default	A predefined value for those field names that are not optional within the layer.

For more information about the content of specific layer standards, see [AIA Long Format Layer Standard](#) on page 528 and [Editing Component Fields](#) on page 532.

AIA Long Format Layer Standard

The AIA Long Format Standard contains the following fields:

Field Name	Description
Discipline Designator	Shows divisions of manageable sections. For example, A for architectural, M for mechanical. This field is required.
Major	Designates assemblies or construction systems such as walls and doors. This field is required.
Minor 1	Further differentiates major groups into minor groups such as full-height walls and partial-height walls. This field is optional and user-defined.
Minor 2	Additional information, like title or unit information.
Status	Differentiates phases of work. For example, New indicates new, Demo indicates to be demolished. This field is optional.

The following table lists the rules for the AIA Long Format Layer Standard:

AIA Long Format							
Field	Optional	Width	Fixed	Wildcard	Match	Delimiter	Default
Discipline Designator	No	1	Yes	"@"	No	None	A
Major	No	4	Yes	"@@@@"	No	"_"	Wall

AIA Long Format

Field	Optional	Width	Fixed	Wildcard	Match	Delimiter	Default
Minor	Yes	4	No	"*"	No	"_"	
Status	Yes	4	No	"*"	No	"_"	

BS1192 - AUG Version 2 Layer Standard

The BS1192 - AUG Version 2 layer standard contains the following fields:

Field	Description
Discipline	Identifies the author of the layer by using a single character. For example, A for architect, S for structural engineer. This field is required.
Category	Identifies the building element by using three digits and uses CISfB as a common referencing system. For example, 210 for wall, 315 for door. This field is required.
Graphics	Indicates information that is associated with the category by using a single character. For example, D for dimension, G for graphics, T for text. This field is required.
Grade	Expresses as a single digit the recommended line thickness, where 1 is the thinnest and 9 is the thickest. This field applies mostly when using text where ISO standard pen thicknesses correlate with ISO standard text heights. For example, text that is 2.5mm high that is drawn with a 0.25mm pen is given a pen grade of 2. This field is required.
Level	Differentiates viewing planes in plan, section, or elevation view by using a two-digit alphanumeric character. For example, 01 would be Level/Floor 1, EA the elevation, and SA Section A. This field is optional.
Status	Indicates the state of work by using a single character. For example, N indicates new, R indicates to be removed. This field is optional.
Scale	Indicates the level of detail to be shown by using a single character. For example, P indicates a planning level, D indicates a detail. This field is optional.
Phase/Time	Indicates phasing or alternatives by using a single character.

Field	Description
User	Specifies the user. It is not a fixed width field but is separated from the rest of the layer name with an underscore. For example, A210G701_WALL_L1. This field is optional.

The following table lists the rules for the BS1192 - AUG Version 2 Layer Standard:

**BS1192
- AUG
Version
2**

Field	Optional	Width	Fixed	Wildcard	Match	Delimiter	Default	
Discipline	No	1	Yes	[0A-Z]	No	None	A	
CISfB	CISfB-A	No	1	Yes	#	No	None	1
	CISfB-B	No	1	Yes	#	No	None	0
	CISfB-C	No	1	Yes	#	No	None	0
Graphics	No	1	Yes	[0ACDGHTZ]	No	None	G	
Grade	No	1	Yes	#	No	None	7	
Level	Yes	2	Yes	[0-9A-Z][0-9A-Z]	No	None	00	
Status	Yes	1	Yes	[0NXR]	No	None	0	
Scale	Yes	1	Yes	[0ASPD]	No	None	0	
Phase	Yes	1	Yes	[0-9A-Z]	No	None	0	

BS1192 - Descriptive Layer Standard

The BS1192 - Descriptive layer standard contains the following fields:

Field Name	Description
Discipline	Identifies the author of the layer by using a single character. For example, A for architect, S for structural engineer. This field is required.

Field Name	Description
Element	Identifies the building element by using a descriptive name for it. For example, possible choices for this field are "Equipment" or "Room." This field is required.
Graphics	Indicates information that is associated with the category by using a single character. For example, D for dimension, G for graphics, T for text. This field is required.
Level	Differentiates viewing planes in plan, section, or elevation view by using a two-digit alphanumeric character. For example, 01 would be Level/Floor 1, EA the elevation, and SA Section A. This field is optional.
Status	Indicates the state of work by using a single character. For example, N indicates new, R indicates to be removed. This field is optional.
Scale	Indicates the level of detail to be shown by using a single character. For example, P indicates a planning level, D indicates a detail. This field is optional.
Phase	Indicates phasing or alternatives by using a single character.
User	Specifies the user. It is not a fixed width field but is separated from the rest of the layer name with an underscore. For example, A210G701_WALL_L1. This field is optional.

The following table lists the rules for the BS1192 - Descriptive Layer Standard:

BS1192 - Descriptive

Field	Optional	Width	Fixed	Wildcard	Match	Delimiter	Default
Discipline	No	1	Yes	[0A-Z]	No	None	A
Element	No	15	No	*	No	-	Wall
Graphics	No	1	Yes	[0ACDGHZ]	No	-	G
Level	Yes	2	Yes	[0-9A-Z][0-9A-Z]	No	None	00
Status	Yes	1	Yes	[0NXR]	No	None	0
Scale	Yes	1	Yes	[0ASPD]	No	None	0
Phase	Yes	1	Yes	[0-9A-Z]	No	None	0

Creating a Layer Standard

Use this procedure to create a layer standard, with default settings or based on an existing standard, that specifies naming conventions for layers in drawings.

If your drawing does not contain a layer standard, you can import a layer standard from another drawing or an AutoCAD Architecture template. For more information, see [Importing Layer Standards](#) on page 535.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Click New.

4 To base the new layer standard on an existing standard, select Based On, and select a standard.

5 Enter a name for the new layer standard, and click OK.

6 Edit the new layer standard:

If you want to...	Then...
specify component fields of the layer standard	see Editing Component Fields on page 532.
specify descriptive fields of the layer standard	see Editing Descriptive Fields on page 533.
specify the descriptions for the layer standard	see Editing Descriptions on page 534.
specify the descriptive specifications of the layer standard	see Editing Description Specifications on page 534.

7 Click OK twice.

Editing Component Fields

Use this procedure to specify how you want to set up the fields within the layer standard that determine the different parts of the layer names created with that standard. You can add and delete fields here.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Select the layer standard that you want to edit, and click Edit.

4 Click the Component Fields tab.

5 Modify the component fields:

If you want to...	Then...
delete a component field	select the field, and click  .
add a component field above an existing field	select the field, click  , and enter a name for the new component field.

If you want to...	Then...
add a component field below an existing field	select the field, click  , and enter a name for the new component field.
edit a field name	double-click the name of the field, and enter a new name over the existing name.
change the values of individual components of the fields	select the values that you want to change, and select a new value. For more information, see Component Field Descriptions on page 527.

6 Click OK three times.

Editing Descriptive Fields

Use this procedure to add a description that is applied to each component field in the layer name. You can add a single description to a group of layer name component fields.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Select the layer standard that you want to edit, and click Edit.

4 Click the Edit Descriptive Fields tab.

5 Modify the descriptive fields:

If you want to...	Then...
delete a descriptive field	select the field, and click  .
add a descriptive field above an existing field	select the field, click  , and enter a name for the new descriptive field.
add a descriptive field below an existing field	select the field, click  , and enter a name for the new descriptive field.
edit a field name	double-click the name of the field, and enter a new name over the existing name.
delete a component from a descriptive field	select the component, and click Delete.

6 Click OK three times.

Editing Descriptions

Use this procedure to map longer or different descriptions to the component fields of the layer name.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Select the layer standard that you want to edit, and click Edit.

4 Click the Edit Descriptions tab.

5 Modify the descriptions:

If you want to...

Then...

delete a description

select the field description, and click .

edit a description

select the field description, click . Make changes to the description, and click OK.

add a field with a value and a description

click . Enter a value and a description for the field, and click OK. To add multiple fields, click Apply after each individual field, and click OK to finish.

6 Click OK three times.

Editing Description Specifications

Use this procedure to specify how all the fields in the layer standard determine the layer description that is displayed in the Layer Manager. You can change the field that is used in the description and the order of the fields, and you can add text to the beginning of the layer description.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Select the layer standard that you want to edit, and click Edit.

4 Click the Description Specification tab.

5 Specify how the fields determine the layer description:

If you want to...

Then...

delete a layer standard field

select the field, and click .

add a field above an existing field

select the field, click , and enter a name for the new field.

If you want to...	Then...
add a field below an existing field	select the field, click  , and enter a name for the new field.
edit text	double-click the text for Prior Text, and enter a new name.
change a field value	select the current value for Field, and click a new value.

6 Click OK three times.

Purging Layer Standards

Use this procedure to remove standards that are not in use.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 Click .
- 3 Select the layer standards that you want to purge, and click Purge.
- 4 Click OK.

NOTE To purge all layer standards and layer key styles in a drawing, enter **AecPurgeLayerStyles**. This is beneficial to use when creating custom templates or when importing new layer standards and layer key styles.

Importing Layer Standards

Use this procedure to import layer standards from other drawings or from the *AecLayerStd.dwg* drawing in *\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Layers* folder.

- 1 Click Format menu ► Layer Management ► Layer Manager.
- 2 Click .
- 3 Click Import/Export.
- 4 Click Open.
- 5 Select the drawing with the layer standards that you want to import, and click Open.
All the layer standards in the drawing are displayed in the External File list.
- 6 Under External File, select the layer standard that you want to import, and click Import.
You can select more than one layer standard in a list by holding down *CTRL* while you select the additional layer standards.
If you import a layer standard that already exists in the target drawing, a message is displayed asking if you wish to overwrite the existing layer standard. Click Yes to overwrite the existing layer standard, or click No to cancel.
- 7 Click OK.

The layer standards that you imported are displayed in the Layer Standards dialog box.

Exporting Layer Standards

Use this procedure to export layer standards from the current drawing to a new drawing or to an existing drawing.

1 Click Format menu ► Layer Management ► Layer Manager.

2 Click .

3 Click Import/Export.

4 Export the layer standards:

If you want to...	Then...
export layer standards to a new drawing	click New, enter a name for the new drawing, and click Save.
export layer standards to an existing drawing	click Open, select a drawing, and click Open.

5 Select the layer standards that you want to export, and click Export.

You can select more than one item in a list by holding down *CTRL* while you select the additional items. If you export a layer standard that already exists in the target drawing, a message is displayed asking if you wish to overwrite the existing layer standard. Click Yes to overwrite the existing layer standard, or click No to cancel.

6 Click OK three times.

Appendix: LISP Changes for Layer Snapshots and Layer States

NOTE In AutoCAD Architecture 2009 the Layer Snapshot functionality is discontinued in favor of the Layer State functionality. Existing layer snapshots (LAY) files are automatically converted to layer states (LAS) when the Layer States Manager is invoked in a legacy drawing with layer snapshots. The layer snapshot is deleted after the conversion.

If you have accessed layer snapshots via LISP routines in the past, these LISP functions are the equivalents of the discontinued layer snapshot functions and must be exchanged in your scripts:

Defunct Layer Snapshot Function	New Layer States Function
AeCLayerAddToSnapshot	layerstate-addlayers
AeCLayerExportSnapshot	layerstate-export
AeCLayerGetSnapshot	layerstate-getlayers
AeCLayerImportSnapshot	layerstate-import
AeCLayerRestoreSnapshot	layerstate-restore

For more information about these functions, see the AutoLISP Reference in the AutoCAD Help.

Display System

10

The display system in AutoCAD Architecture controls how AEC objects are presented in a designated viewport. By specifying the display configuration in a viewport and the direction from which to view the objects, you can produce different architectural representations. The display system lets you produce floor plans, reflected plans, elevations, 3D models, or schematic displays without redrawing objects.

Introduction to the Display System

The display system in AutoCAD Architecture is designed so that you only have to draw an architectural object once. The appearance of that object then changes automatically to meet the display requirements of different types of drawings, view directions, or levels of detail.

Display Properties and Display Components

The view-dependent display of objects in AutoCAD Architecture is made possible by a hierarchical system of display settings that specify display properties (visibility, layer, color, linetype, and so on) for individual display components of all the different types of architectural objects under all the different viewing scenarios.

For example, a door object has 5 display components by default: Door Panel, Frame, Stop, Swing, and Glass. (Many display components correspond directly to the physical components of the object, but some, like Swing, do not.) For each of these display components, the drawing default settings specify the relevant display properties as appropriate for the drawing type. In the case of doors, the default settings specify that the Swing component is visible in plan and elevation views, but not in 3D views.

Overrides

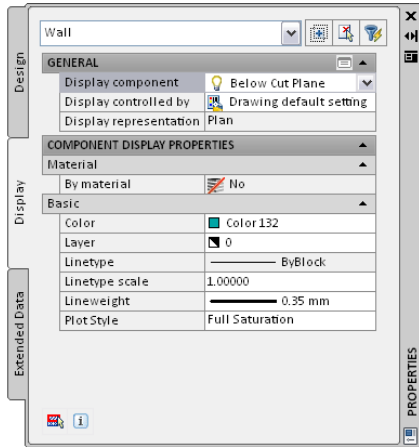

The drawing default settings for a particular type of object apply to all such objects in the drawing, except those for which an override is in effect. For example, you can change a setting for all doors of a particular style (a style override) or for an individual door (an object override).

Establishing and Modifying Default Display Settings

If you are a CAD manager, you will want to fully understand the [Display System Structure](#) on page 543 and [The Display Manager](#) on page 552 topics so that you can modify and organize default settings as necessary to implement your own display standards. But any user can quickly change the appearance of an object in a particular view by modifying values on the Display tab of the Properties palette.

NOTE To hide the Display Tab (or show it if it is currently hidden), enter the following command at the command line: `AecChangeDisplayTabStatus`.

Display tab when display component is selected

To change the display using this tab, you select an object display component (like a hatch or a boundary), and then select or enter a new value for the display property you want to change (such as color, visibility, or lineweight). The results are immediately visible in the drawing area for the current display representation and can be applied to other display representations that use the same component. You can also apply style or object overrides by changing the value of Display controlled by. For detailed instructions, see [Using the Properties Palette to Change Display Properties](#) on page 538.

Using the Properties Palette to Change Display Properties

Beginning with AutoCAD Architecture 2009, you can use the Display tab of the Properties palette to change the display property settings for a selected object in the current display representation. You can change settings for properties that apply to the object as a whole (such as Cut plane height), as well as settings for the object's individual display components (such as Color, Layer, and Linetype for a hatch component).

You can also specify whether your changes will apply to:

- all objects of the selected type (drawing default)
- all objects of the same style as the one to which the component belongs (a style override)
- only the selected object (an object override)

You can also apply your changes to other display representations that use the same display component to draw the selected object.

NOTE To hide the Display Tab (or show it if it is currently hidden), enter the following command at the command line: `AecChangeDisplayTabStatus`.

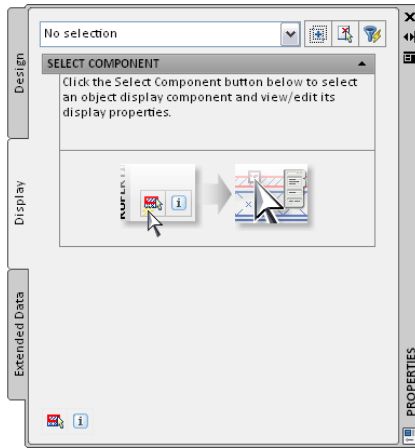

1 If necessary, open the Properties palette using any of the following methods:

- Click Window menu ► Properties Palette.
- On the Navigation toolbar, click .
- Press `CTRL+1`.
- Select an object in the drawing, right-click, and click Properties.

- Double-click an object in the drawing.

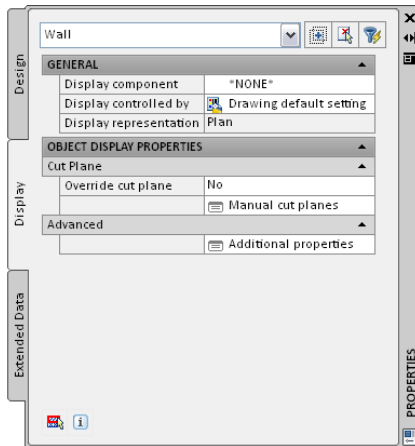

2 On the Properties palette, click the Display tab.

Display tab with no object selected

3 Select an object in the drawing area. Note that the current display representation is identified under the General category on the Display tab

Display tab with one object selected

4 Under the General category, for Display controlled by, select the level at which you want your changes applied, as described in the following table

If the value of Display controlled by is ...	Then your changes will apply to ...
Drawing default setting	all objects of the same type for which no overrides are in effect (for example, all doors in the drawing).
<object type>Style:<style name> (for example: Door Style: Hinged - Single)	all objects with the specified style for which no object overrides are in effect. This is called a style override; it takes precedence over the drawing default setting.
This object	the selected object only. This is called an object override; it takes precedence over either the drawing default setting or the style.

5 Do one of the following:

If you want to ...

Then ...

change one or more display property settings for a particular object display component (or change the visibility setting for multiple components)

proceed to step 6.

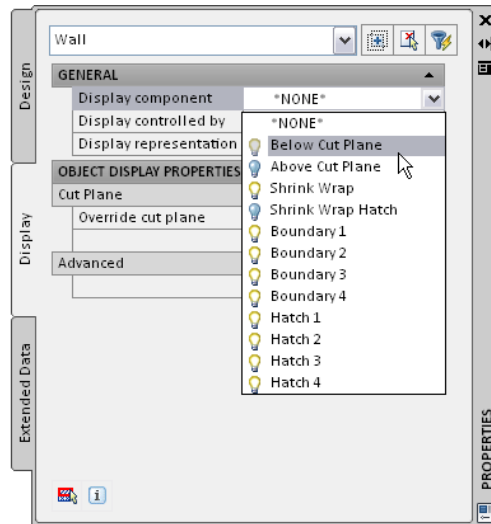

view or modify display properties that apply to the entire object at the level currently specified by the value of Display controlled by

for Display component, select *NONE*, then under the Object Display Properties category, change the value or click the worksheet

button  for whichever property or set of properties you want to modify. The properties shown under this category depend on the type of object selected. For detailed information about modifying display properties for a specific object type, see the relevant Help topic, such as Walls or Doors. Each of these object topics contains subtopics for each category of display property. For example, for instructions on changing settings on the Other tab for a wall object, see [Specifying the Display of Other Characteristics of a Wall](#) on page 828.

6 To change one or more display property settings for a particular object display component, first use one of the following methods to select it:

- If an object is already selected, under the General category on the Display tab, select a component from the Display component drop-down list.

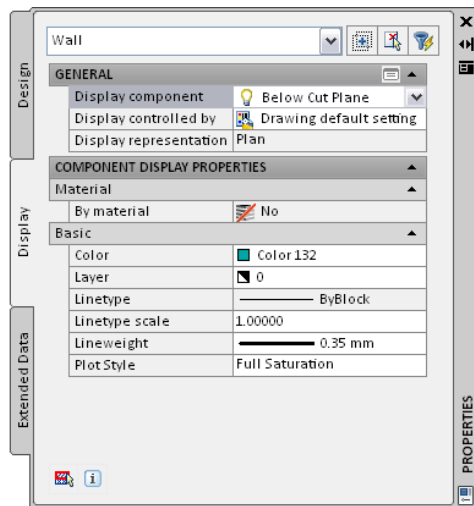

The color of the light bulb icon preceding each component name indicates whether the component is visible (yellow) or not (blue) in the current display representation. When the list is open, you can click one or more of these icons to change the visibility setting for the associated component(s). Your changes take effect in the drawing when you close the drop-down list by clicking a component name, pressing *Enter*, or clicking anywhere outside the list. Pressing *Esc* closes the list and cancels any visibility setting changes you have made while the list was open.

TIP A hatch may obscure other components, which can be selected inadvertently when you click on the hatch in the drawing area. Therefore, the drop-down list is the preferred method for selecting solid hatch components. Note also that the drop-down list contains only components whose appearance is controlled by the display system. Clicking in the drawing area may result in the selection of an object or component whose display cannot be modified through the Display tab (such as MV blocks, custom blocks, AutoCAD objects, and other entities). In such cases, an error message will identify why the selection is invalid.

- If no object is selected, at the bottom of the Display tab, click , and then click the display component in the drawing area.
- Regardless of whether an object is selected, you can right-click in the drawing area, click Select Component, and then click the display component you want to modify.

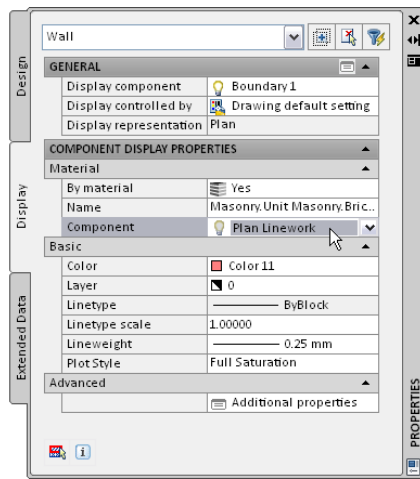

Display tab with object display component selected

NOTE The property settings shown on the Display tab for a selected component are specific to the display system. In most cases these settings will not be the same as the settings (either default or override) for associated layers in the Layer Manager.

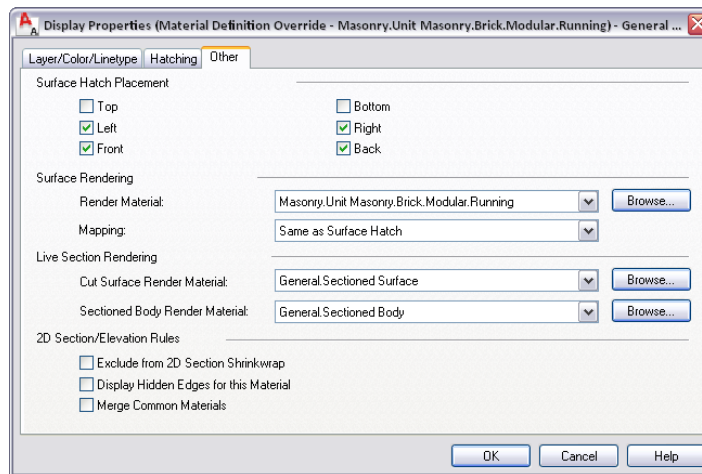

- 7 Enter or select a new value for any display properties you want to change. The results of your changes are immediately visible in the drawing area. Note that the properties shown on the Display tab vary depending on the object and component selected. Most are self-explanatory. For detailed information about modifying display properties for a specific object type, see the relevant Help topic, such as Walls or Doors. Each of these object topics contains subtopics for the applicable categories of display properties. For example, the Walls topic includes separate subtopics for [Specifying the Layer, Color, and Linetype of a Wall](#) on page 825 and [Specifying the Hatching for Components of a Wall](#) on page 825.

NOTE If the value of By Material is Yes, then your changes will apply to all objects with display components controlled by the material definition identified by the Name property, regardless of the value of Display controlled by. This is called a material definition override. When By material is Yes, you can access the drop-down list of material display components and change their visibility settings using the same technique described for display components in the previous step.

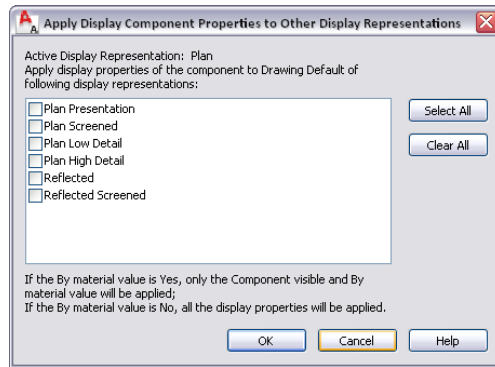

In this case, the Display tab also includes an Advanced category under which the Additional Properties worksheet button  accesses a dialog where you can view and modify display properties associated with the material definition, such as surface hatch placement and surface rendering, as shown below. For detailed instructions, see [Creating and Editing Material Definitions](#) on page 624.

Other tab for material definition override

8 If you want to apply your changes to other display representations at the same level indicated by the Display controlled by value, click the worksheet button  on the title bar of the General category. (Note that the worksheet button is available only when a display component is selected, and the worksheet lists only those display representations that can be applied to that component.)

Worksheet for applying changes to other display representations

- 9 On the worksheet, select the display representations to which you want your changes to apply, and click OK.

NOTE If the value of By material is Yes, only that setting and the Component visible setting will be applied to the selected display representations. If the value of By material is No, all of the display property settings for the component will be applied to the selected display representations.

Display System Structure

You use the display system to manage display properties and view assignments for objects in your project. You can also create new groupings for display purposes.

Elements of the Display System

The display system has 3 major elements:

- A display representation, which controls how an individual object, such as a door or a wall, is displayed
- A display set, which is a group of display representations of objects
- A display configuration, which is a collection of display sets assigned to particular view directions

These 3 elements are hierarchical: each display configuration contains a number of display sets, and each display set contains a number of display representations. To use a display configuration, you assign it to a viewport. The objects in the viewport then use the display properties specified in the display configuration.

Predefined Display Configurations in Templates

You use different display configurations for different tasks, such as sketching and plotting. You also use different display configurations for different types of drawings, such as floor plans, 3D models, and elevations.

AutoCAD Architecture includes templates with predefined display configurations applied to viewports. These configurations are created for typical architectural tasks and drawing types. You can use the configurations and viewports supplied by the templates, or you can modify the display system settings to suit your office standards. If you want to create your own display configurations, you can start a drawing from scratch or from a template that does not contain predefined display configurations.

Materials and the Display System

A material definition is a group of settings for the display properties of a real-world material, such as glass, brick, or wood. The settings define how the components assigned to the material appear in every view.

The materials feature works with the display system to simplify the process of customizing the display of drawings. Rather than specifying individual properties, you can control the display of objects according to the materials assigned to the physical components of the objects.

For example, you can assign brick as the material for all walls whose components consist of this material. The display properties of the bricks are customized to look like a typical brick wall. By assigning the material to walls, you avoid the need to customize the display properties for each wall that uses brick material. In addition, if the materials change during the project, you can reassign components to the new material.

Wall components with assigned brick and concrete materials

Sample styles in AutoCAD Architecture catalogs contain predefined materials assigned to their components. Use these materials in your drawings, customize them, or create your own materials. For more information, see [Creating and Editing Material Definitions](#) on page 624.

Display Settings in External References

You cannot change a display setting in an external reference while reediting it from its host drawing. You can open Display Manager and make changes, but they will not be saved when the external reference is saved and closed in the host drawing. To make changes to display settings in external references, you need to open the external reference drawing directly, make the changes there, and save it. The external reference should then be reloaded to update the changes.

Display Representations

A display representation defines how the components that make up an object are drawn. In traditional CAD and manual drafting, a single object, such as a door, is typically drawn multiple times in different drawings. In these drawings, each instance of a door is a separate collection of linework. In AutoCAD Architecture, you can create an object that changes the way it draws itself depending on the display representation used to represent that object.

Display Components of AEC Objects

Most AEC objects are made up of individual components. For example, a door has the following components: door panel, frame, stop, swing, glass, and threshold. A door may also have muntins.

Each component of an object has both physical and graphical properties that help to determine the display representation of that object.

- The physical properties of an object control width, height, shape, and location of the object in the drawing.
- The graphical properties control visibility (on/off), layer, color, and linetype.

You typically decide the physical properties of an object when you create it. For example, you specify the size of a door and its location in a wall. You control the graphical properties of an object in its display representation. You can define multiple display representations for the same object.

Display Representations and View Directions

A display representation is not dependent on view direction, although it usually is designed with a specific view in mind.

Objects displayed from different view directions that use different display representations

Model display representations for wall, door, and window shown in 3D from an isometric view direction

Plan display representations for wall, door, and window shown in 2D from a plan view direction

Elevation display representations for wall, door, and window shown in 2D from a front view direction

Why Most Objects Have Multiple Display Representations

All objects have predefined display representations. Most objects have Plan, Model, and Reflected display representations, because these are the most common design situations. Some objects, such as cameras and reference AEC objects, have only a General representation, because the display of these objects does not change in different views.

A single object can be drawn in various ways, depending on the needs of different drawing types. For example, the Plan display representation draws the door panel, frame, stop, and swing components. The Nominal display representation draws the door panel, frame, and swing components. Although both representations

draw the door panel, each draws it differently. The Plan representation draws a door panel as a rectangle, while the Nominal representation draws it as a single line.

Door shown in the Plan and Nominal display representations

door in Plan display representation showing frame, panel, swing, and stop

door in Nominal display representation showing frame, panel, and swing

The Plan display representation is appropriate for two-dimensional (2D) views when components are to be displayed from a plan (Top) view. The Nominal display representation is appropriate for 2D views when a limited amount of detail is needed in plan view. For example, display configurations intended for plotting at small scales, where details of objects might be obscured, often use the Nominal display representation.

Default Display Representations

The display representations available for an object and the names of those representations are based on the ways that you might need to view the object. Display representations can include different components of an object or additional display options.

For example, the display properties of stairs in the Plan display representation include settings for break marks and other stair symbols. Break marks appear only in 2D Top view drawings, so other display representations, such as Model and Elevation, do not contain settings for break marks. Similarly, objects that never display break marks do not have settings for them in their Plan display representations.

Plan display representation for stairs includes options for break marks

zigzag break mark

curved break mark

Customizing the Display of an Object

If you do not use materials to control display, you customize the appearance of an object by changing its display properties for the display representation. For example, you can turn off the door swing in the Plan display representation; specify whether the swing is straight or an arc; specify the percent open; or change the layer, color, and linetype of the swing.

To change the display of an object, you specify how changes are applied to the instances of the object in the drawing. You do this by specifying the source of the display properties for the selected display representation.

- To apply the changes to the default display properties of the object, you customize the drawing default settings. The changes affect all instances of the object in the drawing.

Drawing default display properties affect all instances of an object

doors with default display properties

doors with straight swing specified in drawing display properties

- To apply the changes to all instances of the object that have the same style, you override the drawing default settings with the display properties of the object style.

Changes to the display properties of a style affect all objects of that style

doors with default display properties

doors with straight swing specified in door style display properties

- To apply the changes only to the selected object, you override the drawing default settings or style display properties with the display properties of the object.

Display properties of an object apply only to that object

doors with default display properties

door with straight swing specified in door display properties

Objects use the default display properties unless the properties are overridden by the display properties of an object style or an individual object. Generally, you customize the display properties of object styles so that the appearance of different types of the same object is consistent throughout a drawing. You may need to override the display properties of the style for an individual object in order to achieve certain results.

Display Sets

Display sets are collections of object display representations. A display set determines which objects are visible, and how the objects, such as wall assemblies that include doors and windows, are displayed in different views.

Display Representations Included in a Display Set

A display set usually contains display representations that are appropriate for specific tasks or drawing types. For example, the Reflected display set contains display representations for objects typically included in a reflected ceiling plan. This display set uses the Reflected display representation for most of these objects, but uses the Plan display representation for other objects, such as structural members, that appear the same in plan and reflected views.

A display set can contain more than one display representation for an object. For example, a display set for plotting a floor plan might include the Plan and Threshold Plan display representations for doors.

- The Plan display representation contains components for the door panel, frame, stop, and swing.
- The Threshold Plan display representation contains components for the inner and outer thresholds of the door.

Plan and Threshold Plan display representations used alone and together to display a door

door in Plan display representation

door in Threshold Plan display representation

door in Plan and Threshold Plan display representations

If a display set contains no display representations for an object, the object is not displayed when that display set is used. For example, a display set for a reflected ceiling plan does not need representations for railings, which typically are not shown in these drawings.

Display Sets and View Direction

A display set is not dependent on view direction, although it usually is designed with a specific view in mind. For example, a Reflected display set is intended to be used to display objects from the Top view direction in a reflected ceiling plan.

Similarly, a Plan display set might contain Plan display representations for a number of objects intended for two-dimensional (2D) top views. A three-dimensional (3D) model display set might contain the Model display representation for a number of objects. The display representations included in a display set depend on what representations are available for each object, and whether objects need to be drawn differently from different view directions.

Default Display Sets

Drawings based on templates provided with AutoCAD Architecture contain display sets for many purposes. All drawings, even those that are not created from templates, contain the following default display sets: Elevation, Model, Model High Detail, Model Low Detail, Plan, Plan High Detail, Plan Low Detail, and Reflected. These display sets contain display representations for each object based on the most common design situations.

Display Configurations

A display configuration is a collection of display sets assigned to view directions.

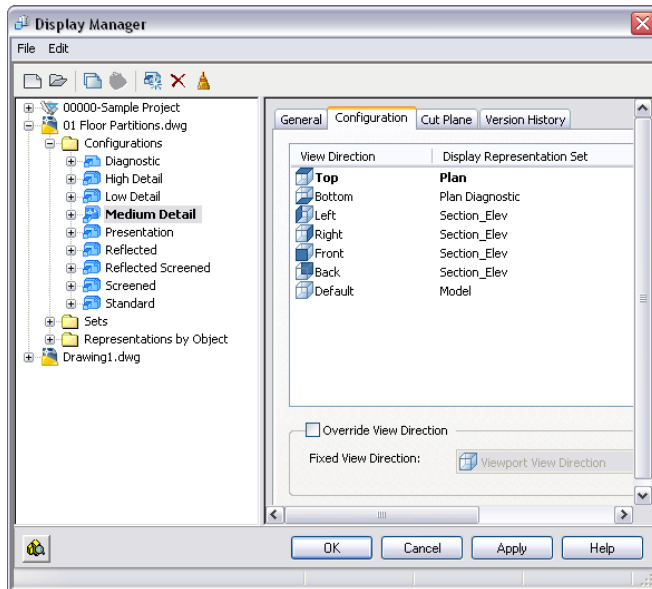

Display Configurations, Viewports, and Templates

A display configuration typically is created for a specific design task or drawing type. To use a display configuration, you assign it to a viewport. Drawings based on templates provided with AutoCAD Architecture contain layout tabs with viewports to which appropriate display configurations are assigned. You can use the configuration assigned to a viewport, assign a different one, or customize the configuration.

Display Sets Assigned to View Directions

You can identify the display set assigned to each view direction using the Display Manager. The Display Manager is a utility for managing elements of the display system. The following illustration shows a drawing with two display configurations, Medium Detail and Standard.

Sample display configurations in the Display Manager

In the Display Manager, the active viewport in the drawing (in bold type) is assigned the Medium Detail display configuration. In the left pane, the display sets used are listed below the configuration name. An icon next to each display set indicates the view direction to which the display set is applied. The Configuration tab in the right pane shows the view direction to which each display set is mapped. In this example, the current view direction in the drawing is Top, which uses the Plan display set. Objects in the active viewport are shown using the display representations in the Plan display set.

If the view direction in the active viewport is changed to Front, the objects are shown using the display representations in the Section_Elev display set. This is also true when the view direction in the active viewport is changed to Right, Left, or Back.

The display set assigned to the Default view direction is used when any view direction other than the six orthogonal views is selected, or when a view direction is not assigned a display set. If the view direction of the active viewport is changed to Bottom, objects are shown using the display set assigned to the Default view direction—the Model display set.

For more information about the Display Manager, see [The Display Manager](#) on page 552.

Displaying Objects in a Viewport

The display configuration, the current viewport, and the object interact in the following manner to determine what is shown in a viewport:

- The active viewport has a current view direction and a current display configuration. For example, the view direction is Top, and the display configuration is Medium Detail.
- The display configuration has one or more display sets and uses the display set that is assigned to the current view direction. For example, in the Medium Detail display configuration, the Plan display set is assigned to the Top view.

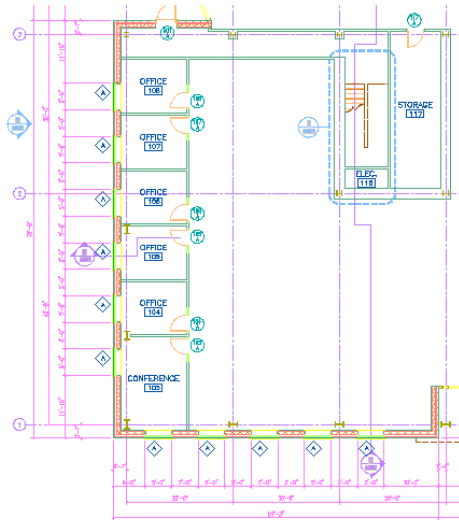

- The display set has associated display representations and it selects the representation(s) associated with the object that needs to be shown. For example, in the Plan display set, doors, windows, and walls use their Plan display representations.
- The object is shown in the active viewport using the appropriate display representation(s) and display properties.

Examples of View Directions That Use Different Display Sets

A display configuration assigns display sets to specific view directions. When a view direction is selected, the display representations in the display set determine how each object is displayed in the viewport.

For example, the following illustration shows a viewport assigned the Plot display configuration and the Top view direction. In this illustration, the objects are shown with a Plan display representation.

Objects from Top view using a display set for plan views

If the Front view direction is selected in this viewport, the same objects are displayed with an Elevation display representation.

Objects from Front view using a display set for elevation views

If the SW Isometric view direction is selected, the same objects are displayed with a three-dimensional (3D) representation.

Objects from SW isometric view using a display set for model views

Default Display Configuration

The display configurations in a drawing depend on the template used to create the drawing. A drawing that is not created from a template contains the Standard display configuration, which includes the Plan and Model display sets.

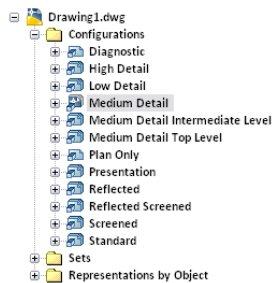

The Display Manager

The Display Manager is the central location of display system information for your drawing in AutoCAD Architecture. You use the Display Manager to create and modify display configurations, display sets, and display representations. You can also assign a display configuration to a viewport and view how objects are displayed in different representations. You can resize the Display Manager window and the left and right panes as needed to view display information.

Left Pane of the Display Manager

The left pane of the Display Manager organizes the display information for your drawings in a hierarchical tree view. You can add, purge, rename, copy, and send display system components in the tree view. As you select items in the left pane, the right pane is updated appropriately.

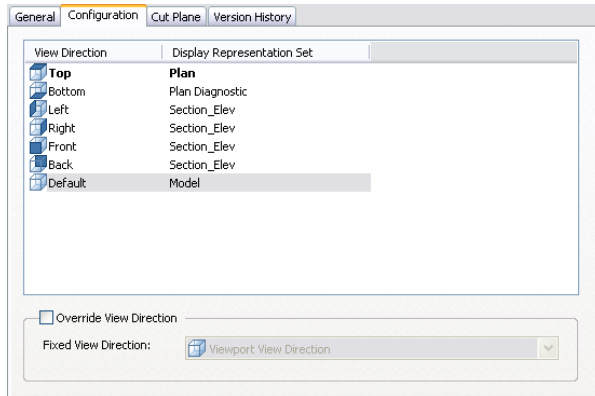

Left pane showing a tree view of display configurations and their components

Right Pane of the Display Manager

The information displayed in the right pane of the Display Manager depends on what you select in the left pane. You can view the display sets and mapped view directions associated with each display configuration. You can view the display representations of different objects and access the default graphical display properties of objects in your drawings. You can also preview how an object is displayed.

Right pane showing details of a selected display configuration

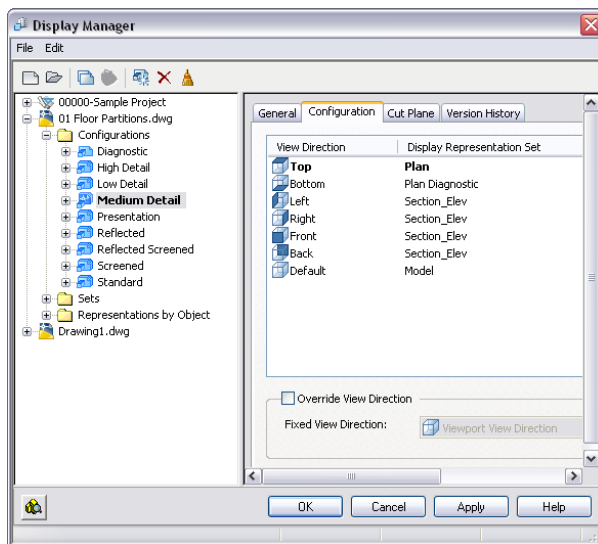

View Direction Icons in the Display Manager

The icons used with display sets and view directions identify how a display set is used in a configuration. When you expand a display configuration, the display sets used in it are shown. The icon next to each display set indicates the view direction to which it is applied in the display configuration.

In the following example, the Model display set is applied to the default view direction. The right pane shows that the Section_Elev display set is applied to the front, back, left, and right view directions. The Plan display set is applied to the top view direction. In the right pane, icons correspond to the six orthogonal view directions and the default view direction.

Using icons to identify view directions to which display sets are applied

Opening the Display Manager

Use this procedure to open the Display Manager.

- 1 Click Format menu ► Display Manager.
- 2 Move and resize the Display Manager or resize the left and right panes as needed to view display information.

Viewing Display Configurations

Use this procedure to view the display configurations available in the current drawing. The display configurations depend on the template used to create the drawing. A drawing not created from a template contains the Standard display configuration, which includes the Model and Plan display sets.

The following icons can be assigned to a display configuration:

Icon	Description
	Multiple view display configuration
	Fixed view display configuration
	Multiple view display configuration (drawing default)
	Fixed view display configuration (drawing default)
	Default display set used in the display configuration. This set is used for all views that are not otherwise connected to a display set.
	Display set used for the top view of the display configuration.
	Display set used for the bottom view of the display configuration.
	Display set used for the left side view of the display configuration.
	Display set used for the right side view of the display configuration.
	Display set used for the front view of the display configuration.
	Display set used for the back view of the display configuration.
	Display set used for the multiple views of the display configuration, but not as the default display set.

- 1 Click Format menu ► Display Manager.
- 2 Expand Configurations, and select a configuration.
- 3 Click the Configuration tab.

The left pane lists the display sets included in the configuration. The right pane lists the display sets assigned to each view direction. If a display set is not listed next to a view direction, the display set for the Default view direction is used when that view direction is selected. The Default view direction is also used for any view directions other than the six orthogonal views.

- 4 Click the Cut Plane tab.

The Cut Plane tab contains settings for the height of the cut plane and the height above and below the cut plane that are included in views when you assign this display configuration.

If you are working with a project, you can also calculate the cut plane based on the level heights from the project. For more information, see [Global Cut Planes](#) on page 388.

5 If you are working with a project and use project standards, you can use the Version History tab to modify the version history of the display configuration.

For more information, see [Project Standards](#) on page 409.

6 Click OK.

Viewing Display Sets

Use this procedure to view the display sets in the current drawing.

1 Click Format menu ► Display Manager.

2 Expand Sets, and select a display set.

The icons next to the display set names in the left pane indicate whether a display set is used in a display configuration within the current drawing. The icon with a red check mark indicates that a display set is assigned. The icon with a green dot indicates that a display set is a standard set. Although standard sets can be renamed, they cannot be deleted.

3 Click the Display Representation Control tab.

The right pane contains a matrix that lists each object and display representation. A check mark under a display representation indicates that the display set uses this representation to show the corresponding object. For example, in the Model display set, most objects use the Model display representations.

Display representations selected for each object in the Model display set

Objects	Display Representations									
	Plan	Plan High Detail	Plan Intermediate Level	Plan Low Detail	Plan Overlapping	Plan Presentation	Plan Screened	Plan Top Level	Reflected

Railing	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Roof	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Roof Slab	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Schedule Table	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Slab	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

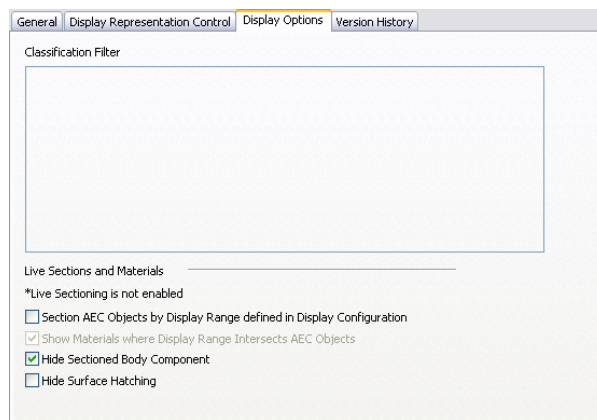

Display sets can have different icons depending on their function in the drawing:

Icon	Description
	The display set is a standard display set and cannot be deleted.
	The display set is currently used in a display configuration in the drawing.
	The display set is a standard display set and is currently used in a display configuration in the drawing.
	The display set is neither a standard display set nor is it used in a display configuration in the drawing.

4 Click the Display Options tab.

Settings on this tab enable you to filter objects by their classification. In addition, you can specify settings that affect how materials are displayed when you generate a live section view of a building model.

Display options specified for a selected display set

5 If you are working with a project and use project standards, you can use the Version History tab to modify the version history of the display set.

For more information, see [Project Standards](#) on page 409.

6 Click OK.

Viewing Display Representations

Use this procedure to view the display representations in the current drawing.

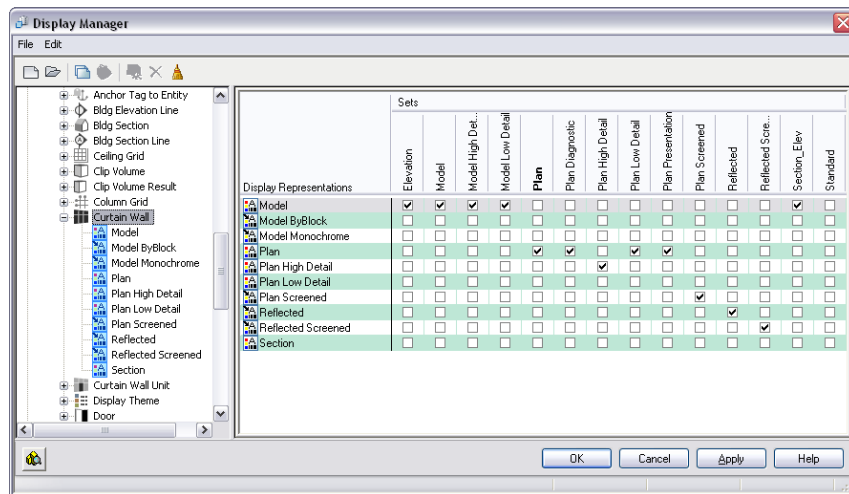

- 1 Click Format menu ► Display Manager.
- 2 Expand Representations by Object, and select an object.

Display representations can have different icons depending on their function in the drawing:

Icon	Description
	Standard display representation with properties that the user can set.
	User-defined display representation with properties the user can set.
	Display representation without user-definable properties.

In the right pane, rows list the display representations that exist for that object, and columns list display sets. A check mark under a display set indicates that the display representation is used in that display set. A display representation can be used in multiple display sets.

Curtain wall display representations used in display sets

The icon next to the display representation name indicates whether it is a predefined display representation () or custom display representation ().

3 Click OK.

Viewing an Object in a Display Representation

Use this procedure to see how an object appears in different display representations and view directions.

1 Click Format menu ► Display Manager.

2 Click  .

3 Reposition the Floating Viewer and the Display Manager so that both are visible.

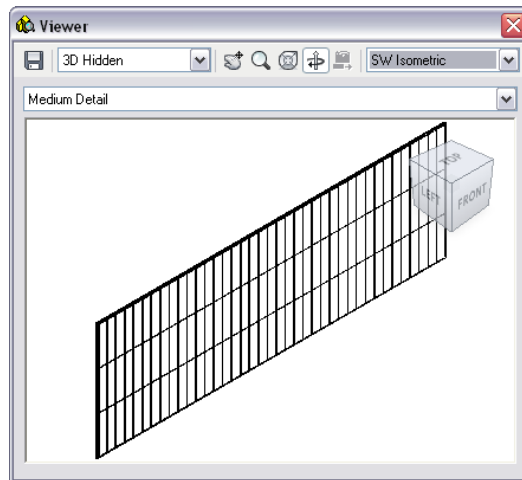

4 Expand Representations by Object, and select an object.

5 In the right pane, select a display representation.

NOTE Overrides to the default display representation, made in the display properties of an object style or an individual object, do not show in the Display Manager.

The Floating Viewer displays the object in the display representation.

Floating Viewer displaying a curtain wall

- 6 Use the controls in the Floating Viewer to view the object from different view directions and with hidden lines removed or with shading.
- 7 Repeat steps 4 and 5 to view objects in various display representations.
- 8 Click  to close the viewer.
- 9 Click OK.

Viewing the Display Representation of an Object in a Display Set

Use this procedure to see how an object appears in the display representation used object in a selected display set.

- 1 Click Format menu ► Display Manager.
- 2 Click .
- 3 Reposition the Floating Viewer and the Display Manager so that both are visible.
- 4 Expand Sets, and select a display set.
- 5 Click the Display Representation Control tab.
- 6 Select an object.

NOTE Overrides to the default display representation, made in the display properties of an object style or an individual object, do not show in the Display Manager.

The Floating Viewer displays the object in the display representation selected for it in the display set.

- 7 Use the controls in the Floating Viewer to view the object from different view directions and with hidden lines and shading.
- 8 Repeat steps 6 and 7 to view other objects in the display representation used in the display set.
- 9 Select another display set, and repeat steps 6 and 7 to view objects as they appear in that display set.
- 10 Click  to close the viewer.

11 Click OK.

Accessing the Default Display Properties of an Object

Use this procedure to access and view the default display properties of a display representation of an object. Default display properties apply to all instances of the object in the drawing unless the properties are overridden by the object style or an individual object.

- 1 Click Format menu ► Display Manager.
- 2 Expand Representations by Object.
- 3 Expand an object, and select a display representation.

The right pane of the Display Manager shows the default display properties of the object for the selected display representation.

NOTE Overrides to the default display representation, made in the display properties of an object style or an individual object, do not appear in the default display properties in the Display Manager.

4 Click OK.

Creating and Editing Display Configurations

A display configuration is a collection of display sets that controls the representation of objects viewed from different directions in a drawing. You apply a display configuration to the viewport in which you want the objects to appear. You can also select a display configuration to use as the default for model space and new viewports.

Drawings based on templates provided with AutoCAD Architecture contain display configurations for common tasks and drawing types. You can modify them and their display sets and display representations to meet your needs. You can also copy these elements of the display system to use as the basis for custom display configurations.

Process Overview: Creating a Display Configuration

AutoCAD Architecture templates provide display configurations for common design, drafting, and production tasks. You can also create custom display configurations.

The process of creating a display configuration has the following steps:

- 1 Create a display configuration with default properties.
- 2 Create display sets to associate with different view directions.
Although you can assign display sets to any view direction, you usually create them with specific view directions in mind. For example, you may want to create display sets for plan, elevation, and model views of a building model. You can add more display representations to the display sets later.
- 3 Create or modify display representations for each object you want to display.
You create a new display representation by duplicating an existing display representation for an object. Use a display representation that is similar to the one you want to create so that you have fewer settings to modify. Although you can use display representations in any view direction, you usually create them with specific view directions in mind.
- 4 Assign new, modified, or existing display representations to display sets.

A display set can include any display representation that you specify. Objects can use more than one representation in a display set. Remember that you need to include at least one display representation for every object that is to appear in a viewport.

5 Assign display sets to view directions in the display configuration.

You add display sets to a display configuration by assigning them to any of the six orthogonal view directions or to the Default view direction. The display set assigned to the Default view direction is used if no display set is assigned to a view direction.

6 Assign the display configuration to a viewport.

The display configuration becomes active when you assign it to a viewport. You can assign a display configuration to multiple viewports. You can also export display configurations to other drawings.

Tips for Working with Display Configurations, Sets, and Representations

This topic provides suggestions for working effectively with display configurations and their elements.

- Templates provided with AutoCAD Architecture and the drawings based on those templates contain display configurations for common design, drafting, and production tasks and various drawing types. If your drawing does not contain these display configurations, you can import them. For more information, see [Display Configurations](#) on page 549. Templates and the drawings based on them contain layout tabs with display configurations assigned to viewports for specific tasks. Examine your building model in these different layouts to see if objects are displayed as you want them to appear.
- Before creating or modifying display configurations, review the predefined configurations to see if they meet your needs or if you can readily adapt them for your project.
- When possible, use a predefined display configuration as the basis for configurations you create. Starting with a display configuration that is similar to what you need helps you to work efficiently. You can modify only the settings that need to change, rather than creating everything from scratch.
- When you modify a display representation, the changes affect every display set and display configuration that use that representation. To apply changes more selectively, create a new display representation for the object and assign it to the display sets in which the changes are to appear.
- Similarly, when you modify a display set, the changes appear in every display configuration that uses the display set. And if you modify a display configuration, the changes appear in every viewport to which the configuration is assigned. To apply the changes more selectively, create custom display sets and configurations.
- Remember that changes made to display representations through the Display Manager apply only to the default display properties of objects. Changes to the display properties of object styles and individual objects override the default display properties. In addition, if the default display properties assign a material to object components, the display properties of the material determine the appearance of the object.

Creating a Display Configuration

Use this procedure to create a display configuration. You can create a display configuration using standard default properties or by creating a duplicate of an existing configuration.

- 1 Click Format menu ► Display Manager.
- 2 Expand Configurations.

3 Create a display configuration:

If you want to ...	Then ...
create a display configuration with default properties (containing no display sets)	right-click Configurations, and click New.
create a display configuration from an existing display configuration	right-click the display configuration you want to copy, and click New.

4 Enter a name for the new display configuration, and press *ENTER*.

5 Specify the display sets and display representations to use in this display configuration:

If you want to ...	Then ...
create a display set for this configuration	see Creating a Display Set on page 561.
create display representations to use in this display configuration	see Creating a Display Representation for an Object on page 562 and Assigning a Display Representation to a Display Set on page 563.
assign display sets to view directions	see Assigning a Display Set to a View Direction on page 566.

6 Click OK.

Creating a Display Set

Use this procedure to create a display set. You can create a display set using standard default properties or by creating a duplicate of an existing display set.

1 Click Format menu ► Display Manager.

2 Expand Sets.

3 Create a display set:

If you want to ...	Then ...
create a display set with default properties (containing no display representations)	right-click Sets, and click New.
create a display set from an existing display set	right-click the display set you want to copy, and click New.

4 Enter the name for the new display set, and press *ENTER*.

5 Specify the display representations to use in this display set:

If you want to ...	Then ...
create display representations to use in this display set	see Creating a Display Representation for an Object on page 562.

If you want to ...	Then ...
assign display representations to this display set	see Assigning a Display Representation to a Display Set on page 563.
add this display set to a display configuration	see Assigning a Display Set to a View Direction on page 566.
use this display set as one of the default display sets	see Specifying a Display Set as a Default Display Set on page 567.

6 Click OK.

Creating a Display Representation for an Object

Use this procedure to create a display representation for a selected object. You create a display representation by duplicating an existing one for the object.

Each object has one or more display representations, depending on whether the object needs to change in different views. Select an existing representation that is similar to the one you want to create. That way, the display properties are available for you to customize in the new representation.

For example, to create a display representation for stairs and use a custom break mark, duplicate a plan display representation for stairs that contains settings for the break mark.

1 Click Format menu ► Display Manager.

2 Expand Representations by Object.

3 Select the object for which to create the new display representation.

4 In the right pane of the Display Manager, right-click the display representation to duplicate, and click Duplicate.

5 Enter a name for the new display representation, and press *ENTER*.

The new display representation has the display properties of the representation you duplicated.

The display representation created in the right pane is not listed in the Representations by Object directory in the left pane until you close and reopen the Display Manager.

6 Double-click the new display representation to edit its properties.

For more information about editing display properties, see [Editing a Display Representation](#) on page 562.

7 Assign the display representation to the display sets in which they will be used.

For more information, see [Assigning a Display Representation to a Display Set](#) on page 563.

8 Click OK.

You can click Apply instead of OK to save the changes and continue working in the Display Manager.

Editing a Display Representation

Use this procedure to change the following default display properties of a display representation:

- Visibility (on or off), and whether the display of a component is controlled by its material assignment

- Layer, color, linetype, and lineweight
- Display properties that are specific to the object and the display representation, such as the stair line and break mark in plan display representations of stairs

By default, the layer of object components is layer 0. The default color and linetype are ByBlock. With these defaults, the object components inherit the color and linetype properties of the “parent” object. For example, when the color and linetype of the door frame component are ByBlock, the door frame has the color and linetype of the door object. Object components cannot exist outside their parent object as can typical AutoCAD block objects.

Changes made to a display representation apply to every display set and display configuration that use the display representation. To apply changes more selectively, create a display representation based on the representation you want to modify. You can then change the display properties of the new representation and assign it to specific display sets. For more information about creating display representations, see [Creating a Display Representation for an Object](#) on page 562.

NOTE Changes you made to a display representation using this procedure apply only to the default display properties for the object. Changes to the display properties of object styles or of individual objects override the default display properties.

- 1 Click Format menu ► Display Manager.
- 2 Expand Representations by Object.
- 3 Expand the object that contains the display representation you want to edit.
- 4 Select the display representation to edit.

The display properties you can edit depend on the object and the display representation that you select. For example, a wall in a model representation displays only the Layer/Color/Linetype tab; a wall in a plan representation displays two additional tabs to specify display properties for hatching and cut plane components.

- 5 Click the Layer/Color/Linetype tab to change the AutoCAD properties, including visibility of the object components and whether their display is controlled by the material assignment.
- 6 If applicable, click tabs such as Hatching or Other to change object-specific display properties.
For more information about object-specific display properties, see the procedures for specifying display properties of an object style in the Help topic for each object. For example, to specify the display properties of wall styles, see [Specifying the Display Properties of a Wall Style](#) on page 889.
- 7 When you finish editing display properties, click OK.

Assigning a Display Representation to a Display Set

Use this procedure to add or remove display representations in a display set. Changes made to a display set affect every display configuration that uses the display set.

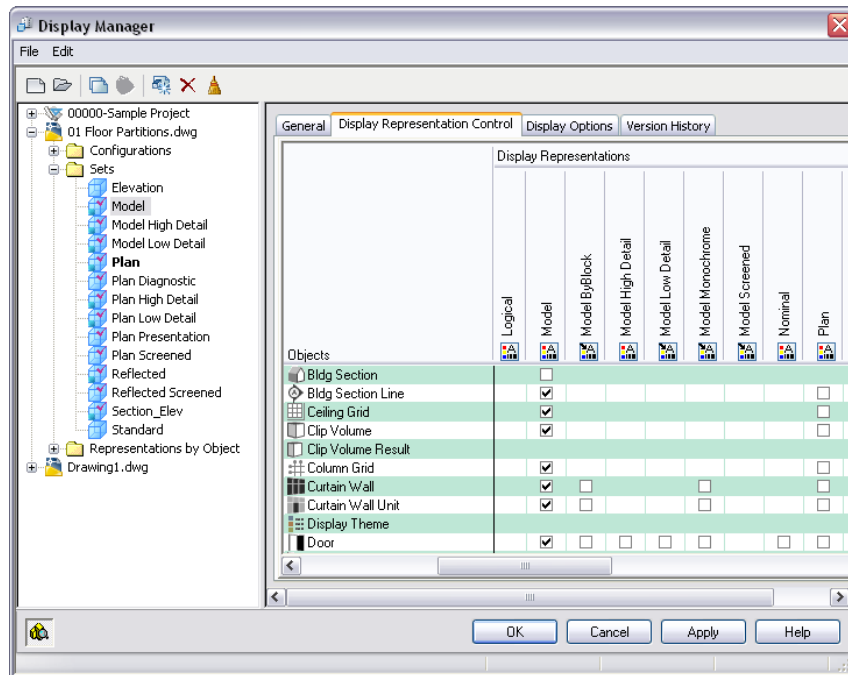

Keep the following points in mind when you add or remove display representations in a display set:

- A display set can use more than one display representation for an object. For example, some display sets for plan views include both Plan and Threshold Plan display representations for doors.
- To use a display representation for an object other than the current one, be sure to clear the current display representation after selecting the new one. Otherwise, the display set uses the display properties of both display representations.
- If no display representation is selected for an object, the object does not appear when the display set is active in a viewport.

- If no check box appears under a display representation for an object, the object does not have the display representation. For example, objects such as layout curves and layout grids have only one display representation.
- You can compare two display sets to view the differences in display representation assignments. For more information, see [Comparing Display Representations Between Display Sets](#) on page 565.

- 1 Click Format menu ► Display Manager.
- 2 Expand Sets.
- 3 Select the display set you want to edit.
- 4 Click the Display Representation Control tab.

Editing a display set

5 In the right pane, add or remove display representations:

If you want to ...

Then ...

add a display representation for an object to the display set

scroll through the list to find the object. Select a display representation to use. If no check box appears under a display representation, the object does not have the display representation.

remove a display representation for an object in the display set

scroll through the list to find the object. Clear the display representation you want to remove.

use the same display representation for all objects in the display set

right-click the name of the display representation, and click Select All. Be sure to clear any other display representations for the objects in this display set.

remove an object from a display set

scroll through the list to find the object. Right-click the object name, and click Clear All.

If you want to ...	Then ...
add all display representations to all objects in the display set	right-click in the Objects heading area, and click Select All Display Representations.
clear all display representations from all objects in the display set	right-click in the Objects heading area, and click Clear All Display Representations.

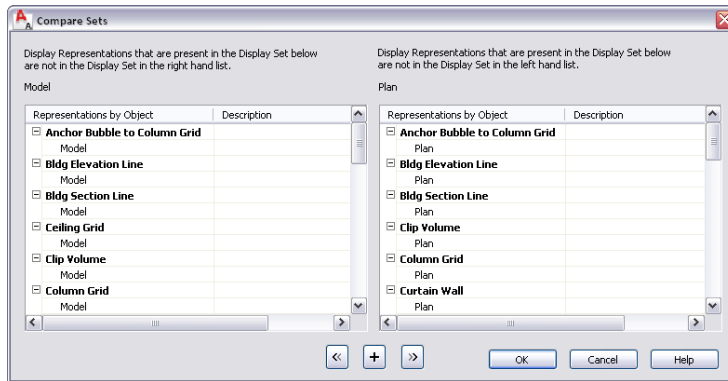

6 NOTE You can use these steps to assign display representations from the Representation by Objects directory. Expand *Representations by Object* in the left pane, select an object, and add or remove display representation assignments.

Click OK.

Comparing Display Representations Between Display Sets

Use this procedure to view the differences in display representation assignments between two display sets. The Compare Sets dialog box displays two lists. Each list contains display representations that are assigned to that particular display set, but are not assigned to the display set in the adjacent column.

Comparing display sets to view different display representation assignments

You can use the Compare Sets dialog box to assign one or more display representations to either display set.

- 1 Click Format menu ► Display Manager.
- 2 Click Sets.
- 3 In the right pane, hold down the CTRL key and select the two display sets you want to compare.
- 4 Right-click one of the selected display set names, and click Compare Sets.

NOTE The Compare Sets command is available only when two display set names are selected. You cannot compare more than two display sets at a time.

- 5 Each list shows the display representation assignments that are different from the other display set.

6 To assign display representations:

If you want to ...	Then ...
assign a display representation on the left side to the display set on the right side	select the display representation name under the display set on the left side, and click  .
assign a display representation on the right side to the display set on the left side	select the display representation name under the display set on the right side, and click  .
assign all display representations to the other display set so both sets have identical assignments	Click  .

7 Click OK twice.

Assigning a Display Set to a View Direction

Use this procedure to specify the display set assigned to each view direction in a display configuration.

- 1 Click Format menu ► Display Manager.
- 2 Expand Configurations.
- 3 Select the display configuration you want to edit.
- 4 Click the Configuration tab.
- 5 Under Display Representation Set, select the appropriate display set for each view direction.
The display set becomes active when the view direction is selected in the viewport in which the display configuration is assigned. The display set assigned to Default is used for view directions to which you do not assign a display set and for the four isometric views.
- 6 Click OK.
To see the results of your changes, you must assign the display configuration to a viewport. For more information, see [Assigning a Display Configuration to a Viewport](#) on page 566.

Assigning a Display Configuration to a Viewport

Use this procedure to assign a display configuration to a viewport. You can specify a display configuration for a viewport, model space, or tiled viewport at any time during the design process.

NOTE You can also assign a display configuration to the current viewport in the Display Manager. Right-click the display configuration, and click Set To Current Viewport.

- 1 Select the viewport for which you want to assign a display configuration.
- 2 In the drawing status area, select the setting for Display Configuration.

Displaying the configurations you can assign to the current viewport

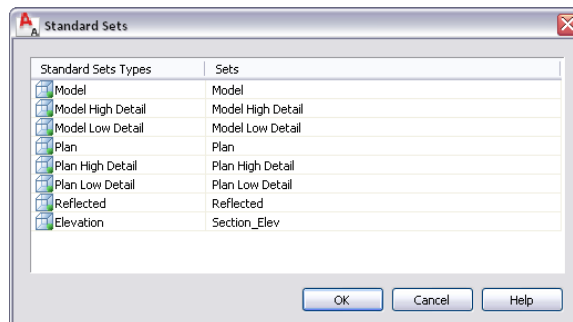

- 3 Select the display configuration that you want to use.
- 4 If necessary, enter **rea** (Regenerate All) to update the display to show the new display configuration.

Specifying a Display Set as a Default Display Set

Use this procedure to change the display sets defined as default display sets. For more information about default display sets, also known as standard sets, see [Display Sets](#) on page 548.

- 1 Click Format menu ► Display Manager.
- 2 Right-click Sets, and click Standard Sets Adjustment.
The Standard Sets Types column lists the default display sets for the drawing. The Sets column lists the display set specified for each default display set.
- 3 Locate the standard set you want to change, and click its display set name in the Sets column.
- 4 Select the display set name to use for the standard set type.

Specifying a display set for the Model standard set type

- 5 Click OK twice.

Specifying the Default Display Configuration

Use this procedure to specify the default display configuration applied to new viewports, model space, or tiled viewports in the current drawing. Existing viewports with assigned display configurations are not affected.

NOTE You can also assign the default display configuration in the Display Manager. Right-click the display configuration, and click Set as Drawing Default.

- 1 In the drawing status area, click .
- 2 Click Drawing Setup.
- 3 Click the Display tab.

- 4 Under Drawing Default Display Configuration, select the display configuration to apply to new viewports, or when the TILEMODE system variable is set to 1.
- 5 Click OK.
- 6 If necessary, enter **rea** (Regenerate All) to update the display in model space to show the new display configuration.

Specifying the Display Configurations Used in Xref Overlays

Use this procedure to specify whether the objects in an xref drawing are to use the display configurations in the xref when the drawing is referenced as an overlay by the host drawing.

By default, objects in both overlay and attached xref drawings use the display configurations assigned in the host drawing. This procedure describes how to specify that an xref overlay use only its own display configurations and not those in the host drawing. If you do not turn on this option, objects in the xref drawing can use their own display configurations or those of the host drawing. Xref drawings that are referenced as attachments can use either group of display configurations. For more information, see [Changing the Display Configuration Used in Xref Drawings](#) on page 569.

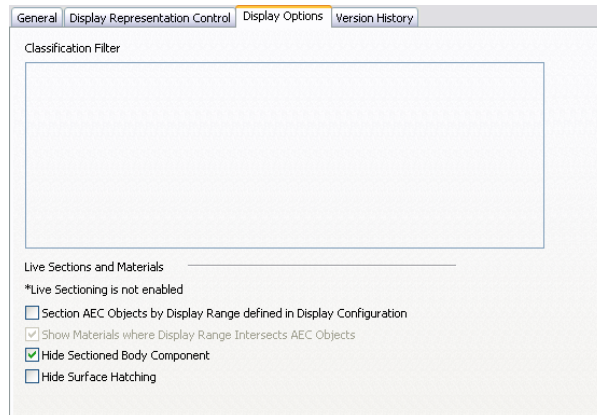

In the following example, the objects in the xref drawing inserted as an overlay use the Screened display configuration (north and east walls, doors, and windows). The host drawing uses the Medium Detail display configuration (south and west walls, doors, and windows).

An xref overlay that does not use the active display configuration in the host drawing

- 1 Open the drawing that you want to reference in another drawing.
- 2 In the drawing status area, click .
- 3 Click Drawing Setup.
- 4 Click the Display tab.
- 5 Under Drawing Default Display Configuration, select When used as an Xref Overlay use Display Configurations from this drawing only.
Clear this option if you want the xref drawing to use either its own display configurations or the display configurations in the host drawing.

Specifying that objects use display configurations only from the current drawing

6 Click OK.

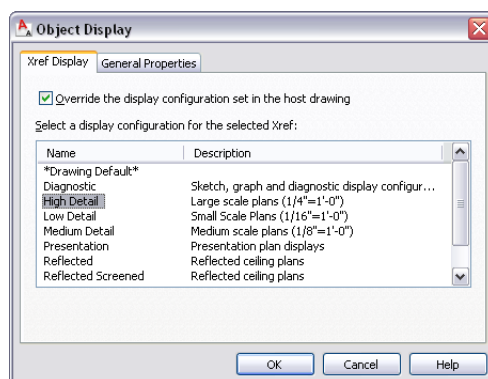

Changing the Display Configuration Used in Xref Drawings

Use this procedure to change the display configuration of an xref drawing that is referenced as either an attachment or an overlay in a host drawing.

NOTE If you specified that the drawing should always use its own display configurations when inserted as an xref overlay, you cannot change the display configuration used to display the xref objects in the host drawing. For more information, see [Specifying the Display Configurations Used in Xref Overlays](#) on page 568.

- 1 Open the host drawing that contains the xref drawing for which to specify a different display configuration.
- 2 Select the xref drawing you want to change, right-click, and click Edit Object Display.
- 3 Click the Xref Display tab.
If the settings on the tab are unavailable, you cannot change the display configuration used for this xref overlay.
- 4 Select Override the display configuration set in the host drawing.
- 5 Select the display configuration that you want to use.

Selecting a display configuration from those in the xref drawing

The list of display configurations are those available in the xref drawing. Select Drawing Default if you want to use the default display configuration specified in the host drawing.

6 Click OK.

7 Enter **rea** (Regenerate All) to see the changes to the display of objects in the xref drawing.

Displaying Objects by Classification

Use this procedure to hide or show objects in a display set based on the classification of the objects. For example, if you classify objects by construction status (new, existing, or demo), you can exclude objects with the demo classification from the display. When the display is used in the drawing, those objects do not appear.

Objects filtered from the display are not removed from the drawing. Their display is turned off only in viewports using the display set in which they are filtered. You can change the filter to display them again. Because the objects still exist in the drawing, the display of other objects does not change. For example, if you filter doors from a floor plan, the walls in which they are placed are still cut in the space occupied by the doors.

For more information about defining classifications and assigning them to object styles, see [Classification Definitions](#) on page 2574.

1 Click Format menu ► Display Manager.

2 Expand Sets.

3 Select the display set you want to edit.

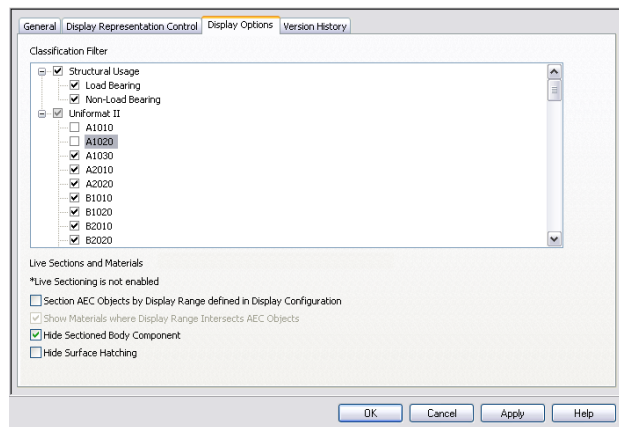

4 Click the Display Options tab.

The classification filter lists all classifications in the current drawing. All classifications are selected by default.

5 To hide objects of a specified classification, clear the check box under Classification Filter.

For example, to hide all doors and walls classified as A1010 and A1020, clear the check boxes for A1010 and A1020 under Uniformat II.

Hiding objects based on their classification

To redisplay objects in a classification that were hidden, select the classification.

6 Click OK.

Specifying Settings for Live Sections and Materials

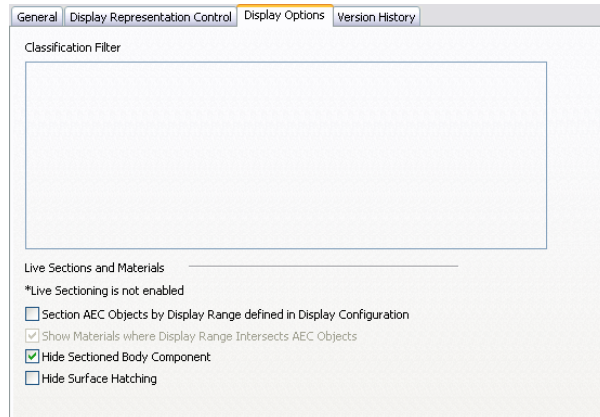

Use this procedure to specify how live sections and materials are displayed when the selected display set is active in a viewport and a live section view of the building model is enabled. These settings let you refine

the appearance of a section. For example, you can remove surface hatching that may obscure details in the section.

For more information about materials, see [Materials](#) on page 601. For more information about live sections, see [Creating and Editing a Live Section View](#) on page 2165.

- 1 Click Format menu ► Display Manager.
- 2 Expand Sets.
- 3 Select the display set you want to change, and click the Display Options tab.

Specifying display options for live sections and materials

- 4 Under Live Sections and Materials, specify display settings:

If you want to ...	Then ...
use the display range of the display configuration to determine the vertical extents of a live section view	select Section AEC Objects by Display Range defined in Display Configuration. If you want to graphically indicate where objects in the model extend below the display range, select Show Materials where Display Range Intersects AEC Objects.
remove the display of the portion of sectioned objects beyond the bounding box of the live section	select Hide Sectioned Body Component.
remove surface hatching on sectioned objects	select Hide Surface Hatching.

WARNING You should clear this setting for Plan display sets. If this setting is selected, any 2D sections inserted in Plan view will not be displayed.

- 5 Click OK.

Managing Display Configurations

The Display Manager is a utility for managing display configurations, display sets, and display representations: renaming them or deleting them, copying them between drawings, emailing them to other users, and purging unused elements from drawings.

Renaming a Display Configuration or a Display Set

Use this procedure to rename a display configuration or a display set. You cannot rename the Standard display configuration.

1 Click Format menu ► Display Manager.

2 Select a display configuration or a display set:

If you want to ...	Then ...
rename a display configuration	expand Configurations, right-click the display configuration, and click Rename.
rename a display set	expand Sets, right-click the display set, and click Rename.

3 Enter the new name, and press *ENTER*.

4 Click OK.

Renaming a Display Representation

Use this procedure to rename a display representation. You can rename any display representation that you create as well as some that are provided in AutoCAD Architecture templates. You cannot rename predefined display representations.

1 Click Format menu ► Display Manager.

2 Expand Representations by Object.

3 Select the object for which to rename a display representation.

4 Right-click the display representation to rename, and click Rename.

If Rename is unavailable on the shortcut menu, the display representation is predefined.

Predefined display representations have this icon  next to their names.

5 Enter the new name, and press *ENTER*.

6 Click OK.

Deleting a Display Configuration or a Display Set

Use this procedure to delete a display configuration or a display set.

Keep the following points in mind when you delete display configurations or display sets:

- You cannot delete the display configuration assigned to the current viewport.
- You cannot delete predefined display configurations, indicated by a red check mark to the left of the configuration name.
- You cannot delete a display set used in a display configuration, nor can you delete the Standard display configuration.

NOTE Deleting a display configuration does not delete the display sets and display representations used in it. Deleting a display set does not delete the display representations used in it. For more information, see [Deleting a Display Representation](#) on page 573.

- 1 Click Format menu ► Display Manager.
- 2 Select a display configuration or a display set:

If you want to ...	Then ...
delete a display configuration	expand Configurations, right-click the display configuration, and click Delete.
delete a display set	expand Sets, right-click the display set, and click Delete.

- 3 Click OK.

Deleting a Display Representation

Use this procedure to delete a display representation that is not assigned to a display set. You can delete display representations that you create as well as some that are provided in AutoCAD Architecture templates. User-defined display representations have this icon  next to their names. You cannot delete predefined display representations. Predefined display representations have this icon  next to their names.

- 1 Click Format menu ► Display Manager.
- 2 Expand Representations by Object.
- 3 Select the object for which to delete a display representation.
- 4 To remove the display representation from all display sets, right-click the display representation, and click Clear All.
- 5 Right-click the display representation to delete, and click Delete.
You will receive an error message if you try to delete a predefined display representation or one that is assigned to a display set.
The name of the display representation deleted in the right pane is listed in the Representations by Object directory in the left pane until you close and reopen the Display Manager.
- 6 Click OK.

Adding Notes and Reference Files to a Display Configuration or a Display Set

Use this procedure to enter notes and attach reference files to a display configuration or a display set. You can also edit notes and edit or detach reference files.

- 1 Click Format menu ► Display Manager.
- 2 Select a display configuration or a display set:

If you want to ...	Then ...
add notes or files to a display configuration	expand Configurations, and select the display configuration.
add notes or files to a display set	expand Sets, and select the display set.

- 3 Click the General tab.
- 4 To add a description to the display configuration, enter it for Description.
- 5 Click Notes.

6 To add a note, click the Notes tab, and enter the note.

7 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

8 Click OK twice.

Using Display Settings in Multiple Drawings

You can use your display configurations, display sets, and display representations in multiple drawings.

You can copy display configurations, display sets, and display representations between drawings. When you copy a display configuration, the display system also copies any display sets and display representations included in the selected configuration that do not exist in the destination drawing. Similarly, if you copy a display set, the display system copies any display representations that do not exist in the destination drawing.

If a display set or a display representation with the same name exists in the destination drawing, it is not overwritten with the new display information. To transfer the new information, rename the existing display set or representation in the destination drawing before copying display configurations or display sets.

For example, you might want to copy a display set named New Reflected, which contains a display representation for doors named Reflected Screened. The current drawing also contains a display representation for doors named Reflected Screened. You must rename the Reflected Screened display representation in the current drawing before copying the new display set and its display representations.

Emailing Display Configurations

If your system has email, you can email display configurations to other users from the Display Manager. You can send the entire display system in your drawing to another user of AutoCAD Architecture. The Display Manager copies the display system information to a new drawing, and attaches the drawing to a new email message created using your email program. Users of AutoCAD Architecture who receive your display system by email can import it into their drawings, open the attached drawing file, and export your display system to their drawings; or they can use the attached drawing file as a template for new drawings. For further information about importing and exporting display systems, see [Sending Display Configurations to Other Users](#) on page 576.

Copying Display Settings Between Drawings

Use this procedure to copy display configurations, display sets, and display representations from the current drawing to another drawing. You can copy display settings between existing drawings. You can also copy them from an existing drawing to a new drawing.

NOTE You can also drag and drop display configurations, display sets, and display representations between drawings.

1 Click Format menu ► Display Manager.

The Display Manager is displayed, with the current drawing expanded in the tree view. Any drawings open in the current session are also shown in the tree view.

2 In the Display Manager, open the drawing into which you want to copy the display representation, display set, or display configuration, if necessary:

If you want to...	Then...
copy the display configuration, display set, or display representation to a drawing that is not open in the Display Manager	in the Display Manager, click File ► Open, select the drawing you want, and click Open.
copy the display configuration, display set, or display representation to a new drawing	in the Display Manager, click File ► New drawing, enter a name for the drawing, and click Save.

3 Expand the Configurations, Sets, or Representations by Object folder.

4 Select the display configurations, display sets, or display representations that you want to copy:

If you want to...	Then...
copy an individual display configuration, display set, or display representation	right-click the display configuration, display set, or display representation, and click Copy.
copy all display configurations, display sets, or display representations	right-click the Configurations, Sets, or Display Representations folder, and click Copy.

5 Right-click the drawing into which you want to paste the display settings, and click Paste.

The display configurations, display sets, or display representations are pasted into the selected drawing. If the drawing already contains a setting with the same name, the duplicate name is displayed in the Import/Export - Duplicate Names Found dialog box.

6 Resolve duplicate names, if prompted:

If you want to...	Then...
prevent the Display Manager from overwriting the existing display configuration, display set, or display representation with the new item of the same name	select Leave Existing, and click OK.
replace the existing display configuration, display set, or display representation with the new item	select Overwrite Existing, and click OK.
keep the existing display configuration, display set, or display representation and add the new item with a different name	select Rename to Unique, and click OK. The Display Manager appends a number to the name of the new setting. Right-click a setting, and click Rename to change the name.

7 Click OK.

Sending Display Configurations to Other Users

Use this procedure to email all the display configurations and their elements in a drawing to other users of AutoCAD Architecture. The software creates a new drawing that contains only the display information from the current drawing and attaches the drawing to an email message. Objects, layers, and other drawing content and settings are not included in the new drawing.

- 1 Click Format menu ► Display Manager.

- 2 Right-click the drawing name, and click Send.

An email message with the subject “ADT Display System,” is created using your email program. A drawing file containing the display information is attached to the message.

If email is not available on your system, the Send option is not available.

- 3 Complete and send the message in your email program.

- 4 Click OK.

Purging a Display Configuration

Use this procedure to purge unused display configurations from a drawing.

You cannot purge a display configuration assigned to a viewport or model space, or predefined display configurations such as Standard.

- 1 Click Format menu ► Display Manager.

- 2 Right-click Configurations, and click Purge.

All display configurations that you can purge are selected in the Purge Display Configurations dialog box.

- 3 Clear any display configurations that you do not want to purge, and click OK twice.

Purging a Display Set

Use this procedure to purge unused display sets from a drawing.

You cannot purge a display set assigned to a display configuration, or predefined display sets such as Standard, Model, or Plan.

TIP To find out if a display set is assigned to any display configurations, select Configurations in the left pane. The right pane lists each display configuration and the display sets it uses.

- 1 Click Format menu ► Display Manager.

- 2 Right-click Sets, and click Purge.

All display sets that you can purge are selected in the Purge Display Sets dialog box.

- 3 Clear any display sets that you do not want to purge, and click OK twice.

Purging a Display Representation

Use this procedure to purge unused display representations from a drawing. You cannot purge a display representation assigned to a display set, or predefined display representations such as Model or General.

- 1 Click Format menu ► Display Manager.

2 Expand Representations by Object.

3 Select the display representations to purge:

If you want to ...	Then ...
purge unused display representations for a specific object	right-click the object name, and click Purge.
purge all unused display representations in the drawing	right-click Representations by Object, and click Purge.

All display representations that you can purge are selected in the Purge Display Representations dialog box.

4 Clear any display representations that you do not want to purge, and click OK twice.

Working with Standard Display Settings

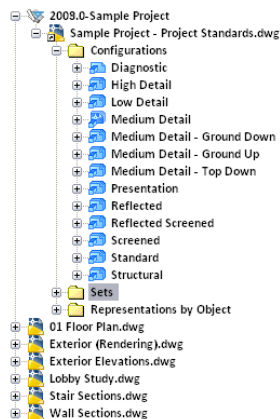

The Project Standards feature provides a mechanism for users to establish, maintain and synchronize display settings across an AutoCAD Architecture project. Within a project, you can define standard display settings that are used across all project drawings.

For more information about projects and project standards, see [Drawing Management](#) on page 217 and [Project Standards](#) on page 409.

Standard display settings are organized in a standards drawing that is assigned to the project. Once a group of display settings have been defined as project standard settings, and introduced in the project drawings, they have a link to the standards and can be synchronized with them. With the same link, display settings from a project drawing can update the standard display settings, too.

Standard display settings can be accessed, edited, synchronized, copied, and updated in Display Manager.

Standard settings in Display Manager

Standard Icons

Standard display settings are displayed in Display Manager. Depending on their status with regards to the project standards, there are a number of different icons to differentiate them.

Icon	Description
	<p>Standard display setting</p> <p>When a light blue icon appears on a display setting in a project drawing or project standards drawing, the display setting is a standard setting and is in synch with the standard. No update or synchronization is necessary.</p>
	<p>Standard display setting that is outdated</p> <p>When this icon appears on a display setting in a project drawing, the display setting is a standard setting, but is out of date. This means that the corresponding display setting in the project standards drawing has a newer GUID than the one in the project drawing. To update the display setting in the project drawing, see Synchronizing Individual Display Settings with AEC Standards on page 451.</p>
	<p>Standard display setting that has a non-standard (newer) version</p> <p>When this icon appears on a display setting in a project drawing, the setting is a standard setting, but has a version GUID that cannot be found in the project standards. If you encounter this icon, you can either overwrite the non-standard version with the current version from the standards drawing, as described in Synchronizing Individual Display Settings with AEC Standards on page 451, or you can update the standards with the version from the project drawing, as described in Updating Standard Display Settings in the Project Standards Drawing from a Project Drawing on page 581.</p>
	<p>Standard display setting that is excluded from synchronization</p> <p>When this icon appears on a display setting, the setting is excluded from synchronization. For more information, see Excluding Display Settings from Synchronization on page 579.</p>
	<p>Standard display setting that has no version information</p> <p>When this icon appears on a display setting in a project standards drawing, the display setting has no version information. Version information can be deleted, as described in Purging the Version Information from a Project Standards Drawing on page 467.</p> <p>To add version information to a display setting, see Updating Standard Display Settings in a Project Standards Drawing on page 579.</p>
	<p>Standard display setting that has been changed, but not versioned</p> <p>When this icon appears on a display setting in a project standards drawing, the setting has been modified, but not versioned yet. In order for the changes to be included in the synchronization, the setting must be versioned, as described in Updating Standard Display Settings in a Project Standards Drawing on page 579.</p> <p>This icon appears only in project standards drawings. Changes in project drawings are versioned automatically when you click Apply or OK in Display Manager.</p>
	<p>Not standardized display setting</p> <p>When a dark blue icon appears on a display setting in a project drawing, this setting has no equivalent in the project standards.</p>

Synchronizing Individual Display Settings with AEC Standards

Use this procedure to synchronize display settings in a project drawing with the project standards.

- 1 Open a project drawing.
For more information about projects and project standards, see [Drawing Management](#) on page 217 and [Project Standards](#) on page 409.
- 2 On the Format Menu, select Display Manager.
- 3 In the Display Manager tree, navigate to the display setting you want to synchronize.
You can synchronize the following items:
 - display configurations
 - display sets
 - display representations
- 4 Select the item in the tree, right-click, and select Synchronize with Project Standards.
- 5 In the Synchronize Drawing with Project Standards dialog box, select the items to synchronize, as described in [Synchronizing a Project Drawing with AEC Standards](#) on page 446.
- 6 Click OK to start the synchronization process.

Excluding Display Settings from Synchronization

Use this procedure to specify individual display settings that you want to be ignored during synchronization.

Specified display settings will not be overwritten with standards during automatic synchronization and will not be displayed as version mismatches during semi-automatic or manual synchronization, unless you select the Show objects set to ignore during project standards synchronization check box in the Synchronization dialog box.

- 1 Click Format menu ► Display Manager.
- 2 Navigate to the display configuration, display set, or display representation to be excluded, right-click, and click Ignore During Synchronization.
Note that the Ignore During Synchronization option now has a check mark next to it. If you click the option again, the check mark disappears and the selected display setting is removed from the list of components to be ignored.

Updating Standard Display Settings in a Project Standards Drawing

Use this procedure to change and version a standard display setting in the project standards display drawing.

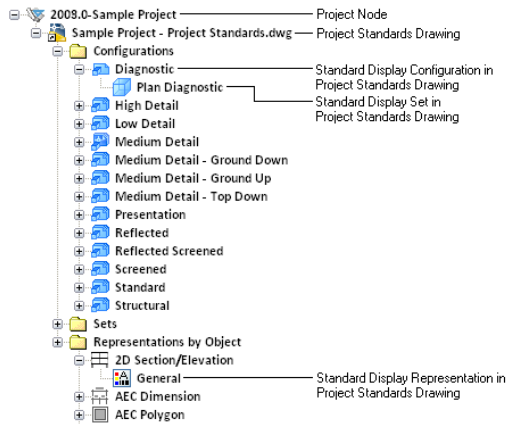

Display settings in the project standards display drawing and in the project drawings are versioned. The version is used to determine whether a display setting needs to be updated during synchronization. The version information includes the GUID (Global Unique Identifier), the date and time of the last modification, the windows login name of who last modified the item, and an optional comment.

When you change a standard display setting in the open standards drawing, you are not automatically prompted to version the change. You can make multiple changes, save and close the drawing, reopen it, and then version the display setting when it is ready for propagating in the project. As long as the changes are saved to the project standards drawing, no edits will be lost, even without versioning in between.

NOTE When you make changes to the display standards drawing, you need to update the standard styles drawings with the new setting as described in [Synchronizing Project Standards with Each Other](#) on page 585. Otherwise, inconsistent display of objects might occur.

As long as your changes are saved, but not versioned, any synchronizations taking place during that time will not recognize the display settings as changed, since the object comparison is performed on the version GUID, and not the actual object properties. As a consequence, changed but unversioned display settings in the project standards will not be updated in the project drawings. To have the changes synchronized with the project, you need to version the display settings first.

Project standards in Display Manager

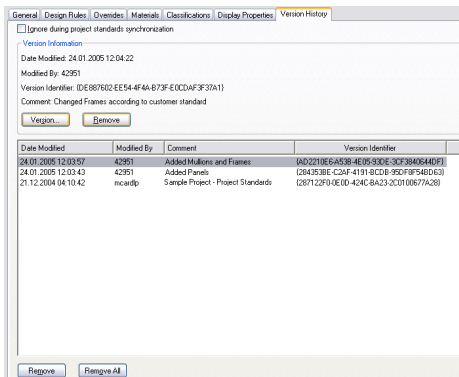

Updating a standard display setting

- 1 Open the standards display drawing of the current project.
- 2 Click Format menu ► Display Manager.

TIP The standard display drawing in Display Manager are listed under the project node (). If no project node is displayed, the current drawing is not part of a project.

- 3 Select the display setting you want to edit, and make your changes.
- 4 Click the Version History tab of the changed display setting.

5 Click Version.

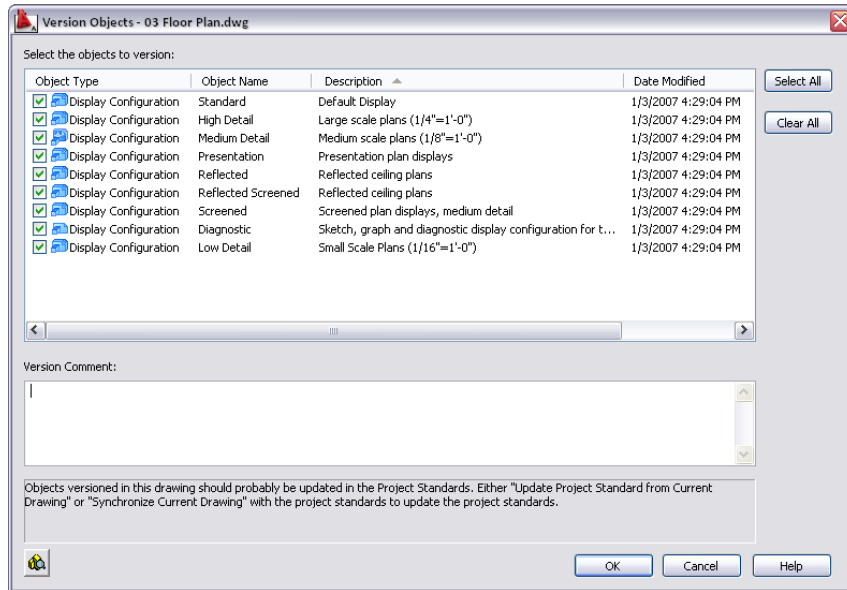

6 If necessary, enter a comment for the new version.

7 Click OK.

The new version is appended to the Version History tab.

8 To version multiple display settings in a project standards drawing, select a group of settings and version them:

9 Select the display settings that should be versioned.

10 If desired, enter a comment.

The comment will be applied to all objects selected for versioning.

11 Click OK.

Updating Standard Display Settings in the Project Standards Drawing from a Project Drawing

You can change a standard display setting in the project standards display drawing by overwriting it with the corresponding display setting from a project drawing. When you have updated a project standard display setting from a project drawing, the project needs to be synchronized to use the updated display setting. For information, see [Synchronizing a Project with the Standards](#) on page 440.

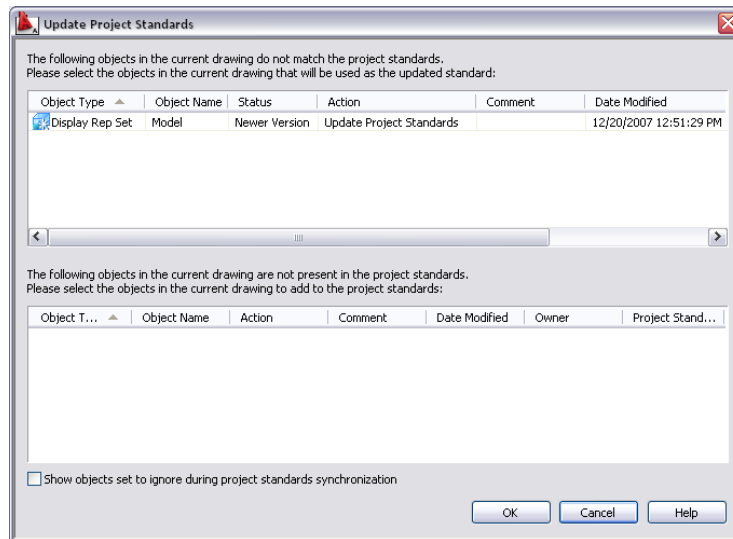

NOTE When you make changes to the display standards drawing, you need to update the standard style drawings with the new setting as described in [Synchronizing Project Standards with Each Other](#) on page 585. Otherwise, inconsistent display of objects might occur.

- 1 Open a project drawing.
- 2 Click Format menu ► Display Manager.
- 3 Expand the node of the project drawing, and select the standard display setting with which you want to update the project standards.

NOTE A standard display setting in a project drawing can be recognized by a blue icon.

- 4 Right-click, and click Update Standards from Drawing.

NOTE You can also select to update multiple display settings here.

The selected display setting is listed in the top panel.

- 5 To update the project standards from the project drawing, select Update Project Standards from the Action drop-down list of the display settings.
- 6 To not update the project standards from the display setting in the project drawing, select Do not Update Project Standards from the Action drop-down list of the display settings.

In this case, the version in the project standards drawing is not overwritten with the version in the project drawing. During the next synchronization of the project drawing, the display setting will be displayed as out of synch with the project standards.

- 7 To ignore the out of synch version of the display setting, select Ignore from the Action drop-down list.

In this case, the item will not be displayed in future updates, except when you select Show objects set to ignore during project standards synchronization or remove the Ignore flag from the display setting in Display Manager, as described in [Excluding Display Settings from Synchronization](#) on page 579.

- 8 Click OK.
- 9 In Display Manager, click OK or Apply.
- 10 Click Yes to save the updated project standards drawing.

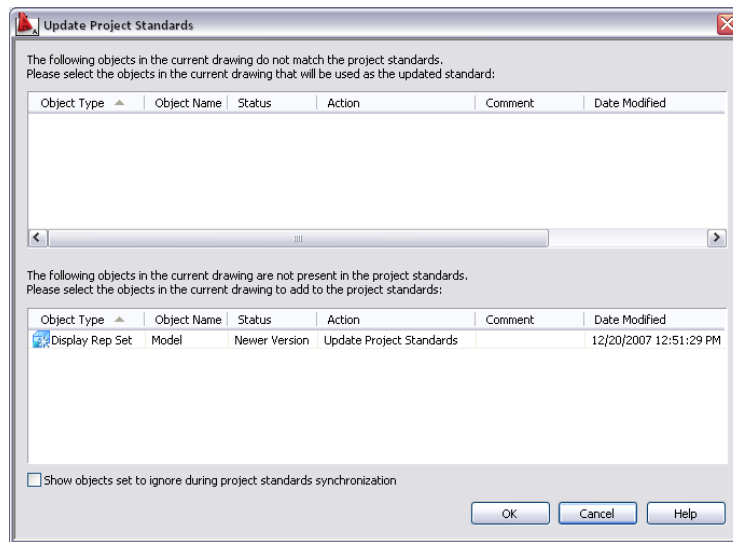

Adding Standard Display Settings from a Project Drawing to a Project Standards Drawing

You can add not standardized display settings from the current project drawing to the project standards. You can do this, for example, if you have created a complex display configuration in a project drawing and want to include that into your standards.

After copying a display setting to the project standards, you need to synchronize the project to use the new standard setting.

- 1 Open a project drawing from Project Navigator.
- 2 Click Format menu ► Display Manager.
- 3 Add a new display setting to the current project drawing.
- 4 Select the new setting, right-click, and click Update Standards from Drawing.

NOTE You can select multiple display settings here.

The new setting is listed in the lower panel, which displays styles and display settings in the project drawing that do not exist in the project standards.

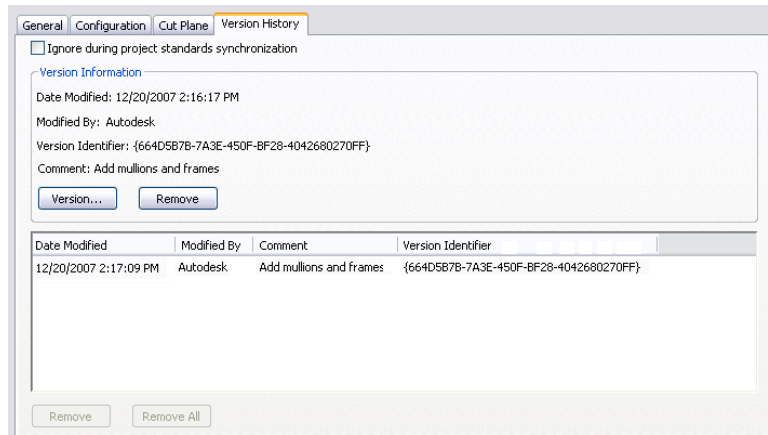

- 5 To add the display setting to a project standards drawing, and thereby make it a standard setting, select Add to Project Standards in the Action drop-down list.
- 6 To skip over the not standardized display setting, select Skip from the Action drop-down list. In this case, the not standardized display setting remains in the project drawing, and is not entered in the standards.
- 7 To ignore the display setting, select Ignore from the Action drop-down list. In this case, the not standardized display setting will not be listed again in future updates, except if you select Show objects set to ignore during project standards synchronization or remove the Ignore flag from the display setting in Display Manager, as described in [Excluding Display Settings from Synchronization](#) on page 579.
- 8 Click OK.
- 9 In Display Manager, click OK or Apply.
- 10 Click Yes to save the updated project standards drawing.

Editing the Version History of a Standard Display Setting

Each display setting in a project standards drawing has a version history. The version history displays the unique version identifier, date and time of the modification, user name and any additional comments entered by the user.

You can edit the history by selectively removing individual versions, or removing all versions. You cannot remove the current version.

- 1 Open a project standards drawing.
- 2 Click Format menu ► Display Manager.
- 3 Select a standard display setting from the project node.
- 4 Click the Version History tab.

- 5 To add a new version, click Version, and enter the versioning information.
- 6 To remove an existing version, select the version from the Version History list, and click Remove.
To remove all versions in one step, click Remove All.
- 7 If you want the display setting to be ignored during synchronization of standards, select Ignore during project standards synchronization.
- 8 Click OK.

Purging the Version History from a Project Standards Drawing

You can remove the version history from all standard styles and display settings in a project standards drawing with one command. Purging the version history will remove all versions except the current one from the standard styles and display settings. You can do that to avoid cluttering your styles and display settings.

When you purge the version history, no version GUID except for the current one remains. That means that the synchronization can no longer separate between an older version of a standard display setting and a non standard version of a standard display setting. Each display setting in a project drawing that does not have the current GUID of the corresponding standard display setting, will be labeled a “non-standard”, or newer version.

- 1 Open the project standards drawing.
- 2 On the command line, enter **AecClearVersionHistory**.
The version history is removed from all standard styles and display settings in the drawing.

Purging the Version Information from a Project Standards Drawing

You can remove the version information from all standard styles and display settings in a project standards drawing. When you remove the version information, the version history and the current version information is deleted.

When you run a synchronization, the standard style or display setting still participates in the synchronization and is considered the “latest version” when comparing with versions of the object in project drawings. No attempt is made during synchronization to automatically create a version GUID or history list. If you want to add version information to the standard style or display setting, you need to manually version the object as described in [Updating Standard Objects in a Project Standards Drawing](#) on page 461.

- 1 Open the project standards drawing from which you want to remove the version information.
- 2 On the command line, enter **AecPurgeVersion**.

The version information is removed from all standard styles and display settings in the drawing.

Synchronizing Project Standards with Each Other

Project standard styles and display settings can be distributed among multiple standards drawings, and depend on each other. For example, the styles in a styles drawing should use the display settings from the standard display drawing. If display changes are introduced in a standard styles drawing, and not synchronized with the standard display drawing, styles can display inconsistently across the project. Therefore, you should synchronize project standards drawings with each other when changes have been made to individual standards drawings.

You can synchronize project standards drawings with each other either from the project node in Display Manager or from the CAD Manager menu.

When project standards drawings are synchronized with each other, the following criteria are used to determine how the components are updated:

- Standards drawing type: The display settings in the standard display drawing update the display settings in all standard styles drawings.
- Assigned style types: When a drawing has in the standards configuration setup been associated to a style type, the styles in this drawing will update all other standards drawings that may contain standard styles of that type. For example, if the standards drawing “Door Styles.dwg” has been associated with the Door style type, the styles in that drawing will overwrite any existing door standard styles in all of the other standards drawings. Note that in most cases, you will not place standard styles anywhere but in the designated standards drawing for that style type.
- Search order: When more than one standards drawings in the standards configuration setup have been associated to a style type, the first standards drawing in the search order will update all other drawings associated to that style type.

Synchronizing project standards drawings with each other is an automatic synchronization process, where no user interaction is possible. That means that no styles or display settings can be excluded from the synchronization process.

- 1 Verify that the project of which you want to synchronize the standards is the current project.
- 2 On the Format Menu, click Display Manager.
- 3 Select the Project Standards node in the tree view, right-click, and click Synchronize Project Standards Drawings.
- 4 When the synchronization is finished, click OK to exit Display Manager.

NOTE Alternatively, you can click AEC Project Standards ► Synchronize Project Standards on the CAD Manager menu. If the CAD Manager menu does not appear in your menu bar, click Windows ► Pulldowns ► CAD Manager Pulldown.

Troubleshooting the Display System

If you have problems displaying objects in your drawing, use the following troubleshooting suggestions.

Object Not Displayed in a Viewport

Why isn't my object displayed?

When AEC objects in your model do not display correctly in a viewport, the following actions might help to solve the problem.

- In the drawing status area, verify the name of the selected display configuration. Select a different display configuration, and see if the problem is resolved.
- In the Display Manager, find out what display set is being used in the display configuration assigned to the viewport in question. The name of the current display configuration is highlighted. The name of the current display set is also highlighted.
- In the detailed view of the display sets in the Display Manager, make sure that a display representation for the object is selected in that display set.
- Is the object hidden because objects of its classification are filtered in the current display set? On the Display Options tab, verify that objects are not hidden.
- If a display representation is selected in the current display set, look at the display properties of the display representation. Are the display components turned off? Are components on layers turned off?
- Is the display of components controlled by the material assigned (is ByMaterial selected in the display properties)? If so, look at the display properties of the material assigned to object components to determine the settings.
- Is the object drawn on a layer that is turned off?

Viewport Not Updating Properly

Why isn't my viewport updating?

Under certain circumstances, such as when you switch view directions in shade modes other than 2D wireframe, the display is not restored correctly.

In such cases, enter **objrelupdate** on the command line, and either select the problem AEC object or press *ENTER* to select all the AEC objects. This forces the display system to regenerate all the current display representations.

Objects Copied from Another Drawing Display Differently

I dragged objects to another drawing. Why do they look different now?

Objects dragged or copied from one drawing to another use the display properties of the display configuration assigned to the viewport in the destination drawing. The display configuration in the original drawing is not copied with the objects.

Verifying the Existence of Objects Not Displayed in a Drawing

Is there a quick way to verify that an object exists in a drawing but is not displayed?

Enter `DisplayDxfName` on the command line to label each object in the drawing with its name. Labels appear even for objects that are not displayed. For example, if you created a display set that did not include a display representation for doors, and you then assigned the display set to a display configuration used in the current viewport, doors would not be displayed in that viewport. An object can also exist in a drawing and not be displayed if the object was filtered by its classification in the current display set.

`DisplayDxfName` can help you determine whether the objects are simply not displayed or if they are not present.

1 At the command line, enter `displaydxfname`.

2 Enter `y` (Yes).

3 Enter `rea` (Regenerate All).

Displaying the names of objects, including those that are not shown

4 To turn off object names, enter `displaydxfname`.

5 Enter `n` (No).

Object Linetype Displayed Incorrectly

Why doesn't the linetype for my object display the way I expect?

The linetype scale for components of AEC objects works with the AutoCAD linetype scale specified in the `LTSCALE` variable to control the linetype of AEC objects. The default value for linetype scale of all components of AEC objects is 1.0. This value is multiplied by the current value for `LTSCALE` to produce the linetype scale of object components.

For example, if the `LTSCALE` value is 48.0, and the linetype scale in the display properties of an object is 1.0 for an object component, then the linetype scale of the component is 48.0. If you change the linetype scale in the display properties to 2.0, the linetype scale of the component is effectively 96, or 2.0 x 48.

Style Manager

The Style Manager is a utility that provides a central location in AutoCAD Architecture where you can view and work with styles in drawings or from intranet sites.

Style Manager

The Style Manager is a utility that provides a central location in AutoCAD Architecture where you can view and work with styles in drawings or from intranet sites.

Styles

Styles are sets of parameters that determine the appearance or function of objects in AutoCAD Architecture. For example, a door style determines the type of door represented in a drawing, such as single or double, bi-fold or hinged. The door style also determines the shape of the door, such as rectangular or arched, as well as default frame dimensions, standard sizes, and display properties.

You assign a style to all instances of an object that are to have the same characteristics. For example, you could assign one door style to all office doors in a building and another door style to all fire doors in the building.

Objects in the software that use styles include two-dimensional (2D) sections and elevations, AEC polygons, curtain walls, curtain wall units, doors, endcaps, mass elements, openings, railings, roof slab edges, roof slabs, schedule tables, slab edges, slabs, spaces, stairs, structural members, wall modifiers, walls, window assemblies, and windows.

Using the Style Manager, you can also manage layer key styles, schedule data formats, and definitions for cleanup groups, mask blocks, multi-view blocks, profiles, and property sets.

NOTE To view layer key styles in the Style Manager, run a Layer Management command (Layer Manager, Layer Key Styles, or Layer Key Overrides) before you display the Style Manager.

Using the Style Manager

The Style Manager allows you to readily create, customize, and share styles with other users. In the Style Manager, you can perform the following tasks:

- Access styles from open drawings and intranet sites
- Drag styles onto a palette to create tools

- Set up new drawings and templates by copying styles from other drawings or templates
- Sort and view the styles in your drawings and templates by drawing or by style type
- Preview an object with a selected style
- Create and edit styles
- Delete unused styles from drawings and templates
- Send styles to other AutoCAD Architecture users by email

Standard and Predefined Styles

Most of the objects in AutoCAD Architecture have a default standard style. Catalogs provided with the software contain additional predefined styles that you can copy to tool palettes to use in your drawings.

You can also access the styles for bar joists, curtain walls, doors, members, railings, roof slabs, slabs, spaces, stairs, walls, and windows, as well as property set definitions and schedule tables from drawings located in the `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial or Metric` folder. For more information about specifying the location of files at installation, see “Install AutoCAD Architecture 2009” in the *AutoCAD Architecture 2009 Installation Guide*.

Creating Tools from Styles

You can create object tools by dragging a style from the Style Manager to a tool palette. When you drag a style onto a tool palette, a reference is created that associates the tool to the style. The reference location can be the current drawing, another drawing, or a remote location. If you edit the style in the Style Manager, the tool automatically uses the updated style.

If an existing tool references a style from another drawing, the style is not added to the current drawing until you add an object of that style to the drawing. The reference location is used only if the current drawing has been saved.

Upgrading from a Previous Release

If you are upgrading from Release 1 or Release 2 of Autodesk Architectural Desktop, the Style Manager replaces the Style dialog box used for creating, copying, editing, purging, importing, and exporting styles.

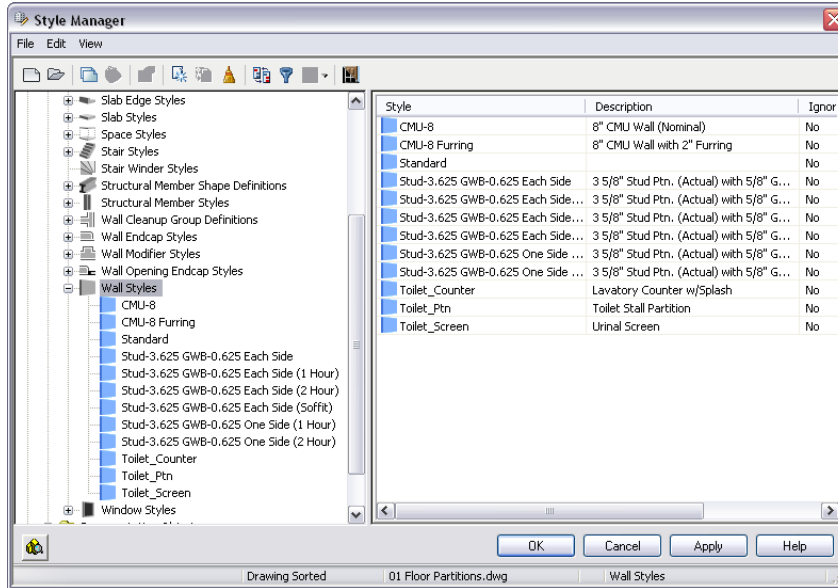

Styles in External References

You cannot change an object style in an external reference while refediting it from its host drawing. You can open Style Manager and make changes, but they will not be saved when the external reference is saved and closed in the host drawing. To make changes to styles in external references, you need to open the external reference drawing directly, make the changes there, and save it. The external reference should then be reloaded to update the changes.

Getting Started with the Style Manager

When you open the Style Manager, style information from all open drawings and templates is displayed. The Style Manager is split into two resizable panes and has a menu bar, a toolbar, and a status bar.

The Style Manager

Left Pane of the Style Manager

The left pane of the Style Manager displays the styles in all open drawings and templates in a hierarchical tree view that you can navigate by expanding and collapsing the different levels in the tree. You can sort styles in the tree view by the drawing that contains them or by style type. The tree view is always displayed in the left pane, regardless of how you sort the styles.

Styles are organized into three categories: Architectural Objects, such as Door Styles; Documentation Objects, such as Schedule Table Styles; and Multi-Purpose Objects, such as Layer Key Styles. Within each category, styles are listed alphabetically.

Right Pane of the Style Manager

The style information displayed in the right pane depends on what you select in the tree view in the left pane. You can preview how an object is displayed with a style, view style descriptions, view drawing information, and view the distribution of styles of a selected type across multiple drawings and templates.

Style Manager Menu Bar and Toolbar

The top of the Style Manager includes a menu bar and a toolbar that enable you to quickly access the menu commands. If you position your mouse over a toolbar icon, a tooltip identifies the icon.

Status Bar

The status bar at the bottom of the Style Manager indicates how styles are sorted in the tree view. The status bar also lists the drawing and style type or style currently selected.

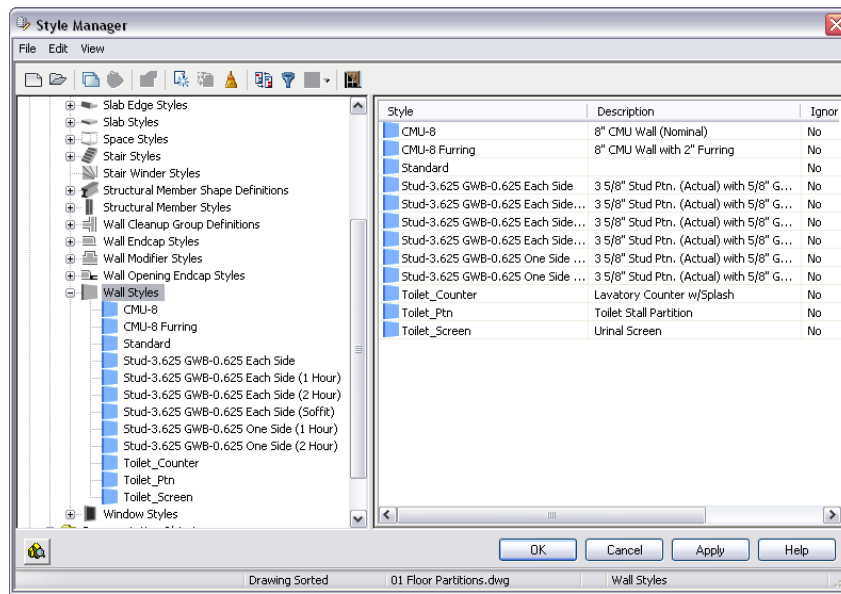

Opening the Style Manager

Use this procedure to open the Style Manager. You also access the Style Manager when you right-click object tools on the tool palettes.

When you open the Style Manager, all drawings and templates that are open in the current session are displayed in the tree view.

1 Click Format menu ► Style Manager.

The Style Manager

NOTE If drawings or templates are read-only, their read-only status is indicated by a lock on the folder next to the drawing in the tree view and also by a lock icon on the status bar.

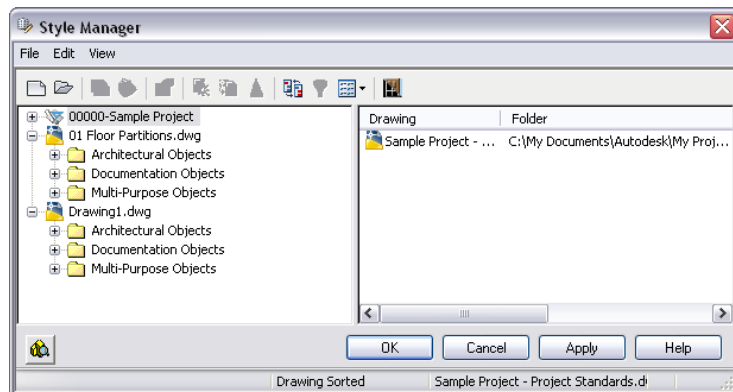

2 Move and resize the Style Manager, or resize the left and right panes as needed to view style information.

Sorting Styles in the Style Manager

Use this procedure to sort information in the Style Manager by drawing and by style. When you open the Style Manager, the names of open drawings and templates are displayed in the tree view in the left pane.

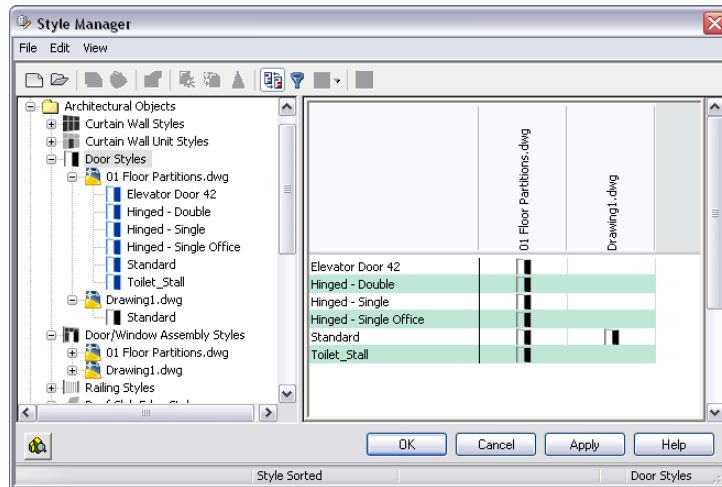

When you expand a drawing in the tree view, the individual styles within the drawing are grouped into three categories: Architectural Objects, Documentation Objects, and Multi-Purpose Objects. If you expand a category, the individual styles are listed alphabetically by style type.

Sorting styles by drawing in the Style Manager

To see the styles available in each drawing for a particular style type, such as door styles, you can sort the styles by style type. In sorted view, styles are grouped by category, and organized by type and then by drawing.

Sorting styles by style type

The status bar at the bottom of the Style Manager indicates whether the styles are sorted by drawing or by style type.

- 1 Click Format menu ► Style Manager.
By default, styles are sorted by drawing.
- 2 On the View menu, click Explore ► By Style.
- 3 Expand a category, a style type, and then a drawing to view the styles available in each drawing.
- 4 On the toolbar, click  to restore the by-drawing sort order.
- 5 Click  again to sort the styles by style type.

Viewing Styles in the Style Manager

Use this procedure to preview how objects appear in selected styles and to view style descriptions. You can also filter styles to view only a selected type, such as wall styles.

NOTE Certain structural member styles do not display properly in the Style Manager Viewer or the Floating Viewer. This is because the “sample” member that displays in the viewer is a single segment that is relatively short. If a structural member style uses large start and end offsets (such as some of the Bar Joist sample styles) or requires multiple segments (such as a bent member), the viewer displays a defect marker. If properly defined, the member displays correctly when added to the drawing.

- 1 In the Style Manager, expand the category and the style type that you want to view.
- 2 Select a style.
- 3 In the right pane, click the Viewer tab.
The object is displayed in the viewer with the characteristics of the selected style. Use the viewer control to see the object from different view directions and in wireframe, hidden, and shaded views.
- 4 Click the List tab to view information about the style.
The style description is generated by the AutoCAD LIST command.

- 5 To view the styles of only one style type, select a style type, and in the toolbar, click  .
Only the styles of the selected type, such as wall styles, are displayed in the Style Manager.
- 6 Click  again to display all styles.

Viewing Styles Across Multiple Drawings

Use this procedure to display a chart view of the styles of a single style type distributed across the drawings open in the Style Manager. In the chart, you can see the styles used in more than one drawing and the styles used only in a single drawing.

- 1 In the Style Manager, sort the styles by style type.
- 2 In the tree view, click the style type with the styles that you want to view the drawings.
In the right pane, a matrix lists the styles of the selected type that are available in each drawing.
- 3 In the left pane, select a style.
- 4 In the right pane, click the Viewer tab.
The object is displayed in the viewer with the characteristics of the selected style. Use the viewer control to see the object from different view directions, and in wireframe, hidden, and shaded views.
- 5 Click the List tab to view information about the style.
The style description is generated by the AutoCAD LIST command.
- 6 To view only the styles of one style type, select a style type, and in the toolbar, click  .
Only the styles of the selected type—such as wall styles—are displayed in the Style Manager.
- 7 Click  again to display all styles.

Working with Drawings and Templates in the Style Manager

When you first open the Style Manager, any drawings or templates that are open in AutoCAD Architecture are displayed in the tree view. You can open other drawings or templates and create new drawings or templates within the Style Manager.

Opening Drawings in the Style Manager

When you create a new drawing or template, or open an existing drawing or template within the Style Manager, that drawing or template is open for use within the Style Manager only, and not in your drawing session. You can open the drawing in the software after you exit the Style Manager.

Determining the Status of a Drawing

You can identify whether a drawing or template is open in the software or open only within the Style Manager. The icon next to the drawing or template in the tree view indicates its status in the Style Manager:

Drawing icon	Drawing status
	Drawing is open in the software and in the Style Manager.

Drawing icon	Drawing status
	Drawing is open only in the Style Manager.
	Drawing is locked.

A drawing may be locked in the Style Manager for the following reasons:

- The drawing is read-only.
- The drawing was created in a previous version of the software.
- The drawing is referenced into a drawing that is currently open.
- The drawing is open in another application (for example, Volo View).
- The drawing file is locked on a network.

Hold the cursor over Lock in the status bar to view a tooltip that states the reason for the lock.

TIP You can save your styles in a read-only source drawing and copy them to other drawings as necessary.

Closing Drawings in the Style Manager

Any drawings and templates that you create or open in the Style Manager are displayed every time you open the Style Manager until you close them from within the Style Manager.

Starting a New Drawing or Template in the Style Manager

Use this procedure to start a new drawing or template in the Style Manager. The new drawing or template does not contain any styles and is open for use in the Style Manager only. It is not open in the AutoCAD Architecture session. You can open the drawing in the software after you exit the Style Manager.

- 1 Click Format menu ► Style Manager.
- 2 In the Style Manager, click File ► New Drawing, or on the Style Manager toolbar, click .
- 3 Under File Name, enter the new drawing name.
- 4 Under Save as Type, select Drawing (.*dwg*) to create a drawing, or select Drawing Template File (.*dwt*) to create a template.
- 5 Click Save.
- 6 Click OK.

Opening a Drawing or Template in the Style Manager

Use this procedure to open a drawing or template in the Style Manager. The drawing or template is open within the Style Manager only. It is not open in the AutoCAD Architecture session. You can open the drawing in the software after you exit the Style Manager.

If you open an Autodesk Architectural Desktop Release 1 or 2 drawing in the Style Manager, the drawing is opened as a read-only drawing.

- 1 Click Format menu ► Style Manager.

- 2 In the Style Manager, click File ► Open Drawing, or in the Style Manager toolbar, click .
- 3 Select one or more files, and click Open.
- 4 Click OK.

Dragging a Drawing into the Style Manager

Use this procedure to open a drawing or template in the Style Manager by dragging it from Microsoft® Windows® Explorer. The drawing or template is open within the Style Manager only. It is not open in the AutoCAD Architecture session. You can open the drawing in the software after you exit the Style Manager.

- 1 In the Style Manager, sort the styles by drawing.
- 2 Start Microsoft Windows Explorer.
- 3 In Windows Explorer, select the drawing or template that you want to open in the Style Manager.
- 4 Drag the drawing into the tree view in the Style Manager.
- 5 Click OK.

Closing Drawings and Templates in the Style Manager

Use this procedure to close the drawings and templates open only in the Style Manager. You cannot close drawings in the Style Manager that are open in the AutoCAD Architecture session.

- 1 In the Style Manager, sort the styles by drawing.
- 2 Select the drawing or template that you want to close.
- 3 In the Style Manager, click File ► Close.
- 4 Click OK.

Creating a Style

Use this procedure to create a style. You can create a style using default style properties or by copying a style. After you create the style, you can edit its properties to customize the characteristics of the style.

A style is not stored in the drawing until you exit the Style Manager. A style is saved in a drawing when you save the drawing.

- 1 Click Format menu ► Style Manager.
The Style Manager is displayed with the current drawing expanded in the tree view.
- 2 Expand a category and then expand the style type for which you want to create a style.
- 3 Create a style:

If you want to...	Then...
create a style with default properties	right-click the style type, and click New.
create a style from an existing style	right-click the style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new style, and press *ENTER*.
- 5 Edit the new style.

For more information about creating a specific objects style or definition, see the style or definition topics associated with the object.

6 When you finish specifying the properties of the style, click OK twice.

After you have created a style, you can drag the style onto a tool palette to create a tool. For more information, see [Creating a Tool from a Style](#) on page 597.

Copying and Assigning a Style to an Object

Use this procedure to create a style based on an existing style, and assign it to an object.

You can, in one intuitive process, copy an existing object style, rename it, change the style properties as needed, and assign the new style to an object. This functionality will help you if you need to create many styles, or if you need to create templates and styles drawings.

1 In the drawing area, select an object with the style you want to copy.

2 Right-click, and click Copy <Object> Style and Assign.

For example, if you selected a wall, click Copy Wall Style and Assign.

3 Rename the object style.

By default, the original style name is incremented with a (2).

4 Change the properties of the new style as necessary.

For more information about changing the properties of an object style, refer to the appropriate section in the Help. For example, for information about wall styles, see [Wall Styles](#) on page 874.

5 Click OK.

The new style has been assigned to the object. You can access the new style in the Style Manager under the appropriate object style type.

Creating a Tool from a Style

Use this procedure to create a tool from a style. You can create tools from the following styles and definitions: AEC polygon, curtain wall, curtain wall unit, door, door/window assembly, mask block, mass elements, multi-view block, railing, roof slab, schedule table, slab, space, stair, structural member, wall, window, zone template, and zone.

For detailed information about creating and customizing tools, see the appropriate topic in the online Help.

1 Open the tool palette on which you want to create a tool.

2 Click Format menu ► Style Manager.

3 Locate the style you want to copy, and drag it to the tool palette.

The default tool name is the name of the referenced style.

The image that identifies the new tool uses the view direction last used in the Properties palette for the selected object type.

4 Click OK.

Renaming a Style

Use this procedure to rename a style.

- 1 In the Style Manager, right-click the style you want to rename, and click Rename.
- 2 Enter a new name for the style, and press *ENTER*.
- 3 Click OK.

Copying Styles Between Drawings

Use this procedure to copy styles or definitions from the current drawing to another drawing. You can copy styles and definitions between existing drawings. You can also copy them from an existing drawing to a new drawing.

If a style references other styles, those styles are also copied to the other drawing. For example, if you copy a wall style into a new drawing, the wall endcap style used in the wall style is also copied to the new drawing.

NOTE You can also drag and drop styles and style types between drawings.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view. Any drawings open in the current session are also shown in the tree view.

- 2 In the Style Manager, open the drawing into which you want to copy the style, if necessary:

If you want to...	Then...
copy the style to a drawing that is not open in the Style Manager	in the Style Manager, click File ► Open, select the drawing you want, and click Open.
copy the style to a new drawing	in the Style Manager, click File ► New drawing, enter a name for the drawing, and click Save.

- 3 Expand a category, and expand a style type.

- 4 Select the styles or definitions that you want to copy:

If you want to...	Then...
copy an individual style or definition	right-click the style or definition, and click Copy.
copy all styles or definitions of a selected type, such as all wall styles	right-click the style or definition type, and click Copy. If your styles are sorted by style type, right-click the drawing name under the selected style or definition type, and click Copy.

- 5 Right-click the drawing into which you want to paste the style(s), and click Paste.

The styles or definitions are pasted into the selected drawing. If the drawing already contains a style with the same name, the duplicate name is displayed in the Import/Export - Duplicate Names Found dialog box.

- 6 Resolve duplicate style names, if prompted:

If you want to...	Then...
prevent the Style Manager from overwriting the existing style with the new style of the same name	select Leave Existing, and click OK.

If you want to...	Then...
replace the existing style with the new style	select Overwrite Existing, and click OK.
keep the existing style and add the new style with a different name	select Rename to Unique, and click OK. The Style Manager appends a number to the name of the new style. Right-click a style, and click Rename to change a style name.

7 Click OK.

Sending Styles to Other Users

Use this procedure to email styles or definitions to other users of AutoCAD Architecture. The software creates a new drawing that contains only the style information from the current drawing and attaches the drawing to an email message. If email is not available on your system, the Send option is not available.

- 1 Click Format menu ► Style Manager.
- 2 Expand a category.
- 3 Select the styles or definitions you want to send:

If you want to...	Then...
send an individual style or definition	right-click the style or definition, and click Send.
send all styles or definitions of a selected type, such as all wall styles	right-click the style or definition type, and click Send. If your styles are sorted by style type, right-click the drawing name under the selected style or definition type, and click Send.
send all styles or definitions in the drawing (styles must be sorted by drawing)	right-click the drawing name, and click Send.

A new email message with the subject “ACA Styles” is created using your email program. A drawing file containing the styles and definitions you selected is added to the message as a file attachment.

- 4 Complete and send the message in your email program.
- 5 Click OK.

Purging Styles

Use this procedure to remove unused styles and definitions from a drawing. You can purge any styles that are not applied to an object in the drawing and that are not used in another style. You can purge a single unused style or definition. You can also purge all unused styles or definitions of a selected type. For example, you can purge all unused wall styles.

If a style references other styles or definitions, these are not purged when you purge the style that uses them. For example, if you purge a wall style, the wall endcap style and cleanup group definition used in the wall style are not purged.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view.

NOTE You can also purge a selected style or style type by pressing *DELETE*.

2 Expand a category, and expand a style type.

3 Purge styles or definitions:

If you want to...	Then...
purge one unused style or definition	right-click the style or definition you want to remove, and click Purge.
purge all unused styles or definitions of a selected type	right-click the style or definition type, and click Purge. When prompted, verify that the styles you want to purge are selected, and click OK.

If a style or definition you selected to purge remains in the list after purging, the style or definition is currently applied to an object or is used in another style. For example, you cannot purge a wall endcap style that is used in a wall style or that is applied to an individual wall.

4 Click OK.

Materials

12

A material in AutoCAD Architecture corresponds to a specific finish material in a building model, such as brick, concrete, or glass. Materials are useful for illustrating plans, sections, elevations, and renderings in the design process. Materials also provide a way to manage the display properties of object styles.

Materials

A material in AutoCAD Architecture corresponds to a specific finish material in a building model, such as brick, concrete, or glass. Materials are useful for illustrating plans, sections, elevations, and renderings in the design process. Materials also provide a way to manage the display properties of object styles.

Viewing a building model corner showing materials

Simplifying the Design Process

Using materials makes displaying objects more realistic. You define the display of a material, such as brick or glass, only once in the drawing or the drawing template, and then assign it to the component of an object where you want the material to display. For example, you can define a material “Glass” and then assign it to any number of windows, glass door insets or cubicle walls. You typically assign materials to components in the style of an object, such as the brick in a wall style. Then, whenever you add a wall of that style to your drawing, the brick of that wall displays consistently.

Defining materials in an object style can provide control for the display of objects across the whole project. When the characteristics of a material change, you change them just once in the material definition and all objects that use that material are updated. With the material tool you can apply a material to a single instance of the object.

Visual Styles and Render Materials

You can take advantage of Visual Styles, Rendering Materials, Lights, and Cameras in AutoCAD Architecture. In Content Browser, a Visualization catalog lets you access a number of predefined tools for lights, rendering materials, cameras, and visual styles. For more information about these visualization features, see “Create Realistic Images and Graphics” in the AutoCAD help.

Predefined Materials

AutoCAD Architecture provides a number of predefined material definitions for common design purposes, making it easy for you to start with new drawings. You can use these predefined material definitions “as is” or modify them to fit your designs. You can also create your own material definitions. Object styles provided with the software already have material definitions assigned to them.

Surface Hatching

Materials provide the ability to assign surface hatches to objects. Surface hatches can be displayed in model, section and elevation views. You can control the placement and orientation of the hatch for each object face.

Section Hatching

Materials are helpful to clearly illustrate sections and elevations. The section hatch is specified independently of the surface hatch. Special material components allow a realistic or schematic display of rendered live section views, section cuts, and section bodies.

For more information about live section views, see [Creating and Editing a Live Section View](#) on page 2165.

Rendered live section view with transparent outside material

Material Tool

You create a material tool from a material definition. You can then use this tool in the same way that you would use any other tool in your project. For more information about working with tools, see [Tools](#) on page 76. This is the most efficient method of applying a material definition to an object or the component of an object. For more information, see [Creating a Material Tool from a Material Definition in Style Manager](#) on page 606.

Objects That Support Materials

Objects to which you assign materials are typically three-dimensional (3D) objects. Two-dimensional (2D) objects, such as areas, grids, or AEC polygons, are more like symbolic representations and drawing aids than actual building objects.

Not all components of an object can take on a material definition. For example, a door swing is a symbolic graphic, therefore, it does not support a material assignment. The appearance of a door swing is specified in the display properties of a door style. The door frame, however, is a physical part of the door, and a material definition can be assigned to it.

Object	Components that support materials
Curtain Walls/Curtain Wall Units	infills, frames, mullions
Doors	frames, panels, stops, insets, muntins
Door/Window Assemblies	infills, frames, mullions
Mass Elements	mass element body
Mass Groups	mass group body
Railings	guardrails, handrails, bottom rails, posts, balusters
Roof	roof body
Slabs/Roof Slabs	slab body, slab edge, fascias slab, edge soffits
Space Boundaries	interior boundary, exterior boundary
Spaces	floor, ceiling
Stairs	tread, riser, landing
Structural Members	beam, brace, column body
Walls	wall body, wall shrinkwrap, wall components
Windows	glass, frames, sashes, muntins

Assigning Materials to Objects and Object Styles

The most efficient way to use materials is to apply them to a style. Any object of that style inherits those definitions or the relevant properties. As you add new objects of a style to your project, each will have the same materials assigned to them.

You can also assign materials directly to an object. You may want to do so in these cases:

- You want to override the existing material for a specific object.

- The object in question does not support styles, but does support materials. (This is the case for AEC polygons.)

Examples of Material Assignments

Assigning a material to components of an object will change how the object displays in plan, isometric, section, and elevation views.

For example, if you want to draw a brick exterior wall, you can assign a material that displays a brick surface hatch in model view and a realistic brick display for a rendered view.

Brick wall in hidden line and rendered views

If there are special insulation components in a wall, you can assign a light, half-transparent material to them. For sectioning the wall, you can assign a specific section hatch pattern or fill that differs from the regular brick surface hatch.

Section fill material in a rendering

In another example, you can assign materials to the floor and ceiling components of a space such as a carpet material to the floor and tile to the ceiling.

Working with Material Tools

You can apply materials to objects in 2 different ways:

- Assign material definitions to individual components of an object through the display properties of its style. For more information, see [Process Overview: Creating and Assigning Materials](#) on page 624.
- Use a material tool to apply a material definition directly to an object component in the drawing. For more information, see [Using the Material Tool to Add Materials to Objects](#) on page 605.
- Apply a render material from an AEC material definition to an AutoCAD object. For more information, see [Creating a Material Tool from a Render Material in the Content Browser](#) on page 607.

The Design tool palette includes the default Material tool, which references the Material Definitions file and allows you to apply any of those material definitions. Many of these material definitions can also be applied through material-specific tools located on the Materials tool palette in the Visualization palette group.

You can also create custom material tools from other existing tools, from material definitions in Style Manager, or from render materials in the Content Browser. For more information, see [Creating Custom Material Tools](#) on page 606.

Using the Material Tool to Add Materials to Objects

Use this procedure to configure the default Material tool and use it to apply an existing material definition to a component of an AEC object in a drawing. By default, the tool applies the Standard material definition, but you can modify the tool properties to specify any of the materials defined in the Material Definitions (Imperial).dwg or Material Definitions (Metric).dwg files.

- 1 Click Window menu ► Tool Palettes.
- 2 Click the Tool Palettes title bar, and click Design.

- 3 On the Design palette:

If you want to...	Then...
apply the Standard material definition	click the Material tool.
select a different material definition	right-click the Material tool, and click Properties. Expand Basic ► General, click the value for Definition name, and select the desired definition. Then click OK, and click the Material tool.

The cursor symbol changes to a small square. As you move it over an object component, the component highlights and a tooltip identifies the component and the material to be applied to it.

If a component does not support materials in the current view direction, does not support materials at all, or is in an xref, the tooltip informs you the material cannot be applied, and the cursor changes to a slashed red circle until you move it off that component.

NOTE For information about which objects can have materials assigned, see [Objects That Support Materials](#) on page 603.

- 4 Move the cursor over the object in the drawing until the desired component is identified in the tool tip, and then click to apply the material.
- 5 If you want the material to be applied to this component in all objects of this style, press *ENTER*. If you want it applied only to this component in the current object, enter **O**, and press *ENTER*. (Applying the material to the style is the default option for the first use of the tool on any component; if you choose to apply the material only to the current object, that becomes the default option, and you would need to enter **S** to apply the material to the style the next time you use the tool on that component. In other words, whichever option you choose becomes the default for the next use of the tool.)

NOTE For non-style based objects, such as a roof, the material definition (or the render material part of it in the case of an AutoCAD object) is applied to the object as soon as you click. You are not prompted about applying the material to the style, and you do not have to press *ENTER*.

Creating Custom Material Tools

In addition to using the standard Material tool on the Design tools palette, or the material-specific tools on the Materials tools palette, you can create your own material tools in a number of ways, as explained in the following topics.

Creating a Material Tool from a Material Definition in Style Manager

You can create a new material tool from a material definition in Style Manager. For information about creating a material definition in Style Manager, see [Creating and Editing Material Definitions](#) on page 624.

NOTE You can create a material tool from Style Manager only if the drawing containing the material definition has been previously saved.

- 1 Open the drawing containing the material definition you want to create a material tool from.
- 2 Click Window menu ► Tool Palettes.
- 3 Make the palette active on which you want to place the new material tool.
- 4 Click Format menu ► Style Manager.
- 5 Expand Multi-Purpose Objects, and expand Material Definitions.
- 6 Select a material definition, and drag it from Style Manager to the active tool palette.
- 7 Close Style Manager.

The material definition has been added as a material tool to the tool palette. You can use it to apply the material to objects, as described in [Using the Material Tool to Add Materials to Objects](#) on page 605.

NOTE The material tool uses the material definition you selected in Style Manager. The style location of the material tool is the drawing containing the definition. This means that when using this material tool you have access to all material definitions contained in the drawing.

Copying a Material Tool on a Tool Palette

You can create a new material tool by copying and pasting an existing tool on a tool palette.

- 1 Click Window menu ► Tool Palettes.
- 2 Select the palette that contains the material tool you want to copy.
- 3 Select the material tool, right-click, and click Copy.
- 4 If you want to paste it onto a different palette, make the palette active.
- 5 On the palette, right-click, and click Paste.
- 6 Select the tool, right-click, and click Properties.
- 7 To change the associated material definition, select a different definition under Definition Name.
- 8 To select a different source drawing, click Browse under Style Location.
- 9 In the Select a location File dialog box, select a source drawing, and click Open.
- 10 Select a material definition from the selected source file.
- 11 To update the material tool icon with the new material, select the icon under Image in the top left corner, right-click, and click Refresh Image.
- 12 Click OK.

Creating a Material Tool from a Render Material in the Content Browser

You can create a material tool by dragging a render material from Content Browser to AutoCAD Architecture.

Creating a new material tool in a drawing entails the creation of a new material definition in Style Manager. The material definition is used to create the material tool, but can also be used for different purposes in the drawing, like using the material definition to create object styles.

- 1 Click Window menu ► Content Browser.

Alternatively, you can click  on the Navigation toolbar.

- 2 Open the Visualization catalog and navigate to the Render Material category. Then, select the material you require.

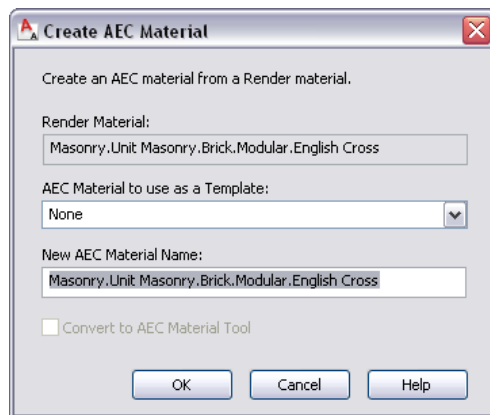

3 Move the pointer over the i-drop® icon next to the tool so that the pointer image changes to an eyedropper ().

4 Click and hold the i-drop® icon until it is full.

5 Use one of the following options to copy the render material to AutoCAD Architecture:

- Drag the material from Content Browser into an AutoCAD Architecture drawing. If you drag a render material from Content Browser directly into an AutoCAD Architecture drawing, an AutoCAD Architecture material definition is created from it. You cannot directly create an AutoCAD Architecture material tool this way. The new material definition is listed in Style Manager, where you can create a material tool from it, as described in [Creating a Material Tool from a Material Definition in Style Manager](#) on page 606.
- Drag the material from Content Browser onto an AutoCAD Architecture palette. If you drag a render material to an AutoCAD Architecture palette, a “temporary” material tool is created.

6 If you have dragged the render material directly into an drawing, the Create AEC Material worksheet is displayed.

- For AEC Material to use as a Template, select an existing material definition that contains the parameters you want to use.

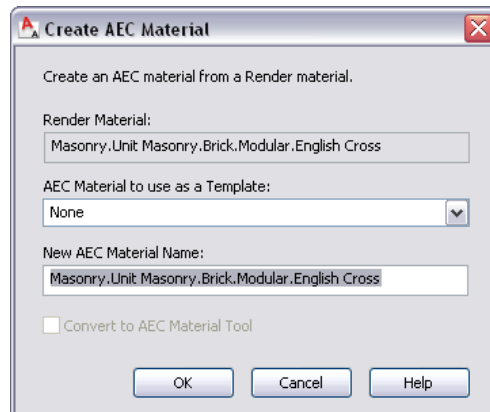

NOTE The material definition you select as template will define all initial material settings except for the rendering material. These include the layer, color, and linetype settings, hatching, surface hatch assignments, and the behavior of the material when used in a section.

- Enter a name for the new material definition.
- Click OK.

The option to automatically create a material tool from the new material definition is grayed out. To create a material tool, see [Creating a Material Tool from a Material Definition in Style Manager](#) on page 606.

7 If you have dragged the render material onto an AutoCAD Architecture palette, finish the creation of the AEC Material tool.

- Select the temporary icon on the tool palette.

- In the Create AEC Material Worksheet, select an existing material definition for AEC Material to use as a Template.

NOTE The material definition you select as template will define all initial material settings except for the rendering material. These include the layer, color, and linetype settings, hatching, surface hatch assignments, and the behavior of the material when used in a section.

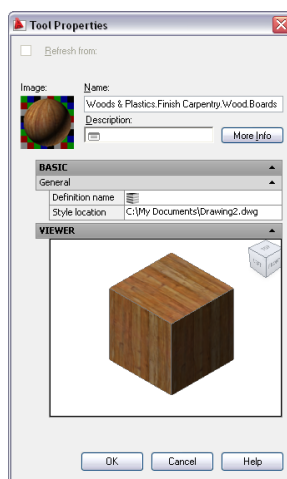

- Enter a name for the new material definition.
- Verify that Convert to AEC Material tool is selected.
- Click OK.

A notification message appears, reminding you to save the drawing after dismissing the notification so that the material tool is saved with the current drawing.

8 If you have created a material tool by dragging a render material to a tool palette, update the tool image to display the AutoCAD Architecture material tool icon.

9 Select the material tool on the palette, right-click, and click Properties.

You can see that the icon preview is different from the Viewer preview.

10 Select the icon preview under Image, right-click, and click Refresh Image. Then, click OK.

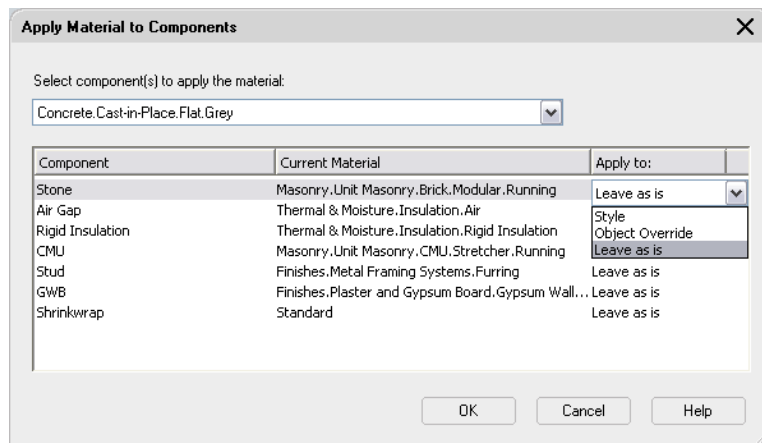

The material tool is now represented on the palette by the AutoCAD Architecture cube icon with correct material display.

Applying Material Tool Properties

Use this procedure to apply the style properties of a material tool to an existing object or component. You can apply the material at the object or style level. You can select one object before starting the command. If more objects are preselected, the command will revert to a selection mode. You can quickly select different material definitions and apply them as overrides to an object or to all objects of the same style without creating multiple material tools. If you want see the results more clearly, shade the object, select an isometric view, and use Object Viewer from the context menu or 3D Orbit.

- 1 Locate the material tool that you want to use and select it.
- 2 Select the object you wish to change.

The Apply Material to Components worksheet displays.

- 3 Select the material to apply.
- 4 Select the component to change.
- 5 Select whether the material should be applied to the style, at the object level or left as is for each component.
- 6 Click OK.

Material Components and Display Properties

Each material definition has the following display components that determine the appearance of object components to which a material has been assigned:

- Linework
- Plan Hatch 3D Body
- Surface Hatch
- Section Hatch
- Sectioned Body and Boundary

After you have specified display components of an object to be By Material, then you can no longer change the display component properties of that object.

The material components correspond to groups of object display properties or to display property types. For example, the material Linework component determines the appearance of linework components in 2D plan views, such as wall shrinkwraps, mass element boundaries or door frames. Surface Hatch determines the appearance of all surface hatching on objects in model and elevation views.

When you specify that the component of an object is displayed by material, the component uses the display properties of the associated material, instead of the display properties of the object. Only object components that correspond to a physical component of the object can be assigned material definitions. For more information, see [Objects That Support Materials](#) on page 603.

Material definitions cannot be assigned to a custom display block, but objects that are within custom display blocks may have material definitions assigned.

For a detailed list of object components mapped to material components, see the Help topics for the objects.

Linework Material Component

The Linework component is used for object components representing linework in 2D plan and elevation views, such as wall boundaries, door frames, or mass element boundaries.

Viewing wall plan view linework material components

Concrete-8 Concrete-
16x8-footing

Brick-4 Brick-4
Furring

Plan Hatch Material Component

The Plan Hatch component is used for hatching display components in plan views, such as wall component hatches, mass element hatches, and slab hatches.

Viewing wall plan view hatching material components

Concrete-8 Concrete-
16x8-footing

Brick-4 Brick-4
Furring

3D Body Material Component

The Body component is used for object components representing linework in 3D model views, such as wall bodies, mass element boundaries, door frames, and window frames.

Viewing 3D body material components

Surface Hatch Material Component

The Surface Hatch component is used for hatching display components in 3D model views, sections, and elevations. Section hatching is used on the cut face of a sectioned object or component.

Viewing surface hatching material on a wall elevation

brick surface hatching

CMU surface hatching

You can specify the faces of an object that display the surface hatch within the material definition. For example, you can specify that the hatch be on only the front and left side of the object.

Specifying wall face surface hatching assignments

For more information about surface hatch faces, see [Specifying the Surface Hatch Pattern of a Material Definition](#) on page 627.

2D Section/Elevation Linework

The 2D Section/Elevation Linework component is used specifically for 2D building sections or building elevations. All linework in a 2D section/elevation can be controlled by this component. For more information about using material definitions in elevations, see [Surface Hatch Linework in Elevations](#) on page 2234.

Viewing 2D elevation linework on a wall

2D section
linework (green)

Section Hatch Material Component

The Section Hatch component is used specifically for building sections. It is used for hatches on object faces cut by a section line. Section hatches can be applied to 2D sections, 3D sections, and live section views. For more information about using material definitions with sections, see [Section Hatch Linework](#) on page 2188.

Viewing a 2D wall section with section hatch

2D section
with section
hatch (red)

Sectioned Body and Sectioned Boundary

The Sectioned Body and Sectioned Boundary components display only in live section views. Live section views are special section views of a 3D building model. The building objects are not converted into a section object but are retained as individual objects in the section. They keep their properties and display components and may be edited in the section. The display of the views exterior to the live section is changed to be Sectioned Body. This display can be semi-transparent or hidden.

Material Component	Description
Sectioned Body	the objects or object parts outside the section
Sectioned Boundary	the outline of the cut line created by the section

For detailed information about live section views, see [Creating and Editing a Live Section View](#) on page 2165.

Live section view with sectioned body (gray) and sectioned boundary (red)

Displaying Materials in a Drawing

Use this procedure to turn on material definitions in a display representation if they are assigned to objects but are not displayed in the drawing. For more information, see [Display System Structure](#) on page 543.

- 1 Click Format menu ► Display Manager.
- 2 Expand Configurations.
The current display configuration is marked in bold.
- 3 Expand the current display configuration.
- 4 Select a display set in the current display configuration.
- 5 Click the Display Representation Control tab.
- 6 Scroll to Material Definition and select a display representation.

By default, material definitions have only a General display representation. If this is the only available display representation listed, select it. If you created another display representation for material definitions, you can select that representation instead.

NOTE Make sure that you select only one display representation for material definitions in each display set. You should also verify that the component's object layer is turned on.

- 7 Repeat steps 4–6 to select a display representation for material definitions in the other display sets in the current configuration.
- 8 Click OK.
The material assignments you made now display in the drawing.

Working with Surface Hatches

Surface hatches are hatch patterns on three-dimensional (3D) objects that display in 3D model views and elevation views.

Each 3D object has a number of faces: Top, Bottom, Left, Right, Front, and Back. You can decide whether an object should carry a surface hatch. For example, if you view a wall in 3D view, you might want to hatch only the side facing you to avoid cluttering the drawing.

The faces of an object that carry the surface hatch are specified in the material definition. All objects with that material definition assigned show the same surface hatch assignment, unless you create an individual surface hatch override.

Defining the faces on a regular object, such as a wall, slab, or box-shaped mass element, is intuitive. Front, Back, Left, Right, Top and Bottom are clearly defined faces that can easily be assigned material definitions. However, defining the direction in which each face lies can be more complex for different, irregularly shaped objects, such as curved objects, extrusion objects, or Free Form objects resulting from Boolean operations.

For information about changing the surface hatch assignments of a material definition, see [Specifying the Surface Hatch Pattern of a Material Definition](#) on page 627.

For information about surface hatch overrides, see [Overriding the Surface Hatch on Individual Objects](#) on page 618.

Specifying object face material assignments

material assigned
to top face

material assigned
to front face

material assigned
to all faces

Surface Hatches on Curved Surfaces

Curved surfaces do not have all the view directions you can specify in the material definition. It is important to know that the faces are designated on curved surfaces to understand how surface hatching is applied when these objects are assigned material definitions.

An object with a vertically curved surface, such as a Barrel Vault mass element, has no front and back faces, as nothing could delineate them. The curved surface of the Barrel Vault mass element is considered to be the top face of the object.

Barrel vault mass element with material assigned to top face

An object with a horizontally curved surface, such as a Cylinder mass element, has no left and right sides, as nothing can delineate them. The curved surface is considered to be the front face.

Cylinder mass element with material assigned to front face

An object that has only one curved surface, such as a Sphere mass element, has only a front face.

Sphere mass element with material assigned to front face

Surface Hatches on Multiple Faces

Irregular and complex objects can have multiple faces in one view direction. If necessary, you can override the surface hatch on all faces with the same view direction, or on individual faces. For information about overriding individual faces, see [Overriding the Surface Hatch on Individual Objects](#) on page 618.

Stair with material assigned to treads

Surface Hatches on Extrusions

The surface hatch placement on objects created from an extruded profile depends on two factors:

- the view directions assigned to the individual edges of the profile
- the direction of the extrusion

The desired extrusion direction depends on the object you want to extrude from the profile. A rail, for example, is extruded in the X direction. A railing post is extruded in the Z direction. Custom door and window shapes are extruded in the Y direction.

Face assignments from edges extruded in the X direction

Face assignments from edges extruded in the Y direction

Face assignments from edges extruded in the Z direction

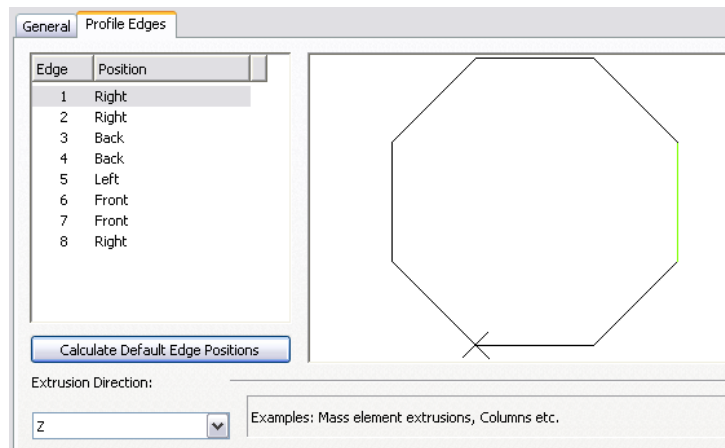

Specifying Faces on Extrusions

Use this procedure to specify the faces on object components created from extruding a profile. These objects and components include extruded mass elements, wall body modifiers, custom railing components, and other components extruded from a profile.

When you create a profile, all the edges are marked for extrusion in the Z direction. These edge positions are calculated based upon the quadrant in which the midpoint of the edge lies. You can change the view direction of edges and the extrusion direction in the profile definition.

Determine the direction of the profile edges before creating objects from the profile. For example, if you created a profile for a custom railing baluster and specified the direction of the individual edges, any baluster added to the railing based on that profile has those assignments. If you later change the edge view direction in the profile, existing balusters do not change accordingly.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand Profiles.
- 3 Select the profile for the extrusion.
- 4 Click the Profile Edges tab.

- 5 Select an extrusion direction.
- 6 For each edge, select a position that corresponds to the view direction you want to assign to the face created from that edge.
The edge positions that are available depend on the extrusion direction you selected.
- 7 Click OK.

Surface Hatches on Free Form Mass Elements

Free Form mass elements are created when you perform a Boolean operation on a standard mass element by adding, subtracting or intersecting another mass element. The resulting mass element can be irregularly shaped. For more information, see [Mass Elements and Mass Groups](#) on page 683.

When a mass element is converted into a Free Form mass element, all previous material assignments of the source mass elements are lost. The new mass element reverts to the Standard material definition. You can assign another definition to the new mass element.

Overriding the Surface Hatch on Individual Objects

The surface hatch specified for a material determines the display of objects that are assigned the material in elevation and model views, as well as the appearance in rendered views. The material definition specifies which faces of objects—Top, Bottom, Left, Right, Front, Back—display a surface hatch.

However, in some instances, you may want to override the surface hatch for a selected face of an object. For example, you may want to turn off the surface hatch where it could obscure small details of an object when the drawing is plotted.

Override Operations

You can change the surface hatches for faces of individual objects in the following ways:

- hide the surface hatch
- change the rotation of the surface hatch
- change the vertical and horizontal offsets of the surface hatch

You can also specify whether the changes are applied only to the selected face or to all faces of the object with the same direction—for example, to all front faces.

Multiple Surface Hatch Overrides

You don't need to create separate overrides for individual changes; you can create one surface hatch override that is both rotated and offset. In most cases, this is the preferred method of working. However, in some cases, you need to assign more than one override. For example, suppose you want to rotate the surface hatch of all front faces of a column, and you want to offset one individual front face. You first add an override for the rotation and select All Front Faces. Then you add an override for the offset in which you select Only Selected Front Face.

Hiding a Surface Hatch

Use this procedure to hide the surface hatch on an object face.

To add an override to a surface hatch, an object needs to have a surface hatch material assigned to it. A surface hatch on an object can come from an assigned material or from the display properties of the object or object style.

If a surface hatch comes from the display properties of the object instead of from the material assignment, you cannot override it on individual faces. You receive an error message upon selecting the object face.

1 Select the object for which you want to hide an individual surface hatch, right-click, and click **Materials ► Add Surface Hatch Override**.

2 Select the object face where you want to hide the surface hatch.

A profile surrounds the selected face.

Profile defining a face of a wall

3 Specify where the override applies:

If you want to...

override only the selected face of the object

Then...

select Only Selected <Direction> Face for Faces. For example, to apply a surface hatch override only to the selected Front face of a wall, select Only Selected Front Face.

If you want to...**Then...**

override all faces of the object in the same view direction

select All <Direction> Faces for Faces. For example, to apply a surface hatch override to all Top faces of a selected column, select All Top Faces.

4 Select Hide Surface Hatching.

Surface hatch hidden on the front face of a wall

**5 Click OK.**

Displaying a Hidden Surface Hatch

Use this procedure to display a previously hidden surface hatch.

An object must have a surface hatch material assigned to it in order to add an override to a surface hatch. A surface hatch on an object can come from an assigned material or from the display properties of the object or object style.

If a surface hatch comes from the display properties of the object instead of from the material assignment, you cannot override it on individual faces. You receive an error message upon selecting the object face.

- 1 Select the object for which you want to redisplay a hidden individual surface hatch, right-click, and click **Materials** ► **Edit Surface Hatch Override**.
- 2 Select the profile around the hidden surface hatch.
- 3 Right-click, and click **Edit Hatch Override**.
- 4 Clear **Hide Surface Hatching**.
- 5 Click **OK**.

- 6 Click  on the In-Place Edit toolbar to save the changes.

Specifying the Rotation of a Surface Hatch

Use this procedure to specify the rotation of a surface hatch.

- 1 Select the object for which you want to rotate an individual surface hatch, right-click, and click **Materials** ► **Add Surface Hatch Override**.
- 2 Select the object face where you want to change the rotation.
A profile surrounds the selected face.

3 Specify where the override applies:

If you want to...	Then...
override only the selected face of the object	select Only Selected <Direction> Face for Faces . For example, to apply a surface hatch override only to the selected Front face of a wall, select Only Selected Front Face .
override all faces of the object in the same view direction	select All <Direction> Faces for Faces . For example, to apply a surface hatch override to all Top faces of a selected column, select All Top Faces .

4 Specify the rotation of the surface hatch.

Specifying surface hatch rotation angles

5 Click **OK**.

Specifying the Horizontal and Vertical Offset of a Surface Hatch

Use this procedure to specify the horizontal and vertical offset of a surface hatch.

An object must have a surface hatch material assigned to it in order to add an override to a surface hatch. A surface hatch on an object can come from an assigned material or from the display properties of the object or object style.

If a surface hatch comes from the display properties of the object instead of from the material assignment, you cannot override it on individual faces. You receive an error message upon selecting the object face.

Changing the offsets of a surface hatch lets you adjust the hatch pattern on individual faces to align with the face edges or to improve the appearance of the hatch.

Specifying surface hatching offset and alignment

standard wall surface hatch

wall surface hatch offset to align with wall edge

- 1 Select the object for which you want to change the hatch pattern offset, right-click, and click **Materials** ► **Add Surface Hatch Override**.
- 2 Select the object face where you want to change the hatch pattern offset.
A profile surrounds the selected face.

3 Specify where the overrides applies:

If you want to...

Then...

override only the selected face of the object

select **Only Selected <Direction> Face for Faces**. For example, to apply a surface hatch override only to the selected Front face of a wall, select **Only Selected Front Face**.

override all faces of the object in the same view direction

select **All <Direction> Faces for Faces**. For example, to apply a surface hatch override to all Top faces of a selected column, select **All Top Faces**.

- 4 Specify the horizontal and vertical offsets of the surface hatch.
- 5 Click **OK**.

Editing Surface Hatch Overrides

Use this procedure to edit a surface hatch override that you applied to an object.

- 1 Select the object that has a surface override you want to change, right-click, and click **Materials** ► **Edit Surface Hatch Overrides**.
- 2 Select the profile of the face you want to edit.
If you have multiple surface hatch overrides on one object face, be sure to select the override you want to change.
- 3 Right-click, and click **Edit Hatch Override**.

4 Edit the surface hatch override:

If you want to...	Then...
hide a surface hatch	select Hide Surface Hatching.
re-display a hidden surface hatch	clear Hide Surface Hatching.
change the rotation of the surface hatch	enter a value for Rotation, or click  and specify the rotation on screen.
change the offset of the surface hatch	enter a value for X Offset or Y Offset, or click  and specify the offset on screen.

5 Click OK.

- 6 Click  on the In-Place Edit toolbar to save the changes.

Displaying a List of Materials

Use this procedure to create a list of material definitions and corresponding volumes for the objects that you select. The list includes all material definitions used in the selected objects as well as the total volume of each material definition. You can use the information for preliminary cost estimates.

- 1 On the command line, enter **materiallist**.
- 2 Select the objects you want to include in the list, and press *ENTER*.
- 3 Press *F2*.

The material definitions list is displayed in the AutoCAD® text window.

NOTE You can also select the list of material definitions, and then press *CTRL+C* to copy it, and *CTRL+V* to paste it into Microsoft® Word.

Displaying a Material Query

Use this procedure to obtain volume information for a selected material definition. The results of the query include the total volume for all objects with a selected material definition. For example, if you have two brick walls within your selection set, and each has a volume of 8.85 m3, the overall volume of brick objects is listed as 17.7 m3. You can use that information for preliminary cost estimates.

- 1 On the command line, enter **materialquery**.
- 2 Select the objects you want to include in the query, and press *ENTER*.
- 3 Select the material definition you want to query.
For example, if you want to query for bricks, select Brick from the list.
- 4 Click OK.
All objects assigned the selected material definition are highlighted in the drawing.
- 5 Press *F2*.

The volume for the selected material definition is displayed in the AutoCAD® text window.

Process Overview: Creating and Assigning Materials

AutoCAD Architecture offers a number of predefined building material definitions in the drawing templates. You can also create your own custom material definitions. All material definitions used in a project are listed under Material Definitions in the Style Manager.

The material definitions are listed in alphabetical order. Devising a naming convention for your material definitions allows you to locate them quickly. For example, you might create glazing definitions named “glass.interior.clear,” “glass.exterior.tinted,” and “glass.exterior.clear.” These would appear in the following order under Material Definitions:

- glass.exterior.clear
- glass.exterior.tinted
- glass.interior.clear

The following steps describe the process of creating a material definition and assigning it to an object or object style:

- 1 Create a material definition for each material needed and specify the display properties of these definitions.
For example, create a brick material definition that shows a dark red surface hatch, matching dark red linework components, an appropriate section hatch, and a brick rendering material. Or, create a glass material definition that has light blue linework, a transparent surface, and a light blue rendering material.
For more information, see [Creating and Editing Material Definitions](#) on page 624.
- 2 In object styles, assign a material definition to represent each component.
For example, in a window style, assign a wood material definition to the frame and the muntins and a glass material definition to the window glass. Or, if you are working with a wall style, assign a brick material definition to the wall body and an insulation material to insulation components.
- 3 Make sure that the corresponding display properties of the object or object style are in all display representations specified as By Material.
- 4 For object components that do not use material definitions, specify the display properties in each display representation.

For example, if you want the graphic representation of a door swing to match the dark brown door frame, open the display properties of the door style, and change the color of the door swing to a dark brown. Perform this step for each display representation in which the door swing appears.

When you create objects from these styles, their components are displayed as follows:

- If you have selected By Material in the Display Properties, then the object components that have material definitions assigned show the display properties you specified in the material definition.
- Object components that have no material definitions assigned show the display properties you specified in the object style.

Creating and Editing Material Definitions

Material definitions are created, edited, copied, or purged in Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and

templates. Material definitions contain settings for the hatching, scale, and color of materials, plus rendering materials. You can find predefined material definitions in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial or Metric`. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Creating a Material Definition

Use this procedure to create a definition for the material you wish to use.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Multi-Purpose Objects, and expand Material Definitions.

- 3 Create a material definition:

If you want to...	Then...
create a new definition with default properties	right-click Material Definitions, and click New.
create a new definition from an existing definition	right-click the material definition you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new material definition, and press *ENTER*.

- 5 Edit the properties of your new definition:

If you want to...	Then...
enter a description of the material definition	click General. Enter a description of the material definition.
change the layer/color/linetype properties	see Defining the Layer, Color and Linetype of a Material Definition on page 626.
change the hatching patterns	see Specifying the Plan and Section Hatch Patterns of a Material Definition on page 626.
assign surface hatching to individual object faces	see Specifying the Surface Hatch Pattern of a Material Definition on page 627.
assign surface and live section rendering materials	see Assigning Render Materials on page 629.
exclude components from 2D shrinkwrap	see Excluding a Material Definition from 2D Section Shrinkwrap on page 631.
add notes, files, or documents to the definition	see Attaching Notes and Files to a Material Definition on page 633.

- 6 When you finish changing the material definition properties, click OK.

Defining the Layer, Color and Linetype of a Material Definition

Use this procedure to define the layer, color, and linetype of the material components. For detailed descriptions of the individual material components, see [Material Components and Display Properties](#) on page 610.

NOTE If you turn off a display component in the material definition, object components assigned that material definition do not display in the drawing. For example, if you turn off the Linework component in a material definition, and assign that definition to a door frame component, the door frame does not display in plan views.

- 1 Click Format menu ► Style Manager.
The Style Manager is displayed with the current drawing expanded in the tree view.
- 2 Expand Multi-Purpose Objects, and expand Material Definitions.
- 3 Select the material definition you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Object Override.
The display representation in bold is the current display representation.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Specifying the Plan and Section Hatch Patterns of a Material Definition

Use this procedure to change the patterns for the Plan, Hatch, and Section Hatch components of a material definition. For detailed descriptions of individual hatch components, see [Material Components and Display Properties](#) on page 610.

For more information about specifying surface hatch patterns, see [Specifying the Surface Hatch Pattern of a Material Definition](#) on page 627.

- 1 Click Format menu ► Style Manager.
The Style Manager is displayed with the current drawing expanded in the tree view.
- 2 Expand Multi-Purpose Objects, and expand Material Definitions.
- 3 Select the material definition you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Object Override.
The display representation in bold is the current display representation.
- 6 If necessary, click  .
- 7 Click the Hatching tab.
- 8 Select Plan Hatch or Section Hatch, and click the setting for Pattern.

9 Select the hatching for the component:

If you want to...	Then...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

10 Click OK.

11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

12 Click Angle, and enter the angle for the selected pattern.

13 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

Specifying surface hatching orientation

object hatch orientation

global hatch orientation

14 Click OK.

Specifying the Surface Hatch Pattern of a Material Definition

Use this procedure to specify the pattern used for the surface hatch.

Specifying material assignment by object face

material assigned to top face

material assigned to front face

material assigned to all faces

NOTE After you assign a material definition to an object, you can edit the surface hatches for the individual faces of the object. For more information about editing surface hatches, see [Overriding the Surface Hatch on Individual Objects](#) on page 618.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Multi-Purpose Objects, and expand Material Definitions.

- 3 Select the material definition you want to change.

- 4 Click the Display Properties tab.

- 5 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 6 If necessary, click  .

- 7 Click the Hatching tab.

- 8 Select Surface Hatch, and click the setting for Pattern.

- 9 Select the hatching for the component:

If you want to...	Then...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.

If you want to...	Then...
select solid fill	select Solid Fill for Type.

10 Click OK.

11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

12 Click Angle, and enter the angle for the selected pattern.

13 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

Specifying surface hatch orientation

object hatch orientation

global hatch orientation

14 Click the Other tab.

15 For Surface Hatch Placement, select the object faces on which the surface hatching is displayed.

16 Click OK.

Assigning Render Materials

Use this procedure to assign materials for rendering object surfaces.

In shaded view and rendered views, objects may display rendering materials instead of the hatch patterns that are displayed in 2D wireframe and hidden line views. The following types of rendering materials are available:

Render Material Type	Description
Surface Rendering Material	Any object face that has surface hatching applied displays the hatching in the AutoCAD renderer

Render Material Type	Description
Live Section Rendering Material	All faces cut by a live section line display the live section rendering material when rendered with the AutoCAD renderer
Live Section Sectioned Boundary Rendering Material	All objects and object parts outside the live section line display the sectioned boundary material when rendered with the AutoCAD® renderer

You can assign rendering materials to two different types of component:

- **Object surfaces:** All object surfaces that have a surface hatch applied to them can also have a rendering material assigned. If you want to assign a rendering material to an object surface, make sure that the Surface Hatch component in the material definition is turned on.
- **Live section views:** The Sectioned Body component of a live section view as well as the live section cut plane can have special rendering materials assigned. If you want to assign rendering materials to a live section view, make sure that the Sectioned Body component in the material definition is turned on.

Rendered live section view with transparent outside component

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Multi-Purpose Objects, and expand Material Definitions.

3 Select the material definition you want to change.

4 Click the Display Properties tab.

5 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

6 If necessary, click  .

7 Click the Other tab.

8 Select rendering materials for the individual material components:

If you want to...

Then...

assign a rendering material to object surfaces

select a material for Render Material. Then select a mapping type for Mapping:

- If you select Same as Surface Hatch, only those surfaces selected under Surface Hatch Placement are rendered.
- If you select Face Mapping, all surfaces are rendered and any hatch alignment overrides are ignored.

assign a rendering material to the cut plane of a live section view

select a material for Cut Surface Render Material.

assign a rendering material to the body component outside the live section line

select a material for Sectioned Body Render Material.

If you don't find the correct rendering material or if you want to see a preview of the material, click the Browse button and browse for the desired material.

9 Select a new rendering material, if necessary.

10 Click OK.

Excluding a Material Definition from 2D Section Shrinkwrap

Use this procedure to exclude components with a specific material definition assigned to them from the shrinkwrap of a 2D section.

When you create a 2D section, you can display a section component named Shrinkwrap. The shrinkwrap is the union of all object faces cut by the section line, merged into one component with one hatch pattern. This is a view frequently used for a 2D section.

By default, all components that are assigned material definitions are included in the shrinkwrap. However, you may want to exclude certain material definitions, such as glass, from the shrinkwrap.

2D section shrinkwrap with glass excluded (left)

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Multi-Purpose Objects, and expand Material Definitions.

3 Select the material definition you want to change.

- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
The display representation in bold is the current display representation.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select Exclude from 2D Section Shrinkwrap.
- 9 Click OK.

Controlling the Display of Hidden Lines by Material

Use this procedure to control whether hidden lines of a material should be displayed in a section or elevation.

You could do this, for example, if you want to display concrete walls and footings that are hidden by the ground and by other walls. Another frequent use could be to display structural members that are located behind walls.

Displaying hidden foundation walls

- 1 Click Format menu ► Style Manager.
The Style Manager is displayed with the current drawing expanded in the tree view.
- 2 Expand Multi-Purpose Objects, and expand Material Definitions.
- 3 Select the material definition you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
The display representation in bold is the current display representation.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Under 2D Section/Elevation Rules, select Display Hidden Edges for this Material.
- 9 Click OK.

Merging Material Definitions in a 2D Section/Elevation

Use this procedure to merge material definitions when creating a 2D section/elevation.

Sometimes a single object in real-life is modeled with different objects in AutoCAD Architecture. An example is concrete foundations, which are modeled from slabs and walls. These objects should appear as one foundation object in sections and elevations. The new option to merge common material definitions facilitates this result. When a 2D section/elevation is created, all objects of that material definition are combined into a single object. Edges between coplanar faces are removed.

Walls and slabs merged (right)

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Multi-Purpose Objects, and expand Material Definitions.

3 Select the material definition you want to change.

4 Click the Display Properties tab.

5 Select the display representation where you want the changes to appear, and select Style Override.

The display representation in bold is the current display representation.

6 If necessary, click .

7 Click the Other tab.

8 Under 2D Section/Elevation Rules, select Merge Common Materials.

9 Click OK.

Attaching Notes and Files to a Material Definition

Use this procedure to enter notes and attach reference files to a material definition. You can also edit notes and edit or detach reference files from a material definition.

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Multi-Purpose Objects, and expand Material Definitions.

3 Select the material definition you want to change.

4 Click the General tab.

5 To add a description to the material definition, enter it for Description.

6 Click Notes.

7 To add a note, click the Text Notes tab, and enter the note.

8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

9 Click OK.

Content Creation Guidelines

13

In this guide the term content refers generically to various types of elements that you can create to customize your installation of AutoCAD Architecture. These elements can be style-based or symbol-based and include items such as plot style tables, layers, layer key styles, layer standards, and drawing template files. While there are many ways in which you can create and structure your custom content, there are several standards and conventions (both documented and de-facto) that you can follow to make your custom tools more efficient and more portable between different environments and organizations. This document is not step-by-step guide for creating custom content; instead it focuses on identifying the relevant standards, conventions and best practices.

General Content Standards and Conventions

It is important to understand the various types of content, where they are stored and how they are made accessible to users. AutoCAD Architecture includes support for various CAD standards. Understanding how these are applied will assist you in creating your own customized content that works with the existing standards and conventions.

Content Types

AutoCAD Architecture content takes several forms and can be stored in a variety of locations.

- **Drawing templates:** The drawing template file is perhaps the most critical of content items in AutoCAD Architecture. In addition to standard AutoCAD items such as layers and dimension styles, the templates contain critical drawing and display settings. All AutoCAD Architecture model and sheet drawings should start with a template. Drawing templates are usually stored in the folder established in the AutoCAD Options dialog for template file storage. Additionally you can specify a default template to be used whenever the QNEW command is invoked. Finally, a default plot sheet template is usually specified as one of the sheet set properties for an AutoCAD Architecture project.
- **Styles:** Most AutoCAD Architecture objects, whether they are geometric objects or documentation objects, are based on styles. Any successful AutoCAD Architecture implementation will most likely consist of several custom styles and definitions. Most styles should be stored in one or more style library drawings, in a location that is accessible by all users. Usually, styles can be easily accessed by users from a tool on a palette or in a tool catalog.

NOTE Although some styles may be stored in the drawing template, this should be kept to a minimum and limited to those styles and definitions that are required for other content in the template.

- **Design and General Documentation Symbols:** These are best stored as AEC Content, which is created using the Create AEC Content wizard. Palette-based tools can also access these symbols.

NOTE Some symbol-based content, such as multi-view blocks used for column grid bubbles, can be stored in the drawing template. As with styles, however, this should be kept to a minimum. Once a symbol is stored as AEC Content, you can access it through Design Center™.

- **Callout Symbols:** These are special symbols that use attributes with field values to automate drawing coordination when you are placing keys for elevations, sections and details. The blocks that define callouts are stored in a library drawing and are accessed through palette-based tools.
- **Schedule Tags:** Based on multi-view block definitions, schedule tags are created with the Define Schedule Tag command found on the Format”pull-down menu. Like callout symbols, schedule tags are stored in a library drawing and accessed from a palette-based tool.
- **Layer Key Styles:** While they can be stored in the drawing template, it is better to keep layer key styles in a central library drawing. The Drawing Setup command on the Format menu can be used to make sure that a specific layer key style automatically loads each time a drawing is opened. This way if a layer key style is updated, a drawing that is already in progress will always be using the latest version.
- **Layer Standards:** Defined in the Layer Manager, layer standards are stored in the same library drawing as the layer key style with which they are associated. When the layer key style is imported into a drawing, the layer standard on which it is based will import also.
- **Display Configurations:** Default display configurations are stored in the drawing template.

TIP Most content types have associated naming conventions that are documented in this guide. As a global convention, it is acceptable to prefix any name with a company or organization name to differentiate your custom content from the default content supplied with AutoCAD Architecture.

National CAD Standard Compliance

The National CAD Standard version 3.1 is a consensus standard compiled from three existing standards and guidelines by NIBS (The National Institute of Building Sciences). These consist of the AIA Layer Guidelines version 3.0, the CSI Uniform Drawing System (UDS) and the Tri-Services Plotting Guidelines. The National CAD Standard v. 3.1 is supported where possible in AutoCAD Architecture through the use of pre-configured Layer Standards, Layer Key Styles, plot style tables and annotation tools. While it is not required that custom content be compliant, when creating new content for use in the United States you should take this support into account.

The Imperial templates provided with AutoCAD Architecture are pre-configured to load the “AIA Version 3” Layer Key Style by default. This is based on the “AIA Version 3” Layer Standard, which is in turn compliant with the AIA Layer Guidelines version 3.0.

The AIA v3 Layer Key Style includes line weights and linetypes that are in accordance with the Uniform Drawing System, and the colors that it specifies are compliant with the Tri-Services plotting guidelines. Additionally, the drawing default display representations for all objects in the template files have been configured to adhere to the Tri-Services Guidelines and Uniform Drawing System recommendations by assigning appropriate colors, linetypes, line weights and plot styles to all display components.

There are twelve templates that are provided with the AutoCAD Architecture sold in the United States, and each one is pre-configured to use a specific plot style table:

Template File Name	Description	Default Plot Style Table
AEC Model (Imperial Ctb).dwt	Used for model drawings with imperial (architectural) units and set up for color-based plotting.	AIA Standard.ctb
AEC Model (Imperial Stb).dwt	Used for model drawings with imperial (architectural) units and set up for named plot styles.	AEC Standard.stb
AEC Sheet (Imperial Ctb).dwt	Used for plot sheet drawings with imperial (architectural) units and set up for color-based plotting.	AIA Standard.ctb
AEC Sheet (Imperial Stb).dwt	Used for plot sheet drawings with imperial (architectural) units and set up for named plot styles.	AEC Standard.stb
AEC Model (Metric Ctb).dwt	Used for model drawings with metric (decimal) units and set up for color-based plotting.	AIA Standard.ctb
AEC Model (Metric Stb).dwt	Used for model drawings with metric (decimal) units and set up for named plot styles	AEC Standard.stb
AEC Sheet (Metric Ctb).dwt	Used for plot sheet drawings with metric (decimal) units and set up for color-based plotting.	AIA Standard.ctb
AEC Sheet (Metric Stb).dwt	Used for plot sheet drawings with metric (decimal) units and set up for named plot styles.	AEC Standard.stb
Structural (Imperial Ctb).dwt	Used for structural model drawings with imperial (architectural) units and set up for color-based plotting.	AIA Standard.ctb
Structural (Imperial Stb).dwt	Used for structural model drawings with imperial (architectural) units and set up for color-based plotting.	AEC Standard.stb
Structural (Metric Ctb).dwt	Used for structural model drawings with metric (decimal) units and set up for color-based plotting.	AIA Standard.ctb
Structural (Metric Stb).dwt	Used for structural model drawings with metric (decimal) units and set up for named plot styles.	AEC Standard.stb

NOTE By default the software is configured to use the *AEC Model (Imperial Stb).dwt* for model drawings and the *AEC Sheet (Imperial Stb).dwt* for plot sheet drawings.

In addition to the default plot style tables assigned to the imperial and metric templates, there are several additional optional tables provided. Many of these are for use with older legacy templates and drawing files:

Plot Style Table	Description
AEC Standard.stb	Default plot style for templates using named plot styles. This table uses generic names for plot styles and passes line weight control to the layer and object properties. All objects plot black.
AIA Standard.ctb	Default plot style for templates set up for color-based plotting. This table maps each color to an explicit line weight according to the Tri-Services guidelines.
AIA Standard Color.ctb	Optional plot style for templates using color-based plotting. All colors are mapped to explicit line weights according to the Tri-Services guidelines. Colors are controlled by the objects and layers.
AEC Standard Color.stb	Optional plot style for templates using named plot styles. This table uses the same names for plot styles as the AEC Standard.stb plot style table, but objects will plot according to their AutoCAD color.
AIA Standard.stb	Legacy plot style for older templates using named plot styles. This table includes plot styles named according to line weight definitions specified in the Uniform Drawing System.
AIA LWT by Object.ctb	Legacy plot style for older templates using color-based plotting. All colors are mapped to black and line weight control is by layer and object properties.
AIA LWT by Object.stb	Legacy plot style for older templates using named plot styles. All line weight control is by layer and object properties.
AIA Standard Color.stb	Legacy plot style for older templates using named plot styles. Plot styles assign line weight explicitly. Colors are controlled by objects and layers.
AIA Color LWT by Object.ctb	Legacy plot style for older templates using color-based plotting. Color and line weight control is by layer and object properties.
AIA Color LWT by Object.stb	Legacy plot style for older templates using named plot styles. All plot styles assign color and line weight according to object and layer assignments.

Legacy named plot style tables have seemingly redundant plot style names that correspond to UDS line weight names. Many of these tables use the same plot settings for multiple plot styles. This was done to

allow for consistency in naming when switching between plot styles. With the newer *AEC Standard.stb* plot style tables, this complex plot style naming has been abandoned in favor of a much more simplified system. Both the *AEC Standard.stb* and the *AEC Standard Color.stb* plot style tables use the same plot style names, however the former will plot all objects black while the latter will plot all objects according to their AutoCAD color. Aside from color vs. monochrome, the plot styles determine saturation:

- **Normal:** Default plot style. Because this plot style is not editable, it is typically not used in the AutoCAD Architecture layer key styles or display settings.
- **Full Saturation:** Objects assigned this plot style will plot either 100 percent black or 100 percent color, depending upon which plot style table is used.
- **50 Percent:** Objects assigned this plot style will plot with a 50 percent screen.
- **25 Percent:** Objects assigned this plot style will plot with a 25 percent screen.
- **Invisible Ink:** This is a unique plot style. Regardless of whether the *AEC Standard.stb* or *AEC Standard Color.stb* plot style table is being used, objects on this plot style will plot cyan, to simulate the effect of a blue lead pencil from manual drafting days, which will not typically come through when reproduced on a monochrome copy machine or standard blue-line machine.

The Uniform Drawing System also specifies formatting for symbology and annotation. This is supported in AutoCAD Architecture through the content provided in the Documentation Tool Catalogs and in the drawing templates themselves.

NOTE For more information on NIBS or to purchase a copy of the National CAD Standard documentation you can visit their web site at <http://www.nibs.org/>

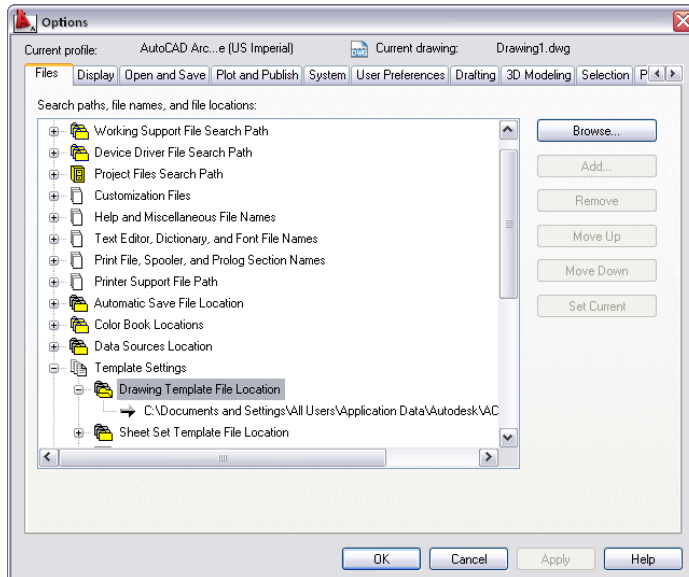

Content Resources

To create and distribute content effectively, it is important to have an understanding of where different types of content are best stored, and the possibilities each one of them provide towards a cohesive, well-managed system of templates, styles, symbols and tools. Careful attention should be paid to ease of user access, centralized storage and automation.

Template Drawings

There are a variety of things that should be kept in the template, however care should be taken to keeping it as “lean” as possible. Before storing content in a template you should consider other options, choosing to store it in the template only after confirming that it is the best possible location. Normally, the template itself should be stored in the location that is specified in the “OPTIONS” dialogue box under “Template Settings”.

Setting the template file location in the “Options” dialog box.

Items that should be included in the template file:

- **Layer definitions:** Pre-defined layers should be kept to a minimum. Most layers are created when needed by the layer key style that is loaded into a drawing. Only include pre-defined layers for those other objects and settings that must be in the template before a Layer Key Style is loaded or any objects created.
- **Text styles:** Include text style definitions to be used for standard notes and dimensions.
- **Title Blocks, Layouts and Page Setups:** These should be created in templates intended for use as plot sheet templates. Templates that are intended to be used for sheet sets, especially, should have page setups saved within them to serve as page setup overrides when publishing a sheet set.
- **Multi-View Blocks:** Normally these should be stored as AEC Content or tags, however if you want to use a custom column grid bubble block instead of the default grid bubble, you should store it in the template.

NOTE Custom blocks do not scale correctly if you copy objects to which they are attached (such as doors with door hardware) and paste them in a drawing that has drawing units specified differently.

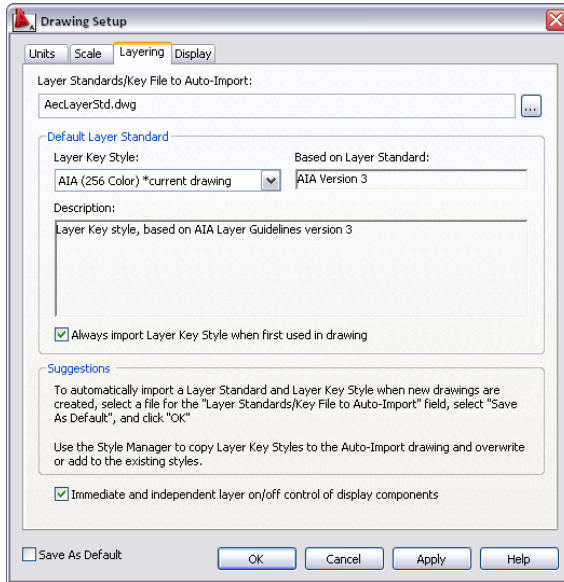

- **Classification Definitions:** Those classification definitions that you use frequently are best stored in your drawing template, so that they are readily available when you need to classify either a style or an individual object.

Items that should not be included in the template file:

- **Most styles:** These should be kept in a style library drawing, with an associated palette-based tool that allows users to import the styles into the current quickly and easily on demand. Storing the styles in a style library and providing tool access to them keeps your drawings from becoming unnecessarily bloated due to unused styles in the drawing database.
- **Symbol-based content:** These items are typically more effectively stored as AEC Content or in the case of callouts and schedule tags, a library drawing. Again, palette-based tools provide quick and easy access to them on an as-needed basis.
- **Dimension styles:** AEC Dimensions and the standard AutoCAD dimension styles upon which they depend for their display do not need to be stored in the template. Instead, you can store these in the same way as other style-based content; in a style library drawing, and provide access to them through palette-based tools.

- **Layer Key Styles and Layer Standards:** While these can be stored in the template, it is better to keep them in a library drawing and use the “Drawing Setup” command to make sure that the most current Layer Key Style is automatically imported into a new drawing and any drawings that are already in progress upon opening. This ensures that you are always working with the most up-to-date version.

The layer settings in the Drawing Setup Dialog. Note that a layer key style is set to auto-import from a “Standards/Key File” and that “Save as Default” is checked on. This will ensure that even if you start a drawing without a template, the correct Layer Key Style will be loaded. Note also that “Always Import Layer Key Style when used in drawing” is also checked on. This is a drawing-based setting and should be set in the template. This will ensure that the most current Layer Key Style will also be used in drawings that are already in progress.

Style Library Drawings

Most style-based content should be kept in a centrally located library drawing, accessible to all users. In most cases, the styles contained in this file can be imported by selecting a tool on a palette. If you anticipate a large quantity of custom styles, you may wish to break your library drawings up by type to keep them more manageable.

General Guidelines for Style Library Drawings:

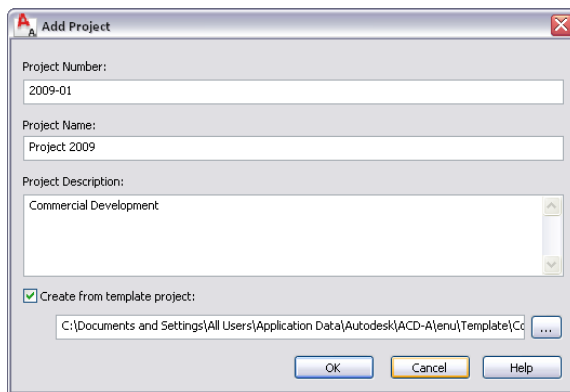

- Start with a valid template drawing that includes all of your display configurations and correct units. This will allow you to edit or review styles in the library in the context in which they will be used.
- If you are storing your style library on a mapped drive make sure that the drive is mapped identically on every user’s computer. AutoCAD Architecture supports UNC (Universal Naming Convention) pathing. If you are confident that your server names will not be changing you may want to consider using this method of pathing to your style libraries to avoid drive mapping problems.
- If you need to restrict users’ ability to make changes to the style library, you can store it in a read-only folder. They will still be able to use the styles that it contains without any problems.

Template Projects

A well-planned template project can help you automate office standards and simplify the process of beginning and setting up a new project. Depending upon the type of work you do, your template project may be very complete or it may just form the basic framework for a project. If your work consists of unique designs and your building types vary, you may find that the most efficient template project is minimal in structure. On the other hand, if you work with a typical building type, or if you work with prototypical buildings you might find that a more complete template project that includes more information concerning specific project structure is more effective.

Creating a template project is not the same as simply copying and renaming an existing project. In order to properly call for a template, you must specify it at the time that you create your new project.

Specifying the template project from the “Add Project” dialog box. This is the only time this can be done. When the new project is created, settings and files from the specified template project will be copied to the new project.

Template Drawings

AutoCAD Architecture Projects have, as one of their Project Properties, template file specifications that determine the drawing templates to use for Constructs, Elements and Views. These template settings are independent from the template settings established in the “OPTIONS” dialog box. These templates should be in a location accessible to all users.

Project Details

Accessible from the project properties dialog box, the project details contain information that can be linked to title blocks via fields, either embedded in MTEXT or block attributes. This data is completely user-defined. You should include data that is common to all of your projects in your template project’s Project Details.

Sheet Sets

All AutoCAD Architecture projects include an AutoCAD Sheet Set (.dst) file. When you use a project as a template, its sheet set file gets copied over to your new project along with all of the other project files and folders, and is renamed to match your new project. The sheet set file contains a variety of critical information that can be pre-configured as part of your overall project template.

Items that can be modified in the sheet set file as part of the template project:

- **Default sheet template file:** This is the one template that is not specified in the project properties, as it is part of the sheet set properties instead. This should be a sheet that has layouts defined in it that represent all of your standard plot configurations. It should also contain each layout saved as a *page setup* for use as page setup overrides when publishing.

- **Subset Structure:** You can add and delete subsets to conform to your office’s standard sheet set layout and structure.
- **Sheets:** You can create sheets in advance to further automate sheet set structure.
- **Sheet Set Custom Properties:** You can define standard properties (data fields) that can be linked to your title block MTEXT or attribute fields.

NOTE If you define custom properties that are to be linked to a title block, you may want to consider providing a default value of “----” so that it will be obvious later on if you have fields whose values have not been set, and it will be easy to edit them.

Items that you should NOT include in a sheet set file for AutoCAD Architecture

- **Resource Drawing Locations:** In AutoCAD Architecture your View drawings automatically become your resource drawings. This setting should remain blank in the sheet set properties for an AutoCAD Architecture project.
- **Label Block for Views:** This is taken care of by the “Title Mark” tool on the AutoCAD Architecture tool palettes. These can also be customized to suit office standards. Leave this setting blank.
- **Callout Blocks:** As with title marks, these are taken care of by the various callout tools on the AutoCAD Architecture tool palettes and can be customized to suit office standards. This setting should remain blank.

Project Standards

All settings established in the “Configure AEC Project Standards” dialog box will copy with the template project to become part of the new project. Standards files that are unique to the project, in other words, standards files that reflect project standards that may be supplemental to or override office standards, should be placed in the “Standards” folder of the template project. These files will be copied and their paths updated in the new project.

As with style library drawings, if you are including a non-project based file in your standards files, you need to decide whether to use mapped drives or UNC file pathing. If you’re using mapped drive letters, they must be mapped identically on all users’ workstations. If you choose UNC, you need to be sure that the server path will be remaining the same for the foreseeable future.

Project Tool Catalogs and Palettes

In addition to office standard custom tool catalogs, each project has it’s own content browser library, with it’s own associated project tool catalogs. These, like other project elements, can be configured in the template project as well. There are a few simple guidelines that you should follow when creating project tool catalogs.

- Create your new catalog from the Project Library view in the Content Browser. The project library can be accessed from the content browser button at the bottom of project navigator:

- If you create new catalogs in the project library, you should place them in the *Standards/Tool Catalogs* folder of your template project.

IMPORTANT In order for project catalogs to properly copy when the template project is selected, you must start your template project from one of the templates provided with AutoCAD Architecture. Remember also that even though the project catalog is copied from the template project, the tools within the catalog are unchanged; their paths remain the same as they are in the template.

Project Structure

If you work with a building type that is fairly consistent from one project to another, or a prototypical building type, you may find it advantageous to pre-define some aspects of the project structure itself. None of this is absolutely necessary and the level to which you choose to pre-define these items is completely optional.

Project Structure Items That Can be Established in the Template Project:

- **Levels and Divisions**
- **Constructs and Elements:** In addition to defining categories and sub-categories, any actual construct or element drawings will be copied to the new project from the template project.
- **Views:** If you've created constructs and elements as part of your template project structure, you can also create view drawings that reference the constructs.

NOTE AutoCAD Architecture provides you with the choice to use Relative XREF Paths, which are turned on by default in the project properties. If you choose not to use relative paths and you create constructs, elements and views as part of your template project, when a new project is created, these items will be repathed automatically according to the new project's path.

Tool Catalogs

The tool catalog is one of the most critical components of any office's custom content collection. It is the "central repository" for all tool-based content, which can and should include tools that provide access to styles, AEC Content, callouts, schedule tags and other miscellaneous annotation items. Because it is so central to an effective content distribution and management system, you should spend time planning its location, organization and structure. You should also take steps to protect the contents of the tool catalog from unauthorized or inadvertent modifications.

If users are going to manually load the catalog into their content browser library, pathing is not critical; it simply needs to be placed in a location that all users can browse to. If you choose to automate the loading of the palette by creating a catalog install file, you need to ensure that the network location of the catalog file is accessed in the same way by all users. As with other types of network-based content, carefully consider the advantages and disadvantages of both mapped network drives and UNC pathing.

If you need to control the ability of users to make modifications to the tool catalog, you can store it in a read-only folder. Users will still be able to access the catalog to use the tools, however only those people with permission to write to that location will actually be able to make changes to it.

Display Control

The AutoCAD Architecture display control system is very flexible and powerful, and is drawing-based. Therefore your default display settings should be established in your template drawing. The templates that come with AutoCAD Architecture already have much of the work involved in setting up a display system done for you. While they may require some adjustments to conform to your office or project standards, you should, in most cases, start with the default templates and make modifications to the existing settings rather than try to create a display system from scratch.

Display Hierarchy and “By Material” Display Control

Display control of individual objects can occur at three levels: drawing default, style overrides and object overrides. When you define an object style you should only apply style overrides when absolutely necessary. Frequently you can use material assignments to control the display of linework and hatching components of objects. For this reason, many objects have “By Material” set as a drawing default for many of their display representations.

Display Control Customization

Like most aspects of AutoCAD Architecture, the display system can be customized. There are a few things that you should keep in mind before doing so, however.

Best Practices for Customizing the Display System:

- Start with one of the default templates. Creating a display system from scratch can be very laborious and time-consuming. It’s better to start with a template that is relatively close to what you need and making modifications to it.
- Modify existing display configurations and display sets before creating new ones.
- Don’t create new display representations for objects unless you absolutely have to. Many times you can find an existing display representation that you aren’t using that you can modify to suite your needs. Remember that every display representation that you create is one that you have to manage.

NOTE Remember that display control is drawing-specific. Changes that you make that you intend to be part of your office standard should be made in your drawing template. You can use the Display Manager to copy display configurations, display sets and display representations between drawings.

IMPORTANT If you create a new display configuration that uses an existing display representation that has been modified, you must remember to copy both the display configuration and the modified display representation to your template. When you copy the display configuration to the template the associated display representations and display sets will only be copied with it if they do not already exist in the template. When you manually copy a display set or a display representation into a template that already contains display sets and representations with the same name, you will be prompted to overwrite the existing definitions.

Level of Detail

Level of detail should always be a consideration when creating new content objects and new display representations. By default there are three display configurations that address level of detail provided in the AutoCAD Architecture template drawings:

Display Configuration	Design Scale [Metric Units in Brackets]
High Detail	1/4”=1’-0” [1:50] or greater
Medium Detail	1/8”=1’-0” [1:100]
Low Detail	1/16”=1’-0” [1:200] or smaller

NOTE You may decide that the default display configurations are not appropriate for your preferred graphic standards. You can create additional display configurations and modify the existing ones to accommodate your own standards.

Architectural objects frequently include hatch patterns parameters as part of their display control. You should make sure that the hatch pattern scale and type is appropriate for the level of detail a given display representation is meant to address. Also remember to address hatch pattern scale and type in your material definitions, as it is a best practice to assign material definitions to style-based components. Hatch patterns that represent annotation standards (diagonal lines that represent brick in plan, for example), should be scaled appropriately for your level of detail. Hatch patterns that represent geometry (bricks in elevation, for example), should be given a scale of 1 unit.

Style-Based Content

Style-based content in AutoCAD Architecture is classified under one of three general groups:

- **Architectural Objects:** Traditional architectural object geometry.
- **Documentation Objects:** Any style-based object that is specifically and uniquely used for annotation and documentation purposes.
- **Multi-Purpose Objects:** Any style-based object that could be used to help define either a documentation object style or an architectural object style.

Many styles can be used to create style-based tools on a palette. Others are used as nested styles or “substyles”. All styles and definitions can be edited from the Style Manager and stored in a central style library drawing.

TIP You can assign a pre-defined keynote from your keynote database to any style that you create in the “General” tab of the style definition.

Architectural Objects

When referring to styles, the term “Architectural Objects” refers to any object style that will result in the creation of a specific type of architectural geometry, such as a wall, door, stair, roof slab, etc. It also refers to “sub-styles” that are related to those object types, such as wall endcaps and slab edge styles.

Walls

Walls are among the more complex objects and are affected by a variety of styles and substyles. When a wall style that references a specific substyle is imported into a drawing it will import all necessary substyles with it.

Wall Styles

Naming Conventions:

You should provide as much information about the wall structure in the name itself as practical. This makes it easier to discriminate between wall styles in a long list without having to refer to the wall style description. The first component listed is the major structural component. The last component listed is usually a finish component:

<Component name>-<Size in decimal units> <Component name>-<Size in decimal units>...

Example Wall Style Names:

Wall Style Description	Example Name
Wall structure: 5/8" gypboard interior finish, 3 1/2" wood stud, 1/2" sheathing, 1" air gap and 3 5/8" brick veneer.	Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625
Wall structure: 5/8" Gypboard interior finish on both sides of a 3 1/2" wood stud.	Stud-3.5 GWB-0.625 Both Sides
Wall structure: 5/8" Gypboard interior finish on both sides of a variable width wood stud.	Stud-X GWB-0.625 Both Sides

Best Practices for Wall Styles:

- Walls are directional, and should be considered as having an exterior and interior side. The exterior, or positive side of the wall is at the top of a wall running left to right. Wall components should be defined so that the index order is from exterior to interior. The component furthest to the exterior side of the wall should have an index assignment of 1, while the most interior component will have the highest index assignment.

- When specifying the edge offset of a component, the value should always be to the most interior edge of the component.
- The width of components is always a positive value.
- Wall Priorities should be standardized and based on the existing AutoCAD Architecture convention, which is documented in the AutoCAD Architecture User Guide.
- Materials should be assigned to all wall components.
- Plan display of wall components should normally be set to observe the drawing default settings. Best practice is to assign materials to wall components and set their linework and hatch pattern parameters to "By Material" in the plan display settings.

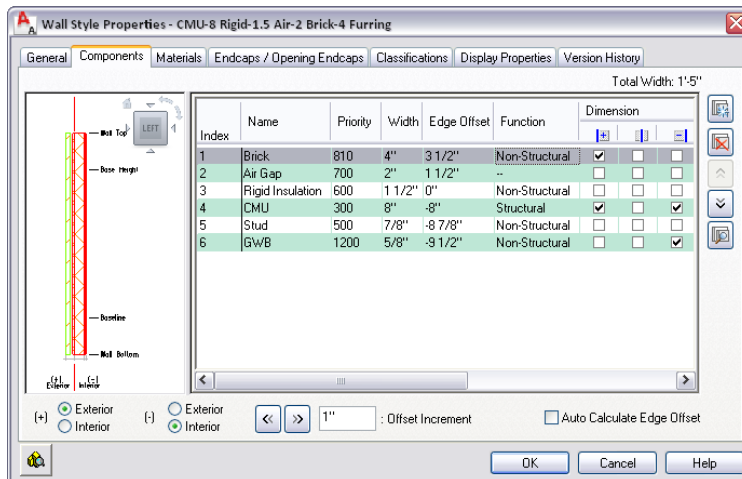

NOTE Prior to the introduction of material definitions in Architectural Desktop 2004 it was common and recommended practice to assign wall style components to nested layers and set their color, line type, line weight and plot style settings to "BYLAYER". While this is still technically valid in AutoCAD Architecture 2009, it is not recommended except for a very few exceptions (such as the "Plan Screened" display representation, which is frequently used to export plan displays to consultants using AutoCAD, who desire the items to be on a prescribed layer and assigned colors appropriate for background drawings).

- Model display of wall components should be set to the drawing defaults, to allow for material assignments to control the color and hatching of walls when viewed in non-orthogonal views.
- Wall styles should be classified. This allows for more flexible scheduling and tagging in the future, as well as more display control options.

NOTE The Uniformat II classification definition is supplied in the *Uniformat II Classifications (1997 ed).dwg* file located in the *AEC Content\Styles* path. This classification definition is fairly comprehensive and in many cases serves well in classifying all types of AutoCAD Architecture object styles according to a uniform standard.

- Walls that have one or more obvious internal dimension points (such as the outside of a structural component) should have those specified in the wall style “Components” tab under the “Dimensions” column. This allows for more accurate application of AEC Dimensions.
- Wall components should be assigned a “Structural” or “Non-Structural” designation under the “Type” column in the “Components” tab, again to allow for more effective use of AEC Dimensions.
- Walls should have an interior and exterior side specified as part of the wall style definition to ensure more accurate AEC Dimensioning.

To ensure accurate dimensioning with AEC Dimensions, the wall in the following image has had its components assigned to either “Structural” or “Non-Structural” types. Dimension points and the exterior/interior sides of the wall are also specified.

Wall Endcap Styles

Wall endcap styles are intended to be used with specific wall styles. They can be used to define actual end conditions as well as opening conditions as part of a Wall Opening Endcap Style.

Naming Conventions:

Wall endcap styles should be named according to the wall style to which they apply, with an indication of the condition they are meant to address:

<Associated wall styles> (<End condition><Index>)

Example Wall Endcap Style Names:

Wall Endcap Style Description	Example Name
For wall style <i>Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625</i> to define the first end condition.	Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625 (End1)

Wall Endcap Style Description	Example Name
For wall style <i>Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625</i> to define a possible second end condition.	Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625 (End2)
or wall style <i>Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625</i> to define a jamb condition.	Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625 (Jamb1)

Best Practices for Wall Endcaps:

- Endcaps are drawn for each component. Components for which there is no endcap defined will terminate as soon as another component's endcap is encountered. For that reason, you need to draw a complete endcap for each component except for those that are intended to terminate at the location on the wall where the endcap is applied.
- Endcaps are applied perpendicular to the direction of the wall. The endpoints of each endcap are normally drawn so that an imaginary line connecting them would be perpendicular to the wall edges, except in the case where an endcap is intentionally skewed.
- It is typically not recommended to define endcaps for walls with variable width components. As a component's width is changed, its associated endcap will adjust to accommodate the change in width, however the endcap will maintain its proportions, causing distortions to occur to the end effect.

Wall Opening Endcap Styles

Wall Opening Endcap Styles apply to door, window, opening and door/window assemblies that are inserted into a wall. They consist of a collection of wall endcap styles that are applied to the head, jamb and sill conditions of the opening.

Wall Opening Endcap Style Naming Conventions:

The naming convention for a wall opening endcap style is similar to that for a wall endcap style:

<Associated wall style> (Opening<Index>)

Example Wall Opening Endcap Style Names:

Wall Opening Endcap Style Description	Example Name
Wall opening endcap style for a wall style named <i>Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625</i> .	Stud-3.5 Brick-3.625 Sheathing-0.5 Air-1 GWB-0.625 (Opening1)

Wall Cleanup Group Definitions

Wall Cleanup Group definitions should allow objects anchored to walls in other cleanup groups to be moved or copied to walls of the current cleanup group unless there is a compelling reason to not allow it. Cleanup between host and xref drawings should be turned on by default unless performance issues arise. There are no naming conventions for wall cleanup group definitions.

Wall Modifier Styles

Wall modifiers are typically best created "on the fly" by first creating a 2D polyline and converting it to a wall modifier. During the process you are prompted for a name to assign to a new modifier style, which is created from your geometry. Modifier styles define minimal information about the shape of the modifier itself. There are no current conventions for naming or application of wall modifier styles.

NOTE Wall modifiers can vary widely in shape and size from one instance to the next, even if they belong to the same style. To ensure that the modifier you wish to apply to a wall represents the shape that you want, first draw a 2D polyline and then use the right-click menu to convert the polyline to a wall modifier. You will be prompted for a new wall modifier style name during the process; each converted polyline must define a different modifier style. For these reasons, you may find it more effective in many cases to use *body modifiers* instead, which are not style-based.

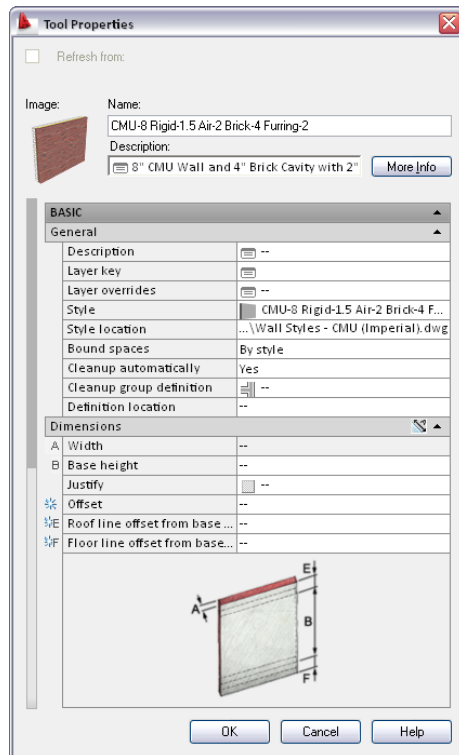

Palette-Based Wall Tools

The only wall-based style that can be assigned to a palette-based tool is the wall style itself. However when the wall style is used, any substyles that it uses, such as wall endcap styles and wall opening endcap styles, will be imported with it automatically. Additionally there are some tool properties that you may want to consider setting as defaults before saving the tool to a catalog:

- **Justification:** In the case of exterior walls, the baseline is usually defined at a critical dimensional location within the wall structure. In these cases it is a good idea to pre-set the justification property of the tool to “Baseline”.
- **Cleanup Group Definition:** If you have defined a wall that should not clean up with other walls that are not of the same type, you can pre-set the cleanup group definition that it is inserted with.

IMPORTANT To pre-set the wall cleanup group definition, you must first specify the library drawing in which the cleanup group definition exists, then define the cleanup group to use. Even if the cleanup group already exists in the current drawing, it will not be used unless you specify the definition location.

Wall tool pre-sets to establish the default cleanup group definition and the justification.

Doors and Windows

Doors and windows comprise three primary AutoCAD Architecture object styles: doors, windows and door/window assemblies.

Door Styles

Naming Conventions:

As with wall styles, the name for a door style should provide as much information about the door as possible. The format is:

<Door Operation> - <Door Type> - <Optional Door Shape> <Optional Case Type>...

NOTE Doors with no shape specified are assumed to be rectangular.

Example Door Style Names:

Door Style Description	Example Name
A single hinge, flush rectangular door.	Hinged - Single
A single hinge, flush rectangular door, explicitly for exterior use.	Hinged - Single - Exterior
A double hinge, paneled arched door.	Hinged - Double -Arched - Paneled
A single overhead door, paneled, for exterior use.	Overhead - Single - Paneled - Exterior
A single hinge, full glazed door, for use in a door/window assembly.	Hinged - Single - Full Glazed - Assy

IMPORTANT It is important to indicate those doors that are intended explicitly for assemblies. They will frequently have conditions defined that will not look correct when inserted into a wall independently from the assembly for which they were defined.

Best Practices for Door Styles:

- All door components should have materials assigned to them.
- Door styles should be classified for more control with scheduling and display control. As with walls, the Uniformat II Classification definition contains a ready-made list of classifications, including basic door classifications.
- In the “Model” display representations of doors components should follow “By Material” settings.
- In the “Elevation” display representations components should be assigned colors with the display rules of your *2D Section/Elevation styles* in mind. Using colors that are coordinated with those styles can be used to automate linework properties in section and elevation objects.

Window Styles

Naming Conventions:

The naming convention for window styles is similar to that for doors, however is a bit more relaxed with more items becoming optional:

<Optional Window Operation> - <Window Type> - <Optional Window Shape> <Optional Case Type>...

NOTE Windows with no window shape specified are assumed to be rectangular. Windows with no operation specified are assumed to be fixed.

Example Window Style Names:

Window Style Description	Example Name
A rectangular Picture Window.	Picture
An arched double casement window.	Casement - Double - Archtop
An awning window, to be used explicitly in a door/window assembly.	Awning - Assy

IMPORTANT It is important to indicate those windows that are intended explicitly for assemblies. They will frequently have conditions defined that will not look correct when inserted into a wall independently from the assembly for which they were defined.

Best Practices for Window Styles:

- All window components should have materials assigned to them.
- Window styles should be classified for more control with scheduling and display control. As with walls, the Unifomat II Classification definition contains a ready-made list of classifications, including basic window classifications.
- In the “Model” display representations of window components should follow “By Material” settings.
- In the “Elevation” display representations components should be assigned colors with the display rules of your *2D Section/Elevation styles* in mind. Using colors that are coordinated with those styles can be used to automate linework properties in section and elevation objects.

Door/Window Assembly Styles

Naming Conventions:

The naming convention for door/window assemblies should reflect as much as possible the infill elements that they include, any cell adjustment parameters and where appropriate, the general position of infills in the assembly. In addition, if certain infills have a fixed size, it is helpful to indicate these as well. Different infill types are separated with a “+” symbol. These are loose guidelines at best; the very flexibility of door/window assembly styles and virtually unlimited combination of infills and grids makes it impossible to develop a fixed naming convention that will apply to all conditions:

<Infill Type> <Optional Infill Size> <Optional Infill Position> <Optional Cell Adjustment Parameter> + <Next Infill Type>....<Optional Door/Window Assembly Shape>

NOTE Door/Window Assemblies with no shape specified are assumed to be rectangular. In the case of a very complex door/window assembly, you may choose to omit some of the less prominent infill types and parameters, choosing instead to include them in a more complete style description.

Example Door/Window Assembly Style Names:

Door/Window Assembly Style Description	Example Name
An arched assembly with 4' windows and a two foot tall arched transoms, centered, with both side cells configured to grow as the assembly width is changed until the 4' size can be accommodated	Windows4-0 Ctr Grow + Transom 2-0 Ctr Arched
Hinged double door with variable width sidelights on each side and a transom.	Hinged Double 6-0x6-8 + Sidelights + Transom
A hinged single door on the right side with a single sidelight and a transom.	Hinged Single 3-9x6-8 Right + Sidelight + Transom

Best Practices for Door/Window Assembly Styles:

- All assembly components should have materials assigned to them.
- Door/Window Assembly styles should be classified for more control with scheduling and display control. This is especially important with assemblies that are explicitly intended to be included in a window or door schedule as a mulled unit.

NOTE In cases where an assembly includes a door or window infill and the assembly is to be included in a door or window schedule, you can choose not to classify the door or window infill. This will help you to make sure that the infill is not included in the schedule as a separate item from the assembly of which is a part.

- The “Model” display representations of assembly components should follow “By Material” settings.
- The “Elevation” display representations components should be assigned colors with the display rules of your *2D Section/Elevation styles* in mind. Using colors that are coordinated with those styles can be used to automate linework properties in section and elevation objects.
- Naming of assembly components: In order to minimize confusion when editing door/window assembly styles, you should be descriptive and consistent when naming the components of the style. In general, each name should end with the type of assembly element it refers to. For example, an infill name might be “Entry Door *Infill*”. In particular, care should be taken to name grids and the divisions they are based on. A grid using a division named “Sidelight Vertical Division” should be named “Sidelight Vertical Grid”

Curtain Walls

Curtain walls comprise two primary AutoCAD Architecture objects: Curtain wall styles and curtain wall unit styles. Curtain walls can also use door, window and door/window assembly styles as infills.

Curtain Wall Styles

Naming Conventions:

As with other style types, the naming for curtainwalls should be as descriptive as possible, but because curtainwalls can be even more varied and complex in their structure than door/window assemblies, you should not expect to fully describe the details of the style in the name:

<Major Element (Descriptive) + <Major Element (Descriptive)>...

Example Curtain Wall Style Names:

Curtain Wall Style Definition	Example Name
A curtain wall whose first floor cell assignment consists of wide mullions meant to simulate wall panels, with a 4' x 4' pattern of standard window mullions and glazing panels above.	Mass Base + 4x4 Grid Above
First floor with stone panels, revolving doors and glazing above in variable pattern (perhaps with nested assemblies or curtain wall unit styles as infills).	Stone Base + Revolving Doors + Variable Grid Above

Best Practices for Curtain Wall Styles:

- All curtain wall components should have materials assigned to them.
- The “Model” display representations of curtain wall components should follow “By Material” settings.
- The “Elevation” display representations components should be assigned colors with the display rules of your *2D Section/Elevation styles* in mind. Using colors that are coordinated with those styles can be used to automate linework properties in section and elevation objects.
- Naming of curtain wall components: In order to minimize confusion when editing curtain wall styles, you should be descriptive and consistent when naming the components of the style. In general, each name should end with the type of curtain wall element it refers to. For example, an infill name might be “Stone Panel *Infill*”. In particular, care should be taken to name grids and the divisions they are based on. A grid using a division named “First Floor Vertical Division” should be named “First Floor Vertical Grid”

Curtain Wall Unit Styles

Naming Conventions:

Curtain wall units, while similar in many respects to door/window assemblies and curtain walls, are limited to simple panel infill definitions. The naming conventions are similar to those for curtain walls, but you can also include indicators of cell adjustment parameters as well:

<Major Element (Descriptive) + <Major Element (Descriptive)>...<Optional Cell Adjustment Parameter>

Example Curtain Wall Unit Style Names:

Curtain Wall Unit Style Definition	Example Name
A curtain wall unit with 2 x 2 glazing panels:	2 x 2 Glazing

Curtain Wall Unit Style Definition	Example Name
A curtain wall unit with 4' wide glazing panels, mullions coming to a point at the top, with the side cells set to grow until a new 4' panel can be added:	Glazing 4-0 Grow + Pointed Mullions

Best Practices for Curtain Wall Unit Styles:

- All curtain wall Unit components should have materials assigned to them.
- Unless a curtain wall unit is to be scheduled as a separate item, you should not classify curtain wall unit styles.
- The “Model” display representations of curtain wall unit components should follow “By Material” settings.
- The “Elevation” display representations components should be assigned colors with the display rules of your *2D Section/Elevation styles* in mind. Using colors that are coordinated with those styles can be used to automate linework properties in section and elevation objects.
- Naming of curtain wall unit components: In order to minimize confusion when editing curtain wall styles, you should be descriptive and consistent when naming the components of the style. In general, each name should end with the type of curtain wall element it refers to. For example, an infill name might be “Stone Panel *Infill*”. In particular, care should be taken to name grids and the divisions they are based on. A grid using a division named “First Floor Vertical Division” should be named “First Floor Vertical Grid”

Roofs and Slabs

Roof slab styles can contain more than one component, similar to wall styles; many of the conventions are therefore the same or similar. Roof slabs can also use roof slab edge styles.

Roof Slab Styles

Naming Convention:

Roof slab styles, like wall styles, include multiple components. The name should indicate the structure of the roof and the dimensions of the major components (minor components such as roofing felt can have the dimension omitted). The first component listed should be the major structural component. The last component should be the finish component (if any):

<Component name>-<Size in decimal units> + <Component name>-<Size in decimal units>...

Example Roof Slab Style Names:

Roof Slab Style Definition	Example Name
Roof Structure: 2x8 Rafter, roofing felt, asphalt shingles.	Rafter-7.25 + Shingles

Best Practices for Roof Slab Styles:

- Materials should be assigned to all roof slab components.
- Roof slabs should be defined with the baseline at the bottom of the major structural component.
- The index order of roof slab components should be indexed from top to bottom, with the top component having index 1.

- Thicknesses of components should always be positive. The thickness offset from the baseline should always be to the bottom edge of the component.
- You should consider classifying all roof slab styles to allow for more display control options.

Roof Slab Edge Styles

Roof slab edge styles are fairly simple and can contain a maximum of only two components: the fascia and the soffit. Unlike wall endcaps, roof slab edge styles are not applied to individual roof slab components, but to the roof slab as a whole.

Naming Conventions:

Roof slab edge styles should be named according to the fascia and/or soffit condition they define:

<Optional nominal fascia size> <Optional fascia> + <Optional nominal soffit size> <Optional soffit> - <Optional default edge cut condition> - <Optional edge overhang>

Example Roof Slab Edge Style Names:

Roof Slab Edge Style Description	Example Name
1x4 Fascia, no soffit, plumb cut, no overhang.	1x4 Fascia - Plumb
1x8 Fascia, 5/8" soffit, plumb cut, 1' overhang.	1x8 Fascia + 5-8 Soffit - Plumb - Overhang 12
4x4 Cant strip edge style (for built-up roof).	4x4 Cant

Best Practices for Roof Slab Edge Styles:

- When creating the profiles for the edge, draw them for the right side of the roof when drawn in section.
- Exercise discretion when turning on "Auto-Adjust to Edge Height". While this will cause the fascia to adjust to a variable width component in a roof slab as it changes thickness, the adjustment is proportional. The fascia will adjust both vertically and horizontally. The same consideration should be taken into account when turning on the option to adjust the soffit to the overhang depth.

NOTE Roof slab edge styles can not be applied as a part of the roof slab style definition; instead you can apply them as a palette-based tool property. Many of the roof slab styles included in the sample content files that ship with AutoCAD Architecture indicate in their names a specific roof slab edge style and when a tool is created from those styles, the slab style is already assigned to the tool properties. These styles originated in an earlier version of the software in which default roof slab edge styles could be assigned to a roof slab style. This capability was removed from the User Interface of the roof slab style editor, however the style properties were left in those sample styles.

Slab Styles

Naming Convention:

Slab styles, like wall styles, include multiple components. The name should indicate the structure of the slab and the dimensions of the major components (minor components such as vapor barriers, linoleum floor finishes, etc., can have the dimension omitted). The first component listed should be the major structural component. The last component should be the finish component (if any):

<Component name>-<Size in decimal units> + <Component name>-<Size in decimal units>...

Example Slab Style Names:

Slab Style Description	Example Name
Slab Structure: 6" Concrete, ceramic tile flooring.	Concrete-6 + Tile-Ceramic

Best Practices for Slab Styles:

- Materials should be assigned to all slab components.
- Slabs should be defined with the baseline at the bottom of the major structural component.
- The index order of slab components should be indexed from top to bottom, with the top component having index 1.
- Thicknesses of components should always be positive. The thickness offset from the baseline should always be to the bottom edge of the component.
- You should consider classifying all slab styles to allow for more display control options.

Slab Edge Styles

Slab edge styles are fairly simple and can contain a maximum of only two components: termed "fascia" and "soffit". As with roof slab edge styles, slab edge styles are not applied to individual slab components, but to the slab as a whole.

Naming Conventions:

Slab edge styles should be named according to the fascia and/or soffit condition they define:

<Optional fascia size> <Optional fascia> + <Optional nominal soffit size> <Optional soffit> - <Optional default edge cut condition> - <Optional edge overhang>

Example Slab Edge Style Names:

Slab Edge Style Description	Example Name
6" Curb.	Curb
36" x 18" grade beam with brick lug.	36x18 Grade Beam + Brick Lug

Best Practices for Slab Edge Styles:

- When creating the profiles for the edge, draw them for the right side of the slab when drawn in section.
- Exercise discretion when turning on "Auto-Adjust to Edge Height". While this will cause the fascia to adjust to a variable width component in a slab as it changes thickness, the adjustment is proportional. The fascia will adjust both vertically and horizontally. The same consideration should be taken into account when turning on the option to adjust the soffit to the overhang depth.

NOTE Slab edge styles can not be applied as a part of the slab style definition; instead you can apply them as a palette-based tool property. Many of the slab styles included in the sample content files that ship with AutoCAD Architecture indicate in their names a specific slab edge style and when a tool is created from those styles, the slab style is already assigned to the tool properties. These styles originated in an earlier version of the software in which default slab edge styles could be assigned to a slab style. This capability was removed from the User Interface of the slab style editor, however the style properties were left in those sample styles.

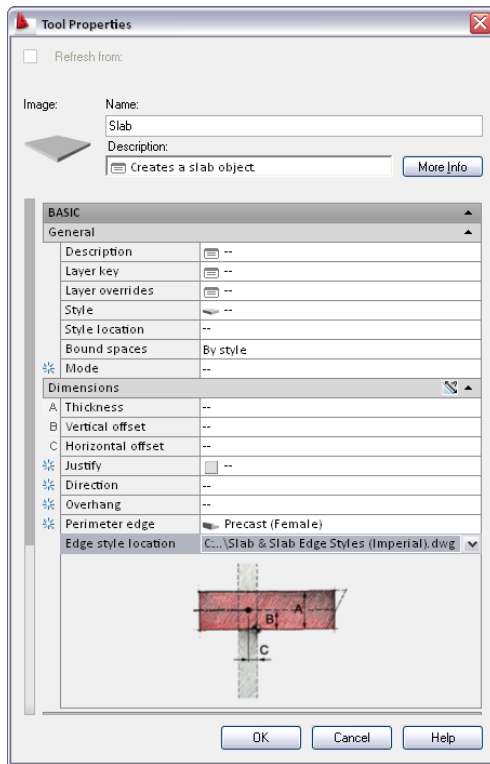

Palette-Based Roof Slab and Slab Tools

To apply a slab edge or roof slab edge style at the time of creation, you can specify them as default properties of a palette-based tool along with other properties:

- You may want to consider “Top”, “Bottom” or “Baseline” justification, depending upon the type of slab and its intended purpose.
- The Vertical Offset can be set to pre-determine an elevation for the slab.
- You can establish an edge style as a default.

IMPORTANT To pre-set the edge style, you must first specify the library drawing in which the edge style exists, then define the edge style to use. Even if the edge style already exists in the current drawing, it will not be used unless you specify the style location.

Slab tool properties, with a slab edge style set as the default.

Stairs and Railings

Stairs can be created using a parametric object or from a 2D sketch. In both cases, the resulting object will be based on a stair style definition.

Stair Styles

There are no naming conventions for stair styles. In general the name should simply indicate the overall purpose or stair type and possibly include the primary structure, material or construction of the stair.

Example Stair Style Names:

Stair Style Description	Example Name
Steel stairs with a housed stringer.	Steel - Housed
Stair style configured to act as a concrete ramp with stringers configured to act as curbs.	Ramp - Concrete + Curb

Best Practices for Stair Styles:

- Consider carefully the ramifications, pro and con, of allowing the landing extension settings and stair component settings to vary amongst stairs of the same style. Turning these options off makes them “hard coded” to the style. Turning them on makes them merely defaults to be applied during the creation of a stair, but able to be overridden.
- When a style is assigned to a custom stair created from linework, the stringer offsets specified in the style definition will be calculated from the lines that you select for the stringer locations.
- Landing extensions that are defined in the stair style will be ignored when creating a custom stair from linework.

Stair Winder Styles

Winder styles can be applied to stairs with the “Turn type” set to either “1/4 Turn” or 1/2 Turn.

Stair Winder Styles Naming Conventions:

The stair style name should indicate the Winder type, followed by specifics as to any tread or riser controls:

<Winder type> - <Optional control parameter>...

Example Stair Winder Style Names:

Stair Winder Style Description	Example Name
Manual winder type, “Use Riser Line” toggled on under “Settings”.	Manual - Riser
Single Point winder type, “Adjust Winder Turn” checked on under “Tread Settings in Turn Area”, with 2 treads per turn.	Single Point - 2 Tread

Best Practices for Stair Winder Styles:

- Before defining a new stair winder style, check the existing style content library files. Most of the typical winder conditions have already been defined.
- When using the single point type, it is important to clear “Use Riser Line” if the turn point will be on the edge or corner of the stair. Otherwise, the treads will overlap and the stair will be defective.

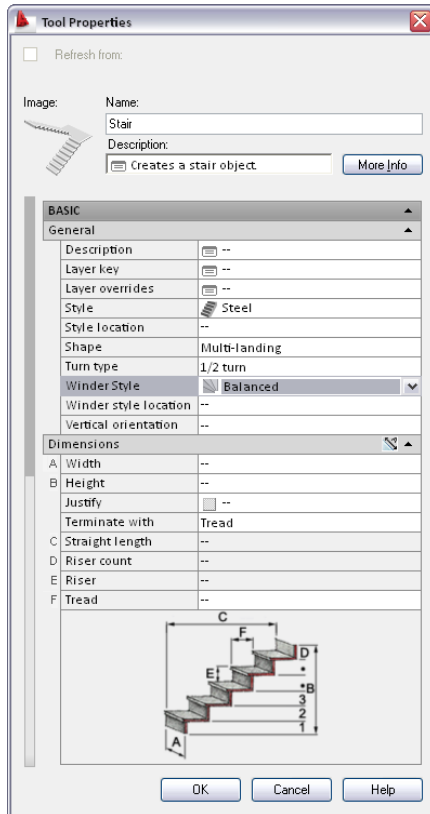

Palette-Based Stair Tools

When creating a tool for a stair style you may want to consider the following optional pre-sets:

- Stair shape: although many properties of a stair can be changed after the stair has been placed, the stair shape can only be set at the time of creation. You may want to consider having the stair shape (multi-landing, U-shaped, spiral or straight) be a default setting for your stair tools.

- Turn type: you can specify either landings or turns. This is also a setting that cannot be changed after the stair has been placed.
- Winder style and winder style location: If you specify a turn as the turn type, you can set the winder style to use on the turn. If you specify the winder style, you can also specify a different drawing from which to import the winder style.
- Stair termination: You can pre-determine whether the stair should end with a riser, tread or landing. This setting can be changed after the stair has been placed as well.

The stair tool properties

Railing Styles

Railing style names should be as descriptive as possible, listing the major components of the railing.

Railing Styles Naming Conventions:

<Rail type> - <Rail Shape> + <Additional component> + <Additional component>...

Example Railing Style Names:

Railing Style Description	Example Name
Guardrail, circular with a handrail and rod balusters.	Guardrail - Pipe + Handrail + Rod Balusters
Guardrail, circular with a handrail and returns:	Guardrail - Pipe _+ Handrail + Return

NOTE If a custom display block applied as a style-level display override defines a component, such as a return, it should be listed as an additional component in the railing style name.

Spaces

Spaces have a multitude of uses, spanning the conceptual design through construction documents phases of a project. Among other things, spaces can begin to define the layout of a building's internal rooms and areas. They can also define rooms and areas for scheduling purposes and for area calculations and evaluations. They can also contain information valuable to users of AutoCAD MEP who need to process the geometry for analysis.

Space Styles

Space style names should be indicative of the type of room or area that the space style is meant to address.

Space Style Naming Conventions:

<Room/Area use> - <Optional relative size> - <Optional building type>

Example Space Style Names:

Space Style Description	Example Name
Large commercial kitchen.	Kitchen - Large - Commercial
Dining room for a restaurant.	Dining_Room - Restaurant
Residential Bedroom.	Bedroom
Bedroom for a hotel suite.	Bedroom - Hotel

Best Practices for Space Styles:

- Spaces can have a “Name” property assigned. These are derived from a *List Definition*. The List Definition should be assigned to the style so that you have a valid list of names to select from when establishing the space object's properties.
- Space styles should have materials assigned to their “Floor” and “Ceiling” components.
- Because space styles can work in conjunction with *Zone Definitions* you may want to store them in the same library file to make it easier to make changes later.

Structural Members

Structural Member Shape Definitions

Structural Member Shape Definitions should be named according to the structural member style(s) for which they are intended to be a part of. For example, if you are defining a steel bar joist member style and you've defined a structural member shape definition on which you plan to base the bottom chord component of the joist, you would name it simply “Steel Joist Bottom Chord”.

Structural Member Styles

Structural members should be named according to the specific structural object type that they are to represent, including dimensional information.

Structural Member Style Naming Conventions:

<Structural member type> <Size>

NOTE Frequently standard structural shape designations include the size of the member. In these cases, the structural name can simply be the structural designation.

Example Structural Member Style Names:

Structural Member Style Description	Example Name
Wide flange steel shape (W8x40).	W8x40
10" K Series Bar Joist.	Bar Joist 10K1
Decorative square tapered square column (specific use).	Decorative Square Column - Tapered 12"-8"
10" Plywood Web Wood Joist.	Plywood Web Joist - 10

NOTE Naming conventions for structural member styles are not fixed. In the case of structural member styles defined as a result of the Structural Member Catalog, it is acceptable and more efficient in many cases to use the default name that is provided by the catalog. As an example the "Plywood Web Joist - 10" style name listed above would be "10in Plywood Web Wood Joist".

Best Practices for Structural Member Styles:

- When naming a structural member style, consider whether it can be used for more than one purpose. For example, wide flange shapes can be used for either columns, bracing or beams. In the case of such an element, you should not indicate a specific use in the member style name.
- When defining custom display blocks for the Model display of structural member styles, you should use other structural members to define the blocks where possible, in lieu of mass elements. An example of this is seen in the example Bar Joist styles that are provided with AutoCAD Architecture. The custom display blocks that define the webbing are made from a structural member style called "Steel Joist Webbing".
- Materials should be assigned to structural member style components.

Documentation Objects

AutoCAD Architecture documentation objects are object types that are explicitly for use as annotation tools. Rather than define 3D geometry, they define data structures and 2D annotation graphics.

NOTE Since documentation objects do not define geometry, it is not necessary to classify their styles for scheduling purposes, however you may want to consider it if you need more display control than that provided by the normal display set controls.

Sections and Elevations

2D sections and elevations define the 2D representation of orthogonal views of a 3D building model. They are not geometric objects in and of themselves, but are more of a “report” of the model.

2D Section/Elevation Styles

The purpose of a 2D Section/Elevation style is to automate the display characteristics of linework in the section/elevation object.

IMPORTANT It is important to have a standardized display system established before creating custom 2D Section/Elevation styles. The Design Rules of a Section/Elevation style are wholly dependent upon the colors assigned to objects in the display representation used by the section/elevation object. By default, this is usually an object’s “Model” or “Elevation” display representation. To find out which specific display representation is used by section/elevations for each object type, you can refer to Display Manager and review the Display Representation Control for the “Section_Elev” display set, or whatever other display set is specified as part of the section/elevation’s properties.

2D Section/Elevation Style Naming Conventions:

<2D Section purpose or use> - <Optional scale>

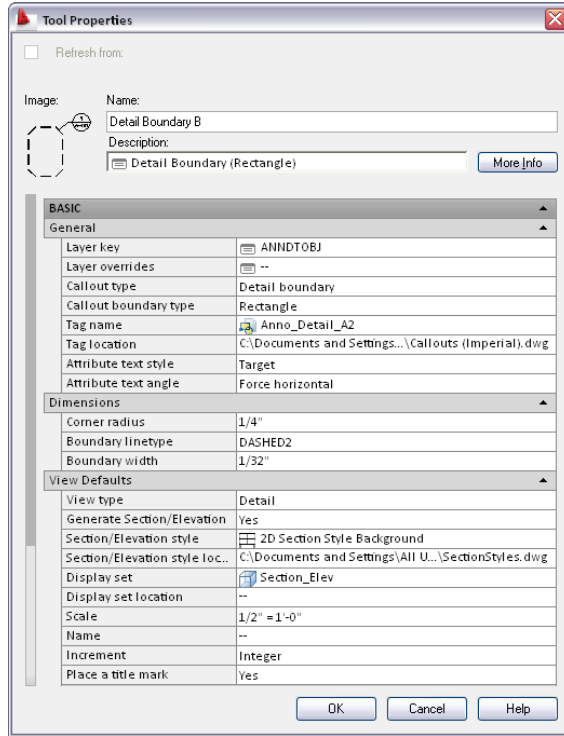

Example 2D Section/Elevation Style Names:

2D Section/Elevation Style Description	Example Name
A section/elevation style to be used for elevations and sections plotted at 1/4”=1’-0”.	Bldg Section-Elevation - 48
A section/elevation style for use as a background for a detail view.	Detail Background

Best Practices for 2D Section/Elevation Styles

- If you define custom components and design rules in your section/elevation style, you should always include a description. The description for the design rules should explain what action each rule takes in the display properties of the style. For example, you might have a display component named “Swing Lines”. The component description would be simply “Door and Window swing lines”. The design rule accompanying the component might have a description of “Make window and door swings a fine line weight and dashed”.
- For a section/elevation style intended to be used as a detail background, you should place all display components on a no-plot layer.
- Section/elevation styles cannot, by themselves, be made into a palette-based tool. Instead you refer to them in a callout tool’s properties. You can specify the library file containing the section/elevation style, and the specific section/elevation style to be used with the callout.

Callout tool properties including the 2D Section/Elevation Style to use, the style library from which to import the style, the default scale and display set to use.

Dimensions

In addition to traditional AutoCAD dimensioning, AutoCAD Architecture provides more intelligent and automated AEC Dimension objects. Thoughtful creation of AEC Dimension Styles can greatly improve productivity during the construction documents phase of a project. Another benefit of AEC Dimension styles is that as AEC objects, they can be controlled with the AutoCAD Architecture Display System, and can be scale-dependent; the same AEC Dimension can be used for any number of scales in the drawing. Changing the display configuration to one set up for a different scale can also cause the AEC Dimensions to modify their appearance to be more appropriate for the new scale.

AEC Dimension Styles

AEC Dimension Style Naming Conventions:

<Maximum number of chains> - <Optional unique purpose>

Example AEC Dimension Style Names:

AEC Dimension Style Description	Example Name
Dimension style with maximum 3 chains, for use in normal construction documents dimensioning.	3 Chain
Dimension style with maximum 2 chains, to display metric units in a drawing configured for imperial units.	2 Chain - Alternate Metric

Best Practices for AEC Dimension Styles:

- Make your dimension styles scale dependent where possible, by using different AutoCAD dimension styles with different settings for “Overall Scale”. By changing display configurations, you can use a different display representation for dimension styles that adjusts to different scales and detail levels.
- It is not necessary to store AEC Dimension styles, or the AutoCAD dimension styles on which they are dependent upon for display in the template drawing. Instead you can use the tool properties to import them as needed from a style library. Necessary AutoCAD dimension styles will also be imported.
- If you have configured the “Dimension” and “Type” parameters of your wall style components, you can and should take advantage of this in the AEC Dimension’s “Content” settings for the “Wall Width” dimension parameters by specifying “From Style” or “Structural from Style”.

Schedules and Property Sets

Schedules, property set definitions, data format styles and display themes are all tightly interrelated. Because of that, you should take the time to plan out carefully your system of property data usage.

Property Set Definitions

In addition to defining data fields for schedules, property set definitions can also be used to create “smart” object tags and can be used to override display settings for objects. Because of their myriad uses, you should plan them carefully. Of utmost importance, you need to carefully consider what specific object type(s) your property set definition will apply to and whether or not it will be style-based or object-based.

NOTE Because Property Set Definitions, Property Data Format Styles, Schedule Table Styles and Display Theme Styles are so inter-dependent you may want to consider storing them in the same style library to make it easier to make modifications later on.

Property Set Definition Naming Conventions:

<Object type><Optional additional description><Attachment (style or object)>

Example Property Set Definition Names:

Property Set Definition Description	Example Name
Property set definition for doors, object-based.	DoorObjects
Property set definition for window frame information, attached to window styles.	WindowFrameStyles

Best Practices for Property Set Definitions:

- Do not include spaces in property set definition names or property names. In the event that you want to have a property displayed in an object tag, it will need to be referenced by an AutoCAD attribute definition by name when the “Define Schedule Tag” tool is used. Attribute definition tags cannot include spaces.
- When a property is selected for use in a schedule table column, the property’s description is the default column header. While this can easily be overridden at any time, if you keep it in mind when you are defining your properties you can streamline the task of creating schedule tables somewhat.
- If you have legacy property set definitions for anchored objects that include formula-based properties that extract information based on the host object’s properties, you should consider replacing them with

the “Anchor Property” in AutoCAD Architecture. An example of this would be a door’s fire-rating property where you want to make sure it is set to match the fire-rating of the wall it is anchored to.

- Take advantage of AutoCAD Architecture’s new ability to hide properties. This is useful if you have a property that is not actually directly edited by a user. By disabling its visibility you can minimize confusion when viewing and editing properties in the “Extended Data” tab of the object properties palette.
- If you have classified your object styles, consider strongly using classifications to further filter the object and style types that your property sets apply to. This is much more reliable than using layer filters.

Property Data Formats

Property Data Formats control the appearance and character/numeric formatting of property set values when they appear in a schedule table.

Property Data Format Naming Conventions:

Naming conventions for property data formats is fairly relaxed and descriptive:

<Data type/purpose> - <Optional description>

Example Property Data Format Names:

Property Data Format Description	Example Name
Property data format to display the area of an object.	Area
Property data format to display a numerical value as a length to 1/16” precision.	Length - Short 1-16

NOTE In cases of numerical values formatted for a specific precision, you can choose to leave the actual precision value out of the data format style name, however you should indicate it in the description.

Best Practices for Data Format Styles:

- Before creating a new data format style, check to make sure there isn’t already an existing one that you can re-use. There are a large number of pre-configured data format styles in the existing “Schedule Tables (Imperial).dwg” or “Schedule Tables (Metric).dwg” files in your AutoCAD Architecture content folder.

Schedule Table Styles

Schedule Table Style Naming Conventions:

<Object type> Schedule <Optional additional qualifier>

Example Schedule Table Style Names:

Schedule Table Style Description	Example Name
Door schedule, using standard door number property (not project-based).	Door Schedule
Door schedule, using project-based door number.	Door Schedule Project Based

Best Practices for Schedule Table Styles:

- If you have classified your object styles, consider strongly using classifications to further filter the object and style types that your schedule applies to. This is much more reliable than using layer filters.
- Pay special attention to the “Applies to” property of your schedule table style. It must match exactly the “Applies to” property of any property set definitions whose properties you intend to use for schedule table columns.

Display Theme Styles

Aside from making sure that your style names are descriptive, there are no conventions or standards for Display Theme Styles.

Zones

Zones allow you to group your spaces together for use in area calculation schemas, as and presentations (showing spaces color-coded by department, for example). Additionally, engineers who are using AutoCAD MEP can use zones to perform complex analysis calculations and reporting.

Zone Styles

Beyond being as descriptive as possible there are no naming conventions for Zone Styles.

Best Practices for Zone Styles:

- If you are using Zone Templates to automate the organization of your zones, then you *must* store the zone styles in the same drawing as the zone template styles.
- You may want to use a style-level display override for your zone styles for presentation displays to control hatching and color.

NOTE In addition to using style display overrides to control the display of zones, you might also consider using a Display Theme Style configured to display Spaces based on a property value.

Calculation Modifier Styles

Calculation Modifier Style Naming Conventions:

<Calculation description> <Purpose>

Example Calculation Modifier Style Names:

Calculation Modifier Style Description	Example Name
Modifier to add ten percent to a calculated area to account for a commons factor add on in a commercial office building.	10 Percent Commons Factor

Zone Template Styles

Zone Templates allow you to automate the organization of your zones into a tree structure. Aside from being as descriptive as reasonably possible there are no naming conventions.

Best Practices for Zone Template Styles:

- When it is appropriate to do so, don't forget to attach a calculation modifier style to the styles that you include in your zone template. This can further automate the process of zone organization.
- Zone template styles *must* be stored in the same drawing as the zone styles that they include. They also must be stored in the same drawing as any calculation modifiers that they use.

List Definitions

There are no naming or "Best Practices" tips for List Definitions.

IMPORTANT Related zone styles, zone template styles and calculation modifier styles must exist in the same drawing. For this reason, you should consider storing all zone styles, zone template styles and calculation modifier styles in the same library drawing. In addition, you should store list definitions in the library drawings containing the zone styles, space styles and property set definitions that they are intended to be used with.

Multi-Purpose Objects

Object styles found under the "Multi-Purpose Objects" category are usually "helper" objects that are used to help define or enhance other object styles, or symbol objects, such as masking blocks or multi-view blocks.

AEC Polygons

AEC Polygons are useful in defining infills for curtain walls and curtain wall units, defining 2-dimensional areas and other annotation tasks. For example, they are also used on the "Cut Line" tool found on the "Annotation" tool palette.

AEC Polygon Naming Conventions:

AEC Polygon naming format will depend upon what their purpose is. An AEC Polygon style meant to define a curtain wall infill, for example, will have a much more rigid naming convention than one meant to merely define an area:

<AEC Polygon purpose> - <Optional description>

Example AEC Polygon Style Names:

AEC Polygon Style Description	Example Name
AEC Polygon style to serve as banding in a stone infill with a revolving door in a curtain wall.	Stone Infill + Revolving Doors - Stone Infill Dark Band

Classification Definitions

Classifications are a way of further defining a more generic object type. For example, wall styles can be used to define objects that aren't walls, such as cabinetry, countertops, soffits, etc. By classifying objects, you can control whether or not they are scheduled or displayed with other similar object types.

Classification Definition Naming Conventions:

Classification definitions are merely a list. Frequently this list is based on some other documented list or data structure. In other cases they may pertain to a specific object type and qualities about that object type. The naming format can vary depending upon these conditions.

Classification Definition Purpose	Naming Convention
Classification definitions based on an existing list or data structure.	<Data structure name or description>
Classification definitions for a specific object type and purpose.	<Object type> <Purpose>

Example Classification Definition Names:

Classification Definition Description	Example Name
Classification definition, applying to all object types, based on the Uniformat II structure.	Uniformat II
Classification definition for doors, windows and assemblies, to classify based on construction phase.	Doors-Windows Phase

NOTE The second example above is exactly that, an example. In reality, a classification definition to classify objects based on phasing might better be defined to apply to all object types.

Best Practices for Classification Definitions:

- While it is possible to classify objects on a “per instance” basis, it is better in most cases to classify object styles. All object styles that define geometry (anything that would be considered an “Architectural Object” rather than a “Documentation Object”) should be classified.
- Be careful not to be too restrictive when specifying the “Applies to:” parameter for a classification definition. In many cases you may find that your classification definition, depending upon what is actually included in its list of classifications, might apply best for several different object types, if not all of them.
- If you have a long classification definition you may want to consider arranging the classifications in a hierarchical manner. For example, if you were developing a classification definition to encompass the MasterSpec II format, you might have at the top level the major division numbers, then have the sections within those divisions defined within each one at a lower level.
- Store commonly used classifications in your template drawings, especially those that might be used to classify individual objects.

Layer Key Styles

Layer Key Styles are the heart of an automated layer standard. There are several pre-defined Layer Key Styles provided with AutoCAD Architecture that are based on existing widely accepted industry standards. You can also define your own Layer Key Style.

Layer Key Style Naming Conventions:

<Optional company name or other unique identifier> <Optional standard name> <Optional descriptive element>

Example Layer Key Style Names:

Layer Key Style Description	Example Name
Layer Key Style based on the British BS1192 standard.	BS1192
Layer Key Style based on the AIA Layer Guidelines version 3, with provisions for deviation from Tri-Services plotting guidelines (using named plot styles).	AIA v3
Layer Key Style created by “Company X” for use with their internal layer standard, which is specifically used on medical projects.	Company X Health Care

Best Practices for Layer Key Styles:

- Base your Layer Key Style on a structured AutoCAD Architecture *Layer Standard*, which defines the actual layer naming format for your layers. Layer keys that are not based on a Layer Standard cannot take advantage of layer key overrides.
- Since Layer Key Styles define the color, line weight, line type and plot style for each layer they define, they should work in conjunction with your display system. Before defining your own Layer Key Style, you should have a display system in effect that has been tested and you should be very familiar with it.
- Remember that several existing Layer Key Styles are already provided with AutoCAD Architecture. You may want to start with these instead of creating a new one from scratch, modifying and adding layer keys as necessary to suit your needs.
- Don't forget to specify, as part of your drawing settings the Layer Standard and Layer Key Style to automatically load in any new drawing. Additionally you should specify that the Layer Key Style be reloaded in any existing drawings if the “master” Layer Key Style in the library drawing has been edited recently. (Refer to “Template Drawings” under the “Content Resources” section of this chapter).

Mask Block Definitions

Mask blocks are symbol-based style definitions that consist of a shape definition to serve as a masking object along with optional additional graphics.

NOTE Mask blocks only affect AEC Objects and cannot mask generic AutoCAD objects such as lines, arcs, circles, etc.

Mask Block Definition Naming Conventions:

Because Mask Block Definitions are symbolic objects, naming conventions are similar to those used for standard block definitions. Since mask block definitions are best stored as AEC Content, you may also want the name to indicate the category of AEC Content in which the mask block definition belongs:

Descriptive field>_<Optional descriptive field>_...<Optional size indication>

Example Mask Block Definition Names:

Mask Block Definition Description	Example Name
2'x2' fluorescent lighting fixture for use in an imperial Architectural project.	I_Elec_Lighting_Fluor_2x2
Custom conference table created by/for "Company X" for use in imperial projects.	Company X_I_Furn_Table_Conf

Best Practices for Mask Block Definitions:

- When creating geometry to serve as additional graphics for the mask block definition, create it on the layer "0" with color, line weight, line type and plot style set to "BYBLOCK", unless you have a specific reason to override any of these values with an explicit value.

NOTE Only the objects selected as "Additional Graphics" can be assigned a unique property for color, line weight, line type and plot style prior to being defined as a mask block. The objects that make up the masking shape will ignore any of those overrides once made part of a mask block definition, following the assignments given to their display representations instead.

- Store mask blocks as AEC Content. This way they can be easily accessed through the Design Center. Additionally, a palette-based tool can be used to allow users to find them without navigating the AEC Content folder structure.

Mass Element Styles

Unlike many other types of AutoCAD Architecture object types, mass elements do not have to exist on a specific mass element style to be effectively used. Many mass elements can be created on the style "Standard" with no adverse effects whatsoever. However you can define mass element styles to predefine material assignments, classification assignments and display representation overrides.

Mass Element Style Naming Conventions:

Mass - <Optional classification assignment> - <Material assignment>

NOTE Classification and material assignments can be abbreviated in the mass element style name.

Example Mass Element Style Names:

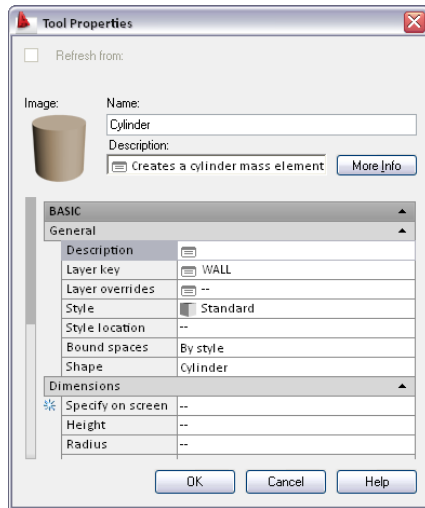

Mass Element Style Description	Example Name
Mass element for use as a decorative column and classified as "B2010 - Exterior Walls" from the "Uniformat II" classification definition and assigned a material of "Finishes.Plaster and Gypsum Board.Plaster.Stucco.Fine.Brown".	Mass - Exterior Wall - Brown Stucco
Unclassified mass element for non-specific use assigned a material of "Finishes.Flooring.Tile.Marble.Deep Green".	Mass - Deep Green Marble Tile

Best Practices for Mass Element Styles:

- Use tools and tool palettes to provide access to your mass element styles. You can accomplish several things with a tool referencing a mass element style:
 - 1 You can create a tool that pre-assigns a specific mass shape as well as a mass style to a mass element.

- 2 You can create a tool that pre-assigns a mass style but leaves the shape undefined. This is useful for assigning a mass style to an existing object with the “Assign Tool Properties To...” right-click tool menu option without changing it’s shape.
- 3 Mass elements by default are created on a generic “MASSELEM” layer key, since they do not, by definition, define a specific type of architectural object. By using a tool, you can override this and place them on a key that is more appropriate for the object type that they are to represent.

Tool properties for a mass element style tool. Note that the name of the tool has been changed to be more descriptive. Additionally, since the mass element that this tool creates is meant to define a decorative column classified as an exterior wall, the tool’s creator has decided to put the mass element on the layer defined by the “WALL” key in the current layer key style. In the example the mass element shape has also been pre-defined to be a cylinder, again, since it is meant to define a specific object type, not just a particular material assignment.

Material Definitions

Material Definitions are integral to the display system in AutoCAD Architecture and are a powerful tool to use with style and object definitions to automate displays in plan, section and elevation. Additionally, you can use a “Material” automatic property definition to tie material assignments (and the properties of those materials) into a schedule table of objects that have the materials assigned to them.

Material Definition Naming Conventions:

<General material category>.<Additional descriptive field>.<Optional additional descriptive field>...<Optional color>

Example Material Definition Names:

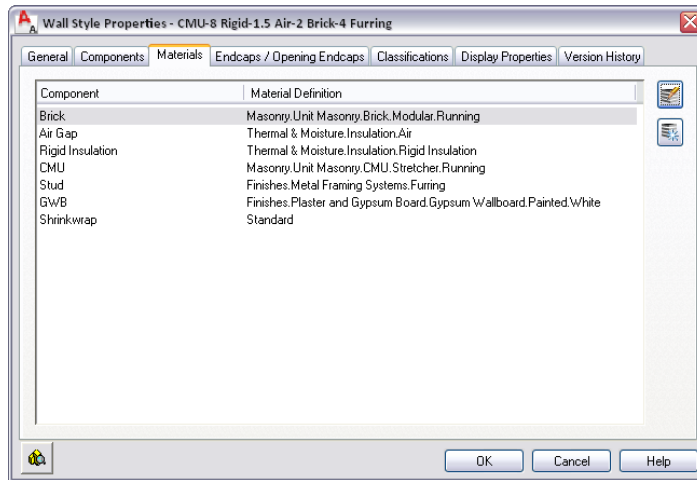

Material Definition Description	Example Name
Cast in place concrete, exposed aggregate, medium texture.	Concrete.Cast-in-Place.Exposed Aggregate.Medium
Dark green marble flooring tile.	Finishes.Flooring.Tile.Marble.Deep Green

Best Practices for Material Definitions:

- Take every step to standardize your materials. You may want to consider storing your main material library drawing as a read-only file, accessible to only a few authorized people in your office to ensure that standard material definitions do not get inadvertently modified.

- Take advantage of Project Standards to make sure your project drawings are consistent with your office and project standard materials.
- Avoid using the “Edit Material” or “New Material” buttons on the “Materials” tab of your style editor. While these may seem like efficient ways of editing and creating new materials “on the fly”, they can be dangerous, as they make it easy to accidentally edit a material that has been applied to a multitude of different object styles, having an unintended and potentially drastic effect on the graphic quality of your drawing, as well as creating a material that deviates from your standard material definitions.

The “Edit Material” and “New Material” buttons available in the style editor. These may seem like efficient and handy ways of creating materials on the fly, but their use should be discouraged as they make it easy to accidentally create non-standard materials.

- Assign commonly used standard materials to palette-based tools so that users can access them quickly and easily without having to browse for your material library file in Style Manager.
- Material Definitions are essentially nothing more than a collection of display representations. *Therefore, every material definition you create should have style overrides placed on every display representation.*
- When defining and editing materials, keep level of detail in mind, especially when you are defining hatch patterns and hatch pattern scale. In the default template drawings there are three display representations for material definitions that are meant to address scale dependency. You can, of course, create additional display configurations and associated display representations for additional scale dependency. The existing display representations for scale dependency are:

Display Configuration	Material Display Representation
General High Detail	High Detail
General Medium Detail	Medium Detail
General Low Detail	Low Detail

- When editing a material definition’s “General Screened” or “General Reflected Screened” you should assign the components to a layer that has a color or plot style assigned to it that will plot screened with color and line type set to “BYLAYER”. These display representations are meant for use with consultants who need a screened background drawing. You can set one of the screened display configurations current and export your AutoCAD Architecture drawing to an AutoCAD format. By assigning the components to screened layers you provide your consultants and collaborators the ability to control their display via traditional AutoCAD layer control.

NOTE By default, the screened display representations in the Imperial and Metric templates for use in the United States assign material display components to the layer “A-Anno-Scrn” in accordance with the AIA layering guidelines.

IMPORTANT If you want to use material definitions to control the display of object components in a 2D Section/Elevation object on the cut line you must first set the “Defining Line” component in the 2D Section/Elevation’s “General” display representation to “By Material”. Next, edit the material definitions being used in the section and set the “2D Section/Elevation Linework” component to the color, line type, line weight and plot style you would like to see in the Section/Elevation. You will also need to make sure the setting “Maintain layer, color, linetype properties from the Display Set used during generation” is toggled off.

Multi-View Block Definitions

Multi-View Block Definitions can be used for both geometric symbols and annotation symbols (primarily chases and column grid bubbles).

Multi-View Block Naming Conventions

Geometry-defining Multi-View Blocks. *<Optional system of measure>_<General object category>_<Specific object type>_<Optional descriptive field>_<Optional descriptive field>*

Annotation-defining Multi-View Blocks. *<Optional system of measure>_<Annotation purpose/type>_<Optional descriptive field>*

Example Multi-View Block Definition Names:

Multi-View Block Definition Description	Example Name
Multi-View Block Definition for a queen size bed for use in an imperial project.	I_Furn_Bed_Queen
Multi-View Block Definition for a wall-mounted flush WC for use in a metric project.	M_Plumb_WC_Flush - Wall
Multi-View Block Definition for a Chase.	Chase
Multi-View Block Definition for a column grid bubble, with a square bubble.	I_ColGrid_Bubble_Square

Block definitions for view block components of Multi-View blocks should also be named consistently and appropriately.

View Block Naming Conventions:

View Blocks for Geometry-defining Multi-View Blocks. *<Optional system of measure>_<General object category>_<Specific object type>_<Optional descriptive field>_<View direction indicator>*

View Blocks for Annotation-defining Multi-View Blocks. *<Optional system of measure>_<Annotation purpose/type>_<Qualifier (“2D”, “Scale-Dependent”, etc.)>*

Example View Block Names:

View Block Description	Example Names
2D plan view for a queen size bed multi-view block.	I_Furn_Bed_Queen_P
2D front view for a queen size bed multi-view block.	I_Furn_Bed_Queen_F
3D model for a queen size bed multi-view block.	I_Furn_Bed_Queen_M
2D grid bubble block with attribute for grid bubble multi-view block.	I_GridBubble_2D

Best Practices for Multi-View Block Definitions:

- Limit the use of multi-view blocks for annotation purposes to grid bubbles, chases and schedule tags. When defining a multi-view block for use as a schedule tag, use the “Define Schedule Tag” tool from the Format pull-down menu.
- There are two possible display representations by default for multi-view blocks. Typically, “General” is used for most plan views. If you need to define a scale-dependent multi-view block, you can use “Plan” instead, along with “Plan High Detail” and “Plan Low Detail”, and any other display representations you might create for different scale plan views. In these cases do *not* use the “General” display representation.
- Use the Create AEC Content Wizard to store your multi-view block definitions, rather than store them in the template. The only exception to this is a custom column grid bubble multi-view block definition.

Profiles

Profiles are general purpose 2D definitions that assist in defining geometry that is included in other styles. For example, a 2D shape can be converted to a profile to define a handrail shape. The profile is then extruded the length of the railing whose style the profile is used in to define the handrail.

Profile Definition Naming Conventions:

<Profile purpose>_<Descriptive field>_<Optional additional descriptive field>_<Optional size indication>

Example Profile Definition Names:

Profile Definition Description	Example Name
Profile to define a handrail grip for a railing style	HR_Grip
Profile to define a glazed door panel.	Door (SingleHinge)_Glazed
Profile to define a 1x4 base for a wall sweep definition.	WallBase_1x4
Profile to define a 2x10 fascia for a roof slab edge style.	Fascia_2x10

Symbol & Tool-Based Content

The terms “Symbols” and “Tools” in the context of this chapter refer mainly to delivery mechanisms for the various types of content that is external to the drawing template: styles, multi-view blocks, masking blocks, and command-based content.

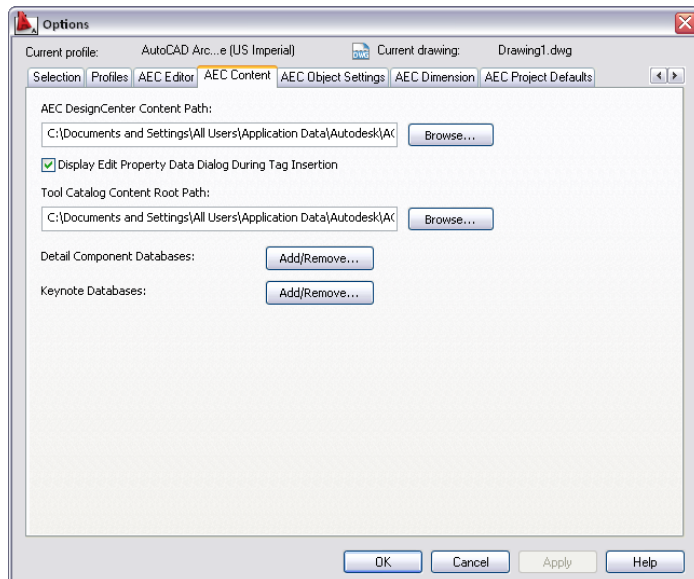

AEC Content

Any symbol-based content with the exception of leaders, callouts and title marks should be created using the AEC Content Wizard and stored as AEC Content so that it can be made accessible either through the “AEC Content” tab in Design Center or through a palette-based tool.

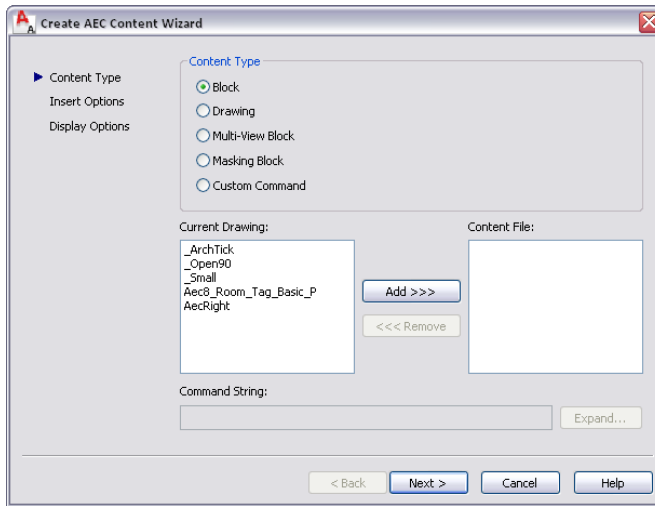

NOTE Custom blocks do not scale correctly if you copy objects to which they are attached (such as doors with door hardware) and paste them in a drawing that has drawing units specified differently.

Best Practices for AEC Content:

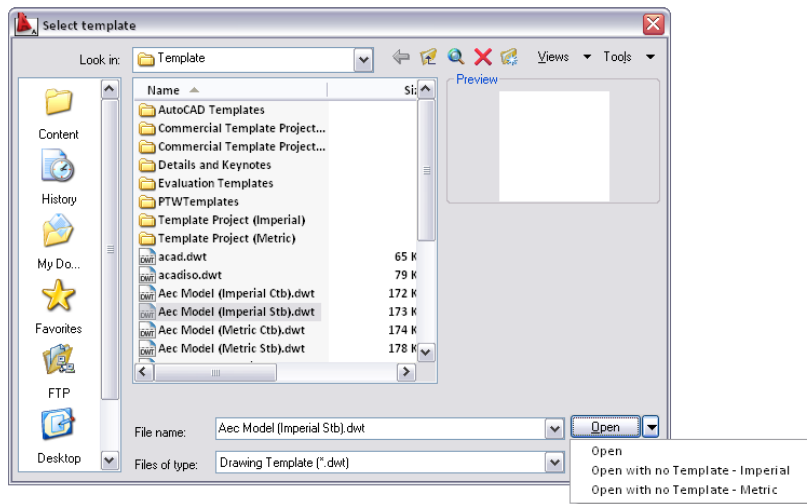

- Store your custom AEC Content files in a folder that is separate from the default “Imperial” and “Metric” folders. The path to your AEC Content can be accessed in the OPTIONS dialog box in the “AEC Content” tab. You can create as many subfolders as you like in the location indicated as the “AEC Design Center Content Path”. They will be accessible from the “AEC Content” tab in the AutoCAD Design Center, and will act like any other type of AEC Content.

- If you have existing 2D and 3D AutoCAD blocks, you can convert them directly to AEC Content using the AEC Content Wizard and choosing “Block” as the content type.

- When creating AEC Content, remember that the resulting file is a new drawing that takes its content and other settings from the drawing in which you are running the AEC Content Wizard. With this in mind, there are some critical steps you should take before launching the Wizard:
 - 1 Start in a clean drawing. Instead of using the QNEW command, which loads a template, use the NEW command and choose “Open with No Template - Imperial” from the “Open” drop down list.

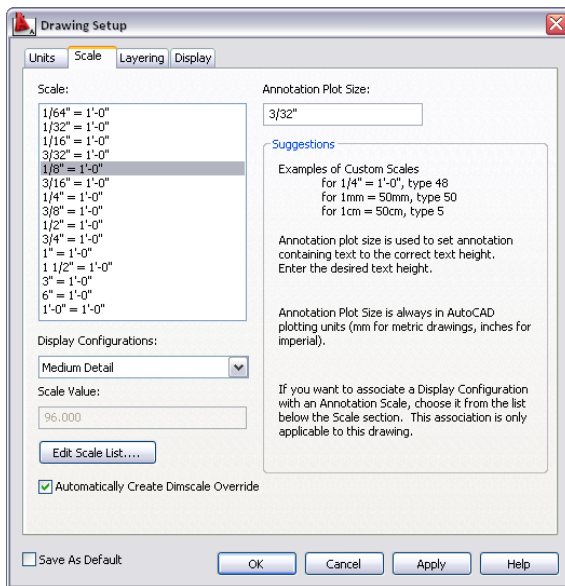

IMPORTANT Make sure you have set your drawing setup parameters to automatically load your layer key style into any new drawing. This is critical in order to assign your content to a layer key.

- 2 Make sure your drawing window background color is set to white. The resulting content file will have an associated icon with it. The icon background color will be the same color as your AutoCAD drawing window background.
- 3 Make sure you have all of the items necessary for your content in the current drawing. In the case of a multi-view block that you may have defined in another drawing, if you simply copy that block into the current drawing, all necessary view blocks will import with it.
- 4 Create the graphics for your content file’s Design Center icon.

IMPORTANT Remember that the Design Center icon is nothing more than a thumbnail. Keep the graphics simple. The default Design Center icon will be created from *all* geometry that exists in the drawing window at the time you save the content file.

- Always assign a layer key to your AEC Content file.
- Always provide a description for the AEC Content file.
- When saving the AEC Content file, make sure you save it to a folder underneath the AEC Content path setting in your OPTIONS dialog box. This is not done by default. You should select the “Browse” button next to the file name field in the AEC Content Wizard to make sure your file is being saved in the right location.
- Most design content files, since they define actual architectural geometry, should be made up of blocks, multi-view blocks and mask blocks.
- Documentation content files, regardless of whether they are based on blocks or multi-view blocks have the additional requirement that they be inserted at a scale relative to your anticipated plot scale, and taking into account the “Annotation Plot Size” setting in the drawing setup dialog box. As a baseline, you can use one AutoCAD unit (either an inch or a millimeter, depending upon whether your working in imperial or metric units). Anything in the content file that is one unit in size will be the annotation plot size when plotted at the drawing scale specified at the time it was inserted. Items that are not meant to be plotted at the annotation plot size can be sized proportionally.

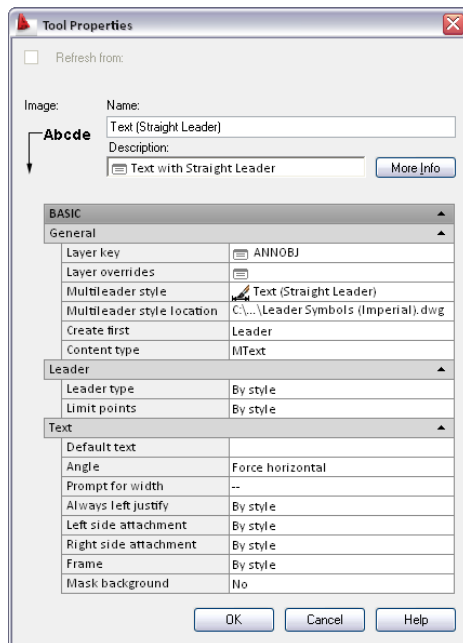

Palette-Based and Miscellaneous Annotation Tool Content

Palette-based tools, combined with tool catalogs, offer an effective means of distributing and standardizing content, as well as automating insertion and creation parameters.

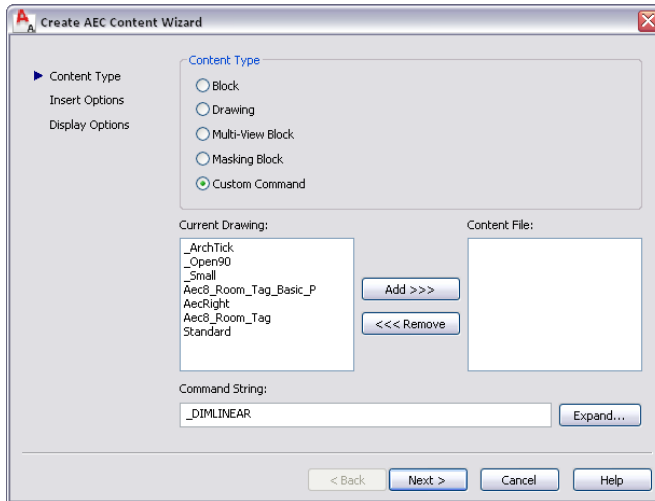

General Best Practices for Palette-Based Tools:

- All annotation content should be created to take advantage of the Annotation Plot Size.

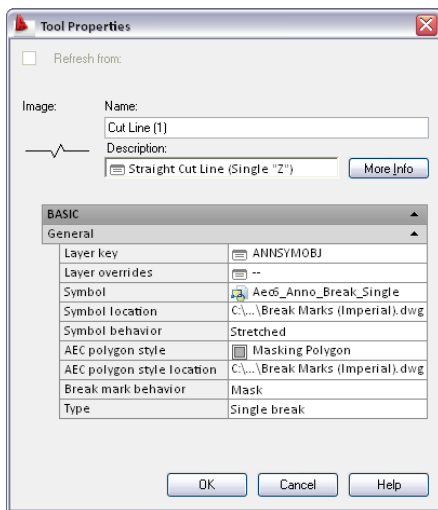

- Tools should normally be saved in a catalog. That way, if the palette on which they exist in the user's workspace gets inadvertently deleted, the tool can be restored from the original palette.
- When creating palette based tools, make it a habit to look for automation opportunities. With the exception of tools for AEC Content, there are a variety of properties that can be pre-configured to further automate and standardized object creation.
- If you have a need for callouts that use different graphic qualities, you can limit the number of actual tools that you create by taking advantage of dynamic blocks. The disadvantage to doing this, however, is that you may lose some standardization, as the same callout tool could have multiple bubbles in the same drawing by simply changing the view state parameter of the callouts after they've been inserted.
- Store Schedule Tags in the same file as your schedules and property set definitions. While this is not technically necessary in order for them to work properly, it makes editing them easier.
- Text and labels in schedule tags should be MTEXT objects. MTEXT that links to a property definition will automatically be converted to a properly formatted attribute definition.
- Carefully consider the tool properties for leaders. There are several pre-sets that can make creating a simple leader much less time consuming and more standardized.

- If you create tools for standard AutoCAD dimensions, use the AEC Content Wizard to do so. That way you can use the “Custom Command” option and use layer keys to make sure that the dimensions go to the correct layer.

- Break line tools should have supporting elements stored in the same drawing as the break line symbol. As with other multi-component tools, such as schedule tags, it makes them easier to modify in the future. All of the properties for break marks are set in the tool properties, including whether or not the break mark masks or trims objects.

- Title blocks should be stored in a sheet template drawing rather than as a separate drawing.
- Use MTEXT objects instead of attribute definitions in your title blocks. When you include fields in an MTEXT object, it will word-wrap where necessary.

TIP The title blocks that are provided in the AutoCAD Architecture sheet templates are NCS compliant. You may want to consider beginning with them and making modifications to suit if you are planning to comply with that standard.

Conceptual Design

Creating Conceptual Models

14

A conceptual model, which represents the idea for a building design, comprises a variety of building blocks. In AutoCAD Architecture, the building blocks include mass elements, mass groups, spaces, and slices. Combined, they produce a three-dimensional (3D) model.

Mass Elements and Mass Groups

Mass elements are primitive parametric objects that have specific shapes, such as arch, box, cylinder, and gable. They function as the building blocks of conceptual design (also schematic design) in AutoCAD Architecture. You can create preliminary studies, or mass models, by grouping mass elements together in mass groups.

Mass Groups and Mass Models

When you create a mass group, you can combine the shapes of mass elements in the mass group by adding, subtracting, and intersecting them in a specific order. The resulting complex shape of the mass group forms your conceptual building design, or mass model. The mass model defines the basic structure and proportion of a building model.

Developing Mass Models

As you continue developing your mass model, you can combine mass elements into mass groups and create complex building shapes by adding, subtracting, and intersecting the mass elements.

You can change mass elements in the mass group as necessary to reflect the building design. You can edit individual mass elements that are attached to a mass group to further refine the building model. You can also nest mass groups within other mass groups. For more information, see [Creating a Mass Group](#) on page 726.

Using the Model Explorer

You can use the Model Explorer to create your entire mass model, or you can create your mass model in the current drawing. You can also modify your mass model or change the relationships of mass elements in the Model Explorer. In addition to a graphics area that displays the mass model, the Model Explorer has a tree view in which you can drag and drop mass elements and mass groups to arrange and view the building

blocks of your model in a hierarchical structure. For more information, see [Using the Model Explorer to Create Mass Models](#) on page 741.

When creating massing studies, you can create mass groups with any AutoCAD three-dimensional (3D) object, including AutoCAD ACIS solids. These can be combined with mass elements in the Model Explorer to allow more complex studies of potential designs. However, only objects that have volume affect the appearance of the mass group. For example, a polyline, even with thickness, does not contribute to the mass group.

Continuing Building Design from a Mass Model

The mass model that you create is a refinement of your original idea that you carry into the next phase of the project, where you can slice floorplates from the mass model. You can convert the floorplates to space boundaries to start space planning, or you can convert them to polylines and then to walls to begin your building design.

Display Configurations and Layouts for Mass Modeling

Drawings created from templates provided with AutoCAD Architecture contain display configurations and layouts that enable you to work effectively with mass elements and mass groups. For example, a layout has two viewports: one is assigned a display configuration that displays only mass groups and the other is assigned a display configuration that displays only mass elements.

Materials in Mass Elements

In AutoCAD Architecture, you can assign materials to a mass element. These materials are displayed in wireframe and working shade views, or when rendered. Materials have specific settings for individual components of a mass element, such as linework or surface hatches.

Mass elements with assigned materials in rendered view

AutoCAD Architecture provides predefined materials for all common design purposes. These materials contain settings for roof slabs. You can use these predefined materials, or modify them to your special designs. You can also create your own materials from scratch.

For more information, see [Using Materials for Mass Elements and Mass Groups](#) on page 737.

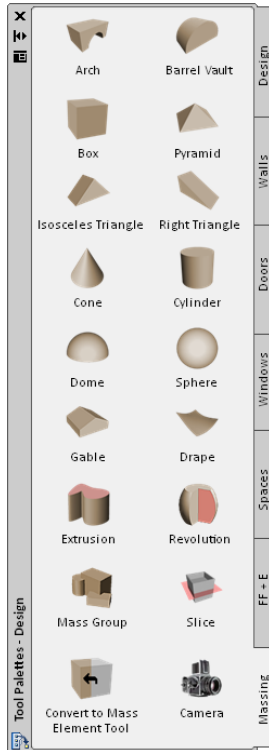

Other Uses of Mass Elements and Mass Groups

You can use mass elements and mass groups to create 3D body pieces of the building model. For example, you can apply them to walls as 3D body modifiers.

Using Massing Tools to Create Mass Elements

Tools provided with AutoCAD Architecture let you quickly place mass elements by selecting a massing tool with a specific style and other predefined properties. You can use the tool with its default settings, or you can change any properties that are not controlled by the style. You can also use massing tools to create new mass elements by applying tool properties to existing 3D solids.

Tool palette containing massing tools

The default tool palettes in the workspace contain massing tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain massing tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog
- My Tool catalog

For more information on accessing tools in these catalogs, see [Content Browser](#) on page 121.

Custom palettes created by your CAD manager or other users may also contain massing tools with mass element styles and properties that are customized for your projects or office standards.

Creating a Mass Element

Use this procedure to add a new mass element that has the properties specified in a selected massing tool. To specify settings when you add a mass element, see [Creating a Mass Element with User-Specified Settings](#) on page 686.

Shapes of Mass Elements

To create mass elements, you start with basic shapes and manipulate them for the desired result. The twelve basic mass element shapes are Arch, Barrel Vault, Box, Pyramid, Isosceles Triangle, Right Triangle, Cone, Cylinder, Dome, Sphere, Gable, and Drape. You can also create custom mass elements by extruding and revolving profiles and by creating free form mass elements.

You can modify a mass element based on its shape. For example, you can specify the width, depth, and height of a Box mass element, and the radius and height of a Cylinder mass element. For more information, see [Editing Mass Elements](#) on page 697.

Specifying the Size of Mass Elements

You can graphically specify size parameters of mass elements.

- A rectangular mass element is any element that has four lines at its base, such as an Arch, Barrel Vault, Box, Gable, Pyramid, Isosceles Triangle, or Right Triangle. You can graphically specify the width, depth, and height of rectangular mass elements.
- When you create a circular mass element, you graphically specify all the valid size parameters. Circular mass elements are Cone, Cylinder, Dome, and Sphere.

Some parameters are fixed during input; for example, the radius of an arch is one quarter of the width, and the rise of a gable is half the height. These parameters can be edited after the mass elements are placed in the drawing.

- 1 Open the tool palette that you want to use, and select a massing tool.
If necessary, scroll to display the tool that you want to use.
- 2 Specify the insertion point of the mass element.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Specify the next point.
This point can be the second corner (for a rectangular mass element), or the radius (for a circular mass element).
- 4 Specify the height, if prompted.
- 5 Specify the rotation of the mass element.
- 6 Continue adding mass elements, and press *ENTER*.

Creating a Mass Element with User-Specified Settings

Use this procedure to add a mass element with settings that you specify.

- 1 Open the tool palette that you want to use, and select a massing tool.
If necessary, scroll to display the tool that you want to use.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a style.
- 4 Under Bound Spaces, define if this mass element can be used as a bounding object for associative spaces.
You can select three options here:
 - Yes: this mass element can be used as bounding object for associative spaces.
 - No: this mass element cannot be used as bounding object for associative spaces.

- By style: this mass element will use the bounding settings from the mass element style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

5 Select a shape.

6 Specify the mass group to which to attach the mass element.

7 Expand Dimensions.

The options that display under Dimensions depend on the shape you selected for the mass element.

8 Specify the dimensions of the mass element:

If you want to...

Then...

specify the width of the mass element in its relative X direction

enter a value for Width.

specify the depth of the mass element in its relative Y direction

enter a value for Depth.

specify the height of the mass element in its relative Z direction

enter a value for Height.

specify the radius of the mass element

enter a value for Radius.

specify the rise of the mass element

enter a value for Rise.

9 In the drawing area, specify the insertion point of the mass element.

You can move or hide the Properties palette to expose more of the drawing area.

10 Continue adding mass elements, and press *ENTER*.

Creating an Arch Mass Element

Use this procedure to dynamically create an Arch mass element. The insertion point of an Arch mass element is at the centroid of its bottom face.

Arch mass element in 3D and plan views

- 1 On the Massing tool palette, select the Arch tool.
- 2 Specify the first corner of the Arch.
- 3 Drag the cursor and specify the second corner of the Arch.
- 4 Drag the cursor and specify the height of the Arch.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Arch mass elements, and press *ENTER*.

Creating a Barrel Vault Mass Element

Use this procedure to create a Barrel Vault mass element. The insertion point of the Barrel Vault mass element is at the centroid of its bottom face.

Barrel Vault mass element in 3D and plan views

- 1 On the Massing tool palette, select the Barrel Vault tool.
- 2 Specify the first corner of the Barrel Vault.
- 3 Drag the cursor and specify the second corner of the Barrel Vault.
- 4 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 5 Continue adding Barrel Vault mass elements, and press *ENTER*.

Creating a Box Mass Element

Use this procedure to create a Box mass element. The insertion point of the Box mass element is at the centroid of its bottom face.

Box mass element in 3D and plan views

- 1 On the Massing tool palette, select the Box tool.
- 2 Specify the first corner of the Box.
- 3 Drag the cursor and specify the second corner of the Box.
- 4 Drag the cursor and specify the height of the Box.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Box mass elements, and press *ENTER*.

Creating a Pyramid Mass Element

Use this procedure to create a Pyramid mass element. The insertion point of a Pyramid mass element is at the centroid of its bottom face.

Pyramid mass element in 3D and plan views

- 1 On the Massing tool palette, select the Pyramid tool.
- 2 Specify the first corner of the Pyramid.
- 3 Drag the cursor and specify the second corner of the Pyramid.
- 4 Drag the cursor and specify the height of the Pyramid.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Pyramid mass elements, and press *ENTER*.

Creating an Isosceles Triangle Mass Element

Use this procedure to create an Isosceles Triangle mass element. The insertion point of an Isosceles Triangle mass element is at the centroid of its bottom face.

Isosceles Triangle mass element in 3D and plan views

- 1 On the Massing tool palette, select the Isosceles Triangle tool.
- 2 Specify the first corner of the Isosceles Triangle.
- 3 Drag the cursor and specify the second corner of the Isosceles Triangle.
- 4 Drag the cursor and specify the height of the Isosceles Triangle.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Isosceles Triangle mass elements, and press *ENTER*.

Creating a Right Triangle Mass Element

Use this procedure to create a Right Triangle mass element. The insertion point of a Right Triangle mass element is at the centroid of its bottom face.

Right Triangle mass element in 3D and plan views

- 1 On the Massing tool palette, select the Right Triangle tool.
- 2 Specify the first corner of the Right Triangle.
- 3 Drag the cursor and specify the second corner of the Right Triangle.
- 4 Drag the cursor and specify the height of the Right Triangle.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Right Triangle mass elements, and press *ENTER*.

Creating a Cone Mass Element

Use this procedure to create a Cone mass element. The insertion point of the Cone mass element is at the centroid of its bottom face.

Cone mass element in 3D and plan views

- 1 On the Massing tool palette, select the Cone tool.
- 2 Specify the insertion point of the Cone.
- 3 Drag the cursor and specify the radius of the Cone.
- 4 Drag the cursor and specify the height of the Cone.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Cone mass elements, and press *ENTER*.

Creating a Cylinder Mass Element

Use this procedure to create a Cylinder mass element. The insertion point of the Cylinder mass element is at the centroid of its bottom face.

Cylinder mass element in 3D and plan views

- 1 On the Massing tool palette, select the Cylinder tool.
- 2 Specify the insertion point of the Cylinder.
- 3 Drag the cursor and specify the radius of the Cylinder.
- 4 Drag the cursor and specify the height of the Cylinder.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Cylinder mass elements, and press *ENTER*.

Creating a Dome Mass Element

Use this procedure to create a Dome mass element. The insertion point of the Dome mass element is at the centroid of its bottom face.

Dome mass element in 3D and plan views

- 1 On the Massing tool palette, select the Dome tool.
- 2 Specify the insertion point of the Dome.
- 3 Drag the cursor and specify the radius of the Dome.
- 4 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 5 Continue adding Dome mass elements, and press *ENTER*.

Creating a Sphere Mass Element

Use this procedure to create a Sphere mass element. The insertion point of a Sphere mass element is at its centroid.

Sphere mass element in 3D and plan views

- 1 On the Massing tool palette, select the Sphere tool.
- 2 Specify the insertion point of the Sphere.
- 3 Drag the cursor and specify the radius of the Sphere.
- 4 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 5 Continue adding Sphere mass elements, and press *ENTER*.

Creating a Gable Mass Element

Use this procedure to create a Gable mass element. The insertion point of a Gable mass element is at the centroid of its bottom face.

Gable mass element in 3D and plan views

- 1 On the Massing tool palette, select the Gable tool.
- 2 Specify the first corner of the Gable.
- 3 Drag the cursor and specify the second corner of the Gable.
- 4 Drag the cursor and specify the height of the Gable.
- 5 Enter a rotation angle, or press *ENTER* to accept the default angle of 0.
- 6 Continue adding Gable mass elements, and press *ENTER*.

Creating a Drape Mass Element

Use this procedure to create a Drape mass element. A drape is useful when you are working with a conceptual model of a building site. You can create polylines and AEC Polygons at different elevations to represent topographic lines, and then drape a mass element over the polylines to show the contours of the site.

For the generated terrain surface, you can choose between a regular mesh with user-defined mesh density and mass element size, and a non-regular mesh defined by the input contour curves and points (Delaunay triangulation).

For a non-regular mesh, you can select either a rectangular mesh of user-specified size (the topography will be extrapolated from your input if the selected rectangular region is larger than the area covered by the contour curves and points), or a non-rectangular mesh whose surface size and shape are determined by the area of the input contour curves and points.

NOTE AutoCAD Architecture uses the Autodesk Civil 3D technology to define the terrain surface; however, the extrapolation of the terrain is used in AutoCAD Architecture only.

Creating a Drape mass element

- 1 On the Massing tool palette, select the Drape tool.
- 2 Select the polylines or AEC Polygons to represent contours, and press *ENTER*.
- 3 Specify whether the source contours should be deleted after creating the drape mass element, and press *ENTER*.
- 4 Specify which mesh type you want to generate.

If you want...

Then...

a surface with user-defined mesh density and mass element size (non-triangulated surface)

enter **y** (Yes) for Generate Regular Mesh [Yes/No].

a surface defined from the input contours and points (Delaunay triangulation)

enter **n** (No) for Generate Regular Mesh [Yes/No].

- 5 If you are generating a regular mesh, complete the following steps:
 - Specify the first corner point of the mesh.
 - Specify the opposite corner point of the mesh.

- Specify the mesh subdivisions in the X-direction.
- Specify the mesh subdivisions in the Y-direction.
- Enter the base thickness of the resulting mass element.

6 If you are generating a non-regular mesh, specify whether you want it to be rectangular or non-rectangular:

If you want...	Then...
a rectangular mesh	enter y (Yes) for Generate Rectangular Mesh [Yes/No].
a non-rectangular mesh	enter n (No) for Generate Rectangular Mesh [Yes/No].

7 If you are generating a non-regular, rectangular mesh, complete the following steps:

- Specify the first corner point of the mesh.
- Specify the opposite corner point of the mesh.
- Enter the base thickness of the resulting mass element.

NOTE If the selected mesh area extends beyond the selected contours, the topography of the resulting mass element is extrapolated from the input values.

8 If you are generating a non-regular, non-rectangular mesh, enter the base thickness for the resulting mass element, and press *ENTER*.

Creating a Doric Column Mass Element

Use this procedure to create a Doric Column mass element. The insertion point of a Doric Column mass element is at the centroid of its bottom face.

Doric Column mass element in 3D and plan views

- 1 On the Massing tool palette, select a massing tool.
- 2 On the Properties palette, select Doric for Shape.
- 3 Specify the insertion point.
- 4 Drag the cursor; or specify the radius of the Doric Column and press *ENTER*.
- 5 Drag the cursor; or specify the height and press *ENTER*.
- 6 Enter a rotation angle and press *ENTER*; or press *ENTER* to accept the default angle of 0.
- 7 Continue adding Doric Column mass elements, and press *ENTER*.

Creating Profiles for Extrusion and Revolution Mass Elements

Use this procedure to define a profile from a polyline to create either of the following mass elements:

- Extrusion, in which the shape of the two-dimensional (2D) profile is projected to create a 3D mass element
- Revolution, in which the 2D profile is revolved around its *X* axis to create a 3D mass element

You can draw more than one polyline within the outermost polyline to create voids in the resulting mass element. Polylines cannot intersect or overlap.

1 Draw one or more closed polylines in the shape you want to extrude or revolve.

2 Select the polyline, right-click, and click Convert To ► Profile Definition.

3 Enter **c** (Centroid) for the insertion point of the profile.

The insertion point of the profile is aligned with the centroid of the mass element.

4 Press *ENTER* to specify a new profile definition.

5 Enter a name for the profile, and click OK.

You can now use the profile as an Extrusion or Revolution mass element. For more information, see [Creating a Mass Element by Extruding a Profile](#) on page 694 or [Creating a Mass Element by Revolving a Profile](#) on page 695.

Creating a Mass Element by Extruding a Profile

Use this procedure to create a custom-shaped mass element by using a profile as the basis of its shape. The extrusion projects the shape of the profile to create the mass element.

The width and depth of the Extrusion mass element are based on the original width and depth of the profile. You can specify different width and depth values, if necessary.

The insertion point is at the centroid of the bottom face of the Extrusion mass element.

Creating an Extrusion mass element from a profile

1 Create the profile to use as the basis of the mass element.

For more information, see [Creating Profiles for Extrusion and Revolution Mass Elements](#) on page 694.

2 On the Massing tool palette, select the Extrusion tool.

3 On the Properties palette, expand Basic and expand General.

4 Select the profile you created in step 1 for Profile.

5 Specify the insertion point in the drawing.

6 Specify the height of the Extrusion mass element.

7 Specify a rotation angle, or press *ENTER* for a rotation angle of zero degrees.

8 Press *ENTER*.

Creating a Mass Element by Revolving a Profile

Use this procedure to create a mass element by defining a profile as the basis of its shape, and then revolving the profile about an axis. The axis of revolution is along the *X* axis of the profile as it is drawn. The insertion point is at the centroid of the bottom face of the Revolution mass element.

Creating a Revolution mass element from a profile

1 Create a profile to use as the basis of the mass element.

For more information, see [Creating Profiles for Extrusion and Revolution Mass Elements](#) on page 694.

2 On the Massing tool palette, select the Revolution tool.

3 On the Properties palette, expand Basic and expand General.

4 Select the profile you created in step 1 for Profile.

5 Specify the insertion point in the drawing.

6 Specify a rotation angle, or press *ENTER* for a rotation angle of zero degrees.

7 Press *ENTER*.

Creating a Mass Element from a 3D Solid

Use this procedure to create a Free Form mass element from an AutoCAD ACIS solid that has the properties of the mass element tool you select. You can edit these properties after creating the mass element.

The resulting Free Form mass element is a faceted approximation of the 3D solid. The smoothness of curved edges is controlled by the FACETDEV variable. This variable specifies the number of facets to display on curved AEC objects. For more information, see [Specifying the Display Resolution of Objects with Facets](#) on page 169.

1 Open the tool palette that you want to use.

If necessary, scroll to display the tool that you want to use.

2 Right-click a mass element tool, and click Apply Tool Properties to ► 3D Solid.

3 Select the 3D solids to convert.

4 When prompted to erase the original geometry, press *ENTER* to keep the 3D solid, or enter *y* (Yes) to erase it.

5 Enter *n* (Name) to give a description to the mass element, and press *ENTER*.

6 Enter a name, and press *ENTER* twice.

7 Edit the properties of the mass element in the Properties palette, if needed.

NOTE Due to the topological structure of the free form mass element, its facet deviation cannot be changed. The FACETDEV command will have no effect on an existing free form mass element.

Creating a Mass Element Tool

Use this procedure to create a mass element tool and add it to a tool palette. You may want to create your own tools if you frequently place multiple mass elements of specific styles that have the same properties.

1 Open the tool palette on which you want to create a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a mass element in the drawing	select the object, and drag it to the tool palette.
create a tool from a mass element style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another palette	right-click the tool, and click Copy. Open the other palette, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 On the Properties palette, expand Basic, and expand General.

7 Click the setting for Description, enter a description of the mass element created from this tool, and click OK.

8 Specify a layer key and any layer overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.

9 Select a mass element style.

10 Select the drawing file containing the style used for this mass element.

11 Under Bound Spaces, define if this mass element tool can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this mass element tool can be used as bounding object for associative spaces.
- No: this mass element tool cannot be used as bounding object for associative spaces.
- By style: this mass element tool will use the bounding settings from the mass element style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

12 Select a shape.

13 Expand Dimensions.

The options that display under Dimensions depend on the mass element tool you copied to create the new tool.

14 Specify the dimensions of the mass element:

If you want to...	Then...
specify the width of the mass element in its relative <i>X</i> direction	enter a value for Width.
specify the depth of the mass element in its relative <i>Y</i> direction	enter a value for Depth.
specify the height of the mass element in its relative <i>Z</i> direction	enter a value for Height.
specify the radius of the mass element	enter a value for Radius.
specify the rise of the mass element	enter a value for Rise.

15 Click OK.

Editing Mass Elements

After you create mass elements, you can edit and reposition them to generate the form of your building mass model.

You can use grips to manipulate mass elements. The grip editing features available depend upon the shape of the selected mass element. Because mass elements are parametric, each shape has a specific behavior when you modify it. For example, if you select and drag the corner grip point of a Box mass element, the width and depth of the mass element are modified.

AutoCAD Architecture offers several methods for editing mass elements:

- You can directly edit mass elements using grips for dimensions and other physical characteristics.
- You can change mass element settings on the Properties palette.
- You can select editing commands from the shortcut menu for a selected mass element.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.

Using Grips to Edit Mass Elements

Use the following procedures to edit mass elements using grips.

Editing Mass Element Dimensions

- 1 Select the mass element.
- 2 Select the grip for the dimension you want to change.

Viewing mass element grips and dimensions

3 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

Changing the Location or Position of a Mass Element

- 1 Select the mass element.
- 2 Select the Location grip.

In model view, the Location grip has three edit modes: Edit Along Object's XY Plane, Edit Along Object's YZ Plane, and Edit Along Object's XZ Plane. Press *CTRL* to cycle among modes until you are in the desired mode. The default edit mode is along the XY plane. In plan view, the Location grip is restricted to movement in one plane.

- 3 Move the mass element to the desired location, and click; or enter a value, and press *ENTER*.
If you want to enter a specific value for the second direction in any edit mode (for example, in the Y direction when editing along the XY plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the mass element along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the mass element is constrained to the second dimension direction. When editing along the XY plane, for example, you can enter a value for X dimension, and then press *TAB*. The X dimension is locked at that value, and movement of the mass element is constrained to the Y dimension direction.

- 4 Right-click, and click Deselect All to turn off grips.

Changing the Area of a Rectangular Mass Element

Use this procedure to change the area of a rectangular mass element using grips. A rectangular mass element is any element that has four lines at its base, such as an Arch, Barrel Vault, Box, Gable, Pyramid, Isosceles Triangle, or Right Triangle.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change mass element area dimensions on the Properties palette.

Editing a Box mass element with its corner grip

Using Corner grips to change area

- 1 Select the rectangular mass element to display its grips.
- 2 Click a corner (Width and Depth) grip, and move it to the new location, or enter a value and press *ENTER*.

The location of the opposite corner remains fixed while you move the mass element corner.

If you want to enter a specific value for the second direction in the Width and Depth edit mode, press *TAB* to cycle to the second direction value.

Changing the Edge of an Extrusion Mass Element

Use this procedure to change the area of an extrusion mass element using the Edge grip.

The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the mass element and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added as necessary.

Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.

Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change the mass element area dimensions on the Properties palette.

- 1 Select the extrusion mass element.
- 2 Select an Edge grip.

- 3 Specify the new edge location:

If you want to...	Then...
offset the edge	move the edge to the desired location and click; or enter a value and press <i>ENTER</i> .
add a vertex and create an edge	press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location and click; or enter a value and press <i>ENTER</i> .
change the selected edge to an arc	press <i>CTRL</i> twice to switch to the Convert to Arc edit mode. Stretch the midpoint to the desired location and click; or enter a value and press <i>ENTER</i> .

You can press *CTRL* to toggle among the edit modes.

- 4 Right-click, and click Deselect All to turn off grips.

Changing the Height of a Mass Element

Use this procedure to change the height of a mass element using grips.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change the mass element height on the Properties palette.

Editing a Pyramid mass element with its Height grip

- 1 Switch to a 3D view.
- 2 Select the mass element to display its grips.
- 3 Click the Height grip at the top of the mass element, and move it to the new location.
The height of the mass element changes as you move the grip.

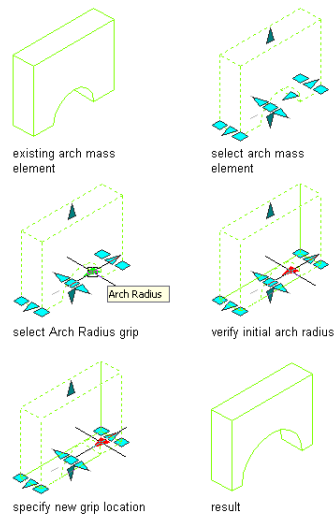

Changing the Arch Radius of an Arch Mass Element

Use this procedure to change the radius of the arch within an Arch mass element using grips.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change the arch radius on the Properties palette.

Editing an Arch mass element with its Arch Radius grip

- 1 Select the Arch mass element to display its grips.
- 2 Click the Arch Radius grip, and move it to the new location.

The radius of the arch changes as you move the grip.

Changing the Roof Height of a Gable Mass Element

Use this procedure to change the roof height of a Gable mass element using grips.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change the Gable roof height on the Properties palette.

Editing a Gable mass element with its Height grip

- 1 Switch to a 3D view.
- 2 Select the Gable mass element to display its grips.
- 3 Click the Height grip at the midpoint of the roof ridgeline.
- 4 Move the grip to change the height of the roof.

The height of the roof ridgeline and the walls change as you move the grip, leaving the roof slope and gable configuration unchanged.

Changing the Rise of a Gable Mass Element

Use this procedure to change the wall height of a Gable mass element using grips.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change the gable rise on the Properties palette.

Editing a Gable mass element with its Rise grip

- 1 Switch to a 3D view.
- 2 Select the Gable mass element to display its grips.
- 3 Click the Rise grip at the top of the wall.
- 4 Move the grip to change the height of the wall.

The height of the wall changes as you move the grip, while the roof ridgeline position remains fixed. This changes the roof slope and gable configuration.

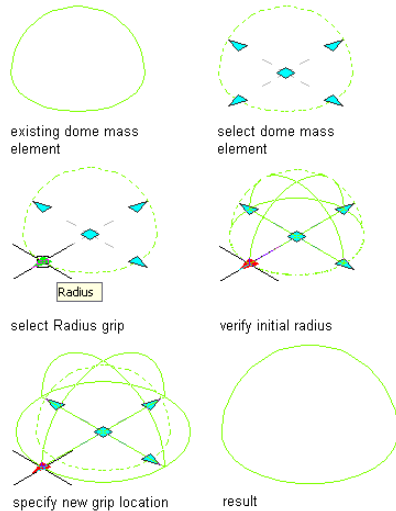

Changing the Radius of a Circular Mass Element

Use this procedure to change the radius of a circular mass element using grips. Circular mass elements include Cones, Cylinders, Domes, Doric Columns, Spheres, and Revolutions.

For more information about mass element grips, see [Using Grips to Edit Mass Elements](#) on page 697.

You can also change the mass element radius on the Properties palette.

Editing a Dome mass element with its Radius grip

- 1 Select the circular mass element to display its grips.
- 2 Click the Radius grip on the mass element.
You can select any one of the radius grips on the same circle to change the size.
- 3 Move the grip in or out.
The mass element becomes larger or smaller depending on the direction you move the grip.

Changing the Shape, Size, and Mass Group of a Mass Element

Use this procedure to change one mass element into another, add it to a mass group, and change its size.

- 1 Double-click a mass element.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a new basic shape for Shape.
- 4 To attach the mass element to a mass group, select a mass group for Attached to.
- 5 Expand Dimensions.
- 6 Enter new dimension values for the mass element.

NOTE When you change the size of a mass element, the center point remains constant and the change is applied to both sides of the element.

Combining Mass Elements Using Boolean Operations

Use this procedure to combine mass elements using Boolean operations.

- 1 Select the mass element to which you want to join another mass element.
- 2 Selected the desired Boolean operation:

If you want to...

Then...

combine the total volume of two or more mass elements into a composite object

right-click, and click Boolean ► Union.

If you want to...**Then...**

remove the common area of one mass element from another

right-click, and click Boolean ► Subtract.

remove non-overlapping portions and create a composite solid from the common volume

right-click, and click Boolean ► Intersect.

3 Select the objects you want to combine, and press *ENTER*.

4 Enter **y** (Yes) to erase the original geometry, or enter **n** (No) to keep the original geometry in the drawing.

NOTE A boolean operation creates a free form mass element. Due to the topological structure of the free form mass element, its facet deviation cannot be changed. The FACETDEV command will have no effect on an existing free form mass element.

Dividing a Mass Element

Use this procedure to divide a mass element. The divide plane you specify splits the original mass element into two separate mass elements.

1 Select the mass element you want to divide, right-click, and click Split.

2 Specify the divide plane start point.

3 Specify the divide plane endpoint.

Dividing a mass element

The original mass element is split along the divide plane, creating two mass elements.

NOTE Dividing a mass element creates free form mass elements. Due to the topological structure of the free form mass element, its facet deviation cannot be changed. The FACETDEV command will have no effect on an existing free form mass element.

Trimming a Mass Element

Use this procedure to trim a mass element. The divide plane you specify acts as the trim line, and you specify which side of the mass element to remove.

- 1 Select the mass element you want to divide, right-click, and click Trim.
- 2 Specify the divide plane start point.
- 3 Specify the divide plane endpoint.
- 4 Select the side of the mass element to remove.

Trimming a mass element

NOTE Trimming a mass element creates a free form mass element. Due to the topological structure of the free form mass element, its facet deviation cannot be changed. The FACETDEV command will have no effect on an existing free form mass element.

Converting a Mass Element to a Free Form Mass Element

Use this procedure to convert mass elements to Free Form mass elements.

- 1 Select the mass element to convert, right-click, and click Convert To ► Free Form Mass Element.
- 2 When prompted to erase the original geometry, press *ENTER* to keep the mass element, or enter *y* (Yes) to erase it.
- 3 If you want to display the parameters of the mass element, enter *s* (Show bounding box), and press *ENTER*.
- 4 If you want to describe the mass element, enter *n* (Name), and press *ENTER*.
- 5 Enter a name, and press *ENTER* twice.

NOTE Due to the topological structure of the free form mass element, its facet deviation cannot be changed. The FACETDEV command will have no effect on an existing free form mass element.

Converting a Mass Element to a 3D Solid

Use this procedure to convert mass elements to 3D solids. Most objects create 2D geometry in plan view; therefore, select a 3D view first for best results.

- 1 Select the mass element to convert, right-click, and click Convert To ► 3D Solid.
- 2 When prompted to erase the original geometry, press *ENTER* to keep the mass element, or enter *y* (Yes) to erase it.

Converting a Mass Element to a Wall

Use this procedure to convert mass elements to walls.

- 1 Select the mass element to convert, right-click, and click Convert To ► Wall.
- 2 When prompted to erase the original geometry, press *ENTER* to keep the mass element, or enter *y* (Yes) to erase it.
- 3 Specify a point to start the baseline.
- 4 Specify a point to end the baseline.
The Wall Styles worksheet displays the wall styles that exist in your current drawing.
- 5 Select a wall style and click OK.

Converting a Mass Element to a Slab or Roof Slab

Use this procedure to convert mass elements to slabs or roof slabs.

- 1 Select the mass element to convert, right-click, and click Convert To ► Slab or Convert to ► Roof Slab.
- 2 When prompted to erase the original geometry, press *ENTER* to keep the mass element, or enter *y* (Yes) to erase it.
The Slab Styles or Roof Slab Styles worksheet displays the slab or roof slab styles that exist in your current drawing.
- 3 Select a style and click OK.

Converting a Mass Element to a Space

Use this procedure to convert mass elements to spaces. Depending on whether the converted mass element shape is an extrusion- type shape (box, cylinder, extrusion) or a non-extrusion-type shape (pyramid, gable, freeform, etc.), either an extruded 3D space or a 3D freeform space is generated by the conversion.

- 1 Select the mass element to convert, right-click, and click Convert To ► Space.
- 2 When prompted to erase the original geometry, press *ENTER* to keep the mass element, or enter *y* (Yes) to erase it.

Converting an Object to a Mass Element

Use this procedure to convert objects to Free Form mass elements. The resulting Free Form mass element is a faceted approximation of the object. The smoothness of curved edges is controlled by the FACETDEV variable.

This variable specifies the number of facets to display on curved AEC objects. For more information, see [Specifying the Display Resolution of Objects with Facets](#) on page 169.

- 1 Open a tool palette that has the Convert to Mass Element tool and select the tool.
- 2 Select the object(s) that you want to convert to a Free Form mass element, and press *ENTER*.
The Convert to Mass Element worksheet opens.

- 3 Enter text for Description.
- 4 To convert all of the selected objects into one mass element, select Convert to single boolean mass element.
- 5 Alternatively, to convert the objects within your selection to separate mass elements, select Convert to individual mass elements.
- 6 To erase the original geometry of the objects, select Erase layout geometry.
- 7 Click OK.

Dividing the Face of a Mass Element

Use this procedure to divide the face of a mass element. In order for the face to split, the mass element is converted to a Free Form mass element.

- 1 Select the mass element whose face you want to divide, right-click, and click Split Face.
- 2 Select the first point on the face.
- 3 Select the second point on the same face, and press *ENTER*.
The original mass element is converted to a Free Form mass element, and the selected face is divided along the line you specified.

Joining the Faces of a Mass Element

Use this procedure to join previously split faces of a mass element. After the faces are joined, the mass element is converted to its original shape.

- 1 Select the mass element whose faces you want to join, right-click, and click Join Faces.
- 2 Select the edge of the coplanar faces, and press *ENTER*.
The mass element is converted to its original shape, and the selected faces are joined into a single face.

Editing the Faces of a Free Form Mass Element

Use this procedure to edit individual faces of a Free Form mass element. You must convert the mass element to a Free Form mass element in order to edit its faces.

The following illustration shows how Initial and Free Form mass element grips are displayed.

Initial and Free Form mass element grips

When you select a Free Form mass element Face grip, the following tooltip is displayed.

Free Form mass element Face grip tool tip

You have six choices while editing a face of a Free Form mass element. A tooltip displays to indicate which option is current.

If you want to...	Then...	Tooltip Displayed
move the face orthogonally while stretching adjacent faces	click and drag the Face grip to the new Face location.	Move face orthogonally, stretch adjacent faces
move the face freely while stretching adjacent faces	click and hold the Face grip, press <i>CTRL</i> once, and specify the new Face location.	Move face freely, stretch adjacent faces
move the face orthogonally while maintaining the planes of adjacent faces	click and hold the Face grip, press <i>CTRL</i> twice, and specify the new Face location.	Move face plane, maintain plane of adjacent faces
pull the face orthogonally while adding adjacent faces	click and hold the Face grip, press <i>CTRL</i> three times, and specify the new Face location.	Pull face orthogonally, add adjacent faces
pull the face freely while adding adjacent faces	click and hold the Face grip, press <i>CTRL</i> four times, and specify the new Face location.	Pull face freely, add adjacent faces

If you want to...	Then...	Tooltip Displayed
pull or push the face orthogonally while either adding adjacent faces or creating a hole	click and hold the Face grip, press <i>CTRL</i> five times, and specify the new Face location.	Push face orthogonally, add adjacent faces, possibly create a hole

As you cycle through the options by pressing *CTRL*, the tooltip advances sequentially to indicate the current option. Pressing *CTRL* more than five times returns you to the first option, allowing you to continue cycling through the edit choices.

The cursor is constrained when you choose an orthogonal option and unconstrained when you choose a free option.

Moving a Mass Element Face Orthogonally While Stretching Adjacent Faces

- 1 Select the mass element you want to edit.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Free Form for Shape.

The mass element is in in-place edit mode. Each face of the Free Form mass element is available to edit in this mode.

- 4 Select the Face grip for the face of the mass element to edit.
Depending on the original shape of the mass element, Edge and Vertex grips are displayed.
- 5 Click and drag the Face grip to specify the new location.
- 6 Press *ESC*, or right-click and click Deselect All to exit the editing session.

NOTE You cannot pull the mass element face at such an angle, either horizontally or vertically, that the adjacent faces become non-planar. If this distorted condition occurs, the mass element face automatically returns to its original position and an error message is displayed on the command line.

Moving a mass element orthogonally while stretching adjacent faces

The face of the Free Form mass element is moved orthogonally and its geometry remains unchanged, while its adjacent faces are stretched and tilted.

Moving a Mass Element Face Freely While Stretching Adjacent Faces

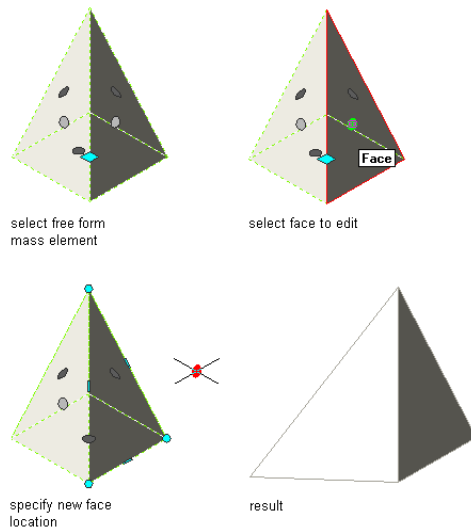

- 1 Select the mass element you want to edit.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Free Form for Shape.

The mass element is in in-place edit mode. Each face of the Free Form mass element is available to edit in this mode.

- 4 Select the Face grip for the face of the mass element to edit.
Depending on the original shape of the mass element, Edge and Vertex grips are displayed.
- 5 Click and hold the Face grip, press *CTRL* once, and specify the new location.
- 6 Press *ESC*; or right-click, and click Deselect All to exit the editing session.

NOTE You cannot pull the mass element face at such an angle, either horizontally or vertically, that the adjacent faces become non-planar. If this distorted condition occurs, the mass element face automatically returns to its original position and an error message is displayed on the command line.

Moving a mass element freely while stretching adjacent faces

The face of the Free Form mass element is moved freely and its geometry remains unchanged, while its adjacent faces are stretched and tilted.

NOTE The location of the current UCS is temporarily moved to coincide with the original position of the Face grip that you select when you are working with this option. Only the UCS origin is changed, not its orientation.

Moving a Mass Element Face Orthogonally While Maintaining the Planes of Adjacent Faces

- 1 Select the mass element you want to edit.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Free Form for Shape.

The mass element is in in-place edit mode. Each face of the Free Form mass element is available to edit in this mode.

- 4 Select the Face grip for the face of the mass element to edit.
Depending on the original shape of the mass element, Edge and Vertex grips are displayed.

- 5 Click and hold the Face grip, press *CTRL* twice, and specify the new location.
- 6 Press *ESC*, or right-click and click Deselect All to exit the editing session.

NOTE You cannot pull the mass element face at such an angle, either horizontally or vertically, that the adjacent faces become non-planar. If this distorted condition occurs, the mass element face automatically returns to its original position and an error message is displayed on the command line.

Moving a mass element face orthogonally while maintaining the planes of adjacent faces

The face of the Free Form mass element is moved orthogonally and its geometry is changed, while the planes of its adjacent faces are maintained.

Pulling a Mass Element Face Orthogonally While Adding Adjacent Faces

- 1 Select the mass element you want to edit.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Free Form for Shape.
The mass element is in in-place edit mode. Each face of the Free Form mass element is available to edit in this mode.
- 4 Select the Face grip for the face of the mass element to edit.
Depending on the original shape of the mass element, Edge and Vertex grips are displayed.
- 5 Click and hold the Face grip, press *CTRL* three times, and specify the new location.
- 6 Press *ESC*, or right-click and click Deselect All to exit the editing session.

Pulling a mass element face orthogonally while adding adjacent faces

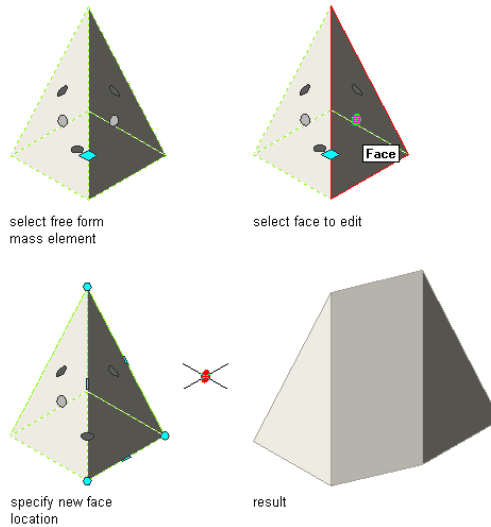

The face of the Free Form mass element is moved orthogonally and its geometry remains unchanged, while adjacent faces between the original geometry and the moved face are added.

Pulling a Mass Element Face Freely While Adding Adjacent Faces

- 1 Select the mass element you want to edit.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Free Form for Shape.
The mass element is in in-place edit mode. Each face of the Free Form mass element is available to edit in this mode.
- 4 Select the Face grip for the face of the mass element to edit.
Depending on the original shape of the mass element, Edge and Vertex grips are displayed.
- 5 Click and hold the Face grip, press *CTRL* four times, and specify the new location.
- 6 Press *ESC*, or right-click and click Deselect All to exit the editing session.

NOTE You cannot pull the mass element face at such an angle, either horizontally or vertically, that the adjacent faces become non-planar. If this distorted condition occurs, the mass element face automatically returns to its original position and an error message is displayed on the command line.

Pulling a mass element face freely while adding adjacent faces

The face of the Free Form mass element is moved freely and its geometry remains unchanged, while adjacent faces between the original geometry and the moved face are added.

NOTE The location of the current UCS is temporarily moved to coincide with the original position of the Face grip that you select when you are working with this option. Only the UCS origin is changed, not its orientation.

Pushing or Pulling a Mass Element Face Orthogonally While either Adding Adjacent Faces or Creating a Hole

- 1 Select the mass element you want to edit.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Free Form for Shape.
The mass element is in in-place edit mode. Each face of the Free Form mass element is available to edit in this mode.
- 4 Select the Face grip for the face of the mass element to edit.
Depending on the original shape of the mass element, Edge and Vertex grips are displayed.
- 5 Click and hold the Face grip, press *CTRL* five times, and specify the new location.
Push into the mass element to create a hole, or pull out of the mass element to add adjacent faces.
- 6 Press *ESC*, or right-click and click Deselect All to exit the editing session.

Pulling a mass element face orthogonally while adding adjacent faces

The face of the Free Form mass element is pulled orthogonally and its geometry remains unchanged, while adding adjacent faces between the original geometry and the moved face.

Pushing a mass element face orthogonally to create a hole

The face of the Free Form mass element is pushed orthogonally and its geometry remains unchanged, while creating a hole in the mass element.

Assigning Materials to a Mass Element

Use this procedure to assign materials to the individual components of a mass element.

- 1 Select the mass element to which you want to assign materials, right-click, and click Edit Object Display.
- 2 To verify that the material assignment determines the display properties of the component, click the Display Properties tab, select the display representation where you want the changes to appear, and click  .
- 3 Click the Layer/Color/Linetype tab, verify that By Material is selected for the component, and click OK.
- 4 Click the Materials tab.

The Component column displays all components of the mass element that can be assigned a material. Components that are only symbolical graphics, like the bounding box, are not listed because they cannot have a material assignment.

The Material Definition column displays the currently assigned materials. If no previous material assignments were made, the default material is Standard.

5 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

6 Click OK twice.

Specifying the Display Properties of a Mass Element

Use this procedure to change the following display properties of the components of a mass element:

- Visibility (component is on or off)
- By Material (material assigned to the component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE If a material assignment determines the properties of a mass element display component, you can change the properties of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Assigning Materials to a Mass Element](#) on page 715.

1 Select the mass element you want to change, right-click, and click Edit Object Display.

2 Click the Display Properties tab.

3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current one.

4 If necessary, click .

5 Click the Layer/Color/Linetype tab.

6 Select the component to change, and select a different setting for the property.

7 Click OK twice.

Specifying the Hatching of a Mass Element

Use this procedure to specify the hatching of components of an individual mass element. Hatching is displayed only in display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

NOTE If a material assignment determines the hatching properties of a mass element display component, you can change the hatching by clearing By Material or by overriding the material assignment with a different material. For more information, see [Assigning Materials to a Mass Element](#) on page 715.

- 1 Select the mass element you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.
The display representation in bold is the current one.

- 4 If necessary, click  .
- 5 Click the Hatching tab.
- 6 Select a display component, and click the setting for Pattern.
- 7 Select the hatching for the display component:

If you want to select...	Then...
a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
single hatching	select User-defined for Type, and clear Double Hatch.
double hatching	select User-defined for Type, and select Double Hatch.
solid fill	select Solid Fill for Type.

- 8 Click OK.
- 9 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.
- 10 Click Angle, and enter the angle for the selected pattern.
- 11 Click Orientation, and specify how the hatching is oriented:

If you want to orient...	Then...
the hatching to the object, regardless of the object rotation	select Object.
the hatching to the World Coordinate System	select Global.

- 12 Click OK twice.

Changing the Location of a Mass Element

Use this procedure to relocate a mass element by changing the coordinate values of its insertion point. The mass element also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the mass element are parallel to the XY

plane, its normal is parallel to the Z axis. You can change the orientation of the mass element by aligning its normal with another axis. You can also rotate the mass element on its plane by changing the rotation angle.

For more information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Select the mass element you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the mass element:

If you want to...	Then...
relocate the mass element	enter new coordinate values under Insertion Point.
locate the mass element on the XY plane	make the normal of the mass element parallel to the Z axis: under Normal, enter 1 for Z, and enter 0 for X and Y.
locate the mass element on the YZ plane	make the normal of the mass element parallel to the X axis: under Normal, enter 1 for X, and enter 0 for Y and Z.
locate the mass element on the XZ plane	make the normal of the mass element parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.
change the rotation of the mass element	enter a new value for Rotation Angle.

- 5 Click OK twice.

Specifying the Cut Plane Display of a Mass Element

Use this procedure to specify the properties of one or more cut planes for a mass element. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the mass element you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all mass elements in the drawing, select Drawing default setting. To apply changes to all mass elements of this style, select Mass Element Style:<style name>. For more information on styles, see [Mass Element Styles](#) on page 720.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.

- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)

You can also access and modify these same cut plane settings through the mass element's context menu, as follows

- 1 Select the mass element, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.
The display representation in bold is the current display representation.

- 4 If necessary, click .
- 5 In the Display Properties dialog, click the Other tab, and then change the settings as needed.
- 6 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Mass Element

Use this procedure to attach hyperlinks, notes, or files to a mass element. You can also edit hyperlinks and notes, and edit or detach reference files from a mass element.

- 1 Select the mass element to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
- 4 Click OK.
- 5 To add a note, click the setting for Notes, and enter the note.
- 6 Click OK.
- 7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, and select a file. Click open, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 8 Click OK twice.

Mass Element Styles

A mass element style is a collection of settings for variables associated with a mass element. Depending on the scope of the drawing, you could create different mass element styles to represent different types of mass elements.

Properties Controlled by Mass Element Styles

The mass element style determines the properties of mass elements you create. When you edit the display properties of a mass element style, those changes are applied to existing mass elements of that style throughout the current drawing.

Creating Mass Element Styles

Typically, you create mass element styles that represent the basic building blocks of the drawing. When you name a mass element style, mass elements are grouped and can generate reports based on the first part of the mass element style name.

Editing Mass Element Styles

The changes you make to a mass element style take effect the next time you use that style. Mass elements already created with that style are not updated unless you change the display properties of the mass element style.

Managing Mass Element Styles

When you create, import, export, or edit styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Creating a Mass Element Style

Use this procedure to create a mass element style. You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Multi-Purpose Objects, and expand Mass Element Styles.

- 3 Create a mass element style:

If you want to...	Then...
create a style with default properties	right-click Mass Element Styles, and click New.
create a style from an existing style	right-click the mass element style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new mass element style, and press *ENTER*.

5 Edit the new mass element style:

If you want to...	Then...
specify materials for mass element components	see Assigning Materials to a Mass Element Style on page 722.
specify the display properties of the style	see Specifying the Display Properties of a Mass Element Style on page 723.
specify hatching for components of the style	see Specifying the Hatching for Components of a Mass Element Style on page 723.
add notes and files to the style	see Attaching Notes and Files to a Mass Element Style on page 725.

6 When you finish specifying the properties of the mass element style, click OK.

Specifying the Materials of a Mass Element Style

A mass element consists of a number of components whose display properties can be determined by the materials assigned to each component.

You assign one material to each physical component of the mass element. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the mass element style, instead of using material display properties, you can turn off the material assignments in the display properties of the style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in three-dimensional (3D) model views and in elevations.

Mass Element Materials and Display Components

The following table lists mass element components and the material components that determine them in specific views.

Mass Element Component	Material Component
Plan, Plan High Detail, Plan Low Detail, Plan Presentation, Plan Screened	
Above Cut Plane	Plan Linework
Below Cut Plane	Plan Linework
Hatch	Plan Hatch
Cut Plane	No Material

Mass Element Component	Material Component
Model	
Entity	3D Body
Bounding Box	No Material
Reflected, Reflected Screened	
Entity	3D Body
Bounding Box	No Material
Hatch	Plan Hatch

Assigning Materials to a Mass Element Style

Use this procedure to assign materials to the individual components of a mass element style. The component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the mass element. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, the hatch is a physical component. The cut plane is a symbolic component.

NOTE If a material assignment does not determine the display properties of a mass element component, you can change the display properties of the mass element style as described in [Specifying the Display Properties of a Mass Element Style](#) on page 723.

- 1 Open a tool palette that has a mass element tool.
- 2 Right-click a mass element tool, and click Mass Element Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

11 Click OK.

Specifying the Display Properties of a Mass Element Style

Use this procedure to change the following display properties of the display components of a mass element style:

- Visibility (component is on or off)
- By Material (material assigned to the component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

To change these display properties for an individual mass element, see [Specifying the Display Properties of a Mass Element](#) on page 716.

NOTE If a material assignment determines the display properties of components in the mass element style, you can change the properties of the display component by clearing By Material. You can also override the material assignment with a different material. For more information, see [Assigning Materials to a Mass Element Style](#) on page 722.

- 1 Open a tool palette that has a mass element tool.
- 2 Right-click a mass element tool, and click Mass Element Styles.
- 3 Select the mass element style you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 Click the Layer/Color/Linetype tab.
- 7 Select the component to change, and select a different setting for the property.
- 8 Click OK.

Specifying the Hatching for Components of a Mass Element Style

Use this procedure to specify the hatching of components of a mass element style. Mass element hatching is displayed only in display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Open a tool palette that has a mass element tool.
- 2 Right-click a mass element tool, and click Mass Element Styles.
- 3 Select the mass element style to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and click Style Override.
The display representation in bold is the current one.
- 6 Click the Hatching tab.
- 7 Select a display component, and click the setting for Pattern.

8 Select the hatching for the display component:

If you want to...	Then...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

9 Click OK.

10 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

11 Click Angle, and enter the angle for the selected pattern.

12 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

13 Click OK.

Defining a Mass Element Style as Bounding for Associative Spaces

Use this procedure to define a mass element style that can bound associative spaces.

When a mass element style is set as bounding, by default all mass element that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the mass element style in an individual mass element, if necessary.

1 Click Format menu ► Style Manager.

2 Expand Multi-Purpose Objects, and expand Mass Element Styles.

3 Select a mass element style.

4 Click the General tab.

5 Select the check box for Objects of this style may act as a boundary for associative spaces.

6 Click OK.

Attaching Notes and Files to a Mass Element Style

Use this procedure to enter notes and attach reference files to a mass element style. You can also edit notes and edit or detach reference files from a mass element style.

- 1 Open a tool palette that has a mass element tool.
- 2 Right-click a mass element tool, and click Mass Element Styles.
- 3 Select the mass element style you want to change.
- 4 Click the General tab.
- 5 To add a description to the mass element style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

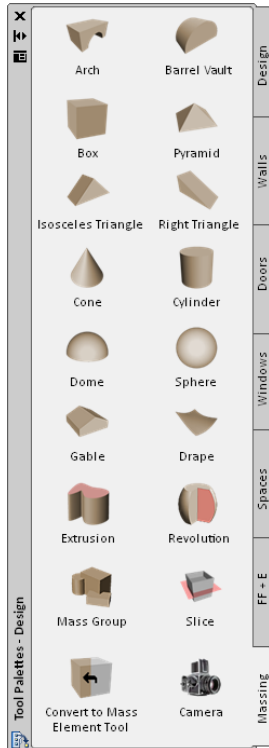

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 9 Click OK twice.

Using Massing Tools to Create Mass Groups

Tools provided with AutoCAD Architecture let you quickly place mass groups by selecting a tool from the Massing tool palette. The mass group tool has predefined properties. You can use the default settings of the tool, or you can change settings for the mass group properties.

Tool palette containing mass group tools

The default tool palettes in the workspace contain sample mass group tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain mass group tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog

For more information on accessing tools in these catalogs, see [Content Browser](#) on page 121.

Custom palettes created by your CAD manager or other users may also contain mass group tools with mass group properties that are customized for your projects or office standards.

Creating a Mass Group

Use this procedure to add a new mass group that has the properties specified in a selected mass group tool.

A mass group is a display object that allows you to visualize and manipulate combinations of mass elements. After you create mass elements, you can combine their shapes through Boolean operations (addition, subtraction, and intersection) in a mass group. The resulting complex shape of the mass group represents your mass model.

Mass Groups and Mass Group Markers

You use a mass group tool to attach mass elements, other AEC objects, or AutoCAD objects to a mass group, which you place in a convenient area of your drawing. The mass elements and other objects that you attach form the body of the mass group. The mass group is created on a different layer than the mass elements that form it.

A mass group marker is displayed in the drawing if you create a mass group and then detach all mass elements from it, or if you release the anchor of objects attached to the group. If you attach elements to the group, or if you anchor attached objects to the group, the mass group marker is no longer displayed.

Using Boolean Operations to Create a Mass Group

You can combine the shapes of mass elements in the mass group—adding, subtracting, and intersecting them in a specific order.

- An additive operation combines the total volume of two or more solids or two or more regions into a composite object.
- A subtractive operation removes the common area of one set of solids from another.
- An intersection removes non-overlapping portions and creates a composite solid from the common volume.

You can attach any closed, solid shape to a mass group. For example, a line has no solid properties and cannot be added to the shape of the mass group. However, an AutoCAD 3D solid does contribute to the final shape.

You can also create and work with mass groups in the Model Explorer. For more information, see [Using the Model Explorer to Create Mass Models](#) on page 741.

To further refine the building model, you can edit individual mass elements that are attached to a mass group.

Materials in Mass Groups

In AutoCAD Architecture, you can assign materials to a mass group. These materials are displayed in wireframe or rendered views. Materials have specific settings for individual components of a mass group.

Mass groups with assigned materials in rendered view

AutoCAD Architecture provides predefined materials for common design purposes, which contain settings for mass groups. You can use these predefined materials, or modify them to your special designs. You can also create your own materials.

For more information, see [Using Materials for Mass Elements and Mass Groups](#) on page 737.

- 1 Open the tool palette that you want to use, and select a mass group tool.
If necessary, scroll to display the tool that you want to use.
- 2 Select the elements to attach to the group, and press *ENTER*.
- 3 Specify the insertion point of the mass group.
You can move or hide the Properties palette to expose more of the drawing area.

Assigning Materials to a Mass Group

Use this procedure to assign materials to the individual components of a mass group.

- 1 Select the mass group to which you want to assign materials, right-click, and click Edit Object Display.
- 2 To verify that the material assignment determines the display properties of the component, click the Display Properties tab, select the display representation where you want the changes to appear, and click .
- 3 Click the Layer/Color/Linetype tab, verify that By Material is selected for the component, and click OK.
- 4 Click the Materials tab.

The Component column displays all components of the mass group that can be assigned a material. Components that are only symbolical graphics, like the bounding box, are not listed because they cannot have a material assignment.

The Material Definition column displays the currently assigned materials. If no previous material assignments have been made, the default material is Standard.

- 5 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

- 6 Click OK twice.

Changing the Size of the Mass Group Marker

Use this procedure to change the size of the mass group marker by editing its display properties.

- 1 Double-click the mass group you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all mass groups in the drawing, select Drawing default setting.

- 5 If necessary, expand Object Display Properties ► Advanced.

- 6 Click the value for Marker size, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)

You can also access and modify the marker size property through the mass group's context menu, as follows

- 1 Select the mass group, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click .

5 In the Display Properties dialog, click the Other tab, and then change the size as needed.

6 Click OK twice.

Adding a New Mass Element to a Mass Group

Use this procedure to add a new mass element to a mass group after you have placed a mass group in the drawing.

1 Select an existing mass group or mass group marker, right-click, and click Add New Element.

2 On the Properties palette, select a shape for the mass element.

3 Select Add, Subtract, or Intersect for Operation.

4 Specify an insertion point in the drawing.

5 Specify additional parameters for the mass element.

Depending on the shape of the mass element, you need to specify a second corner, the radius, or the height.

6 Specify a rotation angle, and press *ENTER*.

The newly created mass element is now part of the selected mass group.

Attaching an Existing Mass Element to a Group Using Grips

Use this procedure to add existing mass elements to a mass group. When an element is attached to a mass group, the element display is turned off and the group display is turned on.

While it is possible to attach any number of objects to a single mass group, performance improves if this group is subdivided into a series of nested groups. Your design is also more manageable if a group is broken into logical divisions. In addition, if one of the subgroups fails to display as expected, it is easier to track down the problem. In most cases, you can adjust the order of the objects in the group to get the correct appearance.

1 Select the mass group.

2 Select the Attach Elements grip.

3 Select one or more mass elements to attach to the mass group, and press *ENTER*.

Detaching a Mass Element from a Group Using Grips

Use this procedure to detach a mass element from a mass group. After you have defined a mass group and added mass elements to it, you may decide that one or more elements do not fit your model. You can detach these from the mass group and use them elsewhere or delete them.

When an element is detached from a mass group, the element display is turned on because it is an individual entity and is no longer part of the group.

- 1 Select the mass group.
- 2 Select the Detach Elements grip.

- 3 Select one or more mass elements to detach from the mass group.
If there is only one element attached to the mass group, you are not prompted to select elements. The single element is detached without further input.
- 4 Press *ENTER*.

Making a Mass Element Additive

Use this procedure to change the operation of a mass element. All objects are additive when they are created. When two mass elements are grouped together, they form one mass containing both objects.

- 1 Select the mass group that contains the mass element you want to change.
- 2 Select the Edit In Place grip.

- 3 Select the mass element you want to make additive, right-click, and click Mass Group Operation ► Additive.
- 4 Select Save All Changes on the In-Place Edit toolbar.

This saves the changes to the mass element and ends the in-place edit session.

Making a Mass Element Subtractive

Use this procedure to change the operation of a mass element. When a mass element in a group operates by subtraction, the mass element subtracts its mass where it overlaps another object.

- 1 Select the mass group that contains the mass element you want to change.
- 2 Select the Edit In Place grip.

- 3 Select the mass element you want to make subtractive.
- 4 On the Properties palette, expand Basic, and expand General.
- 5 Select Subtract for Operation.
- 6 Select Save All Changes on the In-Place Edit toolbar.

This saves the changes to the mass element and ends the edit-in-place session.

Creating an Intersection from Mass Elements

Use this procedure to create a new mass shape using the intersection of two mass elements.

- 1 Select the mass group that contains the mass element you want to change.
- 2 Select the Edit In Place grip.

- 3 Select the mass element you want to make intersecting.
- 4 On the Properties palette, expand Basic, and expand General.
- 5 Select Intersect for Operation.
- 6 Select Save All Changes on the In-Place Edit toolbar.

This saves the changes to the mass element and ends the edit-in-place session.

Creating a Nested Mass Group

Use this procedure to attach a mass group to another mass group. This action nests the current mass group within the mass group that you select.

You may find it easier to nest mass groups using the Model Explorer. For more information, see [Moving a Mass Element or Group from One Mass Group to Another](#) on page 750.

- 1 Select the mass group that you want to nest within another mass group.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Click the mass group where you want to nest the current mass group for Attached to.
- 4 Specify Add, Subtract, or Intersect for Operation.

This option determines how the mass group is nested within the mass group you selected.

Removing a Nested Mass Group from a Mass Group

Use this procedure to remove a mass group from a mass group in which the first mass group is nested. The mass group you remove remains in the drawing.

- 1 Select the mass group you want to remove.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select None for Group.
- 4 Right-click, and click Deselect All to turn off grips.

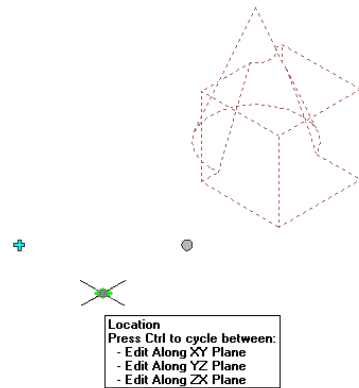

Changing the Location of a Mass Group Using Grips

Use this procedure to relocate a mass group using the Location grip. In Model view, the Location grip has three edit modes: Edit Along XY Plane, Edit Along YZ Plane, and Edit Along ZX Plane. The default edit mode is along the XY plane. In Plan view, the Location grip is restricted to movement in one plane.

If the mass elements that are attached to the mass group are anchored, they move when you move the Location grip. If the anchor of objects has been released, only the mass group marker moves when you move the Location grip. For more information, see [Working with Mass Group Anchors](#) on page 733.

You can also change the location of a mass group using the Properties palette.

- 1 Select the mass group you want to change.
- 2 Select the Location grip.

- 3 Move the mass group to the desired location, and click once; or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the Y direction when editing along the XY plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the mass group along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the mass group is constrained to the second dimension direction. When editing along the XY plane, for example, you can enter a value for X dimension, and then press *TAB*. The X dimension is locked at that value, and movement of the mass group is constrained to the Y dimension direction.

- 4 Right-click, and click Deselect All to turn off grips.

Working with Mass Group Anchors

Use these procedures to release anchors of objects attached to a mass group, or anchor elements to a mass group.

Releasing object anchors from a mass group

- 1 Select the mass group with objects anchored to it.
- 2 Right-click, and click Release Anchor of Attached Objects.

All anchors are released, and the mass group marker is displayed. The display of attached elements is turned on.

Anchoring objects to a mass group

- 1 Select the mass group or the mass group marker that has no objects anchored to it.
The mass group must have mass elements attached to it in order to anchor them to the group.
- 2 Right-click, and click Anchor Attached Objects.
All objects are anchored to the mass group, and the mass group marker is no longer displayed. The display of attached elements is turned off.

Working with Mass Groups

Use these procedures to place an entity reference of a mass group in a drawing, or to reposition the insertion point of a mass group.

You can place a mass group in the drawing multiple times for modeling. Using an entity reference helps to simplify the modeling process.

You can adjust the insertion point of a mass group by selecting a new location and a new rotation.

Placing an entity reference of a mass group

- 1 Select a mass group.
- 2 Right-click, and click Place Reference.
- 3 Move the cursor to the desired location for the entity reference, and click once to place the reference in the drawing.
- 4 Specify the rotation angle, and press *ENTER*.

An entity reference of the selected mass group is placed in the drawing, as specified. The entity reference is distinguished from the mass group by its location marker.

Repositioning the insertion point of a mass group

- 1 Select a mass group.

- 2 Right-click, and click Reposition Insertion Point.
- 3 Specify the new insertion point.
- 4 Enter a rotation angle, and press *ENTER*; or move the cursor, and click to specify the rotation.

If the mass group has an entity reference connected to it, repositioning the insertion point of the mass group affects the rotation of the entity reference.

Specifying the Cut Plane Display of a Mass Group

Use this procedure to specify the properties of one or more cut planes for a mass group. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the mass group you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that **NONE** is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all mass groups in the drawing, select Drawing default setting.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)

You can also access and modify these same cut plane settings through the mass group's context menu, as follows

- 1 Select the mass group, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.
The display representation in bold is the current display representation.
- 4 If necessary, click .
- 5 In the Display Properties dialog, click the Other tab, and then change the settings as needed.
- 6 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Mass Group

Use this procedure to attach hyperlinks, notes, or files to a mass group. You can also edit hyperlinks and notes, and edit or detach reference files from a mass group.

- 1 Double-click the mass group to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
- 4 To add a note, click  next to Notes, enter text, and click OK.
- 5 To attach, detach, or edit a reference file, click  next to Reference documents, and then do any of the following:

If you want to...	Then...
attach a reference file	click  , select a file, and click Open.
edit the description of a reference file	enter text under Description.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

- 6 Click OK twice.

Creating a Mass Group Tool

Use this procedure to create a mass group tool and add it to a tool palette. You may want to create your own mass group tools if you are placing multiple mass groups with the same mass group properties.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to...	Then...
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	right-click the tool, and click Copy. Open the other palette, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 To add keywords to the tool, click More Info.

7 Enter the keywords, and click OK twice.

Using Materials for Mass Elements and Mass Groups

Using materials simplifies defining the display of objects. You define the display of a material, such as brick or glass, only once in the drawing or the drawing template, and then assign it to any object component or object style. For example, you can define a material "Glass" and assign it to any number of windows, glass door insets, or cubicle walls.

Using a common set of materials provides centralized control across the display of objects in a drawing or throughout the whole project. When the particulars of a material change, you change them just once in the material definition, and all objects are updated.

For more information, see [Materials](#) on page 601.

Rendered building with different materials

Predefined Materials

AutoCAD Architecture provides predefined materials for common design purposes. You can use these predefined materials, or modify them to your special designs. You can also create your own materials.

Surface Hatching

Surface hatches can display in both model views and section/elevation views. Placement and orientation of the hatch can be precisely controlled and specified for each object face individually.

For detailed information about surface hatches, see [Working with Surface Hatches](#) on page 615.

Mass Element and Mass Group Display Components and Materials

A mass element or a mass group consists of a number of display components that can be determined by materials.

Workflow

You assign one material to each display component of the mass element or mass group. For example, you assign a dark wood material to the mass element body and a light brown material to the mass element hatch. When you assign a material to a mass group, the display properties of the attached mass elements are overridden with the mass group settings.

If you want to use the display properties of the mass element instead of the material display properties, you can deactivate the material assignments in the display properties of the mass element.

Display Representations

The display properties of an object are specified for each display representation individually. Mass elements and mass groups have display representations for plan, model, reflected, and sketch views. You can create new display representations for mass elements and mass groups by copying an existing representation. For example, you can create a new display representation “Plan 1:25” to create a plan view optimized for display in a view scaled to 1:25. This new display representation has the same display components as the one from which it was copied. The copied components will be influenced by the same material components as the original components.

Material Component Assignments

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in Plan view. The Surface Hatch component of a material is used to hatch all object surfaces in 3D model views and elevations.

For a complete list of material components and their descriptions, see [Material Components and Display Properties](#) on page 610.

The following table lists mass element components and the material components that determine them.

Mass Element Component	Material Component
Plan High Detail, Plan Low Detail, Plan Presentation, Plan Screened	
Hatch	Plan Hatch

Mass Element Component	Material Component
Cut Plane	No Material
Model	
Entity	3D Body
Bounding Box	No Material
Reflected, Reflected Screened, Sketch	
Entity	Plan Linework
Bounding Box	No Material
Hatch	Plan Hatch

The following table lists mass group components and the material components that determine them.

Mass Group Component	Material Component
Plan High Detail, Plan Low Detail	
Marker	No Material
Cut Plane	No Material
Hatch	No Material
Plan, Plan Presentation, Plan Screened	
Entity	Plan Linework
Marker	No Material
Model	
Entity	3D Body
Marker	No Material
Reflected, Reflected Screened	
Entity	Plan Linework
Marker	No Material

Process Overview: Creating and Applying a Material for a Mass Element or Mass Group

If you create a material, you can apply it to all types of objects that support materials. For example, a concrete material could be used for a wall and for a structural element. Mass elements and mass groups are often used for columns, elevator shafts, or chimneys. If you want to create a material to use only for mass elements or mass groups, you should name it accordingly. For example, if the materials have specific names, such as “Mass Element - Concrete Column” or “Mass Group - Cable Shaft,” you can simplify the organization of your material definitions.

- 1 Create a new material definition or edit an existing material definition.

For more information, see [Creating and Editing Material Definitions](#) on page 624.

- 2 In the material definition, define the settings that affect the display of materials in mass elements and mass groups:

If you want to...	Then...
display a surface hatch for a mass element or a mass group in 3D model views	turn on the Surface Hatch component, and specify its display properties. For more information, see Defining the Layer, Color and Linetype of a Material Definition on page 626 and Specifying the Surface Hatch Pattern of a Material Definition on page 627.
display a section hatch for a mass element or mass group in a 2D section, 3D section, or live section	turn on the Section Hatch component, and specify its display properties. For more information, see Defining the Layer, Color and Linetype of a Material Definition on page 626 and Specifying the Plan and Section Hatch Patterns of a Material Definition on page 626.
display the sectioned boundary and sectioned body of a mass element or mass group in a live section	turn on the Sectioned Boundary and Sectioned Body components, and specify their display properties. For more information, see Defining the Layer, Color and Linetype of a Material Definition on page 626.
add special rendering materials for mass elements or mass groups in live sections	select rendering materials. For more information, see Assigning Render Materials on page 629.
exclude mass element or mass group components from a 2D section shrinkwrap hatch	specify this setting in the material definition. For more information, see Excluding a Material Definition from 2D Section Shrinkwrap on page 631.

- 3 Turn on the assigned materials in the individual display representations, and then assign materials to the mass elements and mass groups in your building model.

For more information about assigning materials to mass elements, see [Assigning Materials to a Mass Element](#) on page 715.

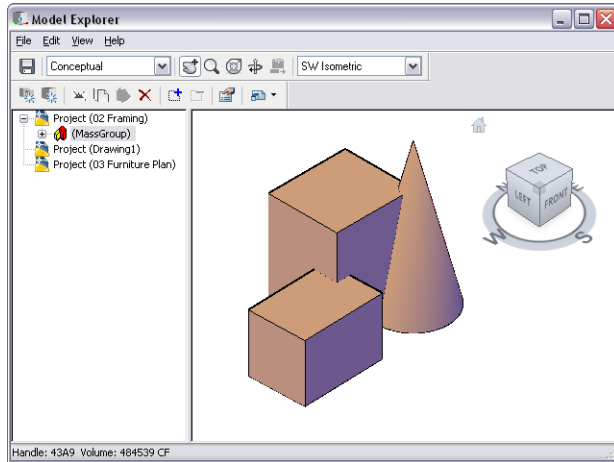

For information about assigning materials to mass groups, see [Assigning Materials to a Mass Group](#) on page 728.

Using the Model Explorer to Create Mass Models

The Model Explorer is a window in which you create, view, and manipulate mass elements and mass groups. You can create your entire conceptual model by using the Model Explorer. The main window is similar to the 3D orbit view. You can attach objects and mass elements to mass groups and view them in the Model Explorer. You can simultaneously view the conceptual and the hierarchical structure of mass groups and mass elements that make up the model.

The Model Explorer is divided into three areas: the tree view in the left pane, the graphics area in the right pane, and the menu bar and toolbar across the top.

Viewing a mass group in the Model Explorer

Left Pane of the Model Explorer

The tree view lists all open drawings as Projects. Any mass groups are displayed under their associated drawing in the tree view. If you expand a mass group, the mass elements attached to it are displayed. One of the following icons is displayed next to each mass element in the mass group, indicating which Boolean operation is used to combine mass elements:

Icon	Boolean Operation Used
	If both squares are yellow, the operation is additive.
	If the top portion of the two squares is yellow, the operation is subtractive.
	If the middle of squares is yellow, the operation is intersection.

An additive operation in the Model Explorer combines the total volume of two or more solids or two or more regions into a composite object. A subtractive operation removes the common area of one set of solids from another. An intersection removes non-overlapping portions and creates a composite solid from the common volume.

The order of objects and mass elements in the tree view dictates the outcome of the group when mass elements are combined. You can drag and drop the mass elements within the mass group to change the order in which they are combined.

You can also drag and drop mass groups to nest them within other mass groups. For example, if you are modeling a building with multiple wings, each wing can be a mass group containing multiple mass elements. You can then add these groups to a mass group of the entire building.

Right Pane of the Model Explorer

The right pane of the Model Explorer displays a graphical view of the mass elements or mass groups that you select in the left pane.

Model Explorer Menu Bar and Toolbar

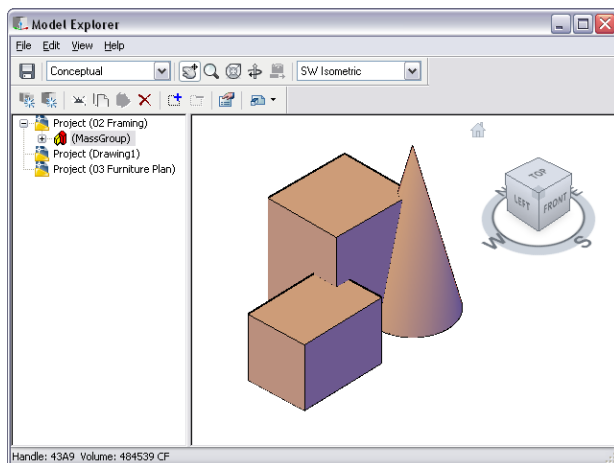

The top of the Model Explorer includes a menu bar and toolbar that allow you to access menu commands. If you position your pointing device over a toolbar icon, a tooltip displays an explanation of the icon. For more information, see [Using Toolbar Commands in the Model Explorer](#) on page 746.

If you turn off the Model Explorer toolbars using commands on the View menu, the tree view and viewer are blank the next time you display the Model Explorer. Click any pull-down menu heading to restore the proper display.

Displaying the Model Explorer

Use this procedure to open the Model Explorer. Any mass groups in the current drawing are displayed in the right pane. The tree view in the left pane lists the mass groups in open drawings.

Viewing a mass group in the Model Explorer

1 Select a mass group, right-click, and click Show Model Explorer.

2 You can move, resize, or close the Model Explorer:

If you want to...

Then...

move the Model Explorer

drag the Model Explorer title bar to the desired location.

resize the Model Explorer

click the edge of the Model Explorer and drag to the desired size.

close the Model Explorer

click the "X" in the upper right corner of the Model Explorer.

Defining the View in the Model Explorer

The Model Explorer lets you display mass groups in different view directions, display configurations, and visual styles. You can also define parallel or perspective views.

1 Select a visual style from the drop-down menu on the top left:

- **3D Hidden:** Displays the objects using 3D wireframe representation and hides lines representing back faces.
- **3D Wireframe:** Displays the objects using lines and curves to represent the boundaries.
- **Conceptual:** Shades the objects and smooths the edges between polygon faces. Shading uses a transition between cool and warm colors. The effect is less realistic, but it can make the details of the model easier to see.
- **Realistic:** Shades the objects and smooths the edges between polygon faces. Materials that you have attached to the objects are displayed.

Alternatively, right-click in the preview area, click Visual Style, and select the desired style.

2 Click the  button to select a display configuration.

Display configurations are collections of object display representations, determining which objects are visible, and how the objects are displayed per view. For more information, see [Display Configurations](#) on page 549.

3 Select a view direction from the drop-down menu on the top right.

Alternatively, right-click in the preview area, click Preset Views, and select the desired view direction.

4 Select the projection type of the mass groups in the preview:

- To select a parallel projection, right-click in the preview area, and click Projection ► Parallel.
- To select a perspective projection, right-click in the preview area, and click Projection ► Perspective.

Navigating the View in the Model Explorer

In the Model Explorer, you have a number of options for navigating through the model view.

1 Use these basic navigation tools as needed:

- To move the view in the drawing area, click  (Pan Realtime.)
Alternatively, right-click in the preview area, and click Pan.

2 To zoom in and out of the drawing area, click  (Zoom Realtime.)

Alternatively, right-click in the preview area, and click Zoom. For further Zoom options, right-click in the drawing area, click More, and select the desired Zoom option.

3 To orbit the model in 3D, click  (Constrained 3D Orbit.)

Alternatively, right-click in the preview drawing area, and click Orbit.

4 To move closer to or farther away from the model, click  (Adjust Distance.)

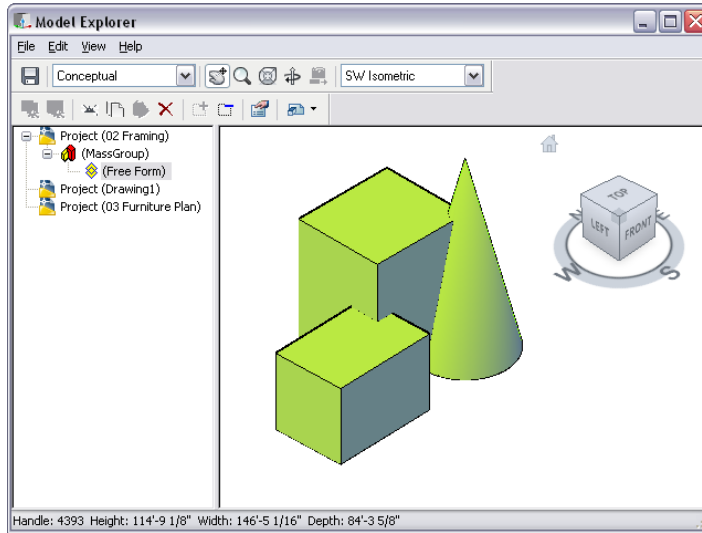

This command works only when you are in perspective projection.

Alternatively, right-click in the preview drawing area, and click More ► Adjust Distance.

Navigating the View with the ViewCube

The ViewCube is a 3D navigation tool that appears when the 3D graphics system is enabled and allows you to switch between standard and isometric views.

In Model Explorer the ViewCube is always visible. When you position the cursor over the ViewCube, it becomes active. You can switch to one of the available preset views, roll the current view, or change to the Home view of the model.

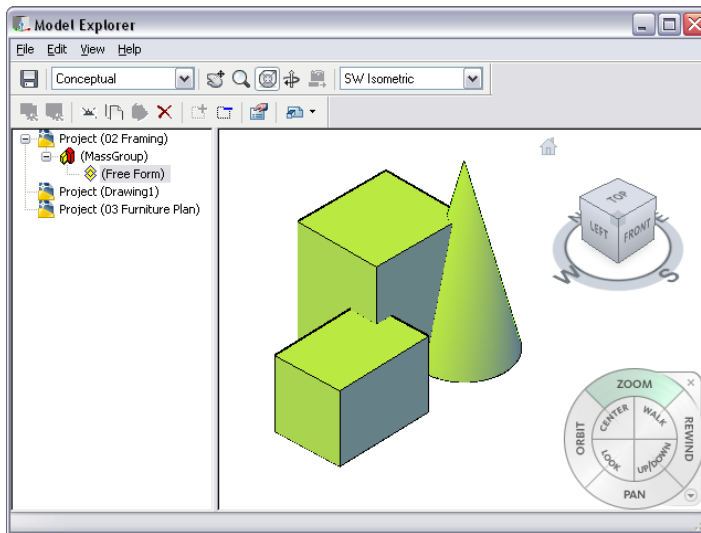

For detailed information about the ViewCube, see “ViewCube” in the AutoCAD Help.

Navigating the View with SteeringWheels

SteeringWheels are tracking menus that are divided into different sections known as wedges. Each wedge on a wheel represents a single navigation tool. You can pan, zoom, or manipulate the current view of a model in different ways.

SteeringWheels can save you time and clicks by combining many of the common navigation tools into a single interface. Wheels are specific to the context that a model is being viewed in.

1 Click the  button.

Alternatively, you can right-click in the preview area, and click Steering Wheel.

2 To close the SteeringWheel, right-click, and click Close Wheel, or click the  button again.
For detailed information, see “SteeringWheels” in the AutoCAD Help.

Viewing Objects on a Nonvisible Layer

Use this procedure to change the settings in the Model Explorer to view all objects, regardless of the visibility of the layer on which they reside. Any object on a layer that is frozen or turned off is not displayed initially.

- 1 Open the Model Explorer.
- 2 On the Model Explorer View menu, click Show All Layers.

The check mark on the menu next to Show All Layers indicates that all objects are displayed in the Model Explorer.

Maintaining Zoom Percentage and Position of an Object

Use this procedure to select an object in the Model Explorer tree view. The zoom percentage and location of the object are maintained. This is useful when you want to examine how the object relates to the rest of the drawing.

In the Model Explorer, you can specify to display the selected object only, and display it at maximum size.

- 1 Open the Model Explorer.
- 2 On the Model Explorer View menu, click Auto Zoom Extents.
- 3 Select the object to view from the tree view.

The Model Explorer graphics window displays only the selected object, zoomed to fit the window.

Using Toolbar Commands in the Model Explorer

The following toolbar commands allow you to work with mass elements and mass groups in the Model Explorer:

Icon	
	New Grouping: Creates a new mass group in the drawing.
	New Element: Creates a new mass element in the drawing.
	Cut: Cuts the selected item in the tree view to the Clipboard.
	Copy: Copies the selected item from the tree view to the Clipboard.
	Paste: Pastes the item on the Clipboard into the tree view at the selected location.
	Delete Item: Deletes an item from the tree view and from the drawing.
	Attach Items: Attaches existing mass elements or objects to the selected mass group. Select one or more elements or objects in the drawing. This option is available only when a mass group is selected in the tree view.
	Detach Items: Detaches the selected mass elements or objects from the mass group. This option is available only when a mass group is selected in the tree view.
	Properties: Opens the properties dialog box for the selected mass element, object, or mass group.
	Display Configuration: Changes the display configuration of the objects in the Model Explorer. You select a display configuration from the list.

Creating a Mass Element with the Model Explorer

Use this procedure to create a mass element in the Model Explorer. For detailed information about specifying the shape and dimensions of a mass element, see [Creating a Mass Element](#) on page 685.

- 1 Open the Model Explorer.
- 2 In the left pane, select the level at which to create the mass element.
If you select the drawing name, the new mass element is created at the next hierarchical level.
If you select a mass group name with a drawing, the new mass element is attached to the selected mass group.
- 3 On the Model Explorer File menu, click Create Element, or click .

- 4 On the command line, specify a shape.
- 5 Specify the insertion point for the mass element.
Depending on the shape you specified, you need to specify a second corner, the radius, or the height.
- 6 Specify the rotation angle.
- 7 Press *ENTER*.

Creating a Mass Group

Use this procedure to create a mass group in the Model Explorer.

- 1 Open the Model Explorer.
- 2 In the left pane, select the level at which you want to create the mass group.
If you select the drawing name, the new mass group is created at the next hierarchical level. If you select a mass group name with a drawing, the new mass group is nested within the existing mass group.
- 3 On the Model Explorer File menu, click Create Group, or click  .
- 4 Specify a location for the mass marker.
The location does not represent the location of mass elements added to the marker. Therefore, you can locate the mass marker in any convenient area.
- 5 Specify the rotation angle.

The new mass group is added to the project tree in the Model Explorer.

Attaching a Mass Element to a Mass Group

Use this procedure to attach existing mass elements to the group after a mass group is created.

- 1 Open the Model Explorer.
- 2 In the left pane, select a mass group, right-click, and click Attach Elements.
- 3 Select the mass elements to add to the group, and press *ENTER*.

Attaching Objects to a Mass Group

Use this procedure to attach objects such as doors, walls, and curtain walls to the group after a mass group is created.

- 1 Open the Model Explorer.
- 2 In the left pane, select a mass group, right-click, and click Attach Elements.
- 3 Select the objects to add to the group, and press *ENTER*.

Changing a Mass Element Operation to Additive

Use this procedure to change a mass element operation to additive. Mass elements are additive when you create them. After a mass element is added to a mass group, its operation can be changed to produce different results.

Adding a mass element to a mass group

1 Open the Model Explorer.

2 In the left pane, select a mass element, right-click, and click Operation ► Additive.

3 In the left pane, click Project to update the display.

The display changes to indicate the new operation property of the mass element.

Changing a Mass Element Operation to Subtractive

Use this procedure to change a mass element operation to subtractive. Mass elements are additive when you create them. After a mass element is added to a mass group, its operation can be changed to produce different results. If the mass element is subtractive, its shape is removed from the mass group.

Subtracting a mass element from a mass group

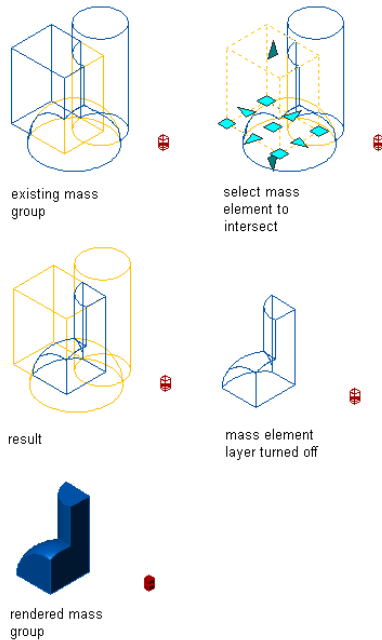

- 1 Open the Model Explorer.
- 2 In the left pane, select a mass element, right-click, and select Operation ► Subtractive.
- 3 In the left pane, click Project to update the display.

The display changes to indicate the new subtractive operation of the mass element.

Changing a Mass Element Operation to Intersection

Use this procedure to change a mass element operation to intersection. Mass elements are additive when you create them. After a mass element is added to a mass group, its operation can be changed to produce different results. The intersect operation creates a shape that is defined by the overlap where the mass element intersects with another mass element.

Creating an intersection mass group from mass elements

- 1 Open the Model Explorer.
- 2 In the left pane, select a mass element, right-click, and select Operation ► Intersect.
- 3 In the left pane, click Project to update the display.

The display changes to indicate the new intersection operation of the mass element.

Specifying the Order of Mass Elements

Use this procedure to specify the order of mass elements. The operation (additive, subtractive, intersection) of each mass element in a mass group is based on the hierarchy of mass elements in the project tree. You can drag and drop mass elements within mass groups in the project tree. By default, mass elements are listed in the left pane of the Model Explorer in the order they are created in the Model Explorer or selected for the mass group.

- 1 Open the Model Explorer.
- 2 Select the mass element you want to move, and drag it to the target location in the project tree.

Moving a Mass Element or Group from One Mass Group to Another

Use this procedure to move a mass element or a mass group from one mass group to another in the Model Explorer project tree.

- 1 Open the Model Explorer.
- 2 In the left pane, select the mass element or mass group you want to move, and drag it to another mass group.

When you move a mass group within another mass group, it is known as a nested mass group.

Creating Slice Floorplates from a Conceptual Model

A slice can be thought of as a representation of a theoretical floor level. Slice floorplates provide a way to translate the 3D geometry of a mass group into something that can be used to generate the individual floors of a building. Slices can be converted to space boundaries or polylines, and then to walls.

Slices and Mass Models

Like mass groups, slices are chosen and manipulated by an associated marker, the slice marker. When you attach mass groups to the slice marker, the slice marker creates the perimeter geometry of the building, known as a floorplate. Anytime you change the mass groups attached to the slice marker, the floorplate is updated.

If you attach mass elements instead of mass groups to the slice, the operational aspects (additive, subtractive, and intersection) of the mass elements are not recognized by the slice. To have these aspects recorded by the slice, attach the mass group. For more information about additive, subtractive, and intersection operations, see [Creating a Mass Group](#) on page 747.

From Slice Floorplate to Walls

After you create floorplates, you can convert slices to space boundaries or polylines, and then generate walls. You cannot create walls directly from a slice. The slice is simply a way to mark each floor level of the mass group.

Generating a Slice

Use this procedure to generate a slice. The slice object is defined by a small crossed box. Like the mass group marker, the slice marker can be located in a convenient place in your drawing. For more information about the mass group marker, see [Creating a Mass Group](#) on page 747.

You can create multiple slices at regular height intervals. A slice marker is created for each slice.

Generating slice objects

3D view of existing mass group

plan view of existing mass group

specify first corner of slice

specify second corner of slice

3D view of result

- 1 Open the tool palette that you want to use, and select a slice tool.
If necessary, scroll to display the tool that you want to use.
- 2 Specify the number of slices you want to create.
- 3 Specify the lower-left and upper-right corners for the slice marker.

TIP Keep the slice marker small so as not to clutter your drawing.

- 4 Specify a rotation for the slice marker.
- 5 Enter the starting height of the slice.
- 6 Enter the distance between slices, and press *ENTER*.
- 7 Press *ENTER*.

Specifying the Slice Elevation

Use this procedure to change the elevation of a slice.

- 1 Select the slice marker, right-click, and click Set Elevation.
- 2 Enter a new slice elevation.

If multiple slices were created together, only the elevation of the selected slice changes. The distance between slices remains constant.

Attaching Objects to a Slice

Use this procedure to attach mass elements or mass groups to a slice to create the building floorplate. You can freeze the layer(s) containing the mass elements and mass groups to display only the slices.

Attaching a mass group to slice objects

- 1 Select the slice marker, right-click, and click Attach Objects.
- 2 Select the mass elements or mass groups you want to include in the slice.
- 3 Press *ENTER*.

Detaching Objects from a Slice

Use this procedure to detach mass elements or mass groups from a slice to change a floorplate.

- 1 Select the slice marker, right-click, and click Detach Objects.
- 2 Select the mass elements or mass groups you want to remove from the slice.
- 3 Press *ENTER*.

Converting a Slice to a Polyline

Use this procedure to convert a slice to a polyline after objects have been attached to a slice marker. You can then convert polylines to spaces, walls, or profiles.

- Select the slice marker, right-click, and click Convert to Polyline.
The outlines of the objects attached to the slice marker are converted to polylines.

Changing the Location of a Slice

Use this procedure to relocate a slice by changing the coordinate values of its insertion point. The slice also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the slice are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the slice by aligning its normal with another axis. You can also rotate the slice on its plane by changing the rotation angle.

For more information about the WCS and the UCS, see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Double-click the slice you want to modify.
- 2 On the Properties palette, expand Basic, and expand Location.

3 Click Additional information.

4 Specify the location of the slice:

If you want to...	Then...
relocate the slice	enter new coordinate values under Insertion Point.
locate the slice on the <i>XY</i> plane	make the normal of the slice parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the slice on the <i>YZ</i> plane	make the normal of the slice parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> , and enter 0 for <i>Y</i> and <i>Z</i> .
locate the slice on the <i>XZ</i> plane	make the normal of the slice parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the slice	enter a new value for Rotation Angle.

5 Click OK.

Attaching Hyperlinks, Notes, or Files to a Slice

Use this procedure to attach hyperlinks, notes, or files to a slice. You can also edit hyperlinks and notes, and edit or detach reference files from a slice.

1 Double-click the slice to which you want to attach information.

2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

4 To add a note, click the setting for Notes, and enter the note.

5 Click OK.

6 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

7 Click OK.

Quick Slice

15

The Quick Slice tool lets you “slice” through one or more objects in a drawing and extract a polyline outline that you can use to create profile shapes.

Quick Slice

The Quick Slice tool lets you “slice” through one or more three-dimensional (3D) objects in a drawing (including mass groups, AutoCAD® blocks, and external references) and extract a polyline outline that can be used to produce a profile shape, such as a roof truss. If you have a 3D model of stairs in your drawing, you can use the Quick Slice tool to create a polyline outline of the stair object in a section view, instead of using a section tool. For more information about section views, see [Sections](#) on page 2147.

Unlike the Horizontal Section, Vertical Section, and Slice tools, which produce multiple polyline segments, the Quick Slice tool produces a single polyline. When you slice through the selected object(s), any overlapping parts of the outline are combined in a boolean operation and converted into a polyline that is inserted on the current layer. The Quick Slice tool also differs from the Slice tool in that it does not create a slice marker. For more information about the Slice tool, see [Generating a Slice](#) on page 751.

Creating a Quick Slice

Use this procedure to extract a polyline outline of a “slice” through one or more 3D objects.

- 1** Select the Quick Slice tool, which is located with the Helper Tools in the Stock Tool Catalog. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.
- 2** Select the object(s) that you want to slice through, and press *ENTER*.
- 3** Specify a starting point for the slice plane.
- 4** Specify a second point to complete a slice plane through the object(s) and generate the polyline outline.
You can now select the polyline outline and view it using the Object Viewer.

Object Viewer

16

The Object Viewer lets you preview objects in your drawing with different visual styles, view directions, and display configurations without changing the display of the drawing area.

Object Viewer

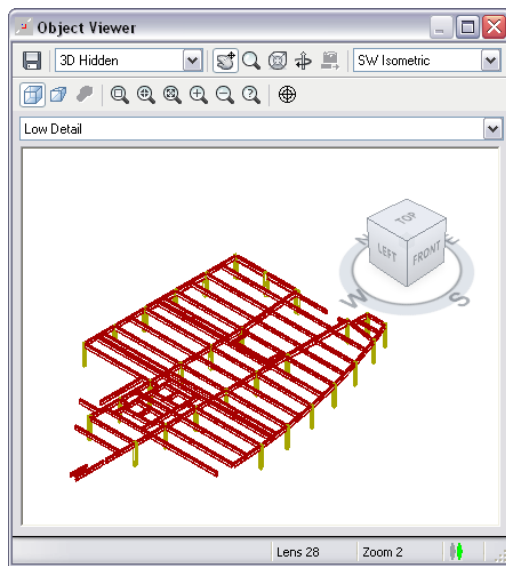

The Object Viewer lets you preview objects in your drawing with different visual styles, view directions, and display configurations without changing the display of the drawing area.

The Object Viewer can be started from different locations in the software. Depending on where the Object viewer is located the viewing and navigation options can vary. For example, if you use Object Viewer to preview an object from the drawing area, a compass is displayed. If you use the object viewer to preview a style in Style Manager, the compass is not displayed, since the style is not an object located in WCS or UCS.

Previewing Objects from the Drawing Area

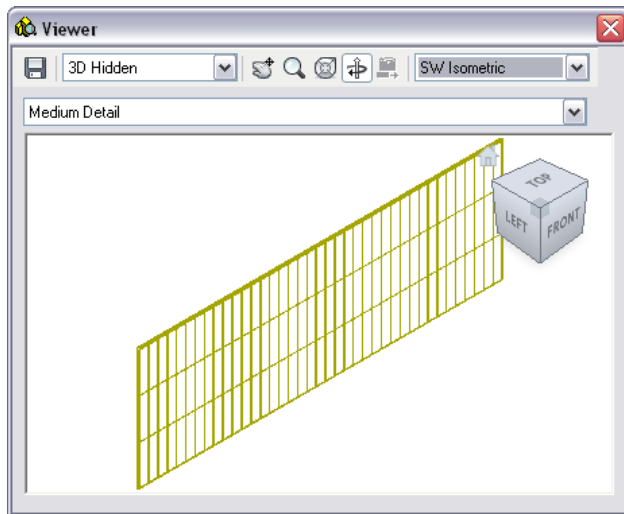

You can select one or more objects in the drawing area, and preview them in the Object Viewer.

- 1 Select the objects in the drawing area for which you want to see a preview.
- 2 Right-click, and click Object Viewer.

Previewing Object Styles in the Style Manager

You can preview the effects of a style that you are creating in the Object Viewer (Floating Viewer) provided with Style Manager.

- 1 Click Format menu ► Style Manager.
- 2 Select the style you want to preview.
- 3 Click the  (Floating Viewer) button at the bottom left of Style Manager.

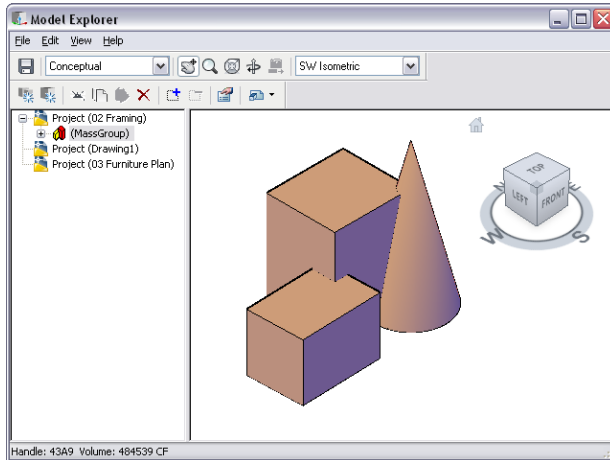

Alternatively, you can click the  button (Inline Edit Toggle) to display the Object Viewer embedded inside Style Manager.

Previewing Mass Models in Model Explorer

The Model Explorer is a window in which you create, view, and manipulate mass elements and mass groups. The Model Explorer uses the Object Viewer to let you preview the mass element and mass group operations you perform.

For more information about Model Explorer, see [Using the Model Explorer to Create Mass Models](#) on page 741.

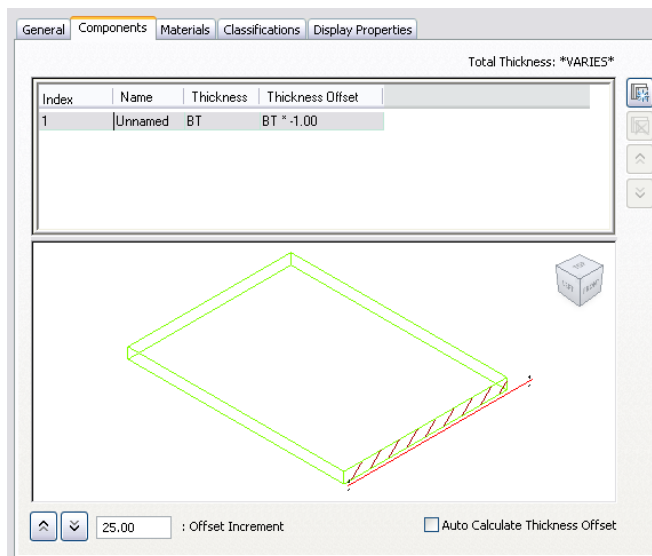

- 1 Click Design menu ► Massing ► Model Explorer.

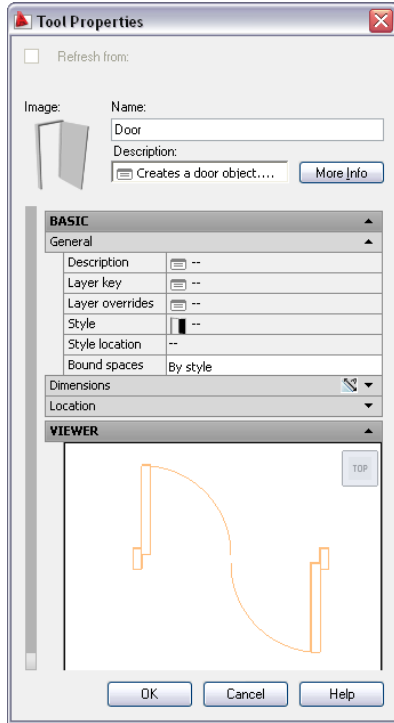

Embedded Object Viewers

A number of dialogs have embedded object viewers in order to let you preview components of a style, a definition, or a tool. See below for a couple of examples of embedded Object Viewers.

Embedded Object Viewer in Roof Slab style tab

Embedded Object Viewer in tool properties

Defining the View in the Object Viewer

The Object Viewer lets you display selected objects, styles, or tools in different view directions, display configurations, and visual styles. You can also define parallel or perspective views.

1 Open the Object Viewer from one of these locations:

- Select an object in the drawing area, right-click, and click Object Viewer.

- Click Format menu ► Style Manager and select a style. Then, click the  button.

Alternatively, you can click the  button (Inline Edit Toggle) to display the Object Viewer embedded inside Style Manager.

- Click Design menu ► Massing ► Model Explorer.

2 Select a visual style from the drop-down menu on the top left:

- **3D Hidden:** Displays the objects using 3D wireframe representation and hides lines representing back faces.
- **3D Wireframe:** Displays the objects using lines and curves to represent the boundaries.
- **Conceptual:** Shades the objects and smooths the edges between polygon faces. Shading uses a transition between cool and warm colors. The effect is less realistic, but it can make the details of the model easier to see.
- **Realistic:** Shades the objects and smooths the edges between polygon faces. Materials that you have attached to the objects are displayed.

Alternatively, right-click in the preview area, click Visual Style, and select the desired style.

- 3 Select a display configuration from the drop-down list below the Visual Styles drop-down list. Display configurations are collections of object display representations, determining which objects are visible, and how the objects are displayed per view. For more information, see [Display Configurations](#) on page 549.

NOTE Display configurations are not available in some embedded Object Viewers.

- 4 Select a view direction from the drop-down menu on the top right. Alternatively, right-click in the preview area, click Preset Views, and select the desired view direction.
- 5 Select the projection type of the objects in the preview:

- Click  to display the objects in a parallel projection.
- Click  to display the objects in a perspective projection. Perspective views require a distance between a theoretical camera and target point. In order to change the lens length of the camera, click  and enter the desired value.

Alternatively, right-click in the preview area, click Projection, and select the desired view projection.

NOTE In embedded Object Viewers, only the context menu options of these commands are available.

Navigating the View in the Object Viewer

In the Object Viewer, you have a number of options for navigating through the model view.

- 1 Open the Object Viewer from one of these locations:
- Select an object in the drawing area, right-click, and click Object Viewer.
 - Click Format menu ► Style Manager and select a style. Then, click the  button. Alternatively, you can click the  button (Inline Edit Toggle) to display the Object Viewer embedded inside Style Manager.
 - Click Design menu ► Massing ► Model Explorer.
- 2 Use these basic navigation tools as needed:
- To move the view in the drawing area, click  (Pan Realtime.) Alternatively, right-click in the preview area, and click Pan.
- 3 To zoom in and out of the drawing area, click  (Zoom Realtime.) Alternatively, right-click in the preview area, and click Zoom. For further Zoom options, right-click in the drawing area, click More, and select the desired Zoom option.
- 4 To orbit the objects in 3D, click  (Constrained 3D Orbit.) Alternatively, right-click in the preview drawing area, and click Orbit.

5 To move closer to or farther away from the object, click  (Adjust Distance.)

This command works only when you are in perspective projection.

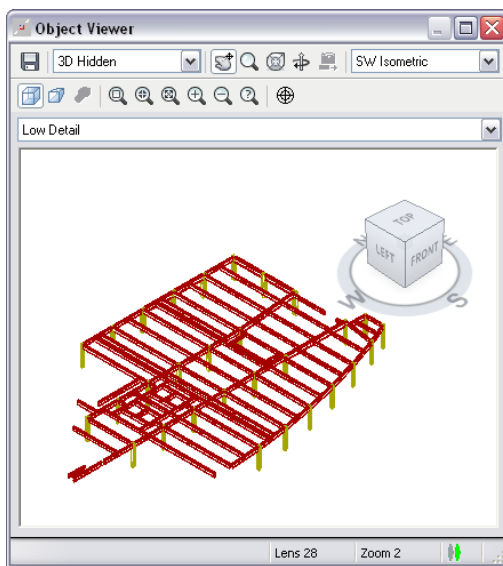

Alternatively, right-click in the preview drawing area, and click More ► Adjust Distance.

NOTE In embedded Object Viewers, only the context menu option is available for all commands.

Navigating the View with the ViewCube

The ViewCube is a 3D navigation tool that appears when the 3D graphics system is enabled and allows you to switch between standard and isometric views.

In Object Viewers, the ViewCube is always visible. When you position the cursor over the ViewCube, it becomes active. You can switch to one of the available preset views, roll the current view, or change to the Home view of the model.

NOTE When you access the ViewCube from Style Manager or from an embedded Object Viewer, no UCS option and no compass are available.

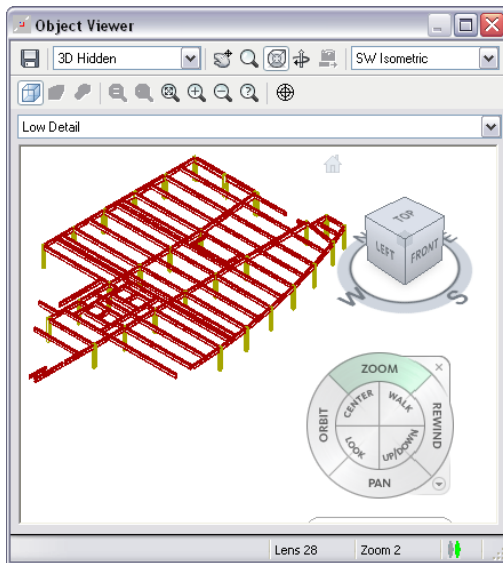

For detailed information about the ViewCube, see “ViewCube” in the AutoCAD Help.

Navigating the View with SteeringWheels

SteeringWheels are tracking menus that are divided into different sections known as wedges. Each wedge on a wheel represents a single navigation tool. You can pan, zoom, or manipulate the current view of a model in different ways.

SteeringWheels can save you time and clicks by combining many of the common navigation tools into a single interface. Wheels are specific to the context that a model is being viewed in.

NOTE SteeringWheels are not available in embedded Object Viewers.

1 Open the Object Viewer from one of these locations:

- Select an object in the drawing area, right-click, and click Object Viewer.

- Click Format menu ► Style Manager and select a style. Then, click the  button.

Alternatively, you can click the  button (Inline Edit Toggle) to display the Object Viewer embedded inside Style Manager.

- Click Design menu ► Massing ► Model Explorer.

2 Click the  button.

Alternatively, you can right-click in the preview area, and click Steering Wheel.

3 To close the SteeringWheel, right-click, and click Close Wheel, or click the  button again. For detailed information, see “SteeringWheels” in the AutoCAD Help.

Setting the View Direction of the Object Viewer to the Drawing Area

You can set the view direction you have specified in the Object Viewer back to the drawing area.

NOTE This command is available only for the Object Viewer when it is started from an object in the drawing area.

1 Select an object in the drawing area, right-click, and click Object Viewer.

2 Change the view direction as desired.

3 Click .

Alternatively, you can right-click in the preview area, and click Set View.

Saving a Preview Image from the Object Viewer

You can save the view in the Object Viewer to a graphic file. File formats supported are PNG, JPEG, BMP, and TIFF.

1 Open the Object Viewer from one of these locations:

- Select an object in the drawing area, right-click, and click Object Viewer.

- Click Format menu ► Style Manager and select a style. Then, click the  button.

Alternatively, you can click the  button (Inline Edit Toggle) to display the Object Viewer embedded inside Style Manager.

- Click Design menu ► Massing ► Model Explorer.

2 Click .

Alternatively, you can right-click in the preview area, and click Save Image.

NOTE In embedded Object Viewers, only the context menu option is available.

3 In the Save Image File dialog, enter a file name and select a file format. Then, click Save.

Napkin Sketch

17

Use Napkin Sketch to create freehand sketch geometry from objects in a drawing. You can create a napkin sketch to reflect ambiguity in a work-in-progress design or to present a more artistically pleasing version of a drawing. You can also generate a napkin sketch of a portion of a drawing and designate it as still in the design stage.

Napkin Sketch

Use Napkin Sketch to create freehand sketch geometry from objects in a drawing. You can create a napkin sketch to reflect ambiguity in a work-in-progress design or to present a more artistically pleasing version of a drawing. You can also generate a napkin sketch of a portion of a drawing and designate it as still in the design stage.

You can create a napkin sketch from an entire drawing or from a portion of a drawing. You can select both AutoCAD® and AEC objects to include in your napkin sketch.

How Objects Appear in a Napkin Sketch

When you generate a napkin sketch, random bumpy line segments are created along objects that you select to include in your sketch. The bumpy lines are short segments that emulate the freehand strokes of a traditional sketch. Lines where segments cross each other are extended in the napkin sketch.

Generating a napkin sketch

Line Formats for Napkin Sketches

When you generate the napkin sketch, you choose from three line formats that control the appearance of the sketch:

- **Tight line format:** Traces the selected geometry once to create the appearance of a more accurate sketch.
- **Loose line format:** Traces the selected geometry twice. (This is the default setting.)

- **Messy line format:** Traces the selected geometry three times.

Line format options

Each pass at tracing the geometry adds more artistic flare to the sketch.

Managing Napkin Sketches

When you create a napkin sketch, the geometry is packaged in a named block and placed on top of the original objects in model space. This means that you can move the original drawing and the sketch drawing independently of each other. You can also edit the napkin sketch as you do with other referenced blocks. Each sketch segment retains the layer and color of the geometry from which it is generated.

Depending on the line format you select for the napkin sketch, up to three complex polylines are generated for each selected object in your drawing. This can significantly increase the drawing size. To keep your drawing size as small as possible, cut and paste your napkin sketches into new drawings.

When you are working with three-dimensional (3D) drawings or complex models, first create a hidden line projection, two-dimensional (2D) section, or 2D elevation object. Unless your drawing is very simple, generating the napkin sketch from these 2D objects saves linework and time.

When you are working with external references, double-click on the napkin sketch and edit it like any other block. For more information about editing external references, see “Edit Referenced Drawings” in the AutoCAD Help.

Napkin Sketch and Intended Plot Scale

You can specify the intended plot scale to control the size of the sketch segments and extensions. Select a larger scale to increase the size of the sketch segments and extensions in the final sketch.

Specifying a plot scale

Creating a Napkin Sketch

Use this procedure to produce a napkin sketch in a plan, isometric, or elevation view. When you are working with three-dimensional (3D) drawings, unless your drawing is very simple, generate the napkin sketch from a two-dimensional (2D) hidden line projection, section, or elevation. For more information, see [Creating a Hidden Line Projection](#) on page 2241, [Sections](#) on page 2147, and [Working With Elevations](#) on page 2195.

1 Open a tool palette that contains a napkin sketch tool.

A napkin sketch tool is located with the Helper Tools in the Stock Tool catalog. For more information, see [Understanding the Content Browser](#) on page 121.

2 Select a napkin sketch tool.

3 Select the objects to include in the napkin sketch, and press *ENTER*.

4 Enter a name for the block created of the napkin sketch.

5 Specify a line format for generating the napkin sketch geometry:

If you want to...

Then...

trace over objects once to create the appearance of a more accurate sketch

select Tight.

trace over objects twice to create a looser sketch

select Loose.

trace over objects three times to create a very loose sketch

select Messy.

6 Clear *Extend Sketch Lines At Corners* if you do not want the extended lines to appear on the napkin sketch.

Extending sketch lines at corners

7 Under *Intended Plot Scale*, select the scale at which you intend to plot the sketch, or select *Other* and enter a custom scale.

8 Click *OK*.

The napkin sketch geometry is generated and placed as a block reference over the drawing objects that you selected. Use the *Move* command to relocate the sketch block reference in the drawing, or cut and paste it into a new drawing.

Editing a Napkin Sketch

Use this procedure to edit the block reference generated when you create a napkin sketch. For more information about editing external references, see “*Edit Selected Objects in Referenced Drawings and Blocks*” in *AutoCAD Help*.

TIP The quickest way to locate and view an AutoCAD topic is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

1 Select the napkin sketch that you want to edit, right-click, and click Edit Block in-place.

The Reference Edit dialog box opens. For more information, see “Reference Edit Dialog Box” in AutoCAD Help.

2 Select the reference to edit, if necessary.

3 Specify how nested objects in the napkin sketch are selected:

If you want to...

Then...

make changes to the sketch lines or any component of the object from which the sketch was drawn

select Automatically select all nested objects.

work with specific nested objects within a napkin sketch, such as a hatch pattern

select Prompt to select nested objects.

4 Specify lock settings for the napkin sketch:

If you want to...

Then...

allow changes to be made to objects other than those selected as your working set

select the Settings tab, and clear Lock objects not in working set.

prevent changes from being made to objects other than those selected as your working set

select the Settings tab, and select Lock objects not in working set.

For information about the Settings tab, see “Reference Edit Dialog Box” in AutoCAD Help.

5 Click OK.

The block reference that represents the napkin sketch is highlighted in your drawing, and the Refedit toolbar opens.

6 Make changes to the block reference as you would to any drawing object.

7 Use the Refedit toolbar to save or discard changes made to the napkin sketch:

If you want to...

Then...

discard any of the changes you made to the napkin sketch

select  .

save edits made to the named napkin sketch

select  .

8 Click OK.

Designing with Architectural Objects

Walls

18

A wall is an AEC object that represents the real-world features of an interior or exterior wall. The wall object contains all the geometry needed to represent a wall in 2-dimensional (2D) and 3-dimensional (3D) views.

Overview of Walls

A wall is an AEC object that represents the real-world features of an interior or exterior wall. The wall object contains all the geometry needed to represent a wall in 2-dimensional (2D) and 3-dimensional (3D) views.

Understanding Wall Components and Wall Styles

A wall has one or more components, which are the materials used to construct the wall. Some components include brick, CMU, concrete, studs, air gaps, and insulation. The components of walls can also have modifiers, which change the shape of the component or its surface.

Wall styles control the appearance of wall objects. Using wall styles, you can specify components, endcaps, materials, and other characteristics to create new types of walls, such as concrete walls, masonry walls, and brick cavity walls. Catalogs provided with AutoCAD Architecture include sample wall styles for common wall types, such as concrete walls with footings or furring, CMU and brick cavity walls, and various stud partition walls.

Wall styles that use various components

You can also work with casework wall styles that include counters, base units, and upper units.

Casework wall style examples

Placing Walls

When you add a wall to a drawing, you select a wall tool and then specify the points that define each wall segment. A wall can have both straight and curved segments.

Straight and curved wall segments

Determining Wall Direction

Wall direction is significant for some modifications to walls. Sample wall styles provided with AutoCAD Architecture were created with the intent that you place perimeter walls in clockwise fashion. After placing a wall, you can determine the wall direction by selecting the wall. The wall direction grip indicates the wall direction. You can also reverse the direction of a wall.

Determining wall direction

Cleaning up Wall Intersections

You can specify that walls intersect and clean up only with certain other walls by assigning the walls to a cleanup group. Walls that belong to the same group clean up where they intersect. Walls that belong to different cleanup groups do not clean up where they intersect. You can also specify how walls in externally-referenced (xref) drawings clean up with walls in the host drawing.

Wall segments that do and do not clean up

wall segments clean up at intersection

wall segments do not clean up at intersection

Adding Doors, Windows, and Other Objects to Walls

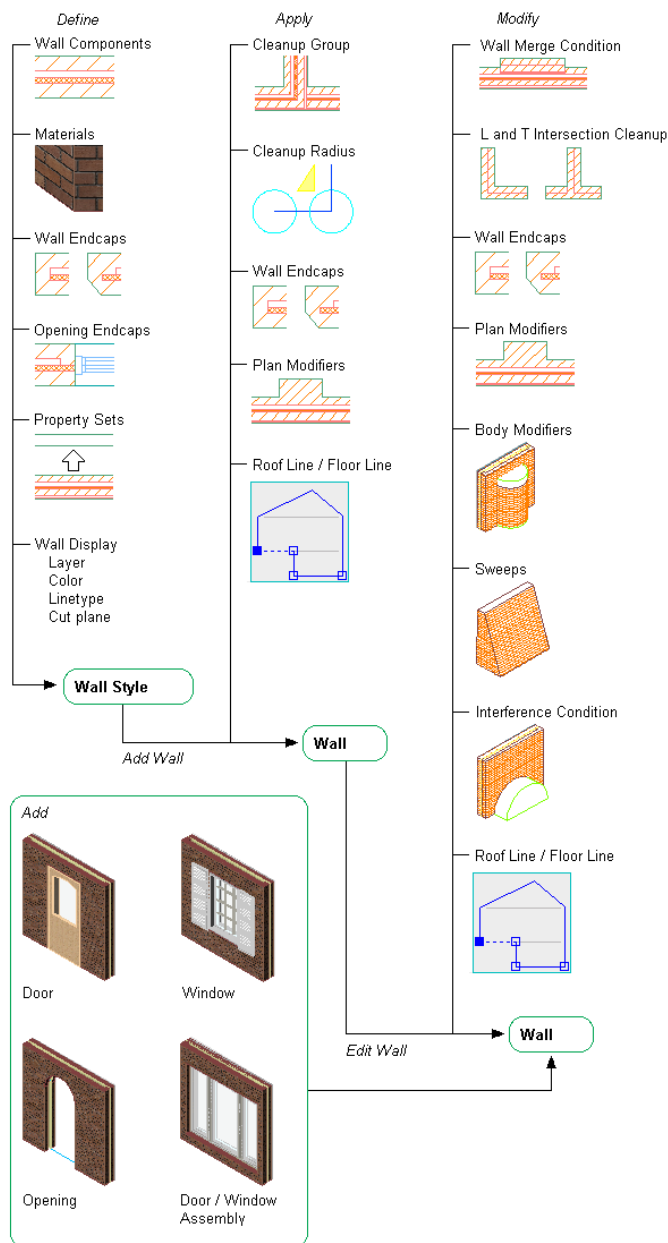

When you add doors, windows, door/window assemblies, and openings to a wall, the wall automatically adjusts to accommodate the object and adds endcaps where needed. By default, these objects are anchored to the wall and remain with the wall if you move it. If you remove an object from a wall, the wall repairs itself in the space where the object was located.

Wall segments with door, window, door/window assembly, and opening

Workflow Overview: Adding Walls to a Drawing

Walls are the basic components of any building plan. In AutoCAD Architecture, powerful modelling capabilities allow you to tailor your walls to a specific use. You can create very simple wall types that rely on standard settings, and add them on the fly. You can also create complex walls with different components, materials, and 2D and 3D endcaps assigned, have detailed cleanup information, and contain interferences with other objects like mass elements. Depending on your needs, creating a wall and its associated styles can consist of very few steps or a number of steps. Some of the components and actions you might use to create a wall in your plan are shown in the following illustration.

Wall Styles

Many characteristics of a wall are determined by the wall style used. You can create simple wall styles that have a more symbolic display, or you can create detailed walls styles with a representational display, containing many elements the real wall will have. These settings are defined in the wall style:

- **Property Set data:** If you want to tag a wall in a drawing, or include it in a schedule table, you need to attach property set data to the wall or the wall style. Property data attached to a wall style typically contains automatic properties, like the wall height or the wall width, or manual properties that are identical for all walls of that style, like for example the fire rating. For more information, see [Adding Property Set Data to a Wall Style](#) on page 876.
- **Wall Components:** In a wall style, you can define wall components.

Wall styles that use various components

For more information, see [Specifying the Components of a Wall Style](#) on page 876

- **Materials:** In a wall style, you can define materials for the 2D and 3D display of walls, as well as for the rendering display of the wall.

Wall with red brick hatch material

To use a material in a wall style, it needs to be defined first in Style Manager. For information about assigning a material to a wall style, see [Specifying the Materials of a Wall Style](#) on page 886.

For information about defining Materials, see [Creating and Editing Material Definitions](#) on page 624.

- **Modifying Wall Endcaps with In-Place Edit Grips:** You can use in-place edit grips to modify wall endcaps and create the wall endcap conditions that you want. Vertex and Edge grips are displayed for all wall components at the wall endcap that you specify. For more information, see [Displaying In-Place Edit Grips for Wall Endcaps](#) on page 895.
- **Creating Wall Endcaps Using Calculate Automatically:** You can use the Calculate Automatically feature with appropriate polyline linework to create wall endcaps. Calculate Automatically will add boundary segments to complete an endcap configuration if the initial polyline is drawn with regard to location and orientation of the particular wall component. For more information, see [Creating Wall Endcaps Using Calculate Automatically](#) on page 902.
- **Creating Wall Endcaps Using AEC Modify Tools:** You can use AEC Modify Tools to manipulate wall components to create appropriate wall endcap configurations. Use Trim, Extend, Subtract, and Merge tools as necessary to do this. You can modify single wall components or you can modify all components at your wall endcap or opening at once. In each case, you will be using the In-Place Edit feature as you modify the wall components to create your wall endcap condition. For more information, see [Modifying Wall Endcaps Using AEC Modify Tools](#) on page 906.
- **Specifying Wall Endcaps by Style:** In the wall style, you can define endcaps for the wall start and end. The standard endcap style is a straight line. If you need different endcaps, you need to create a wall endcap style, and then assign it to the wall style. For more information, see [Applying a Wall Endcap Style to a Wall Style](#) on page 918 and [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

NOTE You can override the wall endcap style on individual walls in the drawing.

- **Specifying Opening Endcaps by Style:** In the wall style, you define the endcaps for any doors, windows, and openings inserted in the wall. By default the opening endcaps are 4 straight lines for the jamb start and end, and the sill and head of the opening.

Opening endcaps around a window

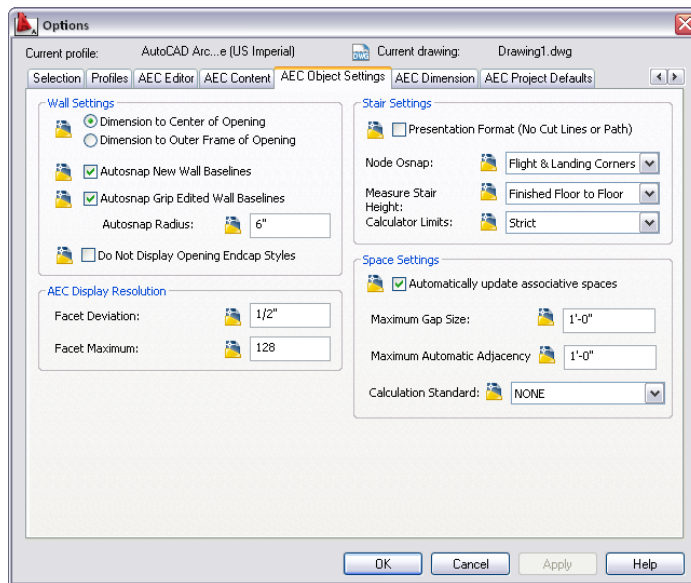

For more information, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

- **Specifying Wall Display:** the visual appearance of a wall is defined in the wall style. Here, you define the layer, color, linetype settings of the individual wall components, hatching, and the cut plane display of the wall in plan views. The display settings defined in the wall style can be overridden for an individual wall. For more information, see [Specifying the Display Properties of a Wall Style](#) on page 889

Specifying Drawing Defaults for Walls

Use this procedure to specify the default settings in the current drawing for dimensioning walls and for wall cleanup. The cleanup settings apply only to new walls that you add to the drawing and do not affect existing walls.

- 1 Click Format menu ► Options.
- 2 Click the AEC Object Settings tab.

- 3 Under Wall Settings, select an option for wall dimensions: Dimension to Center of Opening or Dimension to Outer Frame of Opening.
- 4 To force the endpoint of a new wall that is drawn within the Autosnap Radius of the baseline of an existing wall to snap to that baseline, select Autosnap New Wall Baselines.
- 5 To force the endpoint of a wall that you grip edit within the Autosnap Radius of the baseline of an existing wall to snap to that baseline, select Autosnap Grip Edited Wall Baselines.
- 6 Enter a value for Autosnap Radius.
- 7 Select Do Not Display Opening Endcap Styles if you want to suppress the display of endcaps applied to openings in walls.

Selecting this option speeds drawing performance when the drawing contains many complex endcaps.

8 Click OK.

Using Wall Tools To Create Walls

Tools provided with AutoCAD Architecture let you quickly place walls by selecting a wall tool with a specific wall style and other predefined properties. You can also use wall tools to convert linework to walls and to apply the settings of a wall tool to existing walls.

The default tool palettes in the workspace contain sample wall tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain wall tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog
- Design Tool catalog

Custom palettes created by your CAD manager or other users may also contain wall tools with wall styles and properties that are customized for your projects or office standards.

When you place walls using wall tools, you can use the default settings of the tool, or you can change settings for any wall properties that are not controlled by the style.

Creating a Wall

Use this procedure to add a new wall that has the properties specified in the wall tool that you select. To specify settings when you add a wall, see [Creating a Wall with User-Specified Settings](#) on page 781.

1 Open the tool palette that you want to use, and select a wall tool.

If necessary, scroll to display the tool that you want to use.

2 Specify the start point of the wall segment.

You can move or hide the Properties palette to expose more of the drawing area.

NOTE If you have Dynamic Input activated on the application window status bar (DYN), you can use dynamic dimensions to specify the wall length and angle. After clicking the start point of the wall, dynamic input fields for wall length and wall angle appear around the wall preview. Enter values as desired, and use the TAB key to switch between input fields.

3 Specify the endpoint of the wall segment.

4 Continue adding wall segments.

5 Specify the endpoint of the wall:

If you want to ...

Then ...

close the wall by drawing 2 wall segments that meet the start point at a right angle

enter **or** (Ortho Close), and then specify a point in the direction you want the wall to close. The wall segment is extended until it meets a wall segment perpendicular to the first wall segment.

If you want to ...	Then ...
close the wall by adding a wall segment from the previous point to the start point of the wall	enter c (Close).
complete the wall segment at a point that you specify	specify the endpoint of the wall, and press ENTER .

For more information about Ortho Close and Close, see [Using Ortho Close and Close with Walls](#) on page 923.

Changing the Orientation of a Wall Segment While Drawing It

Use this procedure to switch wall orientation while you are drawing a wall segment.

- 1 Open the tool palette that contains the tool you want to use, and select the tool.
You may have to scroll to display the desired tool.
- 2 Specify the wall segment start point.
- 3 Verify the current wall segment orientation.
- 4 Press **CTRL** to flip the wall segment orientation.
- 5 Specify the wall segment endpoint.

Switching the orientation of a wall segment

Changing the Justification of a Wall Segment While Drawing It

Use this procedure to switch wall justification while you are drawing wall segments. You can either enter **J** on the command line to initiate switching the justification, or you can press **CTRL** to cycle between the justification options.

- 1 Open the tool palette that contains the tool you want to use, and select the tool.
You may have to scroll to display the desired tool.
- 2 Specify the wall segment start point.
- 3 Verify the current wall segment justification.

4 On the command line, enter **J** for Justification, then do the following:

If you want to...	Then, on the command line...
Switch the wall justification to Left	...enter J , then enter L .
Switch the wall justification to Center	..enter J , then enter C
Switch the wall justification to Right	..enter J , then enter R
Switch the wall justification to Baseline	..enter J , then enter B

5 Specify the wall segment endpoint.

The following illustration shows how to switch the justification by entering **J** on the command line.

The following illustration shows how to switch the justification by pressing *CTRL* to cycle between the justification options.

Repositioning a Wall Segment While Drawing It

Use this procedure to reposition a wall segment while you are drawing it. You can offset a wall segment based on a wall component's face or center, or the overall center of the wall. When you specify the offset option and move your cursor over the wall segment, assistant lines with a tooltip display to indicate which part of the particular wall component is selected. A solid line indicates a component face, a dashed line indicates a component center, and a center line indicates the overall center of the wall.

You may want to reposition a wall segment as you are drawing it to align a particular wall component with a specific point or guideline. For example, you may wish to align the outside face of a wall's brick veneer with a column grid line or align the inside face of a wall's structural CMU with a column.

You can also pick any point inside or outside of the wall to specify as an offset point for repositioning the wall. You can enter a value in the dynamic dimension box, or on the Properties palette, under Dimensions, enter a value for Offset, and the wall will move the offset distance entered in the direction from your cursor location to the current justification line.

1 Open the tool palette that contains the tool you want to use, and select the tool.

You may have to scroll to display the desired tool.

2 Specify the wall segment start point.

NOTE You may need to switch the wall segment orientation or justification at this point to properly position it before specifying an offset distance.

3 On the command line, enter **O** for Offset, or right-click and click Offset.

As you move your cursor, assistant lines are displayed with tooltips.

Wall component assistant line examples and tooltips

solid assistant line

dashed assistant line

center assistant line

4 Click to select the wall component to offset from or specify a point outside the wall segment.

The justification line shifts to accommodate the specified offset distance.

5 Specify the wall segment endpoint.

Repositioning a wall segment by specifying a wall component to align with a grid line

specify wall segment start point

specify wall component to offset from

specify wall segment endpoint

Once you have repositioned the wall segment, the Offset value on the Properties palette will be refreshed with the offset distance that you specified. After you specify the wall segment endpoint, this value returns to 0 (zero).

Creating a Wall with User-Specified Settings

Use this procedure to create a wall with straight segments, curved segments, or both with settings that you specify.

Straight segments have a start point and an endpoint. For more information about straight wall segments, see [About Wall Lengths](#) on page 923.

Drawing a straight wall segment

specify wall segment start point

specify wall segment endpoint

result

Curved segments have a start point, a midpoint, and an endpoint. For more information about curved wall segments, see [About Curved Walls](#) on page 923.

Drawing a curved wall segment

specify wall segment start point

specify wall segment midpoint

specify wall segment endpoint

result

- 1 Open the tool palette that contains the tool you want to use, and select the tool.
You may have to scroll to display the desired tool.
- 2 Specify the wall segment start point.
- 3 On the Properties palette, expand Basic, and expand General.
- 4 Select a style.
- 5 Under Bound Spaces, define if this wall can be used as a bounding object for associative spaces.
You can select 3 options here:
 - Yes: this wall can be used as bounding object for associative spaces.
 - No: this wall cannot be used as bounding object for associative spaces.
 - By style: this wall will use the bounding settings from the wall style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

6 Select Yes for Cleanup Automatically if you want the wall to clean up with other walls, and select a cleanup group.

7 Expand Dimensions.

8 Specify wall dimensions:

If you want to ...	Then ...
specify the thickness of the wall	enter a value for Width. If Width is not available, the wall style you selected determines the width of the wall.
specify the height of the wall from the floor to the ceiling	enter a value for Base height.
specify the length of the wall from the start and end-points	enter a value for Length.

9 Specify the wall justification, which places the wall in relation to the points you specify and the direction in which you draw the wall:

If you want to ...	Then ...
specify points that define the left side of the wall	select Left for Justify.
specify points that define the right side of the wall	select Right for Justify.
specify points that define the center line of the wall	select Center for Justify.
select points that define the baseline of the wall	select Baseline for Justify.

10 Specify offsets:

If you want to ...	Then ...
offset the location of the wall from the points you specify	enter a value for Baseline offset.
offset the roof line from the specified base height	enter a value for Roof line offset from base height.
offset the floor line from the baseline	enter a value for Floor line offset from baseline.

11 Draw a wall segment:

If you want to ...	Then ...
draw a straight segment	select Line. In the drawing area, specify the start point and the endpoint of the straight segment.

If you want to ...	Then ...
draw a curved segment	select Arc. In the drawing area, specify the start point, the midpoint, and the endpoint of the curved segment.

You can move or hide the Properties palette to expose more of the drawing area.

NOTE If you have Dynamic Input activated on the application window status bar (DYN), you can use dynamic dimensions to specify the wall length and angle. After clicking the start point of the wall, dynamic input fields for wall length and wall angle appear around the wall preview. Enter values as desired, and use the TAB key to switch between input fields.

12 Continue adding wall segments.

You can enter **u** (Undo) to undo any point except the start point.

13 Specify the endpoint of the wall:

If you want to ...	Then ...
close the wall by drawing 2 wall segments that meet the start point at a right angle	enter or (Ortho Close), and then specify a point in the direction you want the wall to close. The wall segment is extended until it meets a wall segment perpendicular to the first wall segment.
close the wall by adding a wall segment from the previous point to the start point of the wall	enter c (Close).
complete the wall segment at a point that you specify	specify the endpoint of the wall, and press <i>ENTER</i> .

For more information about Ortho Close and Close, see [Using Ortho Close and Close with Walls](#) on page 923.

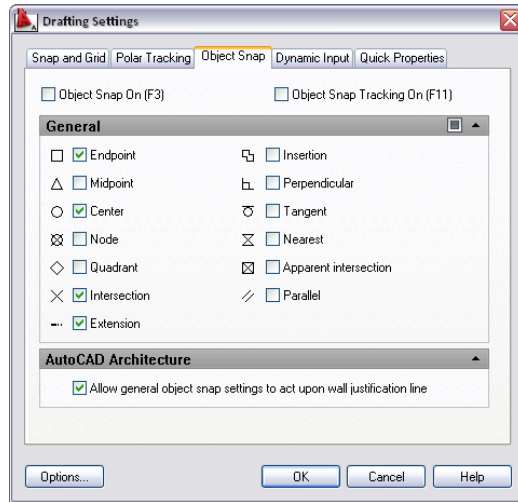

Drawing a Wall Segment Using Justification Line Object Snaps

Use this procedure to draw a new wall segment using any of the Object Snap modes on an existing wall segment justification line. Start by specifying which Osnaps you want to be active. For example, you may want to start a new wall segment from the midpoint of an existing wall segment.

Once you start to add the new wall segment, the justification line is automatically displayed on the existing wall segment, whether or not its display was turned on. If you move your cursor off of the existing wall segment, the justification line will disappear. Selecting a point near the middle of the wall segment will display the Midpoint Osnap on the justification line. Click to specify this point as the new wall segment start point, and then specify the wall segment endpoint.

- 1 Click Format menu ► Drafting Settings, and then click the Object Snap tab.
- 2 Under General, select the object snap modes that you want to be active.

3 Under AutoCAD Architecture, select Allow general object snap settings to act upon wall justification line.

4 Click OK.

5 Open the tool palette that contains the tool you want to use, and select the tool.

You may have to scroll to display the desired tool.

6 On the existing wall segment, click the object snap on the justification line from which you want to start the new wall segment.

7 Specify the new wall segment endpoint.

The following illustration show starting a new wall segment from the midpoint of the justification line of an existing wall segment.

Drawing a new wall segment from an existing wall segment using a justification line object snap

existing wall segment

specify wall segment start point

specify wall segment endpoint

result

Creating a Wall from Linework

Use this procedure to convert any of the following objects to walls:

- Lines
- Arcs
- Circles
- Polylines

For example, you can create line diagrams or sketches of walls using lines, arcs, circles, and polylines to create the building exterior and rooms, and convert these objects to walls. You can edit the wall properties after creating the wall.

You can convert a lines to wall segments as shown in the following illustration.

Creating wall segments from lines

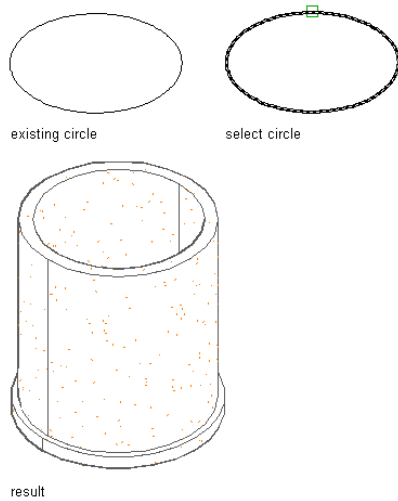

You can convert an arc to a wall segment as shown in the following illustration.

Creating a wall segment from an arc

You can convert a circle to wall segments as shown in the following illustration.

Creating wall segments from a circle

You can convert a polyline to wall segments as shown in the following illustration.

Creating a wall segments from a polyline

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a wall tool, and click Apply Tool Properties to ► Linework.
- 3 Select the linework to convert, and press *ENTER*.
- 4 When prompted to erase the original geometry, press *ENTER* to retain the linework, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the new walls in the Properties palette, if necessary.

Creating a Wall from a 3D Object

Use this procedure to convert a 3-dimensional (3D) object, such as a mass element or an AutoCAD ACIS solid, into a single-component wall.

Converting a mass element to a wall

- 1 Select the object you want to convert to a wall, right-click, and click Convert To ► Wall.
- 2 Enter **y** (Yes) to erase the original object, or enter **n** (No) to retain the object.
- 3 Specify the baseline of the wall:

If you want to ...	Then ...
specify the baseline of the wall by specifying the start point and the endpoint of the wall	specify the start point, and then specify the endpoint when prompted.
specify the baseline of the wall from an existing line or arc in the drawing	enter p (Pick), and select the line or the arc you want to define for the baseline.

NOTE Specifying a baseline away from the object you are converting to a wall affects the insertion of anchored objects, such as doors, windows, and openings. Anchored objects are inserted in a wall relative to the baseline of the wall.

- 4 Select a wall style.
The wall style you select must be a single-component style.
- 5 Click OK.

Creating a Wall Tool

Use this procedure to create a wall tool and add it to a tool palette. You may want to create your own tools if you are placing multiple walls of specific styles that have the same properties.

For example, you are creating an office floor plan with partition walls for cubicles. Although all partition walls use the same wall style in your floor plan, the walls in administrative areas are lower than the walls

in office areas. To work efficiently, you can create a wall tool for each wall height, and select the appropriate tool to place the walls with the correct height in each area of the floor plan.

You can use any of the following methods to create a slab/roof slab tool:

- Drag a wall that has the properties you want to a tool palette.
- Drag a wall style from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Copy an existing wall tool, and then customize the properties of the new tool.
- Drag a wall tool from a tool catalog in the Content Browser, and then customize the properties of the tool.

1 Open the tool palette on which you want to create a tool.

2 Create the tool:

If you want to ...	Then ...
create a tool from a wall in the drawing	select the wall, and drag it to the tool palette. TIP Drag the wall by a point on its perimeter, not by one of its grips.
create a tool from a wall style in the Style Manager	click Format menu ► Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current tool palette	right-click the tool, click Copy, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the tool catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tool's tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Enter a description of the tool.

8 If you do not want to use the default layer key, select a layer key.

9 If you want to override the default layer names, select a layer override.

10 Select a wall style.

11 For Style location, select the drawing file containing the style to be used for this tool, or select Browse and use a standard file selection dialog box to select the file.

12 Under Bound spaces, define if this wall tool can be used as a bounding object for associative spaces.

You can select 3 options here:

- Yes: this wall tool can be used as bounding object for associative spaces.
- No: this wall tool cannot be used as bounding object for associative spaces.
- By style: this wall tool will use the bounding settings from the wall style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

13 Select Yes for Cleanup automatically if you want the wall to clean up with other walls, and select a cleanup group.

14 For Definition location, select Browse, and use a standard file selection dialog box to select the Cleanup group definition to be used for this tool.

15 Expand Dimensions.

16 Specify wall dimensions:

If you want to ...	Then ...
specify the thickness of the wall	enter a value for Width. If Width is not available, the wall style you selected determines the width of the wall.
specify the height of the wall from the floor to the ceiling	enter a value for Base height.

17 Specify the wall justification, which places the wall in relation to the points you specify and the direction in which you draw the wall:

If you want to ...	Then ...
specify points that define the left side of the wall	select Left for Justify.
specify points that define the right side of the wall	select Right for Justify.
specify points that define the center line of the wall	select Center for Justify.
specify points that define the baseline of the wall	select Baseline for Justify.

18 Specify offsets:

If you want to ...	Then ...
offset the location of the wall from the points you specify	enter a value for Baseline offset.
offset the roof line from the specified base height	enter a value for Roof line offset from base height.
offset the floor line from the baseline	enter a value for Floor line offset from baseline.

19 Expand Advanced.

20 Expand Cleanups, and specify cleanup options:

If you want to ...	Then ...
specify the line that the Diagnostic display representation uses for the wall justification line	select Wall Justification Line, or select Wall Center Line.
specify a radial distance from the endpoint of a wall in which other walls will be connected	enter a value for Cleanup radius.

21 Click OK.

Editing Walls

After placing walls, you can change its style, location, size, shape, basic geometry, and override the component priorities and the endcap styles of the wall. You can also move a wall, merge or join walls, reverse the direction of a wall and change the shape of the roof line and the floor line of a wall. In addition, you can modify walls using other objects as interference conditions or body modifiers.

Depending on the type of editing you want to perform, various methods may be available:

- After selecting a wall, you can click any non-grip point along the perimeter and drag the entire object to a new location. You can also move the object by clicking a grip, pressing the Space bar, and then moving the object to the new location and clicking again.
- You can drag the grips that are displayed on a selected wall to reorient it, resize it, or change other physical characteristics.
- For grip edits where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. (This feature is activated by default; you can toggle it on and off by clicking DYN on the application status bar. For more information, see [Dynamic Dimensions](#) on page 101.)
- You can apply the properties of a wall tool to an existing wall or the properties of a curtain wall tool, slab tool, or roof slab tool to an existing wall.
- You can change settings on the Properties palette.
- You can use editing commands from the object's context menu.

Using Grips to Edit Walls

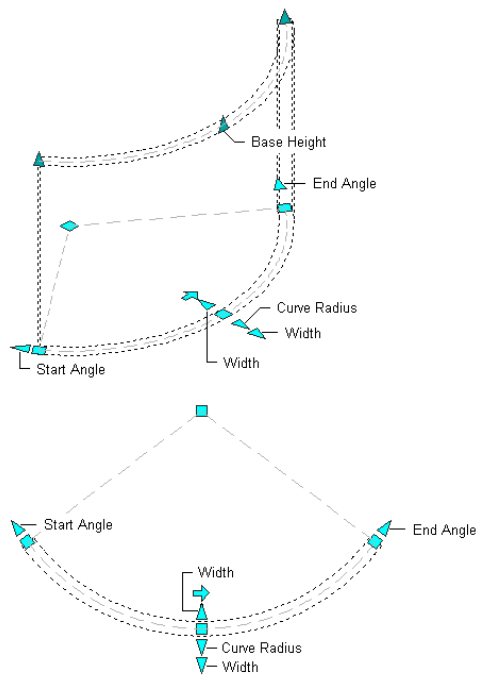

Various types of editing grips are displayed for a selected wall object. You can drag these grips as needed to reposition or resize the object, or you can enter precise distance or angle values using the Dynamic Input feature. When you select a grip that has multiple functions, you can cycle among them by pressing *CTRL*. For more information, see [Dynamic Dimensions](#) on page 101.

The types of editing grips available for a selected wall depend on the view direction and the wall style. Lengthen, Start, Location, Reverse Direction, Width, and End grips are displayed in both plan and three-dimensional (3D) isometric views. Base Height grips are available only in 3D isometric views. Curve 2nd Point, Width, and Curve Radius grips are displayed in both two-dimensional (2D) and 3D views for curved walls. Wall styles that have a fixed width do not display Width grips, while wall styles that have a variable width do.

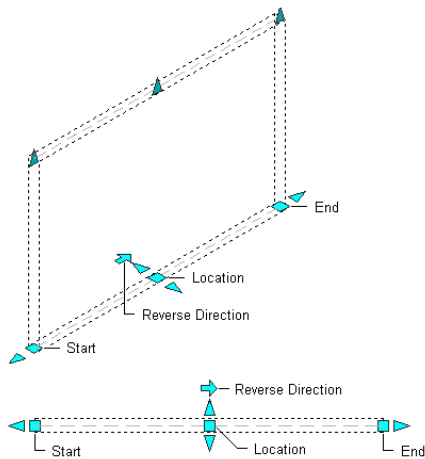

The following illustration shows the Lengthen, Width, and Base Height grips that appear for a straight wall segment in 3D and 2D views.

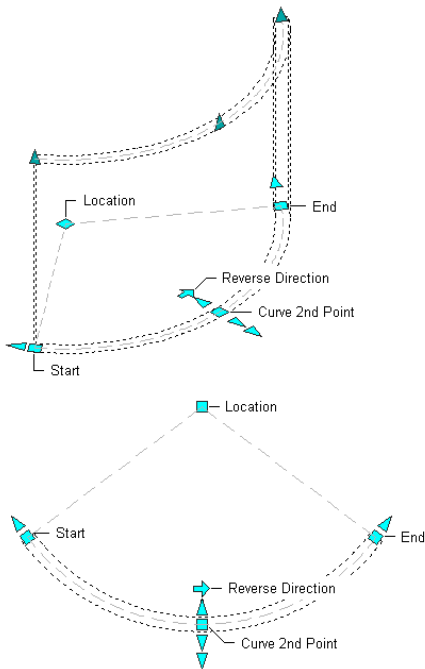

The following illustration shows the Start Angle, End Angle, Width, Curve Radius, and Base Height grips that appear for a curved wall segment in 3D and 2D views.

The following illustration shows the Start, End, Reverse Direction, and Location grips that appear for a straight wall segment in 3D and 2D views.

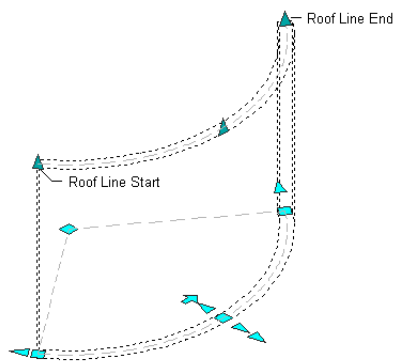

The following illustration shows the Start, End, Reverse Direction, Curve 2nd Point, and Location grips that appear for a curved wall segment in 3D and 2D views.

The following illustration shows the Roof Start Line and Roof End Line grips that appear for a straight wall segment in 3D and 2D views.

The following illustration shows the Roof Start Line and Roof End Line grips that appear for a curved wall segment in 3D and 2D views.

Changing the Location of a Wall

Use this procedure to relocate a wall by using the Location grip. There are 2 cases to consider when working with the location grip: parallel wall segments and non-parallel wall segments.

parallel walls

non-parallel walls

When you are working with connected walls that are parallel, the Location grip has 2 edit modes: Stretch (Parallel) and Move. The default mode is Stretch (Parallel), and the direction of the stretch depends on the orientation of walls connected to the selected wall. For example, if the walls at both ends of the selected wall are parallel to each other, with the Stretch (Parallel) mode, the move direction is limited to the direction of the parallel walls.

When you are working with a stand-alone wall segment or connected walls that are not parallel, the Location grip has 2 edit modes: Stretch (Offset) and Move. In this case, the default mode is Stretch (Offset) and the stretch direction is perpendicular to the direction of the selected wall.

In both cases, the Move location mode allows an unconstrained move of the selected wall without maintaining adjacent wall connections. You can also move a wall by changing its coordinates on the Properties palette.

The following illustration shows how to use the Location grip in Stretch (Parallel) mode to move a connected parallel wall segment and maintain adjacent wall connections.

The following illustration shows how to use the Location grip in Move mode to move a parallel wall segment without maintaining adjacent wall connections.

- 1 Select the wall you want to relocate.
- 2 Select the Location grip.
The Stretch (Parallel) location mode is the default, or you can press *CTRL* to toggle to the Move location mode.
- 3 Move the wall to the desired location and click once, or enter a distance value and press *ENTER*.
When you use the Stretch (Parallel) location mode, wall connections are maintained if the connecting walls use a zero cleanup circle radius. The connected walls are trimmed, extended, and reversed as necessary to maintain connections and the cleanup circle radius. Using the Move location mode results in disconnected walls.
- 4 Press *ESC*, or right-click, and click Deselect All to deselect the wall and turn off all grips.

Changing the Shape of a Wall

Use this procedure to change a straight wall to a curved wall, or to change a curved wall to a straight wall. When you change a straight wall to a curved wall, the software adds a Curve 2nd Point grip at the midpoint of the of the wall segment. You can then use the grip to change the shape of the arc. For more information about curved walls, see [About Curved Walls](#) on page 923.

When you change a curved wall to a straight wall, the software creates a straight segment between the start and endpoints of the curve. You can use grips to adjust the length and location of the wall.

- 1 Select the walls you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand General.

3 Select Arc or Line for Segment type.

4 Select the Curve 2nd Point grip, and move it to adjust the radius for a curved wall.

Changing the shape of a wall segment from straight to arc

Changing the Wall Width while Maintaining the Wall Baseline

Use this procedure to change the thickness of a wall while maintaining the wall baseline. You can also change the wall width on the Properties palette. If the wall width is defined in the wall style applied to the wall, you cannot change the thickness of an individual wall.

For more information about wall grips, see [Using Grips to Edit Walls](#) on page 791.

1 Select the wall.

2 Select a Width grip, move the grip until the width value you want is displayed, and click once.

After selecting a grip, you can also enter a precise value to increase or decrease the width of the wall. For more information, see [Dynamic Dimensions](#) on page 101.

Changing wall width while maintaining wall baseline

Changing the Wall Width while Maintaining the Opposite Face of the Wall

Use this procedure to change the thickness of a wall while maintaining the position of the opposite face of the wall. You can also change the wall width on the Properties palette. If the wall width is defined in the wall style applied to the wall, you cannot change the thickness of an individual wall.

For more information about wall grips, see [Using Grips to Edit Walls](#) on page 791.

- 1 Select the wall.
- 2 Select a Width grip and press *CTRL* to maintain the position of the opposite face of the wall when you change the wall width.
- 3 Move the grip until the width value you want is displayed, and click once.

After selecting a grip, you can also enter a precise value to increase or decrease the width of the wall. For more information, see [Dynamic Dimensions](#) on page 101.

Changing wall width while maintaining wall opposite face

Changing the Wall Base Height

Use this procedure to change the base height of one or more walls. The base height is the height of the wall from floor to ceiling. You can also change the base height on the Properties palette.

For more information about wall grips, see [Using Grips to Edit Walls](#) on page 791.

- 1 Select the wall.
- 2 Select the Base Height grip, move the grip until the height value you want is displayed, and click once.

After selecting the grip, you can also enter a precise value to increase or decrease the base height of the wall. For more information, see [Dynamic Dimensions](#) on page 101.

Using grips to change the base height of a wall segment

Changing the Wall Length

Use this procedure to change the length of one or more walls. You can also change the length on the Properties palette.

For more information about wall grips, see [Using Grips to Edit Walls](#) on page 791.

1 Select the wall.

2 Select a Lengthen grip, move the grip until the length value you want is displayed, and click once.

After selecting the grip, you can also enter a precise value to increase or decrease the length of the wall. For more information, see [Dynamic Dimensions](#) on page 101.

Using grips the change the length of a wall segment

Changing the Wall Justification

Use this procedure to change the justification of a wall. You can also change the justification on the Properties palette.

Justification determines the location of the wall in relation to the direction in which the wall was drawn and the points used to draw the wall. Changing the justification of an existing wall moves the wall and can affect how the wall cleans up with other walls.

For more information about wall grips, see [Using Grips to Edit Walls](#) on page 791.

1 Select the wall, right-click, and click Edit Justification.

Six grips appear, with four indicating the justification options: Left Right, Center, and Baseline. The gray grip identifies the current justification. Start and End grips for the wall segment are also displayed.

2 Select the grip that corresponds to the justification you want.

In the following illustration, the Baseline justification is current, as indicated by the gray grip.

Wall justification grips

Offsetting New Walls from Existing Walls

Use this procedure to add copies of an existing wall that are offset from a component of the wall at a distance that you specify.

This offset command allows you to copy walls by offsetting them a clear distance from the face or center of a specific wall component, such as the stud or the wall finish.

1 Select the wall you want to copy or move, right-click, and click **Offset** ► **Copy**.

2 Specify the location of the offset point:

If you want to ...	Then ...
offset the wall from the face of a wall component	move the cursor over the wall until the face of the component you want is highlighted with a red line, and click once.
offset the wall from the center of a wall component	press <i>CTRL</i> , and move the cursor over the wall until the center of the component you want is highlighted. Click once.

3 Specify the offset distance.

4 Continue adding walls, each new wall offset from the face or center of the wall you added before it.

You can specify a different offset distance each time you add another wall.

Offset copying a wall segment from an existing wall segment component

5 Press *ENTER*.

Repositioning a Wall

Use this procedure to move a wall by offsetting the wall from the center or face of a wall component to a point or distance that you specify.

1 Select the wall you want to move, right-click, and click **Offset ► Move**.

2 Specify the location of the offset point:

If you want to ...

Then ...

offset the wall from the face of a wall component

move the cursor over the wall until the face of the component you want is highlighted with a red line, and click once.

offset the wall from the center of a wall component

press *CTRL*, and move the cursor over the wall until the center of the component you want is highlighted. Click once.

3 Specify the distance from the component face or center to its new position.

Offset moving a wall segment from its existing wall segment component

Adjusting the Position of Wall

Use this procedure to adjust the position of a wall by aligning or offsetting the center or face of a wall component from a reference point that you specify. For example, you can adjust the placement of a stud partition wall by defining the distance from stud to stud on center.

1 Select the wall you want to move, right-click, and click Offset ► Set From.

2 Specify the location of the offset point:

If you want to ...

Then ...

offset the wall from the face of a wall component

move the cursor over the wall until the face of the component you want is highlighted with a red line, and click once.

offset the wall from the center of a wall component

press *CTRL*, and move the cursor over the wall until the center of the component you want is highlighted. Click once.

3 Specify the reference point to which you want to measure.

For example, if you want to move a wall so that its exterior face is aligned with the exterior face of another wall, specify a point on the face of the other wall.

4 Specify the new distance from the wall component face or center to the reference point.

Enter **0** (zero) to align the selected wall with the reference point.

Applying Tool Properties to an Existing Wall

Use this procedure to modify one or more walls by applying the properties of a wall tool. The properties include the wall style and any other settings specified in the tool you select.

- 1 Open the tool palette that contains the wall tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click the tool, and click Apply Tool Properties to ► Wall.
- 3 Select the walls to be modified, and press *ENTER*.
- 4 Edit the properties of the modified walls in the Properties palette, if necessary.

Applying a different wall tool and new property to an existing wall segment

Changing the Style of a Wall

Use this procedure to select a different wall style for one or more walls.

- 1 Select the walls to change, and double-click one of them.
- 2 Expand Basic, and expand General.
- 3 Select a different style.

Changing the style of a wall segment

Changing the Location of a Wall

Use this procedure to relocate a wall by changing the coordinate values of its insertion point. The wall also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the wall are parallel to the XY plane, its normal is parallel to the Z axis. You can change the orientation of the wall by aligning its normal with another axis. You can also rotate the wall on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Double-click the wall you want to change.
- 2 In the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the wall:

If you want to ...	Then ...
relocate the wall	enter new coordinate values under Insertion Point.
locate the wall on the XY plane	make the normal of the wall parallel to the Z axis: under Normal, enter 1 for Z, and enter 0 for X and Y.
locate the wall on the YZ plane	make the normal of the wall parallel to the X axis: under Normal, enter 1 for X and enter 0 for Y and Z.
locate the wall on the XZ plane	make the normal of the wall parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.
change the rotation of the wall	enter a new value for Rotation Angle.

- 5 Click OK.

Merging Walls

Use this procedure to merge the profile of selected walls. This does not provide automatic wall cleanup, but merging walls is useful in tight situations that involve short wall segments.

Merging wall segments

existing wall segments

select wall segment

select wall segment to merge

result

- 1 Select a wall to merge, right-click, and click Cleanups ► Add Wall Merge Condition.
- 2 Select other walls to merge with the first wall, and press *ENTER*.

TIP To identify merged walls, turn on the Graph display representation. Select a wall, right-click, and click Cleanups ► Toggle Wall Graph Display. Select the wall to which you added merge conditions. An arc connects the original wall to each wall it is merged with.

Removing Individual Merge Conditions

Use this procedure to selectively remove merge conditions from a wall.

- 1 Select a wall, right-click, and click Cleanups ► Toggle Wall Justification Display.
- 2 Select the wall that was selected first when the walls were merged.
An arc connects the wall to each wall merged with it.
- 3 Select the Remove Wall Merge Condition grip for the wall you want to remove from the original wall.
The arc and grip are removed to indicate that a merge condition with the wall no longer exists.

Removing All Merged Walls

Use this procedure to remove all merged wall conditions from a group of merged walls.

-
- **TIP** To identify merged walls, turn on the Diagnostic display representation. Select a wall, right-click, and click Cleanups ► Toggle Wall Justification Display. Select the wall to which you added merge conditions. An arc connects the original wall to each wall it is merged with.
-

Select the wall that was selected first when the walls were merged, right-click, and click Cleanups ► Remove All Wall Merge Conditions.

If a message at the command line indicates that no merge conditions were removed, the wall you selected was not the first wall when the merge condition was created. You can press *ENTER* to repeat the command, and then select a different wall.

Joining Walls

Use this procedure to combine the baselines of 2 walls to create one wall segment. Walls that you join must meet the following requirements:

- Linear walls must have colinear baselines and be touching at one endpoint.
- Arc walls must have the same center, radius, and be touching at one end.
- Walls must have the same style and width.
- Walls must belong the same cleanup group.

Joining walls also transfers all sub-objects and anchored objects from one wall to the other. Sub-objects include roofline, floorline, anchors, wall modifiers, wall style overrides, and interference conditions. Anchored objects include doors, windows, and openings anchored to the walls.

NOTE Certain colinear wall segments may appear to be already joined. However, if they were drawn as 2 segments, they are actually separate segments and can be highlighted as separate segments.

The following illustration shows joining 2 straight wall segments after first highlighting each separate segment.

Joining 2 straight wall segments

The following illustration shows joining 2 curved wall segments after first highlighting each separate segment.

Joining 2 curved wall segments

- 1 Select the first wall, right-click, and click Join.
- 2 Select the second wall.

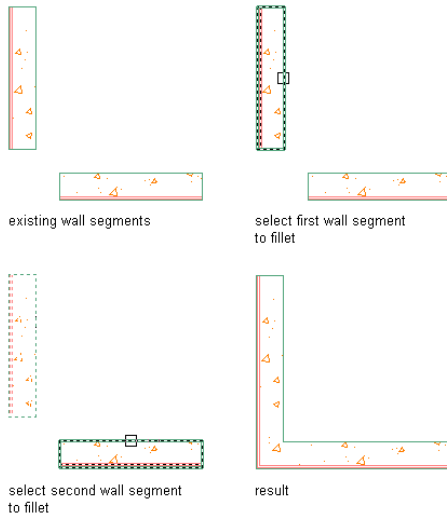

Filleting Walls

Use this procedure to fillet 2 walls. Filleting walls creates a curved wall segment with a specified radius that is tangent to the baselines of the selected walls.

If you specify zero for the fillet radius, the walls are trimmed or extended until they intersect, but no curved wall segment is created. Using a radius of zero allows you to force odd-angled walls to meet. If you select parallel wall segments, the fillet radius is ignored, and a curved wall segment is created that is tangent to the baselines of the selected walls.

The following illustration shows how to fillet two wall segments with a zero radius.

Filleting wall segments with a zero radius

The following illustration shows how to fillet two wall segments with a specified radius.

Filleting wall segments with a specified radius

Trim mode options allow you to specify whether the walls are trimmed or extended to the new segment (trim option) or whether their endpoints remain unchanged (no trim option). If you select no trim, the fillet radius must be greater than zero.

Before filleting walls, ensure that the following conditions exist:

- The walls have the same style and baseline justification.
- The fillet radius is not a negative value.

Solution tip icons may display when you fillet the walls if these conditions are not met.

1 Open a tool palette that contains the Fillet tool.

The Fillet tool is located with the Basic Drafting Tools in the Stock Tool Catalog. You can add this tool to any tool palette, and then use the tool to fillet walls and other objects.

2 Select the Fillet tool.

3 Verify trim mode and radius settings:

If you want to ...	Then ...
trim or extend wall segments to meet each other or to meet the endpoints of the resulting curved wall segment	enter t (Trim), and then enter t (Trim).
keep the endpoints of the wall segments in their original locations and fit the curved wall segment between them	enter t (Trim), and then enter n (No trim).
specify a new fillet radius	enter r (Radius), and then enter a value for the radius. Enter 0 for the radius if you want the wall segments to meet each other without creating a curved wall segment.
fillet multiple walls	enter u (Multiple).

4 Select the first wall.

5 Select the second wall.

Chamfering Walls

Use this procedure to chamfer 2 walls. Chamfering walls creates a new wall segment between 2 walls that are not parallel. Chamfering is useful when you are working with unique wall angles or architectural details.

You can chamfer walls by specifying distance or angle:

- Using the distance option, you specify the length that each wall should be trimmed or extended until it meets the new wall segment or the other wall. If both chamfer distances are zero, the walls are extended until they intersect, but a new wall segment is not created.

Chamfering wall segments using the distance option

- Using the angle option, you specify the length of the chamfer and the angle it forms with the first wall.

Trim mode options allow you to specify whether the walls are trimmed or extended to the new wall segment (trim option) or whether their endpoints remain unchanged (no trim option). If you select no trim, chamfer distances must be greater than zero.

Before chamfering walls, ensure that the walls have the same style and baseline justification. Solution tip icons may display when you chamfer the walls if these settings are not the same for each wall.

- 1 Open a tool palette that contains the Chamfer tool.

The Chamfer tool is located with the Basic Drafting Tools in the Stock Tool Catalog. You can add this tool to any tool palette, and then use the tool to chamfer walls and other objects.

- 2 Select the Chamfer tool.

- 3 Specify default settings for chamfering walls:

If you want to ...

Then ...

trim or extend wall segments to meet each other or to meet the endpoints of the new wall segment

enter **t** (Trim), and then enter **t** (Trim).

keep the endpoints of the wall segments in their original locations and fit the new wall segment between them

enter **t** (Trim), and then enter **n** (No trim).

specify the default length and angle values for the angle option

enter **a** (Angle). Enter the distance from the endpoint to the point on the wall where you want the chamfer to begin. Enter the angle of the chamfer.

specify the default distances for the distance option

enter **d** (Distance). Enter values for Distance 1 and Distance 2. Enter 0 for both distances if you want the walls to meet without creating a new wall segment.

specify the distance option as the default option for chamfering walls

enter **m** (Method), and then enter **d** (Distance).

If you want to ...	Then ...
specify the angle option as the default option for chamfering walls	enter m (Method), and then enter a (Angle).
chamfer multiple walls	enter u (Multiple).

- 4 Select the first wall.
- 5 Select the second wall.

Trimming Walls at L and T Intersections

Use this procedure to trim or extend walls so that they meet and clean up at L-shaped or T-shaped intersections. If walls do not belong to the same cleanup group, they are trimmed but do not clean up with each other.

When you create an L-shaped intersection, the wall endpoints that are closest to each other extend or trim so that their wall justification lines meet exactly.

Creating an L-shaped wall intersection

When you create a T-shaped intersection, the walls you select are extended or trimmed to a boundary wall that you specify.

Creating a T-shaped wall intersection

1 Select the cleanup method you want to use:

If you want to ...	Then ...
create an L-shaped intersection between 2 walls	select the walls, right-click, and click Cleanups ► Apply L Cleanup.
create a T-shaped intersection between 2 walls	select the walls to be extended or trimmed to a boundary wall, right-click, and click Cleanups ► Apply T Cleanup. Select the boundary wall.

Reversing the Direction of a Wall

Use this procedure to change the direction in which a wall is drawn by reversing the start point and the endpoint of the wall. Walls are drawn from the first specified point to the last point. Some commands and properties are affected by that order. For example, you can add wall modifiers to the left or right side of a wall. Left and right sides are west and east, respectively, when a wall is drawn from south to north, regardless of how the wall is displayed in the current view.

There are 2 different ways to reverse the wall direction. When you reverse a wall in-place, the wall position in the drawing does not change; only the wall direction changes, and the wall baseline is switched in the drawing but not in relation to the wall components. This method of reversing walls is common when you create walls from scratch and do not want to change their physical position in the drawing.

When you reverse the wall baseline, the wall position in the drawing changes, but the baseline position in the drawing remains the same. You would use this method when creating walls from polylines or spaces; in this case the baseline position can be important geometry that you do not want to change.

To determine the direction in which a wall was drawn, select the wall. The Reverse Direction grip shows the orientation of the wall. For more information about wall grips, see [Using Grips to Edit Walls](#) on page 791.

To reverse the wall direction in place:

1 Select the wall, right-click, and click Reverse ► In Place.

The outside faces of the wall remain in place, and the baseline shifts, if necessary.

Reversing a wall segment in place

To reverse the wall baseline:

- 1 Select the wall, right-click, and click Reverse ► Baseline.

The position of the baseline in the drawing remains in place, and the wall shifts, if necessary.

Reversing a wall segment about its baseline

Using AutoCAD Commands to Edit Walls

You can use the following standard AutoCAD commands to edit walls:

- BREAK
- EXTEND
- TRIM

For more information about these commands, see AutoCAD Help.

Changing the Roof Line and the Floor Line of a Wall

You can modify the roof and floor lines of a wall to create a non-rectangular wall.

- You edit vertex locations on the roof line to create steps, gables, and other roof conditions.

Modifying the roof line of a wall

- You edit vertex locations on the floor lines to create steps and other floor conditions.

Modifying the floor line of a wall

You can also create non-rectangular roof and floor conditions by projecting to polylines.

AutoCAD Architecture offers multiple methods of editing roof lines and floor lines. You may want to begin by graphically creating a custom roof line or floor line condition. You can then fine-tune that condition by specifying precise values in the Roof/Floor Line worksheet on the Properties palette.

Offsetting or Projecting the Roof Line of a Wall

Use this procedure to change the height or the shape of the roof line of a wall:

- Offset the roof line from the current height of the wall.
- Project the roof line of the wall to a polyline.
- Project the roof line of the wall to another object, such as a roof or stairs.

You can also create a polyline that represents the current roof line of the selected walls. You can then use this polyline to change the roof line of other walls.

NOTE To project the roof line to a polyline, draw the polyline first in elevation view. For best results, the polyline should be parallel to the wall. The polyline does not need to be in the same plane as the wall.

1 Select a wall, right-click, and click Roof/Floor Line ► Modify Roof Line.

2 Change the roof line of the wall:

If you want to ...

Then ...

offset the roof line from the current height of the wall

enter **o** (Offset), and enter an offset distance. Enter a negative value to project the roof line below the current wall height.

project the roof line to a polyline

enter **p** (Project), and select the polyline.

If you want to ...	Then ...
project the roof line to another object, such as a roof or stairs	enter a (Auto-project), and select the object to project to. When projecting to stairs, make sure that the bottom riser or the stringer does not create a zero-height segment of wall.
generate a polyline of the current roof line	enter g (Generate), and select the walls for the polyline to be created from.
remove any changes to the roof line	enter r (Reset), and select the walls to change.

3 Press *ENTER*.

Offsetting or Projecting the Floor Line of the Wall

Use this procedure to change the height or the shape of the floor line of a wall:

- Offset the floor line from the current baseline of the wall.
- Project the floor line of the wall to a polyline.
- Project the floor line of the wall to another object, such as a floor slab or stairs.

You can also create a polyline that represents the current floor line of the selected walls. You can then use this polyline to change the floor line of other walls.

NOTE To project the floor line to a polyline, draw the polyline first in elevation view. For best results, the polyline should be parallel to the wall. The polyline does not need to be in the same plane as the wall.

1 Select a wall, right-click, and click Roof/Floor Line ► Modify Floor Line.

2 Change the floor line of the wall:

If you want to ...	Then ...
offset the floor line from the current base line of the wall	enter o (Offset), and enter an offset distance. Enter a negative value to project the floor line below the current wall base line.
project the floor line to a polyline	enter p (Project), and select the polyline.
project the floor line to another object, such as a slab or stairs	enter a (Auto-project), and select the object to project to. When projecting to stairs, make sure that the bottom riser or the stringer does not create a zero-height segment of wall.
generate a polyline of the current floor line	enter g (Generate), and select the walls for the polyline to be created from.
remove any changes to the floor line	enter r (Reset), and select the walls to change.

3 Press *ENTER*.

Adding a Gable to the Roof Line of a Wall

Use this procedure to add a gable to the roof line of a wall. You can also add a gable on the Roof/Floor Line worksheet on the Properties palette.

NOTE This option is available only if the roof line has not been edited. After the roof line changes, you cannot add a gable using this option. To add a gable to a roof line that has been edited, see [Changing Vertices in the Roof Line or Floor Line of a Wall](#) on page 821.

- 1 Select the wall, right-click, and click Roof/Floor Line ► Edit in Place.
A temporary profile is created for you to edit the geometry of the Roof line.
- 2 Right-click, and click Add Gable.
If Add Gable is not listed on the menu, the roof line was previously edited.
- 3 Select the roof line.

Modifying a wall roof line by adding a gable

A third vertex is added to the roof line halfway between the 2 ends of the roof line and 8'-0" up from the roof line.

- 4 Continue editing the roof line or the floor line, if needed.
For more information, see [Editing the Roof Line or the Floor Line of a Wall](#) on page 818.
- 5 Save or discard the changes:

If you want to ...

Then ...

restore the roof line to its previous shape

click  .

save the changes to the roof line

click  .

Adding a Step to the Roof Line or Floor Line of a Wall

Use this procedure to add a step to the roof line or the floor line of a wall. You can also add a step on the Roof/Floor Line worksheet on the Properties palette.

NOTE This option is available only when the roof line or the floor line has not been edited. After the line has been changed, you cannot automatically add a step using this option. To add a step to a roof line or a floor line that has been edited, see [Changing Vertices in the Roof Line or Floor Line of a Wall](#) on page 821.

- 1 Select the wall, right-click, and click Roof/Floor Line ► Edit in Place.

A temporary profile is created for you to edit the geometry of the roof line or the floor line.

2 Right-click, and click Add Step.

If Add Step is not listed on the menu, the roof line or the floor line was previously edited.

3 Select the roof line or the floor line.

Modifying a wall floor line by adding a step

A third vertex is added to the line halfway between the 2 ends of the line and 4'-0" from the line. A step is created from the selected vertex to the second vertex.

4 Continue editing the roof line or the floor line, if needed.

For more information, see [Editing the Roof Line or the Floor Line of a Wall](#) on page 818.

5 Save or discard the changes:

If you want to ...

Then ...

restore the roof line or the floor line to its previous shape

click .

save the changes to the roof line or the floor line

click .

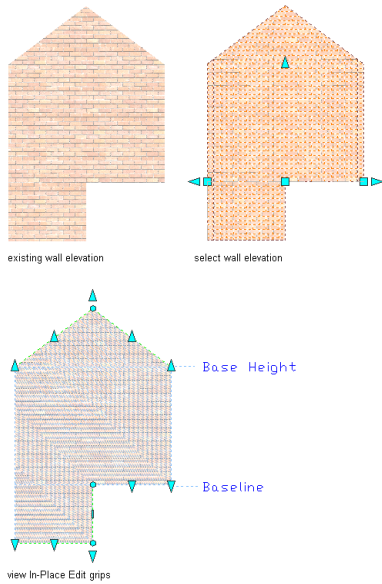

Editing the Roof Line or the Floor Line of a Wall

Use this procedure to edit the geometry of the roof line or the floor line of a wall:

- Add, modify, or remove gables.
- Add, modify, or remove steps.
- Project the roof line or the floor line to a polyline or to other objects, such as roofs, roof slabs, slabs, and stairs.
- Create custom roof line or floor line conditions by adding and adjusting vertices and edges.
- Reverse the roof line or the floor line of the wall without reversing the wall itself.
- Remove all changes to the roof line or the floor line of a wall.

You can also edit the roof line and the floor line on the Roof/Floor Line worksheet on the Properties palette. For more information, see [Changing Vertices in the Roof Line or Floor Line of a Wall](#) on page 821.

Viewing Edit In Place Wall Elevation Grips

NOTE If you want to project the roof line or the floor line to a polyline, draw the polyline before you start this procedure.

- 1 Select the wall that has the roof line or floor line you want to change, right-click, and click Roof/Floor Line ► Edit in Place.

A temporary profile is created for you to edit the geometry of the roof line and floor line.

Wall Elevation Edit In Place Grips

- 2 **NOTE** After you perform an editing task from the context menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the menu, select the profile, and right-click to display the context menu.

Edit the profile:

If you want to ...

Then ...

add a gable to the roof line or the floor line

select the profile, right-click, and click Add Gable.
Select the roof line or the floor line.

If you want to ...	Then ...
add a step to the roof line or the floor line	select the profile, right-click, and click Add Step. Select the roof line or the floor line.
change the shape of the roof line or the floor line	select the profile, and use Move Roof Line, Move Floor Line, Vertex, and Edge grips to adjust the shape.
add vertices to the roof line or the floor line	select the profile, right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .
remove vertices from the roof line or the floor line	select the profile, right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .
project the roof line or the floor line to a polyline	select the profile, right-click, and click Project to Polyline. Select the roof line or the floor line, and select the polyline. Press <i>ENTER</i> to keep the geometry, or enter y (Yes) to erase it.
project the roof line or the floor line to another object, such as a stair or a roof	select the profile, right-click, and click Auto Project. Select the roof line or the floor line, and select the object.
reverse the roof line or the floor line	select the profile, right-click, and click Reverse. Select the roof line or the floor line.
restore the roof line to the base height of the wall, or restore the floor line to the baseline of the wall	select the profile, right-click, and click Remove. Select the roof line or the floor line.

NOTE To add a gable or a step to a roof line or a floor line that has been edited, first use the Remove option on the context menu to remove an existing roof line or floor line condition.

3 Save or discard the changes:

If you want to ...	Then ...
restore the roof line and the floor line to their shape before editing	click  .
save the changes	click  . The wall uses the edited profile to define its geometry.

Reversing the Roof Line or Floor Line of a Wall

Use this procedure to reverse the conditions applied to the roof line or the floor line of a wall. Reversing the roof line or the floor line does not reverse the start point and endpoint of the wall.

The following illustration shows reversing the roof line of a wall.

Reversing the roof line of a wall

The following illustration shows reversing the floor line of a wall.

Reversing the floor line of a wall

- 1 Select the wall that has the roof line or floor line you want to change, right-click, and click Roof/Floor Line ► Edit in Place.
A temporary profile is created for you to edit the geometry of the roof line or the floor line.
- 2 Select the profile, right-click, and click Reverse.
- 3 Select the roof line or the floor line.
The selected line is reversed; the condition is applied to the opposite end of the line.
- 4 Save or discard the changes:

If you want to ...

Then ...

restore the roof line and the floor line to their shape before editing

click  .

save the changes

click  . The wall uses the edited profile to define its geometry.

Changing Vertices in the Roof Line or Floor Line of a Wall

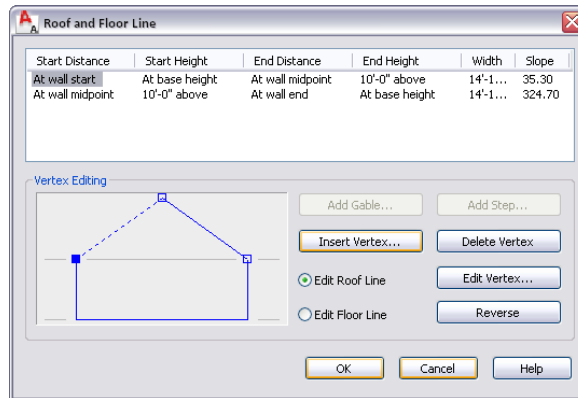

Use this procedure to perform the following tasks on the Roof/Floor Line worksheet on the Properties palette:

- Add, move, or remove vertices in the roof line or the floor line of a wall.
- Add gables or steps to a roof line or steps to a floor line that was previously edited by adding vertices that define these conditions.

You can also edit the roof line and the floor line graphically. For more information, see [Editing the Roof Line or the Floor Line of a Wall](#) on page 818.

- 1 Double-click the wall you want to change.
- 2 Expand Advanced, and expand Worksheets.
- 3 Select Roof/Floor Line.
- 4 Select Edit Roof Line, or select Edit Floor Line.

Changing the vertices of a roof line

The active vertex in the illustration changes when you select a different line to edit. Any changes you make to the wall are reflected in the illustration.

- To add a vertex, click **Insert Vertex**. Specify the horizontal offset and vertical offset for the new vertex and each offset distance, and click **OK**.

For more information about specifying the location of a vertex, see [Specifying Offsets for Roof Line and Floor Line Vertices](#) on page 924.

The following illustration shows modifying the roof line of a wall by adding a vertex.

Modifying a roof line of a wall by adding a vertex

The following illustration shows modifying the floor line of a wall by adding a vertex.

Modifying a floor line of a wall by adding a vertex

- To move a vertex, select the vertex from the table or the illustration, and click **Edit Vertex**. Specify the horizontal offset and vertical offset for the new vertex and each offset distance, and click **OK**.

For more information about specifying the location of a vertex, see [Specifying Offsets for Roof Line and Floor Line Vertices](#) on page 924.

7 To delete a vertex, select a vertex, and click Delete Vertex.

The selected vertex is deleted, and the line automatically connects the 2 adjacent vertices.

8 To reverse the roof line or the floor line, click Reverse.

9 Click OK.

Specifying the Materials of Individual Walls

Use this procedure to select a different material for components of an individual wall.

To change the materials assigned to all walls of the same wall style, see [Specifying the Materials of a Wall Style](#) on page 886.

NOTE If a material assignment does not determine the display properties of a wall component, you can change the properties of the display component as described in [Changing the Display Properties of Individual Walls](#) on page 824.

1 Select the wall you want to change, right-click, and click Edit Object Display.

2 To verify that the material assignment determines the display properties of the component, click the Display Properties tab, select the display representation where you want the changes

to appear, and click .

3 Click the Layer/Color/Linetype tab, verify that By Material is selected for the component, and click OK.

4 Click the Materials tab.

5 Select the component you want to change, and select a different material definition.

Wall segments with assigned materials in realistic visual style

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog, any changes you make to the material definition apply to all objects that are assigned the material.

6 Click OK.

Changing the Display Properties of Individual Walls

In most cases, you want the appearance of walls that belong to the same style to be consistent throughout a drawing. To achieve this, you specify the material assigned to each wall component, or you specify the display properties for each wall style. However, in certain instances, you may need to override a display property for an individual wall to achieve a specific result. All the display properties that you can specify in wall styles are available for individual walls:

- Whether the display properties of wall components are determined by material assignments
- The layer, color, and linetype of the display components of the wall
- The hatching used with each component
- The cut plane height and the display of components relative to the cut plane

- Other specific wall display information, such as whether complex endcaps are displayed and whether the wall is cut around door and window frames

When you change the display properties of an individual wall, the changes apply only to that wall. Other walls of the same style are not affected. To change the display properties of all walls of a specific wall style, see [Wall Styles](#) on page 874.

Specifying the Layer, Color, and Linetype of a Wall

Use this procedure to change the following display properties of the components of an individual wall:

- Visibility (component is on or off)
- By material (a material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

To change these display properties for all walls of the same wall style, see [Specifying the Display Properties of a Wall Style](#) on page 889.

NOTE If a material assignment determines the properties of a wall display component, you can change the properties of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Materials of Individual Walls](#) on page 823.

1 Select the wall you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

2 Click the Display Properties tab.

3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click .

5 Click the Layer/Color/Linetype tab.

6 Select the component to change, and select a different setting for the property.

7 Click OK twice.

Specifying the Hatching for Components of a Wall

Use this procedure to specify the hatching of the components of an individual wall. Wall hatching is displayed only in display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

To change the hatching for all walls of the same wall style, see [Specifying the Hatching for Components of a Wall Style](#) on page 890.

NOTE If a material assignment determines the hatching properties of a wall component, you can change the hatching of the component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Materials of Individual Walls](#) on page 823.

1 Select the wall you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

2 Click the Display Properties tab.

3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click .

5 Click the Hatching tab.

6 Select a component, and click the setting for Pattern.

7 Select the hatching for the component:

If you want to ...	Then ...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

8 Click OK.

9 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

10 Click Angle, and enter the angle for the selected pattern.

11 Click Orientation, and specify how the hatching is oriented:

If you want to ...	Then ...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

12 Click OK twice.

Specifying the Cut Plane Display of a Wall

Use this procedure to specify the properties of one or more cut planes for an individual wall. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

To better visualize the elements of a wall in plan view, you can create cut planes. The main cut plane is where the shrinkwrap and hatching are applied. The plan display shows the components and objects in the wall as they are displayed at the height of each cut plane.

- 1 Double-click the wall you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all walls in the drawing, select Drawing default setting. To apply changes to all walls of this style, select Wall Style:<style name>. For more information on styles, see [Wall Styles](#) on page 874.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object.
- 8 To specify whether to display object components both above and below the cut plane, or to define additional cut planes for the wall, click  Manual cut planes.
- 9 On the Manual Cut Planes worksheet, do either or both of the following:
 - To display object components above and below the cut plane, verify that Automatically Choose Above and Below Cut Plane Heights is selected.
 - To specifically define a cut plane, select Manual Above and Below Cut Plane Heights, click Add, and enter the height of the new cut plane.

If you add a cut plane ...	Then ...
----------------------------	----------

at a height that is lower than the value for Cut Plane Height

objects are displayed using the Layer/Color/Linetype properties specified for the Below Cut Plane component of the object.

at a height that is higher than the value for Cut Plane Height

objects are displayed using the Layer/Color/Linetype properties specified for the Above Cut Plane component of the object.

You can click Remove to delete a cut plane that you added.

You can also access and modify these same cut plane settings through the wall's context menu, as follows:

- 1 Select the wall you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.

3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click .

5 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.

6 Click OK twice.

Specifying the Display of Endcaps in Model Views

Use this procedure to specify whether to display endcaps of openings in a selected wall in a display representation used for model views.

1 Double-click the wall.

2 Click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all walls in the drawing, select Drawing default setting. To apply changes to all walls of this style, select Wall Style:<style name>. For more information on styles, see [Wall Styles](#) on page 874.

5 For Display representation, verify that the desired display representation is selected.

6 If necessary, expand Object Display Properties ► Advanced.

7 For Display opening endcaps, select Yes or No.

Specifying the Display of Other Characteristics of a Wall

Use this procedure to specify display properties for an individual wall that apply only in display representations such as Plan, that are used in the Top view (plan view) of a drawing. These properties include whether to display complex endcaps, to show door and window frames, or to show the miter of specific wall components.

1 Double-click the wall you want to change.

2 On the Properties palette, click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all walls in the drawing, select Drawing default setting. To apply changes to all walls of this style, select Wall Style:<style name>. For more information on styles, see [Wall Styles](#) on page 874.

5 For Display representation, verify that the desired display representation is selected.

6 If necessary, expand Object Display Properties ► Advanced.

7 Click  Additional properties.

8 Specify individual display property settings as needed:

If you want to ...	Then ...
display the component lines within the wall above the cut plane (for example, through a window or door in the wall)	select Display Inner Lines Above. Clear this option if you do not want to display these lines.
display the component lines within the wall below the cut plane (for example, through a window or door in the wall)	select Display Inner Lines Below. Clear this option if you do not want to display these lines.
turn off lines above a window, door, or opening at the cut plane	select Hide Lines Below Openings Above Cut Plane. Clear this option if you want to display the lines.
turn off lines beneath a window or an opening at the cut plane	select Hide Lines Below Openings at Cut Plane. Clear this option if you want to display the lines.
display complex endcaps	select Display Endcaps. Clear this option to display complex endcaps as a single line.
display door openings cutting the wall at the outer edge of the door frame	select Cut Door Frames. Clear this option if you want door openings to cut the wall at the inside of the door frame.
display window openings cutting the wall at the outer edge of the window frame	select Cut Window Frames. Clear this option if you want window openings to cut the wall at the inside of the window frame.
draw wall components by their priority number to control the display of a component over another component	select Component Draw Order by Priority. Clear this option if you want to draw the components in the order that they were created.
perform a slice of the actual 3-dimensional (3D) model at each cut plane to obtain more accurate views of walls with sweeps or body modifiers	select Do True Cut. Clear this option if the wall does not have sweeps or body modifiers, or if they do not change along the height of the wall.
display miter lines at wall corners for selected wall components	Under Draw Miter for Components, select each component whose miter lines you want to display.

9 Click OK.

You can also access and modify these same additional settings through the wall's context menu, as follows

- 1 Select the wall you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 4 If necessary, click .

- 5 In the Display Properties dialog, click the Other tab, and then change the settings as needed.

6 Click OK twice.

Attaching Notes and Files to a Wall

Use this procedure to enter notes and attach reference files to a wall. You can also edit notes and edit or detach reference files from a wall.

- 1 Double-click the wall.
- 2 On the Properties palette, click the Extended Data tab.
- 3 Click the setting for Notes.
- 4 Enter the note, and click OK.
- 5 Click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click  , select a file, and click OK.
edit the description of a reference file	select the file, and click the description. Edit the description.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

6 Click OK twice.

Specifying the Cleanup of Walls

You can control how walls join and clean up with other walls by using cleanup groups. Walls must be in the same cleanup group to clean up properly. By default, walls belong to the Standard cleanup group. You can create new wall cleanup groups for specific sets of walls. You can assign walls to a cleanup group when you create the walls or after you create the walls.

Within the same cleanup group, the priority of each wall component determines how the wall cleans up with the components of the intersecting wall. You can control wall cleanup with several features designed for this purpose:

- Specifying a cleanup group and cleanup circle radius in wall tools for adding new walls to a drawing
- Specifying a cleanup group and the cleanup circle radius for individual walls
- Specifying the priority of each wall component in wall styles or for individual walls
- Specifying cleanup settings that apply to the entire drawing to specify how close together walls must be to join and clean up (Autosnap radius and Cleanup radius)

Cleanup Circles and Wall Justification Lines

Cleanup circles and wall justification lines are features of wall objects that are the basis for how AutoCAD Architecture calculates wall cleanup. Cleanup circles appear for walls only in the Diagnostic display representation, or when you toggle on the display of wall justification lines.

Displaying Cleanup Circles and Wall Justification Lines

The Diagnostic display representation displays the wall segment's cleanup circle radii, direction glyph, and justification line to help you troubleshoot wall cleanup. On the Status Bar, click Display Representation ► Diagnostic.

Viewing wall segments in Medium Detail and Diagnostic display representations

Medium Detail display representation

Diagnostic display representation

In addition, you can also toggle on the display of a wall segment's justification line and cleanup circles while maintaining the display of the wall components. Select a wall segment, right-click, and click Cleanups ► Toggle Wall Justification Display.

Toggling on the display of wall justification line and cleanup circles

Cleanup circles and justification lines appear on all walls in the drawing. In addition, when you select the wall, Cleanup Radius grips are displayed at each cleanup circle. You can move the grip to increase or decrease the cleanup circle radius. Cleanup circles do not appear if the cleanup circle radius for the wall is zero.

Viewing the cleanup circle radius grip

Cleanup Circles and Wall Justification Lines

A cleanup circle is located at the start point and the endpoint of each wall segment. The center point of each cleanup circle is the start point or endpoint of the wall justification line.

The cleanup circle radius determines the size of the cleanup circle. You can specify a cleanup circle radius in the wall tools you use to add walls to a drawing. If needed, you can override the default cleanup circle radius at each end of a wall segment. This allows you to adjust the cleanup circle radius for particular wall styles and for individual situations.

Specifying the cleanup circle radius

A wall justification line is coincident with the center line of the wall or the wall justification, depending on the cleanup settings specified for the wall.

Wall Cleanup Conditions

Walls in the same cleanup group cleanup when one of the following conditions applies:

- The cleanup circle of one wall overlaps the center point of the cleanup circle of another wall.
- The cleanup circle of one wall overlaps the wall justification line of another wall.

Wall cleanup with justification line intersecting cleanup circle

- The wall justification line of one wall intersects the wall justification line of another wall.

Wall cleanup with intersecting justification lines

TIP The best practice for successful wall intersections is to ensure that your individual wall segment justification lines intersect and that you specify a zero (0) radius for your wall segment cleanup circles.

When walls intersect and clean up properly, a new wall joint is created at the intersection of the wall justification lines. The exact location of the wall joint depends on the location of the new wall segment endpoint. In many cases, the wall joint location does not coincide with the existing wall segment center line. The location of the wall joint is based on a weighted average distance between wall segment endpoints, as well as the thickness of the wall segments.

Wall justification lines and wall joint at wall intersections

Wall Cleanups and Priorities

Walls with multiple components clean up based on the priority assigned to each component and the location of each component within the wall. Matching component edges with the same priority are extended or trimmed to their intersection points. Components with a higher priority (a low priority number) cut through components with a lower priority (a high priority number).

Wall cleanup priorities

wall components and priorities

resulting wall component cleanup

To identify the default cleanup priorities for the components used in the sample wall styles provided with AutoCAD Architecture, see [Default Cleanup Priorities of Wall Components](#) on page 879.

The software calculates and performs wall cleanups in the following sequence:

- 1 Component information is gathered from the wall graph:
 - Endcaps are calculated. If an endcap does not fit in the section, a solution tip icon displays. For more information, see [Solution Tips for Walls](#) on page 838.
 - Sides of components are combined with endcaps to produce a component profile (like a 2-dimensional region).
 - If this profile is self-intersecting, a solution tip icon displays.
- 2 Adjacent higher priority components are gathered from the wall graph from neighboring wall segments.
- 3 Higher-priority component profiles are subtracted from the lower-priority component profiles.
- 4 Doors, windows, openings, and interferences are cut and/or applied.
- 5 Shrinkwrap may be calculated and hatching applied.
 - A failed shrinkwrap calculation may also result in the display of a solution tip icon.
- 6 Graphics are drawn to an output device (for example, the AutoCAD screen, Object Viewer, Osnap stream, explode stream, and a plotter).
- 7 Solutions are cached for subsequent draw requests until the wall is modified again.

Guidelines for Successful Wall Cleanup

When cleanup settings or the placement of a wall segment are preventing correct wall cleanup, a solution tip icon displays to indicate the location of the problem and provide possible solutions.

Here are some recommendations for actions you can take to achieve successful wall cleanup:

- Wall justification lines should intersect.
- Review the wall cleanup circle radius settings for each wall segment. A good starting point is to set the wall cleanup circle radius equal to half of the wall width. However, this may not apply to every situation and you may need to adjust the cleanup circle radius to achieve the desired effect.

NOTE A wall segment must be longer than its cleanup circle radius.

- Use a smaller cleanup circle radius. A small cleanup circle radius also makes the graph display more readable. The cleanup circle radius should be a value that is between one-half the wall width and the overall wall width.
- Look for very short wall segments. You can find these short segments by turning on the Diagnostic display representation. You can fix them by adjusting the baselines or by increasing the cleanup circle radii.
- Draw walls with center justification on and use an offset to simulate right or left justification. Using this method, you can draw very short segments and tight wall jogs, provided the appropriate cleanup circle radius is used.
- In order to ensure that exterior walls clean up properly with interior walls, switch the justification lines in the exterior wall segments to the inside so that the interior wall segment justification lines intersect.

Use the following procedure to verify that the wall segments are inserted at a common Z elevation:

- 1 Freeze all layers except for the designated wall layer.
- 2 Select all the walls, and double-click one of them.
- 3 On the Properties palette, expand Basic, and expand Location.
- 4 Click Additional information.
- 5 Under Insertion Point, verify that the Z value is consistent.
If *VARIES* is displayed, at least one of the walls is inserted at a different Z elevation than the other walls. Change this value to the desired elevation, and click OK.
- 6 Under Normal, verify that the Z value is consistent.
If walls do not clean up properly, even though the Z value for the insertion point is the same for all walls on the Location tab, a wall may be at an angle. This can occur when the normal Z value varies. You can use the Properties palette to view both the start and endpoint Z values of the selected walls. In the Properties palette, an entry is left blank when the values vary.

Assigning a Different Wall Cleanup Group Definition to Existing Walls

Use this procedure to change the wall cleanup group assigned to existing walls. Assigning different cleanup groups is useful when you want to prevent 2 walls from cleaning up with each other. To create a new cleanup group, see [Cleanup Group Definitions](#) on page 843.

- 1 Select the walls to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and then expand General.
- 3 Select a cleanup group for Cleanup group definition.

Specifying Cleanup for Individual Walls

Use this procedure to specify the following cleanup settings for one or more walls:

- Whether the wall cleans up with other walls
- The cleanup group for the wall
- Whether the justification line position corresponds to the center line of the wall or to the wall justification
- The cleanup circle radius for both ends of the wall, or separate values for the start and endpoints of the wall

1 Select the walls you want to change, and double-click one of them.

2 On the Properties palette, expand Basic, and then expand General.

3 Turn wall cleanup on or off:

If you want to ...	Then ...
turn off wall cleanup so that the walls do not clean up with any other walls	select No for Cleanup automatically. If you select this option, you do not need to specify other settings.
turn on wall cleanup and specify cleanup settings	select Yes for Cleanup automatically, and proceed to step 4.

4 Select a cleanup group definition.

The walls will clean up with other walls that also belong to the cleanup group definition that you select.

5 Expand Advanced, expand Cleanups, and expand Cleanup Radius Overrides.

6 For justification line position, select the line that the Diagnostic display representation uses to represent the justification line of the walls: the center line of the wall or the wall justification.

7 Specify the cleanup circle radius for the walls:

If you want to ...	Then ...
specify the same cleanup circle radius for the start and endpoints of the walls	enter a value for Cleanup radius, and verify that No is selected for Override start cleanup radius and Override end cleanup radius.
specify a cleanup circle radius for the start point of the walls	select Yes for Override start cleanup radius, and enter a value for Start cleanup radius.
specify a cleanup circle radius for the endpoint of the walls	select Yes for Override end cleanup radius, and enter a value for End cleanup radius.

Start and End are based on the direction the wall was drawn. If you enter zero for any cleanup circle radius, the wall justification lines need to touch for the walls to clean up with other walls.

Overriding the Wall Cleanup Circle Radius

Use this procedure to override the default wall cleanup circle radius at one end of a wall. You can also override the cleanup circle radius on the Properties palette and using the context menu for the selected wall.

- 1 If the wall justification line is not displayed, select a wall, right-click, and click Cleanups ► Toggle Wall Justification Display.
 - 2 Select a Cleanup Radius grip, and move the grip until you have properly resized the cleanup circle.
- If Dynamic Input is active, move the grip until the dimension you want is displayed.

Changing the cleanup circle radius at one end of a wall

Overriding Component Priorities

Use this procedure to change the priority of a wall component so that when it intersects with another wall, it has higher or lower priority than its counterpart on the other wall. The lower the priority number you enter, the higher the priority of the component when the wall intersects with another wall.

For the list of default priorities of the wall components used in sample wall styles provided with AutoCAD Architecture, see [Default Cleanup Priorities of Wall Components](#) on page 879.

- 1 Double-click the wall you want to change.
- 2 On the Properties palette, expand Advanced, and then expand Style Overrides.
- 3 Click the setting for Priority overrides.

4 Add or edit a priority override for a wall component:

If you want to ...	Then ...
add a new priority override	click  , and proceed to step 5.
edit a priority override	proceed to step 5.
delete a priority override	select the priority override you want to delete, and click  .

5 Specify the override settings:

If you want to ...	Then ...
change the component to which you assigned the override	select a different component.
specify a priority override at the start of the wall	select the component, select At start of wall, and enter a value for Priority.
specify a priority override at the end of the wall	select the component, select At end of wall, and enter a value for Priority.
change the priority of an existing override	select the value for Priority, and enter a new value.

6 Click OK.

Troubleshooting Wall Cleanups

This topic provides more details about the solution tips displayed when problems are detected with wall cleanup or display. Answers are also provided for common questions associated with wall cleanups.

Solution Tips for Walls

When you move the cursor over a solution tip icons on a wall, any of the following problem statements may display:

NOTE Not all problems that generate solution tips have an easily identifiable cause or a specific solution. This is often true in the case of Boolean operations where an entity such as a body modifier is added to or subtracted from an object. In these cases the solution tip identifies the kind of object or component involved and suggests corrective action. You may be advised to modify the location or the geometry of the object, but it is essentially a trial-and-error approach. The messages are tips rather than guaranteed solutions.

The walls are not cleaning up correctly

As described under [Guidelines for Successful Wall Cleanup](#) on page 834, there are various conditions that can prevent cleanup. The first step in determining the cause of this problem is to examine the condition of the wall justification lines at the intersection. To display the justification line for a wall, select the wall,

right-click, and click Cleanups ► Toggle Wall Justification Display. (For more information, see [Cleanup Circles and Wall Justification Lines](#) on page 831.)

After looking at the justification lines, try one of the following possible solutions, as applicable:

- Extend or trim the walls using the AutoCAD Extend or Trim commands.
- With the wall selected, right-click, and click Apply 'L' Cleanup or Apply 'T' Cleanup. For more information, see [Trimming Walls at L and T Intersections](#) on page 812.
- Increase the wall cleanup radius by grip-editing (see [Working with Intersections and Small Cleanup Circle Radii](#) on page 841) or by changing the value of Cleanup radius on the Properties palette (see [Specifying Cleanup for Individual Walls](#) on page 836).
- With the wall selected, right-click, and click Cleanups ► Wall Merge Conditions. For more information, see [Merging Walls](#) on page 806.

The wall's endcaps or opening endcaps cannot be displayed due to space limitations

If there is insufficient space to display an endcap, you can either modify the wall to provide more space, or you can modify the endcaps to reduce the amount of space required. Note that some endcap problems are evident only in 3D (isometric) views, so you may need to switch to model space in order to see and resolve the problem. Then, depending on your design requirements, do any of the following:

- Lengthen the wall (see [Changing the Wall Length](#) on page 800).
- Remove one or more endcaps (see [Modifying the Geometry of a Wall Endcap Style](#) on page 918).
- Modify the wall endcap style or opening endcap style to require less space (see [Modifying the Geometry of a Wall Endcap Style](#) on page 918).

The wall cannot be displayed because it does not extend beyond its own cleanup radius or that of an adjacent wall.

In this case, you need to reduce the cleanup radius of the wall, and then regenerate the model.

To reduce the cleanup radius, do either of the following:

- On the Properties palette, enter a smaller value for Cleanup radius.
- Grip-edit the relevant cleanup radius so that it no longer encloses the defective wall.

To regenerate the model, do either of the following:

- Click View menu ► Regen Model.
- On the command line, enter ObjRelUpdate.

A wall's cleanup radius intersects the justification line of another, non-connected wall.

Just as in the case of a wall that does not extend beyond its cleanup radius or that of another, you need to reduce the cleanup radius of the wall, and then regenerate the model.

To reduce the cleanup radius, do either of the following:

- On the Properties palette, enter a smaller value for Cleanup radius.
- Grip-edit the relevant cleanup radius so that it no longer encloses the defective wall.

To regenerate the model, do either of the following:

- Click View menu ► Regen Model.
- On the command line, enter ObjRelUpdate.

Invalid roofline or floorline is causing the wall's 3D body to display incorrectly.

You can edit the roofline or floorline and correct the display using a worksheet accessed from the Properties palette. Expand Advanced ► Worksheets, and then click Roof/floor line. For more information, see [Editing the Roof Line or the Floor Line of a Wall](#) on page 818.

Working with Solution Tip Icons and Short Walls

Why do some short walls display a solution tip icon?

The cleanup circle radius is too large. Reduce the cleanup circle radii of all walls at the wall joint, or adjust the baselines so that the ends of all justification lines fall within the wall joint cleanup circle radii.

Solution tip icon displayed in a wall with a short wall segment

This situation can also occur if a door, window, opening, or door/window assembly is placed too close to the end of the wall and the wall or the objects in it use elaborate endcaps. In such cases, there may not be enough room for these conditions to be drawn correctly.

Solution tip icon displayed in a wall with a window near its end

Working with Intersections and Adjacent Wall Segments

Why do some wall segments that have ends that are close together not clean up properly?

The wall segment justification lines do not intersect each other, or one justification line does not fall within an adjacent cleanup circle. Adjust one wall segment length so that the end of its justification line falls within the adjacent wall segment's cleanup circle.

Adjusting wall segment length for correct clean up

Working with Intersections and Small Cleanup Circle Radii

While using small cleanup circle radii, wall intersections clean up incorrectly or not at all. How can I fix this?

Turn on the Diagnostic display representation or toggle on justification lines and adjust the justification lines or increase the cleanup circle radii until the problem is fixed.

Adjusting wall cleanup circle radius for correct clean up

Also, make sure that there are no short wall segments in the wall. These can occur where center lines intersect, or when a segment is too short to produce a full profile. Delete the short wall segment to fix the cleanup problem.

Incorrect Cleanup Group Assignments When Copying or Moving Doors, Windows, and Openings

When I try to copy or move doors, windows, and openings from one wall to another, the command does not always work. Why?

This situation can occur if the cleanup group for the destination wall does not allow objects from walls assigned to other cleanup groups to be copied to this wall. This design rule is intended to prevent placing objects in walls, such as cubicle partitions, that should not have objects added to them.

You can address this situation in 2 ways:

- Turn off this design rule in the cleanup group definition. For more information, see [Creating a Wall Cleanup Group Definition](#) on page 844.
- Temporarily assign the walls to the same cleanup group, copy or move the objects, and then reassign the walls to their correct cleanup groups.

Opening a Drawing that Displays New Solution Tip Icons

When I closed my drawing, all the wall cleanups looked fine. Now when I open the drawing, there are solution tip icons in the drawing. What causes this, and how can I fix it?

Under some circumstances, the order in which walls are cleaned up affects the display.

When troubleshooting this condition, select the walls in question, and double-click one of them. On the Properties palette, select No for Cleanup automatically, and then select Yes. Try this on different walls to see whether you can locate the unstable wall. Usually, adjusting the justification line of the unstable wall fixes this problem. For more information about verifying justification line, see [Guidelines for Successful Wall Cleanup](#) on page 834.

Working with Wall Cleanups and Xref Drawings

How can I get walls to clean up with walls in xref drawings?

There are several actions you can take to improve wall cleanup when you work with xref drawings that contain walls:

- Verify the design rules of the cleanup groups used in the xref drawings. If the cleanup group in the xref drawing does not allow cleanup with the walls in the host drawing, walls in the 2 drawings do not clean up, even when their cleanup groups have the same name. For more information about the design rules of cleanup groups, see [Creating a Wall Cleanup Group Definition](#) on page 844.
- When adding new walls during a Refedit session, add the existing walls to the current working set. Select the Xref cleanup group of the existing walls for the walls you are adding. Otherwise, the new walls do not clean up with the existing walls until you save changes to the drawings.
- Use the **Regenall** (Regenerate All) and **ObjRelUpdate** (Object Relationship Update) commands to update the relationships among walls in the drawing, especially if you move or transform walls involving xref drawings, or if you undo edits to walls in an xref drawing.
- For more information about xref drawings and wall cleanup, see additional troubleshooting topics in [Troubleshooting Wall Cleanups](#) on page 838.

Occurrence of Copied Walls in Xref Drawings

My xref drawing contains copies of walls that are in my host drawing. How did this happen?

If you added objects, such as doors or windows, to a wall in the host drawing while you had a Refedit session open for an xref drawing, a copy of the selected wall is added to the xref drawing. This occurs because any objects added during a Refedit session are always added to the xref drawing and not to the host drawing. Because the object you added was anchored to a wall, the wall is also added to the xref drawing.

To correct the drawings, review both the host drawing and the xref drawing for duplicate objects. Remove the duplicates from the incorrect drawing files. Allowing the duplicates to remain can create problems with the cutting of walls around doors, windows, door/window assemblies, and openings. Hidden line and shaded views are also affected.

To avoid creating duplicate objects in xref drawings, do not add or edit objects in the host drawing when a Refedit session is open for an xref drawing. Also, instead of opening a Refedit session, you can open the xref itself, and make edits directly. You can then save the xref drawing, and reload the updated drawing in the host drawing.

Adding a Door to a Wall in an Xref Drawing

I added a wall in an xref drawing and then added a door to the wall. The door does not center correctly. What causes this, and how I can correct it?

Some changes that you make during Refedit sessions of xref drawings do not take effect until you save the changes to the xref drawing. When you add doors, windows, door/window assemblies, and openings to a new wall in an xref drawing, their placement is affected by whether the new wall cleans up with other walls in the drawing. Clean up does not occur between walls in xref and host drawings until you save the changes in the Refedit session.

For best results, if you add walls during a Refedit session, save and close the session before adding objects to those walls. Open a new Refedit session (or open the xref drawing directly, outside of the host drawing), verify that the walls clean up as you intend them to, and then add objects to the walls.

Cleanup Group Definitions

A wall cleanup group definition is a designation that you can assign to individual walls to control how intersecting walls clean up. Walls that belong to the same cleanup group clean up where they intersect according to the priority assigned to each component in each wall. Walls that belong to different cleanup groups do not clean up when they meet at corners or intersections.

Walls that do and do not clean up

wall segments clean up at intersection

wall segments do not clean up at intersection

Controlling Wall Cleanup through Design Rules

You use the design rules of a cleanup group definition to determine how walls assigned that cleanup group cleanup when you Xref them in other drawings. The setting for this design rule in the cleanup group definition in the xref drawing controls whether those walls clean up with walls in the host drawing.

Design rules also determine whether you can move or copy objects from walls assigned to other groups to walls assigned to the current cleanup group. Preventing copying or moving objects to walls in a certain cleanup group helps you avoid inadvertently placing objects in walls that should not contain them.

Managing Cleanup Group Definitions

To create, edit, copy, or purge cleanup group definitions, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with definitions and styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Creating a Wall Cleanup Group Definition

Use this procedure to create a wall cleanup group definition. A cleanup group definition must exist in the drawing before you can assign walls and wall styles to the cleanup group.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Architectural Objects, and expand Wall Cleanup Group Definitions.

- 3 Create a cleanup group definition:

If you want to ...	Then ...
create a cleanup group definition with default properties	right-click Wall Cleanup Group Definitions, and click New.
create a cleanup group definition from an existing definition	right-click the cleanup group definition you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new cleanup group definition, and press *ENTER*.

- 5 Select the new cleanup group definition.

- 6 Click the General tab, and enter a description of the cleanup group.

- 7 Click the Design Rules tab.

- 8 Specify the design rules:

If you want to ...	Then ...
allow walls assigned to this cleanup group to clean up with walls in a host drawing when the current drawing is inserted as an Xref	Select Allow wall cleanup between host and xref drawings. Clear this option if you do not want the walls to cleanup with walls in the host drawing.

NOTE The cleanup group definition in the xref drawing controls cleanup with walls in the host drawing.

If you want to ...	Then ...
allow objects anchored to walls assigned to other cleanup groups to be moved or copied to walls assigned to this cleanup group	Select Allow objects anchored to walls in other cleanup groups to be moved or copied to walls in this cleanup group. Clear this option if you do not want objects anchored to walls in other cleanup groups to be moved or copied to walls assigned to this cleanup group.

9 Click OK.

If you want to add notes, files, or documents to a cleanup group definition, see [Attaching Notes and Files to a Wall Cleanup Group Definition](#) on page 845.

Attaching Notes and Files to a Wall Cleanup Group Definition

Use this procedure to enter notes and attach reference files to a cleanup group definition. You can also edit notes and edit or detach reference files attached to the definition.

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Architectural Objects, and expand Wall Cleanup Group Definitions.

3 Select the cleanup group definition that you want to change.

4 Click the General tab.

5 To add a description to the cleanup group definition, enter it for Description.

6 Click Notes.

7 To add a note, click the Notes tab, and enter the note.

8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

9 Click OK.

Adding Objects to Walls

When you add doors, windows, window assemblies, and openings to a wall, the wall automatically adjusts to accommodate the object and adds endcaps where needed. By default, these objects are anchored to the wall. The objects remain with the wall if you move it. If you remove an object from a wall, the wall repairs

itself in the space where the object was located. You can control how the objects are anchored to the start or the end of a wall, within the wall width, and vertically.

Adding a Window to a Wall

Use this procedure to place one or more windows in a wall.

Inserting a window in a wall

1 Select a wall, right-click, and click **Insert** ► **Window**.

2 Specify the settings for the window.

For more information about adding windows, see [Creating a Window with User-Specified Settings](#) on page 1300.

3 Specify an insertion point along the wall.

4 Continue to place windows in the wall, and press *ENTER*.

Adding an Opening to a Wall

Use this procedure to place one or more openings in a wall.

Inserting an opening in a wall

1 Select a wall, right-click, and click **Insert** ► **Opening**.

2 Specify the settings for the opening.

For more information about adding openings, see [Creating an Opening with User-Specified Settings](#) on page 1365.

3 Specify an insertion point along the wall.

4 Continue to place openings in the wall, and press *ENTER*.

Adding a Door to a Wall

Use this procedure to place one or more doors in a wall.

Inserting a door in a wall

1 Select a wall, right-click, and click Insert ► Door.

2 Specify the settings for the door.

For more information about adding doors, see [Creating a Door](#) on page 1229.

3 Specify an insertion point along the wall.

4 Continue to place doors in the wall, and press *ENTER*.

Adding a Door/Window Assembly to a Wall

Use this procedure to place one or more door/window assemblies in a wall.

Inserting a door/window assembly in a wall

1 Select a wall, right-click, and click Insert ► Door/Window Assembly.

2 Specify the settings for the door/window assembly.

3 Specify an insertion point along the wall.

4 Continue to place door/window assemblies in the wall, and press *ENTER*.

Removing Windows, Openings, Doors, or Door/Window Assemblies from a Wall

Select the objects you want remove from the wall, and press *DELETE*. The wall repairs itself where the objects were located.

Anchoring an Object to a Wall

Use this procedure to move objects to a different wall by anchoring the objects.

An anchored object is constrained by the wall. You can move the object along the wall, but the object does not move from the wall unless you detach the object. Objects anchored to walls follow connected wall segments.

The center of the bottom face of the object is anchored to the insertion point on the bottom face of the wall, which is midway in the wall width.

NOTE By default, doors, openings, windows, and window assemblies are anchored to the walls these objects are added to.

- 1 Select the object to attach to the wall, right-click, and click Wall Anchor ► Set Wall.
- 2 Select the wall to attach the object to.

Detaching Objects from a Wall

Use this procedure to detach an object that is anchored to a wall. When you detach an object, the object is no longer constrained by the wall and can be moved off the wall.

- Select the object to release from the wall, right-click, and click Wall Anchor ► Release. The object remains in place but is no longer constrained to the wall. The wall no longer cleans up around the object.

Creating Special Conditions and Customized Wall Surfaces

Wall sweeps, wall (plan) modifiers, body modifiers, and interference conditions are features that you can use to create special conditions, such as chases, and to customize wall surfaces.

Wall Sweeps Created from Profiles

A wall sweep is a wall or a wall component whose shape is extruded horizontally from a profile that was created from a closed polyline. The profile “sweeps” along the length of the wall to define the shape of the wall or the wall component.

Profile and resulting wall sweep

Wall (Plan) Modifiers Created from Polylines

Wall modifiers use the 2-dimensional (2D) geometry of an open polyline to customize the shape of a wall or a wall component. To use wall modifiers, you draw a polyline in the shape you need and create a wall modifier style from the polyline. You can then add wall modifiers of that style to any wall.

Polyline and resulting wall modifier

Body Modifiers Created from 3D Objects

Body modifiers use the 3-dimensional (3D) geometry of an object, such as a mass element or a mass group, to add to, subtract from, or completely replace one component in a wall. If the wall has only one component, the body modifier applies to the entire wall. If the wall has multiple components, the modifier applies only to the component that you specify.

Barrel Vault mass element and resulting body modifier subtracted from a wall

Interference Conditions Created from 3D Objects

Interference conditions use the geometry of 3D objects to create custom openings or cutouts in walls. You can specify how the interference condition is applied to the wall: added to the wall, subtracted to the wall, or ignored.

Interference conditions apply to all wall components that the interfering object touches. The wall stops at the interference condition. The way in which you apply the interference condition to the wall determines how the shrinkwrapping of the wall is affected by the condition in plan view. In model views, the interference condition is always subtractive, regardless of the shrinkwrapping option you selected.

When you edit the object that acts as the interference condition, the wall changes to accommodate the changes to the geometry of the object. For example, you can move the interfering object to change its location on the wall.

A Cylinder mass element added as an additive interference condition

Working with Wall Sweeps

A wall sweep is a wall or a wall component whose shape is extruded horizontally from a profile that was created from a closed polyline. The profile “sweeps” along the length of the wall to define the shape of the wall.

The height and the width of the polyline you use to create the profile define the height and the width of the wall component. The profile is not scaled when swept on the wall. The insertion point of the profile becomes the lower-left corner of the wall component.

After you create wall sweeps, you can miter wall sweeps that meet at a corner. You can also change how the sweep is applied to the wall:

- You can edit the geometry that defines a sweep.
- You can assign a sweep profile to a different wall component.
- You can adjust the miter angles at each end of a wall that has a sweep profile.
- You can remove a sweep profile from a wall or a wall component.

Creating a Profile for a Wall Sweep

Use this procedure to create a profile from a closed polyline. You can then sweep the profile along the length of a wall or a wall component to create a wall with a custom shape.

The height and the width of the polyline you use to create the profile define the height and the width of the wall component. The profile is not scaled when swept on the wall. The insertion point of the profile becomes the lower-left corner of the wall component.

You can also define the shape of a wall sweep as you add it to a wall, using the Start from Scratch option. You may find that option easier to use because you can define the shape in place on the wall. You may want to separately create a profile as described in this procedure if the shape is highly complex or contains many arcs.

- 1 Draw a closed polyline of the shape needed for the resulting wall component.

- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.

- 3 Specify the insertion point of the profile.

The point you specify becomes the lower-left corner of the wall component.

- 4 Press *ENTER*.

- 5 Enter a name for the profile, and click OK.

You can now use the profile as a wall sweep to replace a wall component. For more information, see [Adding a Sweep to a Wall](#) on page 850.

Adding a Sweep to a Wall

Use this procedure to create a custom wall or a wall component by defining its shape from a profile.

You can create the profile as you add it to a wall. However, if the shape you need is elaborate and has curved segments, you may find it easier to create the profile from a polyline first. You can then add the profile to the wall. For more information, see [Creating a Profile for a Wall Sweep](#) on page 850.

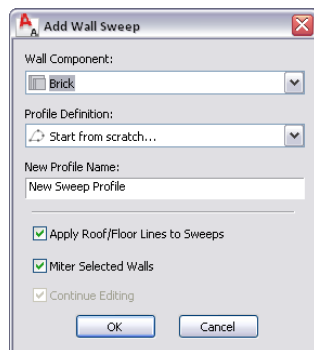

Adding a sweep profile to a wall

- 1 Select the walls to sweep, right-click, and click Sweeps ► Add.
- 2 Select the component to which to apply the sweep.
- 3 Select the profile to use for the sweep.

If you want to define the sweep after you apply it to the component, select Start from scratch, and enter a name for the profile.

Specifying settings for a wall sweep

- 4 Specify how the sweep is applied to the wall:

If you want to ...

Then ...

apply existing roof line or floor line conditions to the sweep

select Apply Roof/Floor Lines to Sweeps.

use the geometry of the sweep to define the roof line and the floor line

clear Apply Roof/Floor Lines to Sweeps.

miter the intersection of the wall containing the sweep and other walls

select Miter Selected Walls.

prevent mitering the intersection of the wall containing the sweep and other walls

clear Miter Selected Walls. You can miter the walls later, if needed. You can also adjust the miter angles.

If you want to ...	Then ...
change the geometry of the sweep when it is applied to the wall	select Continue Editing. For more information about editing the profile, see Editing the Geometry of a Wall Sweep on page 852.
use the existing geometry of the profile to define the sweep	clear Continue Editing.

5 Click OK.

TIP To create additional walls with the same sweep condition, select the wall with the sweep, right-click, and click Add Selected. Add walls with the sweep condition where you need them in the drawing.

Editing the Geometry of a Wall Sweep

Use this procedure to change the shape of a wall component that was defined with a wall sweep. You can select a different profile to change the appearance of the sweep, or you can edit the current profile.

If you want to remove a wall sweep, apply the sweep to a different wall component, or change how the sweep cleans up with intersecting walls, see [Managing Wall Sweeps](#) on page 857.

Use this procedure to display wall sweep edit in-place grips

- 1 Select the wall that has the sweep you want to change, right-click, and click Sweeps ► Edit Profile in Place.
- 2 Select a location on the wall where the shape of the sweep will be convenient to edit. A temporary profile is created for you to edit the geometry of the sweep.

Viewing Wall Sweep Edit In Place Grips

Offsetting an edit in-place wall sweep profile edge

Use this procedure to offset an edit in-place wall sweep profile edge

- 1 Select the wall that has the sweep you want to change, right-click, and click Sweeps ► Edit Profile in Place.
- 2 Select a location on the wall where the shape of the sweep will be convenient to edit. A temporary profile is created for you to edit the geometry of the sweep.
- 3 Select the Edge grip and specify a new grip location. The wall sweep profile now has a offset edge.

Adding a vertex to an edit in-place wall sweep profile edge

Use this procedure to add a vertex to an edit in-place wall sweep profile edge

- 1 Select the wall that has the sweep you want to change, right-click, and click Sweeps ► Edit Profile in Place.

2 Select a location on the wall where the shape of the sweep will be convenient to edit.

A temporary profile is created for you to edit the geometry of the sweep.

3 Select the Edge grip, press *CTRL* and specify a new grip location.

The wall sweep profile now has a new edge vertex.

Converting an edit in-place wall sweep profile edge to an arc

Use this procedure to convert an edit in-place wall sweep profile edge to an arc

1 Select the wall that has the sweep you want to change, right-click, and click Sweeps ► Edit Profile in Place.

2 Select a location on the wall where the shape of the sweep will be convenient to edit.

A temporary profile is created for you to edit the geometry of the sweep.

3 Select the Edge grip, press *CTRL* twice, and specify a new grip location.

The wall sweep profile edge is now an arc.

1 **NOTE** After you perform an editing task from the context menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select the profile, and right-click to redisplay the menu.

Moving an edit in-place wall sweep vertex

wall sweep profile in In-Place Edit mode

select Vertex grip

specify new grip location

result

wall sweep in In-Place Edit mode

select Vertex grip

result

Edit the profile:

If you want to ...

change the location of the sweep

change the shape of the perimeter of the profile or its rings

Then ...

select the Insertion Point grip, and move it to the desired position.

select the profile, and use grips to adjust the shape. The Edge grip has 3 edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.

If you want to ...	Then ...
add vertices to the profile	<p>Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.</p> <p>Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.</p>
remove vertices from the profile	<p>select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.</p>
replace an existing ring of the profile with new geometry	<p>select the profile, right-click, and click Replace Ring. Select the ring to replace, and select the new geometry. Press <i>ENTER</i> to keep the geometry, or enter <i>n</i> (No) to erase it.</p>
add a ring to the profile to subtract an area from the profile	<p>draw the linework in place on the temporary profile. Select the profile, right-click, and click Add Ring. Select the geometry to define the ring. Press <i>ENTER</i> to keep the geometry, or enter <i>y</i> (Yes) to erase it.</p>
remove a ring from the profile	<p>select the profile, right-click, and click Remove Ring. Select the ring to remove, and press <i>ENTER</i>. This option does not appear if the profile has only one ring.</p>
2 Save or discard the changes:	
If you want to ...	Then ...
restore the sweep to its original shape	<p>click  .</p>
save the changes to the current profile	<p>click  . The sweep uses the edited profile to define its geometry. Any other objects or styles that use this profile are also updated with the edited geometry.</p>
save the changes to a new profile	<p>select the profile, right-click, and click Save as New Profile. Enter a name for the new profile, and click OK. The sweep uses the new profile to define its geometry. Other styles or objects that use the original profile are not affected.</p>

Mitering Walls with Sweeps

Use this procedure to miter intersecting walls whose shape is defined by a wall sweep.

NOTE If you miter the end of walls, no endcaps are drawn.

- 1 Select a wall with a sweep that you want to miter, right-click, and click Sweeps ► Miter.
- 2 Select the second wall.
To adjust the angles of the mitered walls, see [Managing Wall Sweeps](#) on page 857.

Managing Wall Sweeps

Use this procedure to edit or remove a wall sweep from an individual wall. You can change the component the sweep is applied to. You can also change the miter angles at each end of the sweep and the offsets in the wall.

- 1 Double-click the wall you want to change.
- 2 On the Properties palette, expand Advanced, and expand Worksheets.
- 3 Select the setting for Sweeps.
- 4 Select a wall sweep, and change its settings:

If you want to ...

Then ...

change the profile used to define the geometry of the sweep

select a different profile for Profile.

apply the sweep to a different wall component

select a different component for Component.

change the miter angles at each end of the wall

enter different values for Start Miter and End Miter.

offset the sweep within the wall

enter a value for Offset Within.

vertically offset the sweep

enter a value for Offset Vertical.

delete the sweep from the wall component

click  .

-
- 5 Click OK.

Working with Wall Modifiers

Wall modifiers (also called plan modifiers) use the 2-dimensional (2D) geometry of an open polyline to customize the shape of a wall or a wall component. To use wall modifiers, you draw a polyline in the shape you need and create a wall modifier style from the polyline. You can then add wall modifiers of that style to any wall. A wall can have more than one wall modifier attached to it.

Placing a Wall Modifier on a Wall

You specify the placement of a wall modifier, including its vertical and horizontal position and its depth. The wall modifier can be added at the drawn size of the polyline or scaled to a specific size. The wall modifier is then extruded vertically along the wall surface.

You can add the wall modifier to one or both sides of the wall. When you select the face, you can also offset the wall modifier from the opposite face to create a bump-out, such as for pipe chases or interior columns.

Applying wall modifiers to a wall

Editing a Wall Modifier

After placing a wall modifier, you can adjust its placement, or assign the modifier to a different wall component. You can also edit the geometry of the wall modifier, and save the changes to the current wall modifier style or to a new style.

Display Properties and Materials for Wall Modifiers

Wall modifiers take on the material assignment and the display properties of the wall component they are assigned to. This allows you to use the same wall modifier on different types of walls.

Wall Modifier Styles

You save the geometry of a wall modifier as a wall modifier style. You can create the style when you add the wall modifier to a wall. You can also create a wall modifier first and then apply it to walls as needed.

To create, edit, copy, or purge wall modifier styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture to work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Converting a Polyline to a Wall Modifier

Use this procedure to create a wall modifier from an open polyline. You can draw the polyline in the location for the wall modifier, or you can project the modifier you create to the wall. The polyline cannot be closed.

The wall modifier you create is added to the selected wall and is also saved as a wall modifier style that you can apply to other walls.

Converting a polyline to a wall modifier

- 1 Draw the polyline in the shape of the wall modifier.
- 2 Select a wall to which you want to apply a wall modifier, right-click, and click Plan Modifiers ► Convert Polyline to Wall Modifier.
- 3 Select the polyline.
- 4 Enter **y** (Yes) to erase the selected polyline, or enter **n** (No) to keep the polyline in the drawing.
- 5 Enter a name for the wall modifier style created from the polyline, and click OK.
- 6 Select the wall component to which the wall modifier applies.
- 7 To offset the opposite face of the selected component in the shape of the wall modifier, select Offset Opposite Face.
- 8 Specify the vertical position of the modifier on the wall component:

If you want to ...

Then ...

specify the beginning height of the wall modifier

enter a value for Start Elevation Offset, and specify whether the offset occurs from the wall top, the wall base height, the wall baseline, or the wall bottom.

specifying the ending height of the wall modifier

enter a value for End Elevation Offset, and specify whether the offset occurs from the wall top, the wall base height, the wall baseline, or the wall bottom.

Enter a negative offset value to specify a location toward the ground.

Placing a wall modifier offset from the wall start point, the wall bottom, and the wall top

9 Click OK.

Adding an Existing Wall Modifier to a Wall

Use this procedure to add a wall modifier of an existing wall modifier style to a wall. You can apply the modifier to one or both sides of the wall or the component. The left and right sides of the wall are determined from the start and endpoints of the wall.

Placing a wall modifier offset from the wall start point, the wall bottom, and the wall top

1 Select the wall to which you want to apply a wall modifier, right-click, and click Plan Modifiers ► Add.

2 Select the start point for the wall modifier.

After you select the first point, a temporary line is displayed to show you the length of the modifier.

3 Select the endpoint for the modifier.

- 4 Select the side of the wall to draw the modifier.
- 5 Enter the depth for the wall modifier.
- 6 Select the wall modifier style.
- 7 Select the name of the component to apply the modifier to.
- 8 To offset the opposite face of the selected component in the shape of the wall modifier, select Offset Opposite Face.

Offsetting a wall modifier from the opposite face of a wall component

- 9 Specify the vertical position of the modifier on the wall component:

If you want to ...

Then ...

specify the beginning height of the wall modifier

enter a value for Start Elevation Offset, and specify whether the offset occurs from the wall top, the wall base height, the wall baseline, or the wall bottom.

specifying the ending height of the wall modifier

enter a value for End Elevation Offset, and specify whether the offset occurs from the wall top, the wall base height, the wall baseline, or the wall bottom.

Enter a negative offset value to specify a location toward the ground.

- 10 Click OK.

After you add a wall modifier, you can edit its geometry or adjust its placement.

Editing the Geometry of a Wall Modifier

Use this procedure to edit the geometry of a wall modifier that is applied to a wall. You can edit the vertices and edges of the wall modifier or replace the geometry with that of another polyline. You can save the changes to the current wall modifier style or to a new style.

To move a wall modifier horizontally or change the vertical offsets of a wall modifier, see [Changing the Horizontal and Vertical Offsets of a Wall Modifier](#) on page 863.

- 1 Select the wall that has the wall modifier you want to change, right-click, and click Plan Modifiers ► Edit in Place.
- 2 If prompted that the modifier is not drawn to size, click Yes.

A temporary profile is created for you to edit the geometry of the wall modifier. If the wall contains multiple wall modifiers, a profile is created for each wall modifier.

3 NOTE After you perform an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select a profile, and right-click to redisplay the menu.

Edit the profile:

If you want to ...	Then ...
change the shape of the perimeter of the profile	select the profile, and use grips to adjust the shape.
hide one or more edges of the profile (plan view only)	select the profile, right-click, and click Hide Edge. Select the edges you want to hide, and press <i>ENTER</i> .
display an edge that you hid	select the profile, right-click, and click Show Edges. Select the edges you want to show, and press <i>ENTER</i> .
add vertices to the profile	select the profile, right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .
remove vertices from the profile	select the profile, right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .
replace a profile with new geometry	select the profile, right-click, and click Replace Modifier. Select the modifier to replace, and select a polyline to define the new geometry. Press <i>ENTER</i> to keep the polyline in the drawing, or enter y (Yes) to erase it. The start and endpoints of the new polyline must be the same as those for the original wall modifier.
remove a wall modifier	select the profile, right-click, and click Remove Modifier. If the wall has multiple wall modifiers, select the wall modifier to remove, and press <i>ENTER</i> .

4 Save or discard the changes:

If you want to ...	Then ...
restore the wall modifier to its original shape	select the profile, and click  .
save the changes to the current wall modifier style	select the profile, and click  . The wall modifier and the wall modifier style use the edited profile to define its geometry. Any other walls that use this wall modifier style are also updated with the edited geometry.
save the changes to a new wall modifier style	select the profile, right-click, and click Save as New Wall Modifier Style. Enter a name for the new wall modifier, and click OK. The wall modifier uses the new

If you want to ...	Then ...
	style to define its geometry. Other walls that use the original style are not affected.

Changing the Horizontal and Vertical Offsets of a Wall Modifier

Use this procedure to change the horizontal position of a wall modifier applied to a wall, or to change its vertical position on a wall.

1 Select the wall that has the wall modifier you want to change, right-click, and click Plan Modifiers ► Edit in Place.

2 If prompted that the modifier is not drawn to size, click Yes.

A temporary profile is created for you to edit the geometry of the wall modifier. If the wall contains multiple wall modifiers, a profile is created for each wall modifier.

NOTE After you perform an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select a profile, and right-click to redisplay the menu.

3 Change the placement of the wall modifier:

If you want to ...	Then ...
move the wall modifier horizontally along the wall	select the Move grip, and move the grip to reposition the wall modifier. After you select the grip, you can also enter a value to move the wall modifier a specified distance.
position the wall modifier relative to the top of the wall	select an isometric view. Select the Offset from top of wall grip, and move the grip to reposition the wall modifier. After you select the grip, you can also enter a value to move the wall modifier a specified distance from the top of the wall.
position the wall modifier relative to the bottom of the wall	select an isometric view. Select the Offset from bottom of wall grip, and move the grip to reposition the wall modifier. After you select the grip, you can also enter a value to move the wall modifier a specified distance from the bottom of the wall.

4 If necessary, continue editing the wall modifier as described in [Editing the Geometry of a Wall Modifier](#) on page 861.

5 Save or discard the changes:

If you want to ...	Then ...
restore the wall modifier to its original position	select the profile, and click  .

If you want to ...**Then ...**

save the changes to the current wall modifier style

 select the profile, and click . The wall modifier and the wall modifier style use the edited profile to define its geometry. Any other walls that use this wall modifier style are also updated with the edited geometry.

save the changes to a new wall modifier style

select the profile, right-click, and click Save as New Wall Modifier Style. Enter a name for the new wall modifier, and click OK. The wall modifier uses the new style to define its geometry. Other walls that use the original style are not affected.

Adjusting the Placement of a Wall Modifier

Use this procedure to adjust the placement of a wall modifier that you added to a wall. You can also add or remove wall modifiers using this procedure. You can also graphically adjust the placement of a wall modifier. For more information, see [Changing the Horizontal and Vertical Offsets of a Wall Modifier](#) on page 863.

To edit the shape of a wall modifier, see [Editing the Geometry of a Wall Modifier](#) on page 861.

Placing a wall modifier offset from the wall start point, the wall bottom, and the wall top

- 1 Double-click the wall that has the modifier you want to change.
- 2 On the Properties palette, expand Advanced, and expand Worksheets.
- 3 Select the setting for Plan Modifiers.
- 4 Under Style, select the wall modifier you want to change.
- 5 If needed, select a different modifier style or component name, and specify which sides to apply the modifier to.
- 6 Enter a value for Start Position Offset and specify whether the offset occurs from the wall start point, the wall endpoint, or the midpoint of the wall.

These settings specify the start point of the modifier along the length of the wall. You can enter a negative value to specify an offset in the reverse wall direction.

7 Edit the vertical position of the modifier on the wall component:

If you want to ...	Then ...
specify the beginning height of the wall modifier	enter a value for Start Elevation Offset, and specify whether the offset occurs from the wall top, the wall base height, the wall baseline, or the wall bottom.
specifying the ending height of the wall modifier	enter a value for End Elevation Offset, and specify whether the offset occurs from the wall top, the wall base height, the wall baseline, or the wall bottom.

Enter a negative offset value to specify a location toward the ground.

8 Edit settings to control the size and placement of the modifier:

If you want to ...	Then ...
place the modifier at the size it was defined in the modifier style	select Use Drawn Size.
specify the length and the depth of the modifier on the wall	clear Use Drawn Size, and enter values for Length and Depth.
mirror the modifier in the X direction	select Mirror X.
mirror the modifier in the Y direction	select Mirror Y.
measure the modifier to the center of the wall	select Measure to Center.

9 To remove a modifier, select the modifier, and click .

10 Click OK.

Removing Wall Modifiers

Use this procedure to remove a wall modifier from an individual wall or a wall component.

NOTE If you offset the modifier to the opposite face of the wall or the wall component when you applied the modifier, you must remove the wall modifier from each face.

- 1** Select the wall that has the wall modifier you want to remove, right-click, and click Plan Modifiers ► Remove.
- 2** Select the modifier.
- 3** Enter **y** (Yes) to create a polyline in the shape of the modifier, or enter **n** if you do not want to create a polyline.

Creating a Wall Modifier Style

Use this procedure to create a wall modifier style from a polyline. The shape of the polyline defines the shape of the wall modifier. After you create the style, you can add it to a wall or a component of a wall. To create a wall modifier style and apply it to a wall at the same time, see [Converting a Polyline to a Wall Modifier](#) on page 858.

To edit a wall modifier style, add the wall modifier to a wall, and then edit the geometry of the wall modifier. For more information, see [Adding an Existing Wall Modifier to a Wall](#) on page 860 and [Editing the Geometry of a Wall Modifier](#) on page 861.

- 1 Draw an open polyline in the shape you want to use for the wall modifier.
- 2 Click Format menu ► Style Manager.
- 3 Expand Architectural Objects.
- 4 Right-click Wall Modifier Styles, and click New.
- 5 Enter a name for the new style.
- 6 Right-click the new style, and click Set From.
- 7 Select the polyline.
- 8 Click OK.

Attaching Notes or Files to a Wall Modifier Style

Use this procedure to enter notes and attach reference files to a wall modifier style. You can also edit notes and edit or detach reference files attached to the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Wall Modifier Styles.
- 3 Select the wall modifier style that you want to change.
- 4 Click the General tab.
- 5 To add a description to the style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 9 Click OK twice.

Working with Body Modifiers

Body modifiers use the 3-dimensional (3D) geometry of an object, such as a mass element or a mass group, to add to, subtract from, or completely replace one component in a wall. If the wall has only one component, the body modifier applies to the entire wall. If the wall has multiple components, the modifier applies only to the component that you specify.

If you add the body modifier to a wall component, or use a body modifier to replace the component, the body modifier uses the material assignment and display properties of the wall component.

After you create a body modifier from an object, you can delete the original object. However, if you have created a complex object, such as a mass group comprising many mass elements, you may want to retain the object in the drawing until you are sure you have the results you want for the wall.

Adding a Body Modifier to a Wall

Use this procedure to create a body modifier and add it to a wall. You can apply the modifier to a single-component wall, or to a component in a multi-component wall.

You can create a 3-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

Adding a body modifier to a wall component

- 1 Place the object in the location where you want to add the body modifier to the wall.
- 2 Select the wall to which you want to add the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to add to the wall.
- 4 Select the wall component to add the object to.
- 5 Select Additive or Additive Cut Openings for Operation.
- 6 Enter a description for the body modifier.
- 7 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 8 Click OK.

Subtracting a Body Modifier from a Wall

Use this procedure to create a 3-dimensional (3D) body modifier and subtract it from a wall. You can apply the modifier to a single-component wall, or to a component in a multi-component wall.

You can create a body modifier from a mass element, a mass group, or any other AEC object with mass. You must place the object in the location you want in the drawing before defining the object as a body modifier.

Subtracting a body modifier from a wall component

- 1 Place the object in the location where you want to subtract the body modifier from the wall.
- 2 Select the wall to which you want to add the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to subtract from the wall.
- 4 Select the wall component to subtract the object from.
- 5 Select Subtractive for Operation.
- 6 Enter a description for the body modifier.
- 7 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 8 Click OK.

Replacing a Wall with a Body Modifier

Use this procedure to create a 3-dimensional (3D) body modifier and replace a wall or a wall component with the modifier. You can apply the modifier to a single-component wall, or to a selected component in a multi-component wall.

You can create a 3D body modifier from a mass element, a mass group, or any other AEC object with mass. You must place the object in the location you want in the drawing before defining the object as a body modifier.

Replacing a wall component with a body modifier

- 1 Place the object in the location where you want to replace the wall with the body modifier.
- 2 Select the wall to which you want to replace with the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to replace the wall or wall component.
- 4 Select the wall component you want the object to replace.
- 5 Select Replace for Operation.
- 6 Enter a description for the body modifier.
- 7 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 8 Click OK.

Editing the Geometry of a Body Modifier

Use this procedure to edit the shape of a body modifier that is attached to a wall. You can edit the body using grips to edit faces, using Boolean commands to add or remove other objects from the body modifier, and other editing commands to change its shape.

- 1 Select the wall that has the body modifier you want to change, right-click, and click Body Modifiers ► Edit in Place.

A temporary mass element is created for you to edit the geometry of the body modifier. If the wall contains multiple body modifiers, a mass element is created for each body modifier. If object was not originally a mass element (for example, if you used a slab as a body modifier), the object becomes a temporary Free Form mass element with faces that you can edit.

NOTE After you perform an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select a profile, and right-click to redisplay the menu.

- 2 Edit the body modifier:

If you want to ...	Then ...
--------------------	----------

change the shape of a body modifier that is a Free Form mass element

select the body modifier. Select a Face grip to activate edge grips for the face. Move the grips to the desired

If you want to ...	Then ...
change the shape of a body modifier that is a conventional mass element	locations. Continue editing other faces in the same manner. select the body modifier. Select grips and move them to change the shape of the body modifier. The grips that are available depend on the type of mass element used as a body modifier and the current view direction.
add an object to a body modifier	place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Union. Select the object, and press <i>ENTER</i> . Enter <i>y</i> (Yes) to keep the object in the drawing, or press <i>ENTER</i> to erase it.
subtract an object from a body modifier	place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Subtract. Select the object, and press <i>ENTER</i> . Enter <i>y</i> (Yes) to keep the object in the drawing, or press <i>ENTER</i> to erase it.
create a body modifier that is the intersection of the original body modifier with another object	place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Intersect. Select the object, and press <i>ENTER</i> . Enter <i>y</i> (Yes) to keep the object in the drawing, or press <i>ENTER</i> to erase it.
trim a body modifier	select the body modifier, right-click, and click Trim. Specify the points that define the trim plane, and select the side of the body modifier to be trimmed. The trimmed body modifier is converted to a Free Form mass element.
divide the face of a body modifier into 2 faces	select the body modifier, right-click, and click Split Face. Specify the points that define the edge created by splitting the faces.
join 2 faces that are on the same plane into a single face	select the body modifier, right-click, and click Join Faces. Select the edge that separates the coplanar faces.
remove a body modifier	select the object that forms the body modifier, and press <i>DELETE</i> .
3 Save or discard the changes:	
If you want to ...	Then ...
restore the body modifier to its original shape	select the body modifier, and click  .

If you want to ...	Then ...
save the changes to the body modifier	select the body modifier, and click  . The body modifier uses the edited mass element to define its geometry.

Managing Body Modifiers

Use this procedure to edit or remove 3-dimensional (3D) body modifiers from an individual wall. You can change the component the body modifier is added to and select a different operation. You can also enter or edit the descriptions of body modifiers.

NOTE To remove a body modifier from a wall component and restore the modifier as a mass element that you can edit or apply to other walls, see [Restoring a Body Modifier to a Mass Element](#) on page 871.

- 1 Double-click the wall you want to change.
- 2 Expand Advanced, and expand Worksheets.
- 3 Click the setting for Body modifiers.
- 4 Select a body modifier, and change its settings:

If you want to ...	Then ...
apply the body modifier to a different wall component	select a different component for Component.
change the operation used to apply the body modifier to the wall	select a different operation for Operation: <ul style="list-style-type: none"> ■ Select Additive or Additive Cut Openings to add the body modifier to the wall component. ■ Select Subtract to subtract the shape of the body modifier from the wall component. ■ Select Replace to replace the wall component with the body modifier.
delete the body modifier from the wall component	select the body modifier, and click  .
enter a description of the body modifier	click Description, enter text, and press <i>ENTER</i> .

- 5 Click OK.

Restoring a Body Modifier to a Mass Element

Use this procedure to remove a body modifier from a wall and add it to the drawing as a mass element. Restoring a body modifier to a mass element allows you to modify the shape as a mass element and then add it to the wall again as a body modifier. You can also restore the body modifier to a mass element while leaving the body modifier still applied to the wall. This is useful if you want to create other walls with the same shape.

If the object used to create the body modifier was a conventional mass element, it is restored to that mass element. For example, a Gable mass element is restored as a Gable mass element. However, if the body modifier was created from another object, such as a slab, or was edited using Boolean operations or face editing commands, the body modifier is restored as a Free Form mass element.

1 Select the walls you want to change, right-click, and click Body Modifiers ► Restore.

2 **NOTE** This procedure restores all body modifiers attached to a wall.

Create mass elements from the body modifiers:

If you want to ...

Then ...

create mass elements from the body modifiers while keeping the body modifiers attached to the wall

press *ENTER*.

remove *all* body modifiers from the wall, and create mass elements from their shapes

enter *y* (Yes), and press *ENTER*.

Working with Interference Conditions

Interference conditions use the geometry of 3-dimensional (3D) objects to create custom openings or cutouts in walls. You can specify how the interference condition is applied to the shrinkwrapping of a wall: added to the wall, subtracted to the wall, or ignored.

How Interference Conditions Affect the Display of Walls

Unlike wall modifiers and body modifiers, which apply to a selected wall component, interference conditions apply to all wall components that the interfering object touches. The wall stops at the interference condition. The way in which you apply the interference condition to the wall determines how the shrinkwrapping of the wall is affected by the condition in plan view:

- Add the interference condition to include the condition in the shrinkwrapping.

- Subtract the interference condition to exclude the object from the shrinkwrapping.

- Ignore the interference condition to draw the shrinkwrapping as if the object were not there. You also use the ignore option to add interference conditions applied to one wall to subsequent walls.

In model views, the interference condition is always subtractive, regardless of the shrinkwrapping option you selected.

Editing Interference Conditions

When you edit the object that acts as the interference condition, the wall changes to accommodate the changes to the geometry of the object. For example, you can move the interfering object to change its location on the wall. Moving the object off the wall does not remove the interference condition for the object.

You can also change how interference conditions are applied to a wall, and you can delete interference conditions.

Adding an Interference Condition

Use this procedure to place objects, such as mass elements, in walls to create custom openings or cutouts in the wall. An example is a column grid structure where columns are connected by walls.

When you define the interference condition, you specify how the wall shrinkwrapping in plan views is affected by the interfering object. You can specify that the object be added to the wall, subtracted from it, or ignored. The option you select affects the wall only in plan views. In model display representations, interference is always subtracted from a wall, regardless of the option you select in this procedure.

NOTE If you want to apply the same object as the interference condition for multiple walls, such as walls that meet at a corner, use the ignore option for subsequent walls after the first wall. In plan views, the effect is additive for all the walls to which you apply the interference condition.

The shrinkwrap display component must be turned on in the display properties of the wall or the wall style for interference to be visible. In most sample wall styles provided with AutoCAD Architecture, shrinkwrap is turned on in plan display representations. For more information about specifying shrinkwrapping for a wall style, see [Specifying the Display Properties of a Wall Style](#) on page 889.

- 1 Place the object in the location where you want to specify the interference condition.
- 2 Select the wall you want to add an interference to, right-click, and click Interference Condition ► Add.
- 3 Select the object intersecting the wall, and press *ENTER*.
- 4 Specify how shrinkwrapping in plan view is applied to the interference condition:

If you want to ...	Then ...
add the interference condition to the shrinkwrapping	enter a (Additive).
take the object shape out of the shrinkwrapping	enter s (Subtractive).
ignore the object when shrinkwrapping is applied	enter i (Ignore).

Removing an Interference Condition

Use this procedure to remove an object that was added to a wall as an interference condition.

- 1 Select the walls you want to change, right-click, and click Interference Condition ► Remove.
- 2 Select one or more objects to remove, and press *ENTER*.

- 3 Enter **r** (Remove) to continue removing interference conditions from other walls, or press *ENTER* to end the command.

Managing Wall Interference Conditions

Use this procedure to change the shrinkwrap effect for an interference condition, or to remove an interference condition from a wall.

- 1 Double-click a wall with interference conditions.
- 2 On the Properties palette, expand Advanced, and expand Worksheets.
- 3 Click the setting for Interference conditions.
- 4 Select an interference condition.
- 5 In the Shrinkwrap Effect column, specify the way shrinkwrap is applied to the interference object:

If you want to ...	Then ...
add the interference condition to the shrinkwrapping	select Add.
take the object shape out of the shrinkwrapping	select Subtract.
ignore the object when shrinkwrapping is applied	select Ignore.

- 6 To delete the interference condition, select the condition, and click .
- 7 Click OK.

Wall Styles

Wall styles control the appearance of wall objects. Using wall styles, you can specify dimensions, components, endcaps, materials, and other characteristics to create new types of walls, such as concrete walls, masonry walls, and brick cavity walls. Catalogs provided with AutoCAD Architecture include sample wall styles for common wall types, such as concrete walls with footings or furring, CMU and brick cavity walls, and various stud partition walls.

Wall styles that use various components

Using Materials in Wall Styles

You can use materials to control how walls of each style are displayed in a drawing. You assign materials to the wall components in the style. The components are then displayed using the display properties of the assigned materials.

AutoCAD Architecture provides a large number of predefined materials for common design purposes. You can use these materials, modify them for your project requirements, and define new materials. For more information about materials and how to define them, see [Materials](#) on page 601.

Creating Tools from Wall Styles

You can create a wall tool from any wall style. You can drag the style from the Style Manager onto a tool palette. You can then specify default settings for any walls created from the tool. For more information, see [Creating a Wall Tool](#) on page 788.

Managing Wall Styles

To create, edit, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Creating a Wall Style

Use this procedure to create a wall style. By copying an existing style, you can create a style using default style properties. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Architectural Objects, and expand Wall Styles.

- 3 Create a wall style:

If you want to ...	Then ...
create a style with default properties	right-click Wall Styles, and click New.
create a style from an existing style	right-click the wall style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new wall style, and press *ENTER*.

- 5 Edit the new wall style:

If you want to ...	Then ...
enter a description of the style	click the General tab, and enter a description.
specify the endcap styles used for wall openings and the ends of walls of the style	see Applying a Wall Endcap Style to a Wall Style on page 918.
specify the structural components of the style	see Specifying the Components of a Wall Style on page 876.
specify materials for the components of the style	see Specifying the Materials of a Wall Style on page 886.
specify wall hatching, cut plane properties, and other display properties of the style	see Specifying the Display Properties of a Wall Style on page 889.

If you want to ...	Then ...
add classifications to a wall style	see Adding Classifications to a Wall Style on page 893.
add notes and files to the style	see Attaching Notes and Files to a Wall Style on page 893.

- 6 When you finish specifying the properties of the wall style, click OK.
- 7 If you want to assign the style to a wall tool, drag the style from the Style Manager to a tool palette.
You can later rename the tool and specify other properties for it as described in [Creating a Wall Tool](#) on page 788.
- 8 Click OK.

Adding Property Set Data to a Wall Style

You can add property set data to a wall style. Property set data is necessary if you want to tag a wall in a drawing later or include it in a schedule table. Property set data typically attached to a wall style are automatic properties, like wall height and wall width, or manual properties that are identical for all walls of that style, like the fire rating. For detailed information about property set data, see [Property Set Definitions](#) on page 2542.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style you want to change.
- 4 Click the General tab.
- 5 Click Property Sets.
- 6 Click  .
If the Add Property Set button is deactivated, no property sets for wall styles have been defined.
- 7 Select the property set you want to add to the style, and click OK.
The properties in the set are listed in the Edit Property Set Data worksheet.
- 8 To remove a property set from a style, click  , clear the property set from the list, and click OK.
- 9 Click OK.

Specifying the Components of a Wall Style

Wall components are the physical structures of the components of a wall, such as concrete, CMU, studs, GWB, insulation, and air gaps.

Wall Components and Their Properties

Each component in a wall style corresponds to a structural component of a wall or a wall material, including air gaps in cavity walls. When you create a wall component, you specify the following characteristics of the component:

- The component name, which usually identifies the material used, such as brick, concrete, CMU, or insulation
- The component cleanup priority, which determines how the component cleans up with the components of intersecting walls
- The width (thickness) of the component
- The vertical offset of the component at the bottom and the top of the wall
- The position of the component within the wall, relative to the baseline of the wall and adjacent wall components
- The function of the component within the wall. Possible functions are structural and non-structural components.
- The position of dimension points on the component. Wall components can be dimensioned to the left and right edges and to the component center.

Using Components from Other Wall Styles

In addition to creating a wall component by specifying its individual properties, you can also copy components from other wall styles into a wall style. The Wall Component Browser is a utility that lets you view the components of other wall styles and copy components into the wall style you are editing.

Dimensioning Wall Components

Each wall component can be dimensioned separately. In the wall style, you define the settings for the dimensioning of the components. A wall component can be dimensioned to its left and right edges, or to its center.

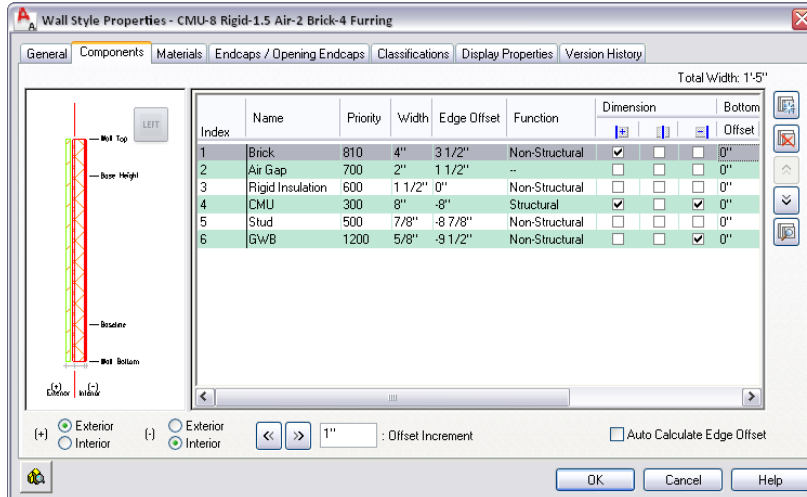

Wall components can be assigned a structural or non-structural function. When the wall is dimensioned, you can choose to dimension all components, or only structural components.

NOTE Additional settings for dimensioning wall components can be set in the AEC dimension style. Here, you can dimension a multi-component wall to its entire width and to the overall wall center. For more information, see [Dimension Points for Walls](#) on page 2247 and [Specifying Object Dimension Points in AEC Dimension Styles](#) on page 2293.

Components Tab

The Components tab of the Wall Styles dialog lets you view wall components as you specify them.

Specifying the properties of wall components

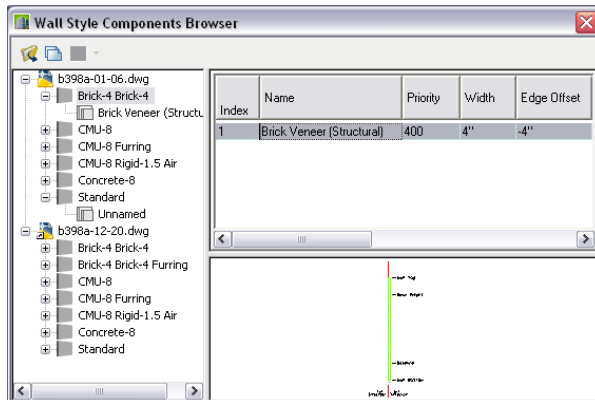

Use the features of the Components tab for the following tasks:

- Add, remove, and edit the properties of wall components for wall style.
- View the components as you specify them.
- Change the order of components relative to other components in the wall style.
- Access the Wall Style Components Browser, which lets you view and copy components from other wall styles in the current drawing and in other drawings.

Wall Style Components Browser

The Wall Style Components Browser is a utility that lets you view and copy wall components from wall styles in the current drawing and in other drawings. You can copy components from these styles to the current wall style. After you add them to the wall style, you can change their properties as needed for the style you are editing.

Viewing wall components from multiple styles and drawings

The Wall Style Components Browser has the following features:

Use this feature ...

To ...

icons

open other drawings, copy wall components, and change the view options for the right pane of the browser.

Use this feature ...**To ...**

tree structure in the left pane of the browser

expand wall styles to view the list of components in the style. Select a wall style in the left pane to view the properties of its components and see the wall style in the right pane. You can use the context menu to copy an individual component or all components of a selected style. You can then paste the component(s) in the style you are editing.

right pane of the browser

view the component properties of a selected style, and preview the style in the viewer area of the pane.

Default Cleanup Priorities of Wall Components

The component priority determines how each wall component cleans up with the components of an intersecting wall. The lower the component index number, the higher the priority of the component when it intersects other walls.

Wall cleanup priorities

wall components and priorities

resulting wall component cleanup

The following table lists the default cleanup priority for components used in sample wall styles provided in AutoCAD Architecture catalogs. You can assign different priorities to wall components in wall styles and individual walls to control cleanup with other walls.

Component	Index
Air Gap	700
Air Gap (Brick/Brick)	805

Component	Index
Air Gap (CMU/CMU)	305
Air Gap (Stud/Stud)	505
Brick	800
Brick Veneer	810
Bulkhead	1800
Casework - Backsplash	2030
Casework - Base	2010
Casework - Counter	2020
Casework - Upper	2000
CMU	300
CMU Veneer	350
Concrete	200
Concrete (Footing)	200
Glass	1200
GWB	1200
GWB (X)	1200,1210,1220,1230
Insulation (CMU/Brick, Stud/Brick)	600
Metal Panel	1000
Precast Panel	400
Rigid Insulation (Brick)	404
Siding	900
Stucco	1100
Stud	500

Component	Index
Toilet Partition	3000

Creating or Editing a Component in a Wall Style

Use this procedure to create a wall component, or to edit existing wall components in a wall style.

You can also add components to a wall style by copying them from other wall styles. For more information, see [Adding a Component from Another Wall Style](#) on page 882.

NOTE Only the first 20 components of a wall style are controlled by the display system. Although you can specify more than 20 components in a wall style, it is suggested that you limit the number of components to 20. Components 21 and higher are controlled by material assignment only.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Components tab.

- 5 Click .
- 6 Enter a name for the new component.
- 7 Enter the cleanup priority for the component when walls intersect.

The lower the priority number, the higher the priority of the component when it intersects with the components of other walls. For more information, see [Default Cleanup Priorities of Wall Components](#) on page 879.

- 8 Specify the width of the component:

If you want to ...

Then ...

specify a fixed width that cannot be edited when you add or edit walls of this style

enter a value for Width.

specify a variable width that can be edited when you add or edit walls of this style

select the setting for Width. Enter a formula that defines how the component width is calculated. For more information, see [Specifying the Width and Edge Offset of a Wall Component](#) on page 925.

Adding the first wall component

9 Specify the edge offset, which is the offset of the exterior edge of the component from the baseline:

If you want to ...

Then ...

graphically specify the offset

select the component, select  or  to offset the component by an increment that you specify. The viewer shows the position of the wall component as you click the icons. The selected component is highlighted in green.

let the software calculate the offset

select Auto Calculate Edge Offset.

specify a fixed offset

enter a value for Edge Offset.

specify a variable offset that is calculated from values that you specify

select the setting for Edge Offset. Enter a formula that defines how the edge offset is calculated for this component. For more information, see [Specifying the Width and Edge Offset of a Wall Component](#) on page 925.

10 To specify the top elevation offset or bottom elevation offset, enter a new value, and select from where the distance is to be measured: Wall Top, Base Height, Baseline, or Wall Bottom.

NOTE Do not define wall components with elevation offsets that are above Wall Top or below Wall Bottom. Walls that have components that are defined this way do not clean up correctly and may not be displayed correctly if you edit their roof line or floor line. To avoid cleanup and display problems, you can define wall components with elevation offsets that are above Base Height or below Baseline.

11 Repeat steps 5 through 10 to add more components to the wall style.

Adding the second wall component

12 To change the order of components in the wall style, select a wall component, and click  or  to move the component to the desired position relative to the other wall components.

13 Click OK.

Adding a Component from Another Wall Style

Use this procedure to copy one or more wall components from another wall style into the wall style you are editing.

NOTE Only the first 20 components of a wall style are controlled by the display system. Although you can specify more than 20 components in a wall style, it is suggested that you limit the number of components to 20. Components 21 and higher are controlled by material assignment only.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Components tab.

5 Click  .

The Wall Style Components Browser lists the wall styles and their components in the current drawing.

6 Locate the wall components you want to copy:

If you want to ...

Then ...

view the wall components for wall styles in the current drawing

in the left pane, select a wall style. The right pane lists the components and their properties and displays the style in the viewer.

view the wall components in wall styles in other drawings

click  . Navigate to the drawing you want, and click Open. In the left pane, select a wall style.

close a drawing that you opened in the browser

select the drawing name, right-click, and click Close. You cannot close the current drawing.

For more information about the information shown in the Wall Styles Component Browser, see [Specifying the Components of a Wall Style](#) on page 876.

7 Copy wall components, and add them to the wall style you are editing:

If you want to ...

Then ...

copy all components in a wall style

select the wall style, and drag the style to the list of components in the Wall Styles Properties dialog. All the components are added to the wall style.

copy an individual wall component

select the wall component, and drag the component to the list of components in the Wall Styles Properties dialog. The component you selected is added to the wall style.

8 Click  to close the Wall Style Components Browser.

9 After you copy wall components to the current wall style, you can edit or delete the new components as needed.

For more information, see [Creating or Editing a Component in a Wall Style](#) on page 881.

10 Click OK.

Defining the Dimension Settings for Wall Components

You have various options for dimensioning individual wall components. In the wall style, you can define the dimension settings for each individual wall component. Each component can be dimensioned to one or both of its edges, as well as to the component center. You also can select to not dimension a specific component at all.

- **Component side to dimension:** In the wall style, you can define for each wall component whether it should be dimensioned to its positive or negative side, or to the center of the component. The positive and negative sides of a wall are determined by the direction in which the wall is drawn: if you draw a wall from left to right, the positive side is the left (top). If you draw a wall from the right side to the left, then the positive side is the right (bottom). If you determine that a wall component is only dimensioned to one side, you can select either the positive or negative side of the wall

Dimensioning Component Center

Dimensioning One Component Edge

Dimensioning Both Component Edges

- **Structural Function:** You can define a wall component as structural or non-structural. When you set up the AEC dimension style you can define that only structural wall components, or all wall components should be dimensioned.

Dimensioning Structural Components

Dimensioning All Components

Alternatively, you can select to dimension a multi-component wall not to each individual component, but to the overall wall width or the overall wall center. You set these points in the AEC dimension style, as described in [Specifying Object Dimension Points in AEC Dimension Styles](#) on page 2293.

In the AEC dimension style you can define the following additional or overriding settings for dimensioning wall components:

- **By Style:** the dimension points selected in the wall style are used to dimension the wall components width.
- **Structural by Style:** the dimension points specified for the structural components of the wall style are used.
- **Overall:** the overall width of the wall is dimensioned.

- Center: the center of the wall is dimensioned.

Dimensioning Overall Wall Width

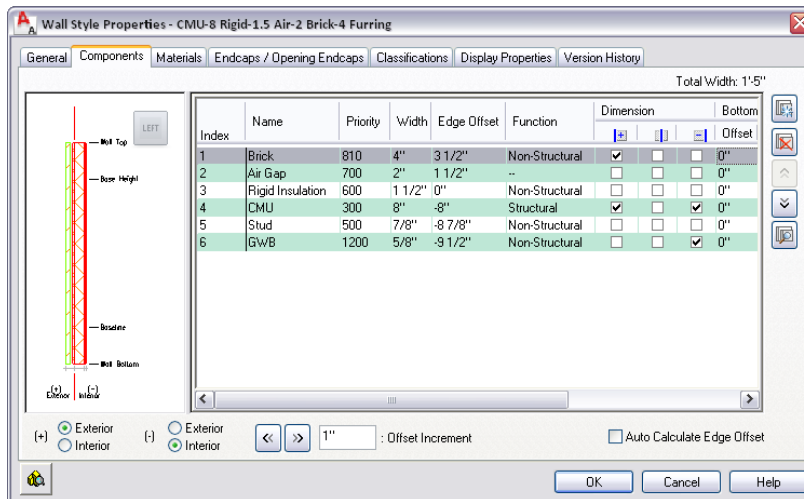

Dimensioning All Wall Components

Dimensioning Wall Center

Defining the dimensioning of components

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Components tab.
- 5 Define if the positive and negative sides of the wall should be an interior or exterior wall side by selecting Interior or Exterior for (+) and (-).
- 6 To define an offset for a wall component, select the component in the list view, and enter a value for Offset Increment.
Alternatively, you can use the arrow keys.
- 7 Under Function, select if the component is a structural component or a non-structural one.
This distinction is important when creating a dimension style for a multi-component wall, as you can define in the dimension style that it only dimensions structural components.
You can also leave the component function as unspecified.
- 8 To specify the dimension settings for a wall component, verify that the component is selected in the list view.

NOTE The component selected is highlighted in the graphic on the left.

9 Under Dimension, select if the component should be dimensioned to one side, to both sides, or to the center of the component.

■ To dimension the component only to one side check the mark under  or  depending on whether you want to dimension the component to the left or right side.

■ If you want to dimension the component to both sides, check both marks for  and .

■ If you want to dimension the component to its center, check the mark for .

10 Click OK to finish setting up component dimensioning in the wall style.

For information on creating a dimension style for wall components, see [Specifying Object Dimension Points in AEC Dimension Styles](#) on page 2293.

Removing a Component from a Wall Style

Use this procedure to delete a component from a wall style. When you remove a component from a wall style, the component is also removed from all existing walls that use this style.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Components tab.

- 5 Select the wall component you want to remove, and click .
- 6 Click OK.

Specifying the Materials of a Wall Style

A wall consists of a number of components whose display properties can be determined by the materials assigned to each component. When you assign materials to a wall style, you assign one material to each physical component of the wall. For example, you assign a wood or metal material to studs, concrete to a concrete component, and so on. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the wall style, instead of using material display properties, you can turn off the material assignments in the display properties of the wall style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in 3-dimensional (3D) model views and in elevations.

Wall Materials and Display Components

The following table identifies the material component that corresponds to each wall component.

Wall Component	Material Component
Plan, Plan Low Detail, Plan High Detail, Plan Presentation, Plan Screened	
Below Cut Plane	No Material
Above Cut Plane	No Material
Shrink Wrap	2D Linework
Shrink Wrap Hatch	Plan Hatch
Boundary 1 - 20	Plan Linework
Hatch 1 - 20	Plan Hatch
Reflected, Reflected Screened	
Below Cut Plane	No Material
Above Cut Plane	No Material
Shrink Wrap	2D Linework
Shrink Wrap Hatch	Plan Hatch
Boundary 1 - 20	Plan Linework
Hatch 1 - 20	Plan Hatch
Model, Model High Detail, Model Low Detail	
Shrinkwrap Body	3D Body
Boundary 1 - 20	3D Body
Sketch	
Baseline	No Material
Marker	No Material
Center Line	No Material

Wall Component	Material Component
Graph	
Radius	No Material
Edge	No Material

Assigning Materials to a Wall Style

Use this procedure to assign materials to the individual components of a wall style. When you assign a material to a wall component, the component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the wall. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, all structural components, such as brick and other masonry, studs, insulation, and air gaps, are physical components that you can assign materials.

NOTE If a material assignment does not determine the display properties of a wall component, you can change the display properties of the wall style as described in [Specifying the Display Properties of a Wall Style](#) on page 889.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog, any changes you make to the material definition apply to all objects that are assigned the material.

- 11 Click OK.

Specifying the Display Properties of a Wall Style

In most cases, you can assign materials to wall components so that the appearance of walls that belong to the same style is consistent throughout a drawing and with other walls and objects that use the same materials.

If a component cannot be assigned a material, or if you do not want to use materials but still want consistency among walls of the same style, you can specify the display properties of the wall components in the wall style:

- The layer, color, and linetype of wall components
- The hatching used with each component
- The cut plane height and the display of components relative to the cut plane
- Other specific wall display information, such as whether complex endcaps are displayed and whether the wall is cut around door and window frames

Specifying the Layer, Color, and Linetype of a Wall Style

Use this procedure to change the following display properties of the components of a wall style:

- Visibility (component is on or off)
- By material (material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

To change these display properties for an individual wall, see [Changing the Display Properties of Individual Walls](#) on page 824.

NOTE If a material assignment determines the display properties of components in the wall style, you can change the properties of the display component by clearing By Material. You can also override the material assignment with a different material. For more information, see [Assigning Materials to a Wall Style](#) on page 888.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Specifying the Hatching for Components of a Wall Style

Use this procedure to specify the hatching of the components of a wall style. Wall hatching is displayed only in display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

6 If necessary, click .

- 7 Click the Hatching tab.
- 8 Select a component, and click the setting for Pattern.
- 9 Select the hatching for the component:

If you want to ...	Then ...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

- 10 Click OK.
- 11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.
- 12 Click Angle, and enter the angle for the selected pattern.
- 13 Click Orientation, and specify how the hatching is oriented:

If you want to ...	Then ...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

- 14 Click OK.

Specifying the Cut Plane Display of a Wall Style

Use this procedure to specify the properties of one or more cut planes for a wall style. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

To better visualize the elements of a wall in plan view, you can create cut planes. The main cut plane is where the shrinkwrap and hatching are applied. The plan display shows the components and objects in the wall as they are displayed at the height of each cut plane.

The cut plane settings you specify in the wall style override the cut plane settings in any display configuration applied to a viewport. When you add doors, windows, openings, or door/window assemblies to a wall, you can specify in the display properties of those objects or their styles whether they respect the cut plane of the wall or of the display configuration.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Cut Plane tab.
- 8 Select Override Display Configuration Cut Plane.
- 9 To specify the cut plane where shrinkwrap, component boundaries, and hatching take effect, enter a value for Cut Plane Height.
- 10 Select Automatically Choose Above and Below Cut Plane Heights to show the components above and below the cut plane height.
- 11 To specifically define a cut plane, select Manual Above and Below Cut Plane Heights, click Add, and enter the height of the new cut plane.

If you add a cut plane ...	Then ...
at a height that is lower than the value for Cut Plane Height	objects are displayed using the properties specified for the Below Cut Plane component on the Layer/Color/Linetype tab.
at a height that is higher than the value for Cut Plane Height	objects are displayed using the properties specified for the Above Cut Plane component on the Layer/Color/Linetype tab.

You can click Remove to delete a cut plane that you added.

- 12 Click OK.

Specifying the Display of Other Characteristics of a Wall Style

Use this procedure to specify other display properties for the wall style, such as whether to display complex endcaps, to show door and window frames, or whether to show the miter of specific wall components. These display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Open a tool palette that has a wall tool.

- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

6 If necessary, click  .

7 Click the Other tab.

8 Select the display properties for the wall style:

If you want to ...	Then ...
display the component lines within the wall above the cut plane (for example, through a window or door in the wall)	select Display Inner Lines Above. Clear this option if you do not want to display these lines.
display the component lines within the wall below the cut plane (for example, through a window or door in the wall)	select Display Inner Lines Below. Clear this option if you do not want to display these lines.
turn off lines below a window, door or opening at the cut plane	select Hide Lines Below Openings at Cut Plane. Clear this option if you want to display the lines.
turn off lines below a window, door or opening above the cut plane	select Hide Lines Below Openings Above Cut Plane. Clear this option if you want to display the lines.
display complex wall and opening endcaps	select Display Endcaps. Clear this option to display complex endcaps as a single line.
display door openings cutting the wall at the outer edge of the door frame	select Cut Door Frames. Clear this option if you want door openings to cut the wall at the inside of the door frame.
display window openings cutting the wall at the outer edge of the window frame	select Cut Window Frames. Clear this option if you want window openings to cut the wall at the inside of the window frame.
draw wall components by their priority number to control the display of a component over another component	select Component Draw Order by Priority. Clear this option if you want to draw the components in the order that they were created.
perform a slice of the actual 3-dimensional (3D) model at each cut plane to obtain more accurate views of walls with sweeps or body modifiers	select Do True Cut. Clear this option if the wall does not have sweeps or body modifiers, or if they do not change along the height of the wall.
display miter lines at wall corners for selected wall components	under Draw Miter for Components, select each component whose miter lines you want to display.

9 Click OK.

Adding Classifications to a Wall Style

Use this procedure to specify classifications for any classification definition applied to a wall style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the style that you want to change.
- 4 Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to wall styles.

- 5 For each classification definition, select the classification you want to apply to the current wall style.
- 6 Click OK.

Defining a Wall Style as Bounding for Associative Spaces

Use this procedure to define a wall style that can bound associative spaces.

When a wall style is set as bounding, by default all walls that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the wall style in an individual wall, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Wall Styles.
- 3 Select a wall style.
- 4 Click the General tab.
- 5 Select the check box for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Wall Style

Use this procedure to enter notes and attach reference files to a wall style. You can also edit notes and edit or detach reference files from a wall style.

- 1 Open a tool palette that has a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style you want to change.
- 4 Click the General tab.
- 5 To add a description to the wall style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.

8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

9 Click OK.

Working with Wall Endcaps and Opening Endcaps

You can define different kinds of wall endcap and wall opening endcaps to control the shape, the width, and the depth of starting and ending wall segments. Generally, you create a wall or opening endcap to use with a specific wall style.

When you are working with wall endcaps, you can use the In-Place Edit mode and manipulate wall components with vertex and edge grips. You can also use AEC modify tools (Trim, Extend, Subtract, and Merge) to modify wall components to create the configuration that you want. The Calculate Automatically feature can also assist you in adding boundary segments to complete your partial endcap designs.

When necessary, you can override the wall endcap style assigned in a wall style. When you override the assigned endcap style, you can select a different endcap style for one or both ends of a wall segment.

Opening Endcap Styles

Wall endcap styles are also used as a basis to define wall opening endcap styles. When a wall has an opening, such as a window or a door, the shape of the wall endcap at each edge of the opening needs to be defined. You use opening endcap styles to specify the wall endcap style applied to each edge of the wall adjacent to an opening. For more information about opening endcap styles, see [Creating a Wall Opening Endcap Style](#) on page 921.

NOTE When you change a wall endcap style, all opening endcap styles based that are also modified.

Process Overview: Options for Working with Wall and Opening Endcaps

You can use the following methods to work with wall and opening endcaps:

- Use In-Place Edit edge and vertex grips to create and modify wall endcaps and opening endcaps. For more information, see [Displaying In-Place Edit Grips for Wall Endcaps](#) on page 895.
- Use the AEC modify tools Trim, Extend, Subtract and Merge to to create and modify wall endcaps and opening endcaps. You can apply AEC objects as boundary conditions to trim or extend some or all of the wall components in your wall. You can use closed polylines to subtract or merge specific areas to or from wall components in your wall. For more information, see [Modifying Wall Endcaps Using AEC Modify Tools](#) on page 906.

- Draw open polylines, properly configured, that define the shape of the desired endcap, then use the Calculate Automatically feature to apply the open polyline to the appropriate wall component in your wall. For more information, see [Creating Wall Endcaps Using Calculate Automatically](#) on page 902.
- Use the Style Manager to create a wall or opening endcap style. For more information, see [Creating a Wall Opening Endcap Style](#) on page 921.
- Apply a defined wall or opening endcap endcap style to a wall style. For more information, see [Applying a Wall Endcap Style to a Wall Style](#) on page 918 and [Applying a Wall Opening Endcap Style to a Wall Style](#) on page 922.

Displaying In-Place Edit Grips for Wall Endcaps

You can use in-place edit grips to modify wall endcaps and create the wall endcap conditions that you want. Vertex and edge grips are displayed for all wall components at the wall endcap that you specify.

The Wall Endcap Profile

When you edit a wall endcap in place, a temporary profile with grips for vertices and edges is created for each component of the endcap. You can edit this profile in both plan and model views. In a model view, your pick point determines the elevation of the wall endcap profile. When working with opening endcaps in a model view, the profile is located on the normal plane of the middle point of the opening segment nearest to your pick point. Components that don't touch the plane or the endcap's control line will not be displayed.

IMPORTANT A wall style that has vertically stacked components may require unique endcap conditions at different elevations of the wall endcap. Change your cutplane height to specify these different wall endcap conditions at the appropriate elevation.

If the profile is very complex or is obscured by the linework of other objects, use the location grip on the temporary profile to move the profile away from the wall. Changes to the profile are saved at its original location.

Viewing in-place edit grips for wall and opening endcaps

- 1 Select the wall that has the wall or opening endcaps that you want to change, right-click, and click Endcaps ► Edit in Place.
- 2 Specify a point near the endcap.

Temporary profiles are created for you to edit the geometry of the wall endcap for each wall component.

NOTE After performing an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the expected editing commands on the context menu, select the profile again, and right-click.

- 3 Select the profile and edit it as desired:

If you want to ...	Then ...
change the shape of the perimeter of the profile	use grips to adjust the shape.

If you want to ...	Then ...
hide an edge of the profile for a single wall component (plan view only)	right-click, and click Hide Edge. Select the edges you want to hide, and press <i>ENTER</i> .
display an edge for a single wall component that you hid	right-click, and click Show Edge. Select the edges you want to show, and press <i>ENTER</i> .
add vertices to the profile of a single wall component	right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .
remove vertices from the profile of a single wall component	right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .
replace the geometry of an endcap component with a new polyline that lies on the end of the wall exclusive of existing endcaps	right-click, and click Replace Endcap. Select the endcap component to replace, and select a polyline to define the new geometry. Press <i>ENTER</i> to keep the polyline in the drawing, or enter <i>y</i> (Yes) to erase it.
remove an endcap component	right-click, and click Remove Endcap.

4 Save or discard the changes:

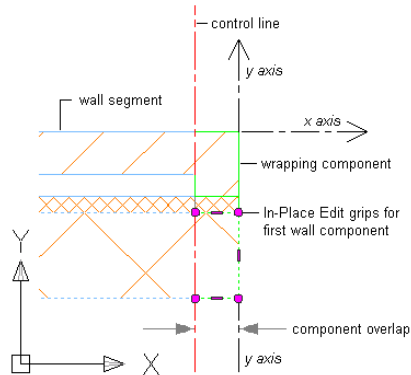

If you want to ...	Then ...
restore the wall endcap to its original shape	click  .
save the changes to the current wall endcap style	click  . The wall endcap and the wall endcap style use the edited profile(s) to define the endcaps's geometry. Any other walls or opening endcap styles that use this wall endcap style are also updated with the edited geometry.
save the changes to a new wall endcap style	select the profile, right-click, and click Save as New Endcap Style. Enter a name for the new wall endcap style, and click OK. The wall endcap uses the new style to define its geometry. Other walls, wall styles, or opening endcap styles that use the original style are not affected.

The Vertex grips allow you to manipulate component corners. When you move a Vertex grip that occurs at the end of an endcap polyline, additional edge grips are added at the midpoints of the new edges that are created.

The Edge grips allow you to offset a component edge, add a vertex to the component edge, or convert a straight component edge to an arc edge. When you offset a component edge or add a vertex to the component edge, additional edge grips are added at the midpoints of the new edges that are created. In addition, when you offset a component edge, new component corner Vertex grips are added.

Often you will work with wall styles that have one or more components that wrap at the wall endcap or opening. For example, a brick wall component in some wall styles wraps at the wall endcap. With this condition, a control line parallel to the Y axis delineates the innermost component face. Remaining components in the wall style will start at this control line. When you select a wall segment in order to apply a new wall endcap condition and display the In-Place Edit grips for the first wall component, you can see that the grips display along the control line.

In the following illustration you can see the component overlap distance and the grips that occur along the control line.

Using In-Place Edit Vertex Grips to Modify a Wall Endcap

The following example shows you how to use an in-place edit vertex grip to modify a wall component.

- 1 Select the wall segment with the wall endcap to modify, right-click and click Endcaps ► Edit In Place.
- 2 Specify a point near the wall endcap.
The initial In-Place Edit grips for the wall component are displayed, as well as the In-Place Edit dialog.

- 3 Select the Vertex grip.
- 4 Specify a new location for the Vertex grip.
- 5 In the In-Place Edit dialog, click Save All Changes.
- 6 In the Wall Endcap Style dialog, you can do the following:
 - Save the new wall endcap as a new wall endcap style.
 - Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.

- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.

The following illustration shows the use of an in-place edit Vertex grip to modify a wall endcap.

Modifying a Wall Endcap with an In-Place Edit Vertex Grip

Using In-Place Edit Edge Grips to Offset a Wall Endcap Edge

The following example shows you how to use an in-place edit Edge grip to offset a wall component edge.

- 1 Select the wall segment with the wall endcap to modify, right-click and click Endcaps ► Edit In Place.
- 2 Specify a point at the wall endcap.
The initial In-Place Edit grips for the wall component are displayed, as well as the In-Place Edit dialog.

- 3 Move your cursor over the Edge grip to display the available modes.
- 4 Select the Edge grip.
- 5 Specify a new location for the Edge grip.
- 6 In the In-Place Edit dialog, click Save All Changes.

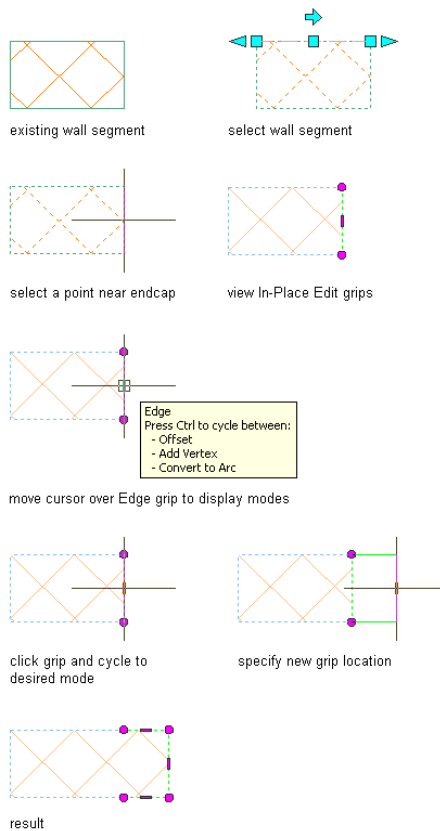

7 In the Wall Endcap Style dialog, you can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.

The following illustration shows the use of an in-place edit Edge grip to offset a wall component edge.

Offsetting a Wall Endcap Edge with an In-Place Edit Edge Grip

Using In-Place Edit Edge Grips to Add a Vertex to a Wall Endcap Edge

The following example shows you how to use an in-place edit Edge grip to add a vertex to a wall component edge.

- 1 Select the wall segment with the wall endcap to modify, right-click and click Endcaps ► Edit In Place.
- 2 Specify a point at the wall endcap.

The initial In-Place Edit grips for the wall component are displayed, as well as the In-Place Edit dialog.

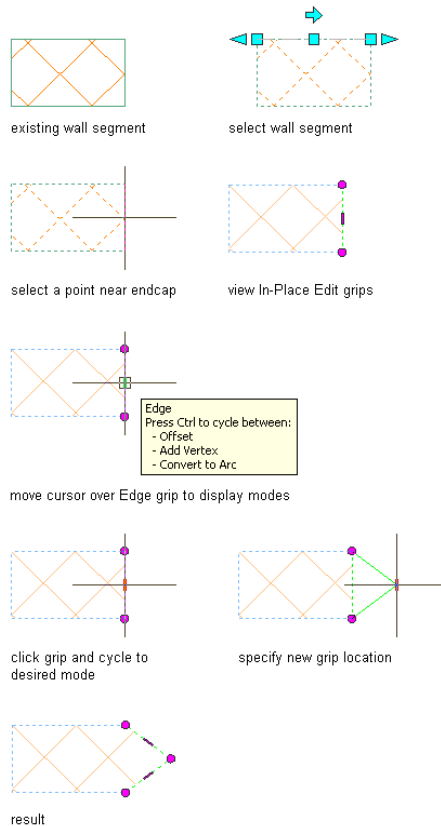

- 3 Move your cursor over the Edge grip to display the available modes.
- 4 Select the Edge grip, and then press *CTRL* once.
- 5 Specify a new location for the Edge grip.
- 6 In the In-Place Edit dialog, click Save All Changes.
- 7 In the Wall Endcap Style dialog, you can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.

The following illustration shows the use of an in-place edit Edge grip to add a vertex to a wall component edge.

Adding a Vertex to a Wall Endcap Edge with an In-Place Edit Edge Grip

Using In-Place Edit Edge Grips to Convert a Wall Endcap Edge to an Arc

The following example shows you how to use an in-place edit Edge grip to convert a wall component edge to an arc.

1 Select the wall segment with the wall endcap to modify, right-click and click Endcaps ► Edit In Place.

2 Specify a point at the wall endcap.

The initial In-Place Edit grips for the wall component are displayed, as well as the In-Place Edit dialog.

3 Move your cursor over the Edge grip to display the available modes.

4 Select the Edge grip, and then press *CTRL* twice.

5 Specify a new location for the Edge grip.

6 In the In-Place Edit dialog, click Save All Changes.

7 In the Wall Endcap Style dialog, you can do the following:

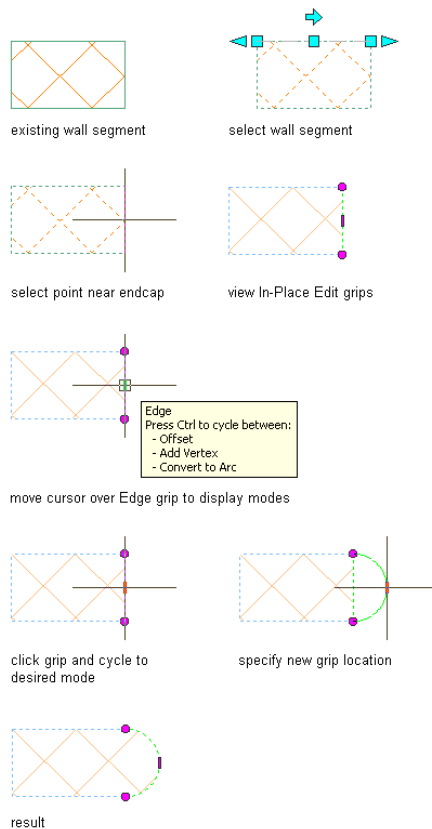

- Save the new wall endcap as a new wall endcap style.

- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.

The following illustration shows the use of an in-place edit Edge grip to convert a wall endcap edge to an arc.

Converting a Wall Endcap Edge to an Arc with an In-Place Edit Edge Grip

Creating Wall Endcaps Using Calculate Automatically

You can use the Calculate Automatically feature with appropriate polyline linework to create wall endcaps. Calculate Automatically will add boundary segments to complete an endcap configuration if the initial polyline is drawn with regard to location and orientation of the particular wall component.

When you draw polylines for an endcap style used in a multi-component wall, you need to draw one polyline for each component, so that each polyline corresponds to the shape of the endcap for one wall component.

Here are some guidelines for drawing polylines to use in endcap styles:

- Use only 2-dimensional (2D) open lightweight polylines.
- Draw the polylines in plan view, adjacent to the wall components that you want to change. This helps you visualize how the endcap should appear for each component of the wall.

Working with Wall Endcap Polylines and Single Wall Components

Valid wall endcap polylines start at the wall component corner on the y axis. In an ideal situation, the polyline endpoint also ends at the other wall component corner on the y axis, so that both the polyline start point and endpoint are coincident with the y axis, and both have the same x value.

IMPORTANT In previous version of AutoCAD Architecture, polylines that did not meet these requirements could be automatically moved, scaled or rotated to fit. This is no longer true.

The following illustration shows an ideal wall endcap polyline condition.

Drawing an ideal wall endcap polyline

Often you will work with wall styles that have one or more components that wrap at the wall endcap or opening. For example, a brick wall component in some wall styles wraps at the wall endcap. With this condition, a control line parallel to the y axis delineates the innermost component face, and the remaining components in the wall style will start at this control line. When you select a wall segment in order to apply a new wall endcap condition and display the In-Place Edit grips for the first wall component, you can see that the grips display along the control line.

In the following illustration you can see the component overlap distance and the grips that occur along the control line.

Adding a Wall Endcap Polyline to a Wall Component

- 1 On an existing single-component wall segment in plan view, draw a polyline to delineate the wall endcap condition.
- 2 Select the wall segment to edit, right-click and click Endcaps ► Calculate Automatically.
- 3 Select the wall endcap polyline.
- 4 Press *ENTER* to accept the wall component that you want.

The Wall Endcap Style dialog is displayed. If you choose to save the applied wall endcap as a new style, you can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.
- You can choose to erase the original polyline layout geometry of the wall endcap.

The specified wall component is merged with the wall endcap polyline.

The following illustration shows how to associate a wall endcap polyline with a specific wall component in a multi-component wall segment.

The following illustration shows a wall endcap polyline that starts and ends at the wall component corners. Both points are on the y axis and share the same x value. No boundary segments need to be added by the Calculate Automatically feature.

The following illustration shows several wall endcap polyline configurations that are not valid.

Working with Wall Endcap Polylines and Multiple Components

When you are working with multi-component wall styles, you can choose which component that you want to merge with. Valid wall endcap polylines can start at the wall segment corner on the y axis. In an ideal situation, the polyline endpoint also ends at the other wall segment corner on the y axis, so that both the polyline start point and endpoint are coincident with the y axis, and both have the same x value.

Specifying the Wall Component to Associate with a Wall Endcap Polyline

- 1 On an existing multi-component wall segment in plan view, draw a polyline to delineate the wall endcap condition.
- 2 Select the wall segment to edit, right-click and click Endcaps ► Calculate Automatically.
- 3 Select the wall endcap polyline.
- 4 The first wall component to which you could associate the polyline is highlighted with a red line offset to the interior of the wall component.
- 5 Press *ENTER* to accept this wall component, or press *TAB* to advance to the next wall component. Continue to press *TAB* until the component that you want is highlighted.
- 6 Press *ENTER* to accept the wall component that you want.

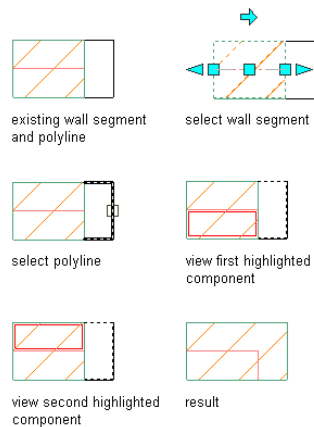

The Wall Endcap Style dialog is displayed. If you choose to save the applied wall endcap as a new style, you can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.
- You can choose to erase the original polyline layout geometry of the wall endcap.

The specified wall component is merged with the wall endcap polyline.

The following illustration shows how to associate a wall endcap polyline with a specific wall component in a multi-component wall segment.

Modifying Wall Endcaps Using AEC Modify Tools

You can use AEC Modify Tools to manipulate wall components to create appropriate wall endcap configurations. Use Trim, Extend, Subtract, and Merge tools as necessary to do this. You can modify single wall components or you can modify all components at your wall endcap or opening at once. In each case, you will be using the In-Place Edit feature as you modify the wall components to create your wall endcap condition.

Create a Wall Endcap Condition with the Trim AEC Modify Tool

You can use the Trim AEC modify tool to create a wall endcap condition by trimming some or all of a wall's components to a boundary. Lines and any AEC object, including another wall segment, can be used as a boundary to trim to.

Using the Trim AEC Modify Tool to Create a Wall Endcap

The following example shows you how to trim all components of a wall segment to a line, resulting in a diagonal wall endcap condition.

- 1 Select the wall segment to trim, right-click and click Endcaps ► Edit In Place.
- 2 Specify a point at the wall endcap.

The initial In-Place Edit grips for one of the wall components are displayed, as well as the In-Place Edit dialog.

- 3 Use a crossing selection set to select all of the wall components at the endcap. All of the Edit In Place grips for the wall components are displayed. Components that are selected will be trimmed to the specified boundary edge.
- 4 Right-click and click AEC Modify Tools ► Trim.
- 5 Move your cursor over the boundary edge to which you want to trim the wall components. A boundary edge guideline is temporarily displayed when you move your cursor over it.

6 Click on the boundary edge to trim the wall components.

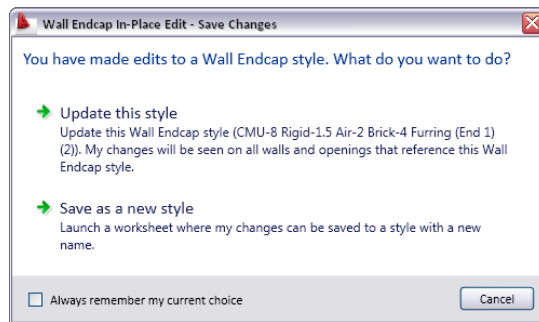

TIP You can also specify two points to delineate a trim boundary edge.

All of the wall components are trimmed to the specified boundary.

7 In the In-Place Edit dialog, click Save All Changes.

8 In the Wall Endcap In-Place Edit dialog, select either Update this style or Save as new style.

If you choose to update the current wall style with the new wall endcap, all existing and new instances of the wall style will display the new wall endcap condition. If you choose to save as a new style, you have further options.

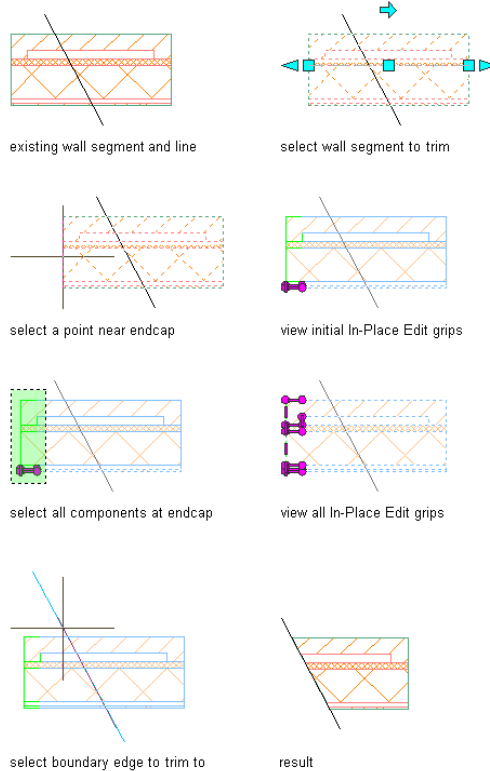

If you choose to save the applied wall endcap as a new style, the Wall Endcap Style dialog is displayed. You can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.
- You can choose to erase the original polyline layout geometry of the wall endcap.

The following illustration shows the use of a line as a boundary to trim all of the components in a wall segment.

Trimming Wall Endcap Components

Create a Wall Endcap Condition with the Extend AEC Modify Tool

You can use the Extend AEC modify tool to create a wall endcap condition by extending some or all of a wall's components to a boundary. Lines and any AEC object, including another wall segment, can be used as a boundary to extend to.

Using the Extend AEC Modify Tool to Create a Wall Endcap

The following example shows you how to extend all components in a straight wall segment to an arc wall segment, resulting in a curved wall endcap condition.

- 1 Select the wall segment to extend, right-click and click Endcaps ► Edit In Place.
- 2 Specify a point at the wall endcap.

The initial In-Place Edit grips for one of the wall components are displayed, as well as the In-Place Edit dialog.

- 3 Use a crossing selection set to select all of the wall components at the endcap.
All of the In-Place Edit grips for the wall components are displayed. Components that are selected will be extended to the specified boundary edge.
- 4 Right-click and click AEC Modify Tools ► Extend.
- 5 Move your cursor over the boundary edge to which you want to extend the wall components.

A boundary edge guideline is temporarily displayed when you move your cursor over it.

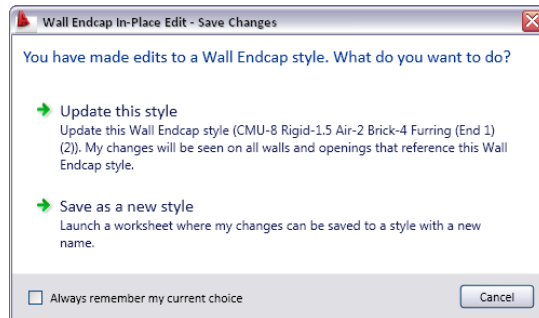

6 Click on the boundary edge to extend the wall components.

All of the wall components are extended to the specified boundary.

7 In the In-Place Edit dialog, click Save All Changes.

8 In the Wall Endcap In-Place Edit dialog, select either Update this style or Save as new style.

If you choose to update the current wall style with the new wall endcap, all existing and new instances of the wall style will display the new wall endcap condition. If you choose to save as a new style, you have further options.

If you choose to save the applied wall endcap as a new style, the Wall Endcap Style dialog is displayed. You can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.
- You can choose to erase the original polyline layout geometry of the wall endcap.

The following illustration shows the use of an arc wall segment as a boundary to extend all of the components in a wall segment.

Extending Wall Endcap Components

Create a Wall Endcap Condition with the Subtract AEC Modify Tool

You can use the Subtract AEC modify tool to create a wall endcap condition by subtracting the area enclosed by a polyline from a wall component.

Using the Subtract AEC Modify Tool to Create a Wall Endcap

The following example shows you how to subtract an area from a wall component to create a wall endcap condition.

- 1 On an existing wall segment in plan view, draw a polyline to enclose an area overlapping the wall component from which you want to subtract.
- 2 Select the wall segment, right-click and click Endcaps ► Edit In Place.
- 3 Specify a point at the wall endcap.

The initial In-Place Edit grips for the wall component are displayed, as well as the In-Place Edit dialog.

Components that are selected will have part of their area subtracted from the specified overlapping polyline-delineated area.

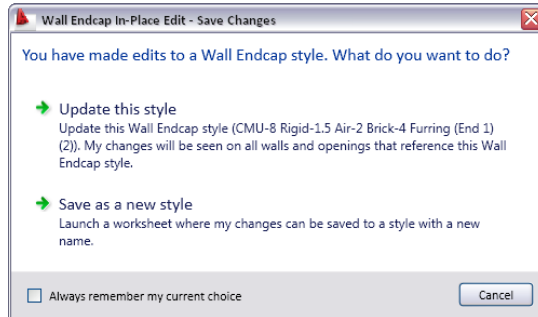

- 4 Right-click and click AEC Modify Tools ► Subtract.
- 5 Select the polyline to subtract from the wall component.

6 Choose to retain or erase the original polyline linework.

7 In the In-Place Edit dialog, click Save All Changes.

8 In the Wall Endcap In-Place Edit dialog, select either Update this style or Save as new style.

If you choose to update the current wall style with the new wall endcap, all existing and new instances of the wall style will display the new wall endcap condition. If you choose to save as a new style, you have further options.

If you choose to save the applied wall endcap as a new style, the Wall Endcap Style dialog is displayed. You can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.
- You can choose to erase the original polyline layout geometry of the wall endcap.

The following illustration shows the use of a closed polyline to delineate an area to be subtracted from a wall component.

Subtracting from Wall Endcap Components

Create a Wall Opening Endcap Condition with the Subtract AEC Modify Tool

You can use the Subtract AEC modify tool to create a wall opening endcap condition by subtracting an area enclosed by a polyline from a wall component.

Using the Subtract AEC Modify Tool to Create a Wall Opening Endcap

The following example shows you how to subtract an area from a wall component to create a wall opening endcap condition.

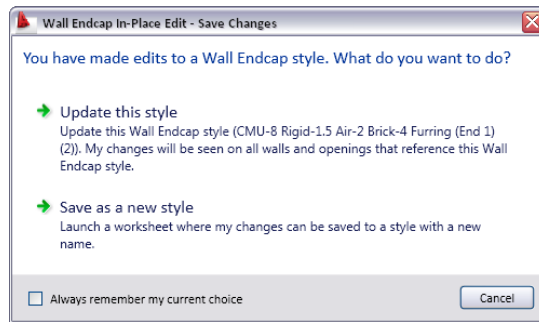

- 1 On an existing wall segment at an opening edge in plan view, draw a polyline to enclose an area adjacent to the wall component from which you want to subtract.
- 2 Select the wall segment, right-click and click Endcaps ► Edit In Place.
- 3 Specify a point at the wall opening endcap.
The initial In-Place Edit grips for one of the wall components are displayed, as well as the In-Place Edit dialog.

Components that are selected will have their area subtracted from the specified polyline-delineated area.

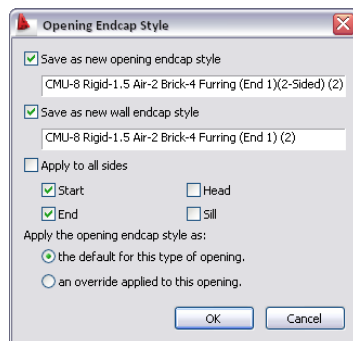

- 4 Right-click and click AEC Modify Tools ► Subtract.
- 5 Select the polyline to subtract from the wall component.
- 6 Choose to retain or erase the original polyline linework.
The subtracted wall component condition is displayed.
- 7 In the In-Place Edit dialog, click Save All Changes.
- 8 In the Wall Endcap In-Place Edit dialog, select either Update this style or Save as new style.

If you choose to update the current wall style with the new wall opening endcap, all existing and new instances of the wall style will display the new wall opening endcap condition. If you choose to save as a new style, you have further options.

If you choose to save the applied wall opening endcap as a new style, the Opening Endcap Style dialog is displayed. You can do the following:

- Save the new wall opening endcap as a new opening endcap style.
- Save the new wall opening endcap as a new wall endcap style.
- Apply the new wall opening endcap condition to all four edges of the opening. Or, you can choose to apply the new wall opening endcap condition to only the Start, End, Head, or Sill of the opening. The Start and End correspond to opening jambs.
- Apply the wall endcap style as a default opening endcap for this wall style. All existing and new instances of this wall style will display the new wall opening endcap condition.
- Apply the wall opening endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall opening endcap condition.

Create a Wall Endcap Condition with the Merge AEC Modify Tool

You can use the Merge AEC modify tool to create a wall endcap condition by merging an area enclosed by a polyline with a wall component.

Using the Merge AEC Modify Tool to Create a Wall Endcap

The following example shows you how to merge an area with a wall component to create a wall endcap condition.

- 1 On an existing wall segment at an endcap in plan view, draw a polyline to enclose an area adjacent to the wall component to which you want to merge.
- 2 Select the wall segment, right-click and click Endcaps ► Edit In Place.

3 Specify a point at the wall endcap.

The initial In-Place Edit grips for one of the wall components are displayed, as well as the In-Place Edit dialog.

Components that are selected will have their area merged with the specified polyline-delineated area.

4 Right-click and click AEC Modify Tools ► Merge.

5 Select the polyline to merge with the wall component.

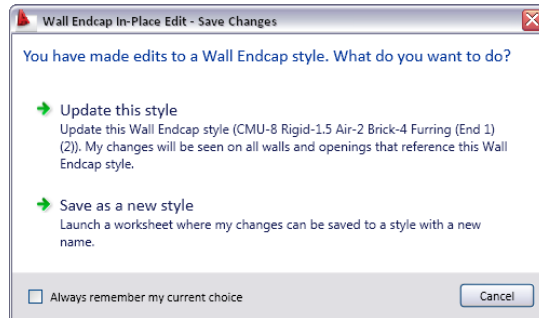

6 Choose to retain or erase the original polyline linework.

The merged wall component condition is displayed.

7 In the In-Place Edit dialog, click Save All Changes.

8 In the Wall Endcap In-Place Edit dialog, select either Update this style or Save as new style.

If you choose to update the current wall style with the new wall endcap, all existing and new instances of the wall style will display the new wall endcap condition. If you choose to save as a new style, you have further options.

If you choose to save the applied wall endcap as a new style, the Wall Endcap Style dialog is displayed. You can do the following:

- Save the new wall endcap as a new wall endcap style.
- Apply the wall endcap style as a default endcap for this wall style. All existing and new instances of this wall style will display the new wall endcap condition.
- Apply the wall endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall endcap condition.
- You can choose to erase the original polyline layout geometry of the wall endcap.

The following illustration shows the use of a closed polyline to delineate an area to be merged with a wall component in a wall endcap.

Merging with Wall Endcap Components

Create a Wall Opening Endcap Condition with the Merge AEC Modify Tool

You can use the Merge AEC modify tool to create a wall opening endcap condition by merging an area enclosed by a polyline with a wall component.

Using the Merge AEC Modify Tool to Create a Wall Opening Endcap

The following example shows you how to merge an area with a wall component to create a wall opening endcap condition.

- 1 On an existing wall segment at an opening edge in plan view, draw a polyline to enclose an area adjacent to the wall component to which you want to merge.
- 2 Select the wall segment, right-click and click Endcaps ► Edit In Place.
- 3 Specify a point at the wall opening endcap.
The initial In-Place Edit grips for one of the wall components are displayed, as well as the In-Place Edit dialog.

Components that are selected will have their area merged with the specified polyline-delineated area.

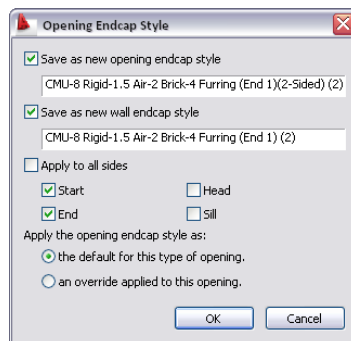

- 4 Right-click and click AEC Modify Tools ► Merge.
- 5 Select the polyline to merge with the wall component.
- 6 Choose to retain or erase the original polyline linework.
The merged wall component condition is displayed.
- 7 In the In-Place Edit dialog, click Save All Changes.
- 8 In the Wall Endcap In-Place Edit dialog, select either Update this style or Save as new style.

If you choose to update the current wall style with the new wall endcap, all existing and new instances of the wall style will display the new wall endcap condition. If you choose to save as a new style, you have further options.

If you choose to save the applied wall opening endcap as a new style, the Opening Endcap Style dialog is displayed. You can do the following:

- Save the new wall opening endcap as a new opening endcap style.
- Save the new wall opening endcap as a new wall endcap style.
- Apply the new wall opening endcap condition to all four edges of the opening. Or, you can choose to apply the new wall opening endcap condition to only the Start, End, Head, or Sill of the opening. The Start and End correspond to opening jambs.
- Apply the wall endcap style as a default opening endcap for this wall style. All existing and new instances of this wall style will display the new wall opening endcap condition.
- Apply the wall opening endcap style as an override to the selected end of this wall style. Only this single instance of this wall style will display the new wall opening endcap condition.

The following illustration shows the use of a closed polyline to delineate an area to be merged with a wall component in a wall opening endcap.

Merging with Wall Opening Endcap Components

Applying Wall Endcap Styles from the Style Manager

Although you can create a new wall endcap style from the Style Manager using the procedure described below, the new style is not automatically applied to any wall style or wall; you must apply it to wall styles or walls in a separate task. For more information, see [Applying a Wall Endcap Style to a Wall Style](#) on page 918 and [Overriding a Wall Endcap Style on a Wall](#) on page 918.

Creating a Wall Endcap Style in the Style Manager

- 1 Draw polyline(s) in the shape of the wall endcap you want to create.
- 2 Click Format menu ► Style Manager.
- 3 Expand Architectural Objects.
- 4 Right-click Wall Endcap Styles, and click New.
- 5 Enter a name for the new wall endcap style, and press *ENTER*.
- 6 Right-click the new style name, and click Set From.
- 7 Select a polyline, and enter the index number for the wall component to which the polyline applies.

When you select polylines to use in wall endcap styles, each polyline corresponds to the shape of the endcap for one wall component. Each polyline is scaled to fit its assigned component.

Wall components are numbered from exterior to interior. Component index 1 corresponds to the outermost exterior component.

- 8 When prompted, enter *y* (Yes) to assign a polyline to another component, or enter *n* (No) if there are no more components.

NOTE You can assign the same polyline to multiple wall components that you want to have the same endcap condition.

- 9 When you finish specifying endcap conditions for wall components, enter the return offset for the endcap.

A positive value offsets the endcap from the wall start point in the positive X direction.

10 Click OK.

You can apply the wall endcap style to a wall style ([Applying a Wall Endcap Style to a Wall Style](#) on page 918, an opening endcap style ([Creating a Wall Opening Endcap Style](#) on page 921,) or to individual walls ([Overriding a Wall Endcap Style on a Wall](#) on page 918.)

Applying a Wall Endcap Style to a Wall Style

Use this procedure to apply a wall endcap style to a wall style. When a wall endcap style is applied to a wall style, all walls of that style will have the specified at both ends. You can override the style-defined endcap style by assigning a different endcap to one wall end.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects.

3 Expand Wall Styles, and select the wall style to which you want to apply the wall endcap style.

4 Click the Endcaps/Opening Endcaps tab.

5 For Wall Endcap Style, select the style you want to apply.

The endcap style is applied to all existing walls of that style, as well as all new walls of that style.

TIP The endcap style defined in the wall style is always applied to both ends of the wall. If you want a different endcap for each end of the wall, you can override the style-defined endcap. For more information, see [Overriding a Wall Endcap Style on a Wall](#) on page 918.

6 Click OK.

Overriding a Wall Endcap Style on a Wall

Use this procedure to override the style-defined wall endcap style for one end of an individual wall.

NOTE A wall endcap style is generally created for use with a specific wall style. Overriding the endcap style for an individual wall may display solution tip icons in the wall.

1 Select a wall, right-click, and click Endcaps ► Override Endcap Style.

2 Select a point close to the wall end where you want assign a different endcap.

3 In the Select an Endcap Style dialog, select an endcap style to use on the wall end, and click OK.

TIP Alternatively, you can double-click the wall to display the Properties palette, and scroll to the Style Overrides category. Under Starting endcap and Ending Endcap, you can select a different endcap style to override the style assignment.

Modifying the Geometry of a Wall Endcap Style

You can modify the geometry of an existing wall endcap style using either of the following methods:

- Enter an in-place edit session to change the endcap profile and save the change back to the style. This is best suited to making small, detailed changes.

- Exchange the endcap definition with a newly created polyline. This is best suited for changing the endcap shape completely without having to reassign a new endcap style to all wall styles that use it.

Editing the Standard Wall Endcap Style

The Standard wall endcap style is a special case. While you can use the Standard style as a starting point for creating a new wall endcap style, the Standard style itself cannot be changed. The Standard style is used when no other endcap style is specified for a wall. It is also used when you remove all components from a wall endcap style.

The Wall Endcap Profile

When you edit a wall endcap in place, a temporary profile with grips for vertices and edges is created for each component of the endcap. You can edit this profile in both plan and model views. In model views, the profile is inserted at the mid-height of the wall. If the wall has components that do not extend to that height, such as a footing, additional profiles are created at the vertical midpoint of these components. Use model views to edit wall endcaps that lie in different planes.

If the profile is very complex or is obscured by the linework of other objects, use the location grip on the temporary profile to move the profile away from the wall. Changes to the profile are saved at its original location.

Changing a wall endcap style by in-place editing

1 Select the wall that has the wall endcap style you want to change, right-click, and click Endcaps ► Edit in Place.

2 Select a point near the endcap.

Temporary profiles are created for you to edit the geometry of the wall endcap for each wall component.

NOTE After performing an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the expected editing commands on the context menu, select the profile again, and right-click.

3 Select the profile and edit it as desired:

If you want to ...	Then ...
change the shape of the perimeter of the profile	use grips to adjust the shape. If the profile has no grips, the Standard style, which you cannot edit, is the current endcap style.
hide one or more edges of the profile (plan view only)	right-click, and click Hide Edge. Select the edges you want to hide, and press <i>ENTER</i> .
display an edge that you hid	right-click, and click Show Edge. Select the edges you want to show, and press <i>ENTER</i> .
add vertices to the profile	right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .
remove vertices from the profile	right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .

If you want to ...	Then ...
replace the geometry of an endcap component with new polyline that lies on the end of the wall exclusive of existing endcaps	right-click, and click Replace Endcap. Select the endcap component to replace, and select a polyline to define the new geometry. Press <i>ENTER</i> to keep the polyline in the drawing, or enter <i>y</i> (Yes) to erase it.
remove an endcap component	right-click, and click Remove Endcap.
4 Save or discard the changes:	
If you want to ...	Then ...
restore the wall endcap to its original shape	click  .
save the changes to the current wall endcap style	click  . The wall endcap and the wall endcap style use the edited profile(s) to define its geometry. Any other walls or opening endcap styles that use this wall endcap style are also updated with the edited geometry.
save the changes to a new wall endcap style	select the profile, right-click, and click Save as New Endcap Style. Enter a name for the new wall endcap style, and click OK. The wall endcap uses the new style to define its geometry. Other walls, wall styles, or opening endcap styles that use the original style are not affected.

Changing the wall endcap style by substituting its profile with a new polyline

- 1 Draw the polyline you want to exchange for an existing wall endcap style.
- 2 Select a wall in the drawing that has the wall endcap style you want to change, right-click, and click Endcaps ► Calculate automatically.
- 3 Select the polyline you have drawn, and press *ENTER*.
- 4 Enter *y* (Yes) to erase the polyline(s), or enter *n* (No) to keep the polyline(s).
If the current wall endcap style is not the Standard style, you are prompted to modify the current style.
- 5 Enter *y* (Yes) to modify the currently active endcap style.
- 6 Enter *w* (Wallstyledefault) to use the modified wall endcap style as the default endcap style for that wall style. Otherwise, enter *o* (Override).

Changing the Return Offset of a Wall Endcap Style

Use this procedure to change the return offset of an existing wall endcap style.

A positive value offsets the endcap from the wall start point in the positive X direction.

Specifying the return offset for an endcap

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects.
- 3 Expand Wall Endcap Styles, and select the endcap style for which you want to change the return offset.
- 4 Click the Dimensions tab.
- 5 Enter a new offset value, and click OK.

Attaching Notes and Files to a Wall Endcap Style

Use this procedure to enter notes and attach reference files to a wall endcap style. You can also edit notes and edit or detach reference files that are attached to a wall endcap style.

- 1 Open a tool palette that contains a wall tool.
- 2 Right-click a wall tool, and click Wall Styles.
- 3 Select the wall style you want to access.
- 4 Click the General tab.
- 5 Under Description, add a description of the endcap style.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and perform the following operations as needed:

If you want to ...

Then ...

attach a reference file

click Add, select a file, and click OK.

edit the description of a reference file

select the file, and click Edit. Enter the description, and click OK.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click Delete.

- 9 Click OK.

Creating a Wall Opening Endcap Style

Wall opening endcap styles are endcap conditions assigned to a wall end adjacent to a door, window, or door and window assembly. An opening endcap style has no independent geometry, but must use a wall endcap style as its geometry definition. For information on creating wall endcap styles, see [Creating Wall Endcaps Using Calculate Automatically](#) on page 902 and [Creating a Wall Endcap Style in the Style Manager](#) on page 917.

NOTE When you change a wall endcap style, all opening endcap styles based on the wall endcap style are modified, too.

Like a wall endcap style, an opening endcap style must be assigned to a wall style. For more information, see [Applying a Wall Opening Endcap Style to a Wall Style](#) on page 922.

- 1 Verify that the wall endcap style you want to base your opening endcap style on is present in your drawing, and has the correct geometry.
- 2 Click Format menu ► Style Manager.
- 3 Expand Architectural Objects.
- 4 Expand Opening Endcap Styles, right-click, and click New.
- 5 Click the Design Rules tab.

In an opening endcap style, you have to define the endcap condition between the wall and the opening separately for each direction: jamb start, jamb end, sill, and head.

- 6 Under Endcap Style, select the wall endcap style for each opening direction.
- 7 Click OK.

For information on how to apply the opening endcap style to a wall style or a wall opening, see [Applying a Wall Opening Endcap Style to a Wall Style](#) on page 922 and [Overriding a Wall Opening Endcap Style on a Wall](#) on page 922.

Applying a Wall Opening Endcap Style to a Wall Style

After you create a wall opening endcap style, you need to assign it to the wall style where you want to use it when adding the following objects to the wall: doors, windows, openings, and door and window assemblies.

When necessary, you can override the wall opening endcap style assigned in a wall style on an individual wall.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects.
- 3 Expand Wall Styles, and select the wall style to which you want to apply the opening endcap style to.
- 4 Click the Endcaps/Opening Endcaps tab.
- 5 For Opening Endcaps, select an opening endcap style to use for each of the opening objects that can interact with the wall.
- 6 You can also edit an existing opening endcap style here, or create a new one from wall endcap styles, if necessary.
- 7 Click OK.

Overriding a Wall Opening Endcap Style on a Wall

Use this procedure to override the style-defined wall opening style for one intersection of a wall with an opening.

NOTE Each wall opening endcap style is generally created for use with a specific wall style. Overriding the endcap style for an individual wall and opening may display solution tip icons in the wall.

- 1 Select a wall with an opening, right-click, and click Endcaps ► Override Endcap Style.
- 2 Select a point close to the wall opening where you want assign a different opening endcap.

3 In the Select an Endcap Style dialog, select an endcap style, and click OK.

Using Ortho Close and Close with Walls

Ortho Close and Close are command-line options that let you efficiently create a closed space when you add walls.

Ortho Close

This option closes the space by drawing 2 walls based on the direction you specify. The direction is extended until it meets a line perpendicular to the initial edge of either the wall. You enter **or** (Ortho) at the command line to use this option when placing walls.

Closing walls with Ortho Close

Close

This option closes the wall by creating a wall segment from the last point specified for the walls to the first point specified in this group of walls. You enter **c** (Close) at the command line to use this option when placing walls.

About Wall Lengths

When you draw a wall, the “true” length of the wall is the distance between the 2 end grips. The wall can appear to have a different length when it cleans up with other walls; the difference can be twice the cleanup circle radius longer or shorter than the “true” length. The “true” length is the length reported by properties and schedules. To get the most accurate information about wall length in schedules, always make sure that walls that clean up with each other have end grips that coincide.

About Curved Walls

The smoothness (tessellation) of curved edges is controlled by the FACETDEV variable. This variable sets the number of facets to display on curved AEC objects. The default value is 1/2" for drawings created from imperial templates and is 12.7 mm for drawings created from metric templates.

The number you specify for facet deviation defines the maximum distance from the chord to the arc, the chord being an edge that is created from faceting the curve, to the true mathematical arc. The facet deviation has a range of greater than zero (0) and no upper limit.

Curved wall segments with facet deviation examples

The minimum number of facets is 8. For example, if you create a cylinder mass element to have a 1'-0" radius, and specify 1 for FACETDEV, the cylinder has 8 faces.

To specify the facet deviation values for the current drawing, see [Specifying the Display Resolution of Objects with Facets](#) on page 169. The settings apply to all curved objects in the drawing, including curved walls.

Specifying Offsets for Roof Line and Floor Line Vertices

When you add or move a vertex on the roof line or the floor line of a wall, you specify the horizontal and vertical offset of the vertex. You can specify the offset relative to other vertices or to the base height or the baseline of the wall. The following table identifies the locations you can specify for the horizontal offset of a vertex. The offset distance is measured in the direction the wall was drawn.

This setting ...	Defines the horizontal offset from ...
From Wall Start	the wall start point.
From Wall End	the wall endpoint.
From Wall Midpoint	the midpoint of the wall.
From Previous Point	the vertex that is one position closer to the wall start point than the vertex you are adding or moving.
From Next Point	the vertex that is one position closer to the wall endpoint than the vertex you are adding or moving.
From Midpoint of Neighbors	the midpoint of the distance between the current vertex and the vertex that is one position closer to the wall endpoint.

The following table identifies the locations you can specify for the vertical offset of a vertex. You can enter a negative distance for the vertical offset to position a vertex toward the ground.

This setting ...	Defines the vertical offset from ...
From Wall Base Height	the base height of the wall.
From Next Point.	the vertex that is one position closer to the wall endpoint than the vertex you are adding or moving.
From Previous Point	the vertex that is one position closer to the wall start point than the vertex you are adding or moving.
From Baseline	the baseline of the wall.

Specifying the Width and Edge Offset of a Wall Component

You can specify the width and edge offset of a wall component by entering values, creating a component with a fixed width and offset. You can also specify a formula for determining these values. The formula can include a value for Base Width. By including the Base Width variable in the formula, you can specify the width of the wall when you add or edit walls of this style to a drawing.

Specifying a formula to determine component width or edge offset

To calculate the edge offset or the width based on the base width, select Base Width and select an operator and an operand:

- If you select Base Width for any component, you can enter a width for walls of this style when you add or modify them in a drawing.
- If all components in the wall style use absolute values, you cannot change the width of individual walls of this style when you add or modify them.

Wall component baseline offset parameters

Curtain Walls

19

Curtain walls provide a grid or framework for inserting objects such as windows and doors. Curtain walls have many similarities to standard walls, such as baseline, roof line, and floor line, and they allow for interferences. You can insert doors, windows, and door/window assemblies into a curtain wall, just like standard walls, but the insertion process is different.

Curtain Walls

Curtain walls provide a grid or framework for inserting objects such as windows and doors. Curtain walls have many similarities to standard walls, such as baseline, roof line, and floor line, and they allow for interferences. You can insert doors, windows, and door/window assemblies into a curtain wall, just like standard walls, but the insertion process is different.

Curtain Wall Grids

Curtain walls are made up of one or more grids. Each grid in a curtain wall has either a horizontal division or a vertical division, but you can nest the grids to create a variety of patterns from simple to complex.

Curtain wall nested grid example

Each cell in a grid can contain either a panel infill, to represent basic cladding materials such as a stone wall panel or glazing, or an object such as a window or a door.

Assigned curtain wall infill types

Curtain Wall Units and Door/Window Assemblies

Other objects you can insert in a grid include curtain wall units and door/window assemblies. Curtain wall units are designed to represent complex elements that are repeated within your main curtain wall.

Assigned curtain wall unit infill

Window assemblies serve a similar function as curtain wall units but can contain panel infills or objects such as doors or windows. Door/window assemblies can be inserted into curtain walls and standard walls.

Assigned door/window assembly infill

Both curtain wall units and door/window assemblies can reduce the need for nested grids, making edits to the curtain wall easier.

Elements of Grids

Grids are the foundation of curtain walls, curtain wall units, and door/window assemblies. Every grid has four element types:

- **Divisions:** Define the direction of the grid (horizontal or vertical) and the number of cells
- **Cell Infills:** Contain another grid, a panel infill, or an object such as a window or a door

- **Frames:** Define the edge around the outside of the primary grid and nested grids
- **Mullions:** Define the edges between the cells

NOTE Division is an abstract element, in contrast to the other three element types that represent physical elements of the curtain wall.

Each element type is assigned a default definition that describes what elements of that type look like.

Element type	Default definitions
Divisions	Primary horizontal grid with a fixed cell dimension of 13' and secondary vertical grid with a fixed cell dimension of 3'
Cell Infills	Cells containing simple panels 2" thick
Frames	Left, right, top, and bottom outer edges of grid 3" wide and 3" deep
Mullions	Edges between cells 1" wide and 3" deep

Specifying grid element types

You can create new element definitions and assign those definitions within the curtain wall. For example, you can create multiple infill definitions, and then assign different infills to specific cells in the grid.

Assigning different infills to curtain wall cells

Likewise, you can create multiple frame definitions and then assign a different definition to each frame edge (top, bottom, left, or right). You can also create multiple mullion definitions.

Specifying different frame definitions for each edge of a frame

Experimenting with Curtain Wall Designs

The templates provided with AutoCAD Architecture offer curtain wall styles as well as curtain wall unit styles and door/window assembly styles. To familiarize yourself with the curtain wall feature, you can look at those existing styles and experiment with them. That will make it easier to understand curtain wall behavior and create your own curtain wall designs. You can find curtain wall styles and curtain wall unit styles under `\\documents and settings\all users\application data\autodesk\ACD-A 2009\enu\styles\imperial` or `\\documents and settings\all users\application data\autodesk\ACD-A 2009\enu\styles\metric`.

Using Curtain Wall Tools To Create Curtain Walls

Curtain walls are created in much the same way as standard walls. You can specify a style, a height, and start and endpoints. Curtain walls can be straight, curved, or a combination of the two.

Tools provided with AutoCAD Architecture let you quickly place curtain walls by selecting a curtain wall tool with a specific curtain wall style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can also use curtain wall tools to create new curtain walls by applying tool properties to existing walls, elevation sketches, 2D layout grids, or custom grids from two dimensional (2D) lines, arcs, and circles.

Tool palette containing a curtain wall tool

The following palettes contain one or more curtain wall tools:

Tool Palette	Curtain Wall Tools
Design palette in the Design palette group	a tool for the Standard curtain wall style and default settings for other curtain wall properties

Tool Palette	Curtain Wall Tools
Design Tool Catalog in Content Browser	a package of curtain wall and curtain wall unit tools. For information about accessing tools in Content Browser, see Using Tool Catalog Items in AutoCAD Architecture on page 146.
custom tool palettes created by your CAD manager	tools with curtain wall styles and properties that your CAD manager customized for your projects or office standards.

When you place curtain walls using curtain wall tools, you can use the default settings of the tool, or you can change settings for any curtain wall properties that are not controlled by the style.

Creating a Straight Curtain Wall

Use this procedure to create a straight curtain wall that has the properties specified in the curtain wall tool that you select. To specify settings when you add a curtain wall, see [Creating a Curtain Wall with User-Specified Settings](#) on page 932.

Drawing a straight curtain wall segment

1 Open the tool palette that you want to use, and select a curtain wall tool.

If necessary, scroll to display the tool that you want to use.

2 Specify a start point for the curtain wall.

You can move or hide the Properties palette to expose more of the drawing area.

NOTE If you have Dynamic Input activated on the application window status bar (DYN), you can use dynamic dimensions to specify the curtain wall length and angle. After clicking the start point of the curtain wall, dynamic input fields for length and angle appear around the curtain wall preview. Enter values as desired, and use the TAB key to switch between input fields.

3 Specify an end point.

4 Press *ENTER*.

Creating a Curtain Wall with User-Specified Settings

Use this procedure to add a curtain wall with settings that you specify.

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

1 Open the tool palette that you want to use, and select a curtain wall tool.

If necessary, scroll to display the tool that you want to use.

2 On the Properties palette, expand Basic, and expand General.

3 If desired, you can enter a description for the curtain wall by clicking the Description setting.

4 Select a style.

The curtain wall style determines many settings of the curtain wall, like the grid, the frames and mullions used, as well as cell infills and display settings. For information about curtain wall styles, see [Curtain Wall Styles](#) on page 941.

5 Under Bound Spaces, define if this curtain wall can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this curtain wall can be used as bounding object for associative spaces.
- No: this curtain wall cannot be used as bounding object for associative spaces.
- By style: this curtain wall will use the bounding settings from the curtain wall style.

For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

6 Expand Dimensions.

7 Modify the dimensions of the curtain wall:

If you want to specify ...	Then ...
the base height of the curtain wall	enter a value for Base Height.
start and end miters	enter miter values for Start Miter and End Miter.
define an offset of the roof line from the curtain wall base height	enter the appropriate value for roof line offset from base height. This offset can be set only during the insertion of the curtain wall.
define an offset of the floor line from the curtain wall base line	enter the appropriate value for floor line offset from base line. This offset can be set only during the insertion of the curtain wall.

TIP The length of the curtain wall is defined on screen. You can however, edit it in the Properties palette later.

8 To make further edits to the roof line and floor line, expand Advanced, and click the Roof/floor line worksheet.

For more information, see [Changing the Roof Line and the Floor Line of a Curtain Wall](#) on page 1021.

9 In the drawing area, specify the insertion point of the curtain wall.

You can move or hide the Properties palette to expose more of the drawing area.

NOTE If you have Dynamic Input activated on the application window status bar (DYN), you can use dynamic dimensions to specify the curtain wall length and angle. After clicking the start point of the curtain wall, dynamic input fields for length and angle appear around the curtain wall preview. Enter values as desired, and use the TAB key to switch between input fields.

10 Specify the endpoint of the curtain wall, and press *ENTER*.

Creating a Curved Curtain Wall

Use this procedure to create a curved curtain wall in a drawing.

The display of curved objects is dependent on the facet deviation set in the application. For information see [Facet Deviation](#) on page 1107.

Drawing a curved curtain wall segment

1 Open the tool palette that you want to use, and select a curtain wall tool.

If necessary, scroll to display the tool that you want to use.

2 On the Properties palette, expand Basic, and expand General.

3 If desired, you can enter a description for the curtain wall by clicking the Description setting.

4 Select a style.

The curtain wall style determines many settings of the curtain wall, like the grid, the frames and mullions used, as well as cell infills and display settings. For information about curtain wall styles, see [Curtain Wall Styles](#) on page 941.

5 Under Bound Spaces, define if this curtain wall can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this curtain wall can be used as bounding object for associative spaces.
- No: this curtain wall cannot be used as bounding object for associative spaces.
- By style: this curtain wall will use the bounding settings from the curtain wall style.

For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

6 Select Arc for Segment type.

7 Expand Dimensions.

8 Modify the dimensions of the curtain wall:

If you want to specify ...	Then ...
the base height of the curtain wall	enter a value for Base Height.
start and end miters	enter miter values for Start Miter and End Miter.
define an offset of the roof line from the curtain wall base height	enter the appropriate value for roof line offset from base height. This offset can be set only during the insertion of the curtain wall.
define an offset of the floor line from the curtain wall base line	enter the appropriate value for floor line offset from base line. This offset can be set only during the insertion of the curtain wall.

TIP The length and the radius of the curtain wall are defined on screen. You can however, edit them in the Properties palette later.

9 To make further edits to the roof line and floor line, expand Advanced, and click the Roof/floor line worksheet.

For more information, see [Changing the Roof Line and the Floor Line of a Curtain Wall](#) on page 1021.

10 Specify a start point for the curved curtain wall segment.

You can move or hide the Properties palette to expose more of the drawing area.

NOTE If you have Dynamic Input activated on the application window status bar (DYN), you can use dynamic dimensions to specify the curtain wall length and angle. After clicking the start point of the curtain wall, dynamic input fields for length and angle appear around the curtain wall preview. Enter values as desired, and use the TAB key to switch between input fields.

11 Specify the midpoint of the curved curtain wall segment.

12 Specify the endpoint of the curved curtain wall segment.

13 Continue placing curtain walls to create, for example, a building exterior or a room.

14 Press *ENTER*.

Creating a Curtain Wall that References a Curve

Use this procedure to create a curtain wall from linework such as lines, polylines, arcs, and circles.

If you want to create a curtain wall with a mixture of straight and curved segments, you can use the Add Curtain Wall command. However, for complicated designs, you might find it easier to draw the segments using lines, arcs, and circles, and then reference that curve as the baseline for the curtain wall. This method has an added advantage in that the curve remains in control of the length and baseline of the curtain wall. Any changes you make to the curve are reflected in changes to the curtain wall.

Creating a curtain wall that references a curve

Use any of the following objects to create the reference curve:

- Line
- Arc
- Circle
- Polyline
- Spline
- AEC objects (excluding stairs, columns, roof slabs, grids, and multi-view blocks. These objects might give you unexpected results when trying to generate a curtain wall from their base curve.)

1 Open the tool palette that you want to use.

If necessary, scroll to display the tool that you want to use.

2 Right-click a curtain wall tool, and click Apply Tool Properties to ► Referenced Base Curve.

3 Select the geometry to reference.

If the geometry you want to reference consists of multiple segments, you must repeat this procedure for each segment.

4 Edit the properties of the curtain walls in the Properties palette, if needed.

Converting a Layout Grid to a Curtain Wall

Use this procedure to create a curtain wall that is based on a 2D layout grid. If you already have 2D layout grids in a drawing, you can easily convert them to curtain walls. Or if you are already familiar with layout grids, it is an efficient way to create a curtain wall, and then experiment with the curtain wall commands to learn more about them.

Converting a 2D layout grid to a curtain wall

When you create a curtain wall from a 2D layout grid, you also create a new curtain wall style. The divisions in the new curtain wall style are taken from the divisions in the layout grid.

Curtain wall grids are one dimensional—divided either horizontally or vertically. To create the horizontal and vertical patterns in the 2D layout grid, the curtain wall uses a primary grid with a secondary grid nested inside it. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

When you create a curtain wall grid from a 2D layout grid, you need to decide the direction of the primary grid in the curtain wall. If you select horizontal, the primary grid has horizontal divisions that cross over the vertical divisions of the secondary grid. If you select vertical, the primary grid has vertical divisions that cross over the horizontal divisions of the secondary grid.

Specifying primary division directions

The horizontal and vertical lines of the 2D layout grid define the divisions for the curtain wall grids. The grid cells, frame, and mullions are assigned default definitions. For more information, see [Assigning Definitions to Curtain Wall Elements](#) on page 968.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a curtain wall tool, and click Apply Tool Properties to ► Layout Grid.
- 3 Select the layout grid to convert.
- 4 When prompted to erase the original geometry, press *ENTER* to keep the layout grid, or enter *y* (Yes) to erase it.
- 5 Press *ENTER* to specify horizontal as the orientation for the primary division, or enter *v* to specify vertical.
- 6 Enter a name for the curtain wall style generated from the grid layout, and click OK.
- 7 Edit the properties of the curtain wall in the Properties palette, if needed.

Creating a Curtain Wall from an Elevation Sketch

You can create a sketch of a custom grid with lines, arcs, and circles, and then convert that linework into a curtain wall.

NOTE Curtain wall grids are either horizontal or vertical. To create a grid pattern with horizontal and vertical cells, nested grids are used. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

The resulting curtain wall is assigned a custom grid division definition, which you cannot modify. You can, however, assign a different division definition to it. For more information, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

- 1 Verify that you are drawing in world coordinate system (WCS).
- 2 Use lines, arcs, and circles to create an elevation sketch.
- 3 Right-click a curtain wall tool, and click Apply Properties to ► Elevation Sketch.

4 Select the linework of the sketch.

5 Press *ENTER*.

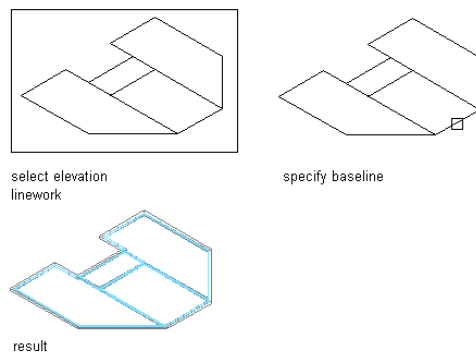

6 Select one of the grid lines as the baseline for the curtain wall or press *ENTER* to use the line along the *X* axis as the default baseline.

Converting linework to curtain walls using the default baseline option

If you draw your linework in the *XY* plane (in Plan view) and accept the default baseline, the resulting curtain wall is displayed as it is projected in the *Z* direction.

Converting linework to curtain walls using the specified baseline option

7 To erase the lines, enter *y* (Yes). To have the lines remain after the curtain wall is created, enter *n* (No).

When you create a curtain wall from an elevation sketch, the properties and design rules of the curtain wall style are applied to the generated curtain wall. The grid of the generated curtain wall will however differ from the curtain wall style, and is defined as a custom grid.

The custom grid is not automatically saved back to the curtain wall style, but is treated as an object override on the generated curtain wall. You can proceed in these ways:

- You can leave the custom grid as an override on the curtain wall object. This is recommended if the curtain wall generated from the elevation sketch has a unique grid that does not need to be reused.
- You can save the custom grid of the elevation sketch back to the existing curtain wall style, changing the curtain wall style to reflect the grid of the elevation sketch.
- You can save the custom grid of the elevation sketch to a new curtain wall style and use that for other, similar curtain walls.

8 Proceed in one of the following ways:

If you want to...	Then...
leave the custom grid on the curtain wall object as an override	no further action is required.

If you want to...	Then...
save the custom grid of the elevation sketch back to the existing curtain wall style	select the curtain wall, right-click, and click Design Rules ► Save to Style. Verify that under Save Changes to Style the correct style is selected, and click OK.
save the custom grid of the elevation sketch to a new curtain wall style	select the curtain wall, right-click, and click Design Rules ► Save to Style. Click New, and enter a name for the new curtain wall style. Then, click OK.

Converting a Wall to a Curtain Wall

Use this procedure to create curtain walls based on existing standard walls. For each wall segment, a separate curtain wall is created. During the conversion process, you are prompted to select a curtain wall style that determines the number and size of cells in the curtain wall grid as well as the appearance of the cells, frame, and mullions. For more information, see [Curtain Wall Styles](#) on page 941.

Converting a wall to a curtain wall

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a curtain wall tool, and click Apply Tool Properties to ► Walls.
- 3 Select the wall, and press *ENTER*.
- 4 Specify if the curtain wall should be aligned to the left side, the right side, the center line, or the baseline of the wall it is created from.

Specifying the alignment of the curtain wall

- 5 To erase the wall, enter **y** (Yes). To have the wall remain after the curtain wall is created, enter **n** (No).
- 6 Press **ENTER**.

Converting a 3D Face to a Curtain Wall

Use this procedure to create curtain walls based on faces of existing mass elements, mass groups, or AutoCAD® entities, such as a mesh, ruled surface, or solid. This might be helpful after you have developed a building model. For more information, see [Using the Model Explorer to Create Mass Models](#) on page 741. For each face, a separate curtain wall is created. During the conversion process, you are prompted to select a curtain wall style that determines the number and size of cells in the curtain wall grid as well as the appearance of the cells, frame, and mullions. For more information, see [Tips for Working Efficiently with Curtain Wall Styles](#) on page 943.

Use this procedure to generate a curtain wall of the face of a 3D object. Objects that have faces that can be used to generate curtain walls are the following:

- mass elements
- mass groups
- 3D spaces
- slabs
- roof slabs
- roofs
- AutoCAD 3D meshes
- AutoCAD 3D solids

- 1 Open the tool palette that you want to use.

If necessary, scroll to display the tool that you want to use.

- 2 Right-click a curtain wall tool, and click **Apply Tool Properties to ► Faces**.

- 3 Select a face to convert, or press **CTRL** and select multiple faces.

You can press **TAB** to cycle through the faces.

The Convert to Curtain Walls worksheet opens.

- 4 Select the curtain wall style.

- 5 To erase the object the face belongs to, select **Erase Layout Geometry**.

- 6 Click **OK**.

Creating a Curtain Wall Tool

Use this procedure to create a curtain wall tool and add it to a tool palette. You may want to create your own curtain wall tools if you are placing multiple curtain walls of specific styles with additional properties that you want to be the same each time you add a curtain wall of each type.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to ...	Then ...
create a tool from a curtain wall in the drawing	select the object, and drag it to the tool palette.
create a tool from a curtain wall style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK.
<p>NOTE You can only drag a style to a tool palette if the style has previously been saved with the drawing. Otherwise you are prompted to save the drawing first, and then create a tool from the style.</p>	
copy a tool in the current tool palette	right-click the tool, and click Copy. Deselect the tool, right-click anywhere in the palette, and click Paste.
copy a tool from another tool palette	open the tool palette containing the tool you want to copy, right-click the tool, and click Copy. Open the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 Expand Basic, and expand General.

7 Click the setting for Description, enter a description of the curtain wall created from this tool, and click OK.

8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.

9 Specify the location of the curtain wall style used in this tool.

By default, the style location is set to Undefined (--) and the styles from the current drawing are displayed in the list of available styles. You can however navigate to one of the curtain wall styles drawings shipped with the product under *c:\documents and settings\all users\application data\autodesk\ACD-A 2009\enu\styles*, or to a user-defined styles drawing.

10 Select a style for the curtain wall tool.

11 Under Bound Spaces, define if this curtain wall tool can be used as a bounding object for associative spaces.

You can select four options here:

- Yes: this curtain wall tool can be used as bounding object for associative spaces.
- No: this curtain wall tool cannot be used as bounding object for associative spaces.
- By style: this curtain wall tool will use the bounding settings from the curtain wall style.
- Undefined (--): If you create a new curtain wall with this tool, it will use the default bounding setting (by style). If you apply the properties of this curtain wall tool to an existing curtain wall, the bounding settings of that curtain wall will be used.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

12 Modify the dimensions of the curtain wall:

If you want to specify ...	Then ...
the base height of the curtain wall	enter a value for Base height.
start and end miter angles	enter miter values for Start Miter and End Miter.
the roof line offset from the base height of the curtain wall	enter a value for Roof line offset from base height.
the floor line offset from the baseline of the curtain wall	enter a value for Floor line offset from baseline.

13 Click OK.

Curtain Wall Styles

Curtain walls are style-based, which means there are preset characteristics assigned to each curtain wall that determine its appearance and function. By changing from one style of curtain wall to another, you can quickly study several different design options. Any changes you make to the style updates all curtain walls of that particular style. You can also apply overrides to a single curtain wall, without changing other curtain walls of the same style.

A curtain wall style controls the following properties of a curtain wall:

- Division definitions/Grids
- Infill definitions
- Frame definitions
- Mullion definitions
- Assignments of grids, infills, frames, and mullions to curtain wall cells
- Materials for each element
- Display properties for each element
- Notes about the style and any associated reference files

Using Materials in Curtain Wall Styles

You can use materials to control how curtain walls of each style are displayed in a drawing. You assign materials to the curtain wall elements in the style. The elements are then displayed using the display properties of the assigned materials.

AutoCAD Architecture provides a large number of predefined materials for common design purposes. You can use these materials, modify them for your project requirements, and define new materials. For more information about materials and how to define them, see [Materials](#) on page 601.

Creating Tools from Curtain Wall Styles

You can create a curtain wall tool from any curtain wall style. You can drag the style from the Style Manager onto a tool palette. You can then specify settings for any curtain wall properties for the tool. For more information, see [Creating a Curtain Wall Tool](#) on page 940.

To create, edit, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture to work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Process Overview: Creating a Curtain Wall Style

When you create a curtain wall style, you assign characteristics to any or all elements of a curtain wall and save them as a named style. In this way, you standardize the appearance of all curtain walls that use the style. When you modify a style, all curtain walls in your drawing that use the style are updated to reflect the changes.

- 1 Define divisions for the curtain wall grid.
For information on defining curtain wall grid definitions, see [Defining Divisions for Curtain Wall Grids](#) on page 945.
- 2 Define the infill for the cells of the curtain wall.
For information on creating infills, see [Defining Infills for Curtain Wall Cells](#) on page 954.
- 3 Define the curtain wall frame, including using profiles and specifying offsets.
For information on defining a frame for a curtain wall, see [Defining Curtain Wall Frames](#) on page 958.
- 4 Define the mullions for the curtain wall, including using profiles and specifying offsets.
For information on ways to define mullions, see [Defining Curtain Wall Mullions](#) on page 963.
- 5 Assign the element definitions you created:

If you want to assign ...	Then ...
a division to a curtain wall grid	see Assigning a Division to a Curtain Wall Grid on page 968.
infills to curtain wall cells	see Assigning Infills to Curtain Wall Cells on page 969.
definitions to curtain wall frames	see Assigning Definitions to Curtain Wall Frames on page 977.
definitions to curtain wall mullions	see Assigning Definitions to Curtain Wall Mullions on page 980.

- 6 Specify the materials of the curtain wall style.
For information on specifying materials, see [Specifying the Materials of a Curtain Wall Style](#) on page 982.
- 7 Specify the display properties of the curtain wall, including layer, color, linetype, and hatching.
For information on specifying the display properties of a curtain wall, see [Specifying the Display of Curtain Walls](#) on page 984.
- 8 Attach notes and reference documents to the curtain wall style.
For information on attaching notes and files, see [Attaching Notes and Files to a Curtain Wall Style](#) on page 989.

Tips for Working Efficiently with Curtain Wall Styles

Use these suggestions to work efficiently and productively with curtain wall styles:

- Name grids and elements very clearly to identify where they are used and what they are. For example, use the name L3-FL1-H to represent a third-level grid used on the first floor and which has a horizontal division.
- Use the element definition that is applied most often as the default element definition. For example, if most cells are stone panels, define the default infill as the stone panel. This panel is then used in every cell that is not specifically assigned to another infill. Apply this rule to the default frame, mullion, and division.
- Use curtain wall units and door and window assemblies to simplify the complexity of a curtain wall style.
- Name the styles for doors, windows, curtain wall units, AEC polygons, and curtain walls to indicate where they are used and what they are.
- Use cell and edge overrides to define special conditions not accounted for in the curtain wall style.

Creating Element Definitions for a Curtain Wall Style

Element definitions determine the appearance of the four basic curtain wall elements. There is a different definition type for each element.

Curtain wall grid element types

Each type of element can have multiple definitions. For example, you can define a division to create a horizontal grid or a vertical grid, and you can define the cells to contain a nested grid or a door/window

assembly. To make reuse easier, you can save the element definitions, and then assign them to grids, cells, frames, or mullions as needed.

Element definitions are style-specific. When you create element definitions for a specific curtain wall style, those definitions are available only for curtain walls of that style. For example, if you define a door and window assembly infill for one curtain wall style, that infill is not available as an option when you edit a curtain wall of a different style.

When you create a new element definition, like a new grid division, a new frame, cell infill, or mullion, you need to define a display component for this element in order to control the visual appearance (layer, color, and linetype properties) of this element separately from the other elements. For example, if you have defined a new panel infill, and want to assign a concrete gray color to that, you need to define a display component for the new infill, and assign it a grey color. For information on defining display components for elements, see [Adding Curtain Wall Element Definitions as Display Components](#) on page 985. If you do not define a display component for a new element, its display will be controlled by the display component of the default element of that type. For example, if you have a new panel infill, but do not define a display component for it, then its display is controlled by the default infill display component.

Creating a Curtain Wall Style

Use this procedure to create a curtain wall style. You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style. You can also create a curtain wall tool based on the newly created curtain wall style. When you use the tool to add curtain walls, each curtain wall has the style specific to the tool.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Create a new curtain wall style:

If you want to create a style ...	Then ...
with default properties	right-click Curtain Wall Styles, and click New.
from an existing style	right-click the curtain wall style you want to copy, and click Copy. Right-click, and click Paste.
from a curtain wall, curtain wall unit, or door and window assembly in the drawing	right-click Curtain Wall Styles, and click New. Right-click the new style, click Set From, and then select a curtain wall, a curtain wall unit, or a door and window assembly in the drawing.

- 4 If necessary, right-click the style again, and click Rename to enter a descriptive name for the new curtain wall style.

- 5 Edit the new curtain wall style:

If you want to ...	Then ...
define the elements of a curtain wall style	see Defining Divisions for Curtain Wall Grids on page 945, Defining Infills for Curtain Wall Cells on page 954, Defining Curtain Wall Frames on page 958, and Defining Curtain Wall Mullions on page 963.
assign element definitions to the curtain wall style	see Assigning Definitions to Curtain Wall Elements on page 968, Assigning a Division to a Curtain Wall Grid

If you want to ...	Then ...
add curtain wall element definitions as display components	on page 968, Assigning Infills to Curtain Wall Cells on page 969, Assigning Definitions to Curtain Wall Frames on page 977, and Assigning Definitions to Curtain Wall Mullions on page 980.
specify layer, color and linetype settings for the display components of a curtain wall	see Specifying the Layer, Color, and Linetype of a Curtain Wall Style on page 985.
specify curtain wall hatching	see Specifying the Hatching for Components of a Curtain Wall Style on page 986.
add custom graphics as display components of a curtain wall style	see Adding Custom Graphics as a Display Component of a Curtain Wall on page 987.
create individual cut planes for curtain wall styles	see Creating Cut Planes for a Curtain Wall on page 988.
specify the materials of the curtain wall style	see Specifying the Materials of a Curtain Wall Style on page 982.
add notes and files to the style	see Attaching Notes and Files to a Curtain Wall Style on page 989.

6 When you finish specifying the properties of the curtain wall style, click OK.

7 If you want to assign the style to a curtain wall tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Curtain Wall Tool](#) on page 940.

8 Click OK.

Defining Divisions for Curtain Wall Grids

The divisions of a grid define the orientation that determines the direction of the grid cells and mullions, and they define a division type that determines the number and size of cells.

NOTE Creating a nested grid is not a division rule. To create a nested grid, add a cell assignment. For more information, see [Creating a Nested Grid in a Curtain Wall](#) on page 971 and [Working with Nested Grids in Curtain Walls](#) on page 969.

You can create a variety of division definitions under different names, and then assign different divisions to each grid in your curtain wall. Although you can create multiple definitions, there can be only one division assignment per grid. You create division definitions for a specific curtain wall style and those definitions can be assigned only to grids in curtain walls of that style.

For more information about assigning divisions to a particular grid, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

Division of Curtain Wall Grids

A curtain wall consists of one or more grids, which are the framework for placing design elements in the curtain wall. The highest-level grid is the primary grid, which is also the outside edge of the curtain wall.

Each grid in a curtain wall has one division assignment that determines whether the grid is divided horizontally or vertically. The division also determines the number of cells, their size, and their placement.

Within the primary grid, you can define multiple levels of grids. These grids within the primary grid are called nested grids. Each subdivision of a grid is called a cell.

Primary grid with 5 horizontal divisions

Primary grid + secondary grid with 8 vertical divisions

Creating a Division Definition for a Curtain Wall

Use this procedure to create divisions for a curtain wall grid.

Because curtain walls can contain multiple nested grids, it is helpful to use a naming convention for grids that indicates the level of each grid and the grid location or the purpose within the curtain wall. For example, L2-FL1-Stone Panels can identify a secondary grid that provides a row of stone panels on Floor 1.

Horizontal division assigned to primary grid

Vertical division assigned to secondary grid

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Click New Division ().
- 7 Enter a name for this division definition.
- 8 Click either Horizontal Orientation () or Vertical Orientation ().
- 9 Select one of the following division types and specify offsets if needed.

Division Type	Description
Fixed Cell Dimension	Creates a grid where the size of the individual cells is fixed at a user-defined size. For more information, see

Division Type	Description
	Specifying a Division with a Fixed Cell Size on page 947.
Fixed Number of Cells	Creates a grid where the number of grid cells is fixed at a user-defined cell number. For more information, see Specifying a Division with a Fixed Cell Number on page 949.
Manual	Creates a grid where the size and number of individual cells is manually determined by the user. For more information, see Specifying a Division with Manually Defined Cells on page 950.
Baseline/ Base Height (horizontal grids only)	Creates a horizontal grid that does not extend to gables or steps in a curtain wall. For more information, see Excluding Gables and Steps from a Curtain Wall Grid on page 951.
Polyline (vertical grids only)	Creates a vertical grid from a polyline that adds a grid line for each vertex of the polyline. For more information, see Dividing a Vertical Curtain Wall Grid at Each Vertex Along a Polyline on page 952.

After you create a division definition, you can assign the definition to a specific grid in a curtain wall. For more information, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

10 When you are finished creating division definitions, click OK.

Specifying a Division with a Fixed Cell Size

Use this procedure to define a division that has a fixed size for the cells contained in it. In this case, the number of cells is determined by the length or height of the grid, depending on the grid orientation.

When you specify a fixed cell size in a grid division, you can control how the cells of the grid adjust to accommodate any leftover space. This space occurs if the length (or the height) of the curtain wall cannot be evenly divided by the fixed size of the cell.

Specifying a fixed size for cells

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Divisions definition or create a new one.
- 7 Under Division Type, select Fixed Cell Dimension.

- 8 Under Cell Dimension, specify a size for the cells.
If you are defining a vertical division, the cell dimension is the length of the cell from mullion to mullion. If you are defining a horizontal division, the cell dimension is the height of the cell.
- 9 To specify an offset for the grid, enter an offset distance in Start Offset/Top Offset or End Offset/Bottom Offset. For more information, see [Specifying an Offset for a Curtain Wall Grid](#) on page 952.

TIP The frame width is calculated as part of the cell size. Therefore, cells adjacent to the frame can appear to be a different size than the other cells. If you do not want the frame width included in the cell size, specify an offset for the grid that is equal to the frame width.

When you draw a curtain wall using a fixed cell dimension, there is often extra space between the last full-size cell and the end of the curtain wall.

- 10 Adjust the cells to accommodate this extra space:

If you want to ...	Then ...
add the space to grid cells	select Auto-Adjust Cells, select Grow for Cell Adjustment, and select the specific cells where the space is to be added. You can select any combination of Specific Cells.
remove the space from grid cells	select Auto-Adjust Cells, select Shrink for Cell Adjustment, and select the specific cells where the space is to be removed. You can select any combination of Specific Cells.

- 11 Under Specific Cells, select the cells where the space is to be added or removed.

You have the following options:

- Start of curtain wall (

948 | Chapter 19 Curtain Walls

- Vertical middle of curtain wall (): If the curtain wall has an uneven number of vertical cells, the middle cell is grown or shrunk. If the curtain wall has a an even number of vertical cells, the two middle cells are grown or shrunk.
- End of curtain wall (): For a vertical division, you can add or remove extraneous space from the end cell of the curtain wall. The end cell is determined by the drawing direction of the curtain wall.
- Top of curtain wall (): For a horizontal division, you can add or remove extraneous space from the top cell of the curtain wall.
- Horizontal middle of curtain wall (): If the curtain wall has an uneven number of horizontal cells, the middle cell is grown or shrunk. If the curtain wall has a an even number of horizontal cells, the two middle cells are grown or shrunk.
- Bottom of curtain wall (): For a horizontal division, you can add or remove extraneous space from the bottom cell of the curtain wall.

You can select multiple options here; for example, you can select to add additional space to the start and end cells, or to the start, middle, and end cells.

12 Click OK.

As the next step, you will assign the division definition to a grid in a curtain wall style. For more information, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

Specifying a Division with a Fixed Cell Number

Use this procedure to define a specific number of cells in a grid. In this case, the size of the cells is determined by the length or height of the grid, depending on how the grid is divided.

In some cases, when you create a complex curtain wall grid, you might want to start with a standard grid with a fixed number of cells, and then later fine-tune that manually. You can first create a grid with fixed cell numbers and then convert that to a manual grid. For information on manual grids, see [Specifying a Division with Manually Defined Cells](#) on page 950.

vertical divisions
with four cells

horizontal divisions
with three cells

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.

- 7 Under Division Type, select Fixed Number of Cells.
- 8 Specify the number of cells.
- 9 To specify an offset for the grid, enter an offset distance for Start Offset or End Offset.
For more information, see [Specifying an Offset for a Curtain Wall Grid](#) on page 952.

NOTE If you want to fine-tune the initial layout with a fixed number of cells, click Convert To Manual Division and edit the grid as described in [Specifying a Division with Manually Defined Cells](#) on page 950.

- 10 Click OK.

For information about assigning the division definition to a specific grid in your curtain wall, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

Specifying a Division with Manually Defined Cells

Use this procedure to manually add gridlines and specify an offset for each one when you need to create a unique grid that does not fit into any of the other division types. You can also start with a fixed cell dimension grid or a fixed number of cells grid, and then manually adjust the grid lines to suit your needs.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Manual for Division Type.
- 8 Click Add Gridline to insert a grid line. Insert as many grid lines as you need. If you need to remove a grid line, select it from the table and click Remove Gridline.
- 9 Under Offset in the gridline table, specify an offset distance for each grid line.

Gridline offset

Gridline	Offset	From
1	2'-6"	Grid Bottom
2	5'-0"	Grid Bottom
3	0"	Grid Middle
4	5'-0"	Grid Top
5	2'-6"	Grid Top

- 10 Under From in the grid line table, select the grid location from which the grid line is offset.

Offset grid line from option

Gridline	Offset	From
1	2'-6"	Grid Bottom
2	5'-0"	Grid Bottom
3	0"	Grid Middle
4	5'-0"	Grid Top
5	2'-6"	Grid Top

- 11 To specify an offset for the grid, enter an offset distance for Start Offset or End Offset.
For more information, see [Specifying an Offset for a Curtain Wall Grid](#) on page 952.
- 12 Click OK.

For information about assigning the division definition to a specific grid in your curtain wall, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

Excluding Gables and Steps from a Curtain Wall Grid

If you are designing a curtain wall that has gables in the roof line or steps in the floor line, there may be occasions when you do not want the grid to extend into those areas. To define your curtain wall in this case, you can define a single-cell horizontal grid that excludes those areas, and then use that grid as a starting point for nested grids. For information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

NOTE For information about adding steps or gables to your curtain wall, see [Changing the Roof Line and the Floor Line of a Curtain Wall](#) on page 1021.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Horizontal for Orientation.
- 8 Select Baseline/Base Height for Division Type.
- 9 Select Divide at Baseline or Divide at Base Height.
 - Divide at Baseline: Forces a division at the baseline to exclude steps from the grid.

division at
bottom of
step

division at
baseline with
zero offset

- Divide at Base Height: Forces a division at the base height to exclude gables from the grid.

division at
bottom of
step

division at
base height
with zero offset

- 10 To offset the division from the baseline, enter a positive number for Baseline Offset.
- 11 To offset the division from the base height, enter a positive number for Base Height Offset.
- 12 Click OK.

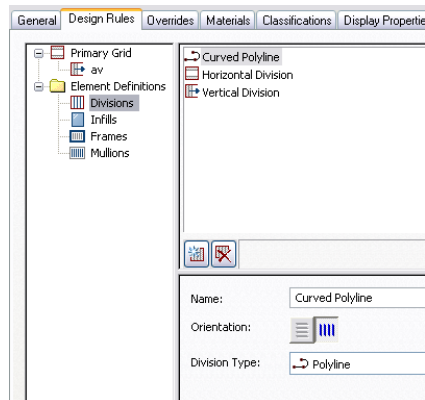

The resulting grid contains a single, horizontal cell. To add additional divisions, use nested grids. For more information, see [Creating a Nested Grid in a Curtain Wall](#) on page 971.

For information about assigning the division definition to a specific grid in your curtain wall, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

Dividing a Vertical Curtain Wall Grid at Each Vertex Along a Polyline

If you create a curtain wall by referencing a polyline, you can define a vertical grid for your curtain wall by placing grid lines at each vertex along the polyline.

- 1 Draw a polyline and use it as a reference curve to create a curtain wall.
For more information, see [Creating a Curtain Wall that References a Curve](#) on page 934.
- 2 Click Format menu ► Style Manager.
- 3 Expand Architectural Objects, and expand Curtain Wall Styles.
- 4 Select a curtain wall style.
- 5 Click the Design Rules tab.
- 6 In the left pane, select Divisions under Element Definitions.
- 7 Select a Division definition or create a new one.
- 8 Select Vertical for Orientation.
- 9 Select Polyline for Division Type.

- 10 Click OK.

For information about assigning the division definition to a specific grid in your curtain wall, see [Assigning a Division to a Curtain Wall Grid](#) on page 968.

Specifying an Offset for a Curtain Wall Grid

By default, grids cells are measured from the start and end points of the curtain wall baseline (for horizontal divisions) or from the floor line to the roof line (for vertical divisions). The width of the grid frame is not considered in calculating the size of the cell. For example, if you draw a curtain wall with a 14' baseline and a 1' frame on the left and right, and you specify a fixed number of vertical cells, the cells do not appear equal in size. The first and last cells appear smaller because they include the frame. To make the cells equal in size, offset the start and end of the grid by the width of the frame.

Specifying grid offset directions

NOTE You can offset the grid only when the division type is Fixed Cell Dimension, Fixed Number of Cells, or Manual.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Fixed Cell Dimension, Fixed Number of Cells, or Manual for Division Type.
- 8 Specify an offset for the grid.

If you want to specify the distance between ... Then ...

the start point of the curtain wall baseline and the start of the first cell in a horizontal grid enter a value for Start Offset.

the end point of the curtain wall baseline and the end of the last cell in a horizontal grid enter a value for End Offset.

the floor line of the curtain wall and the start of the bottom cell in a vertical grid enter a value for Bottom Offset.

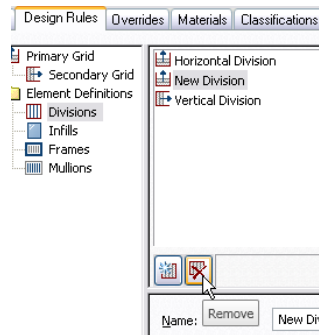

the roof line of the curtain wall and the end of the top cell in a vertical grid enter a value for Top Offset.

- 9 Click OK.

Removing a Division Definition from a Curtain Wall Style

Use this procedure to remove a division definition that you no longer need. You cannot remove a division definition when it is currently assigned to a grid. In addition, you cannot remove the default division definition, but you can modify it.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition that you want to remove.
- 7 Click Remove.

- 8 Click OK.

Defining Infills for Curtain Wall Cells

An infill defines the contents of a curtain wall cell. A curtain wall cell can have the default simple panel or contain a nested grid, an AEC Polygon, curtain wall unit, door, window, or door/window assembly style. The object styles you use in infills must exist in the current drawing to be added to an infill definition. Panels typically represent glazing or other plain cladding, such as stone or concrete. For more information, see [Assigning Infills to Curtain Wall Cells](#) on page 969.

Specifying different infills

NOTE Nested grids and no infill are options you select when assigning an infill to a cell. These options do not require infill definitions. For more information, see [Creating a Nested Grid in a Curtain Wall](#) on page 971 and [Removing an Infill from a Curtain Wall Cell](#) on page 975.

You can define as many infills as you need, and then use cell assignments to specify the cells that use each infill. You can modify, as needed, a default infill that is used for all unassigned cells. For more information about cell assignments, see [Assigning Definitions to Curtain Wall Elements](#) on page 968.

NOTE Create infill definitions for a specific curtain wall style. Those definitions can be assigned only to grid cells in curtain walls of that style.

Materials

Styles use the materials of the object style assigned to each panel. For example, if you specify an infill to use the Standard door style, the materials of that infill are those designated in the door style. Simple Panels need material assigned in the curtain wall style.

If you do not use materials to control the display properties of infills, you can specify their display properties in the curtain wall style. The layer, color, linetype, and other display properties of the default infill are applied to all infills unless you create a custom display component for each infill definition. You can then control the display of each infill definition independently. For more information, see [Specifying the Display of Curtain Walls](#) on page 984.

Creating a Panel Infill for a Curtain Wall

Use this procedure to create a simple panel infill to represent basic cladding materials in the curtain wall, such as a stone wall panel, concrete panel, metal panel, or glazing infill.

Because curtain walls can contain multiple infills, it is helpful to use a naming convention for panel infills that indicates the infill location or purpose within the curtain wall. For example, L3-FL1- Stone Panel can identify a stone panel in a third-level grid on Floor 1.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Click New Infill.
- 7 Enter a descriptive name for the infill.
- 8 Select Simple Panel as the infill type.
- 9 Specify an alignment for the infill.

For more information, see [Specifying an Alignment for a Curtain Wall Infill](#) on page 956.

- 10 Specify an offset for the infill.

For more information, see [Specifying an Offset for a Curtain Wall Infill](#) on page 957.

- 11 Specify a thickness for the panel.

Specifying infill panel thickness

- 12 Click OK.

After you create an infill definition, you can assign it to any cell in a curtain wall grid. For more information, see [Assigning Infills to Curtain Wall Cells](#) on page 969.

Creating a Style Infill for a Curtain Wall

Use this procedure to create a style infill to insert objects into a curtain wall. You can insert doors, windows, door/window assemblies, curtain wall units, and AEC Polygons by defining a specific style of that object as an infill.

TIP After you insert an object in a cell, you can select that object independent of the grid and access editing options for the object.

Because curtain walls can contain multiple object styles, it is helpful to use a naming convention for style infills that indicates the infill location or purpose within the curtain wall. For example, L3-FL1-Octagonal Window can identify an octagonal window in a third-level grid on Floor 1.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Click New Infill.
- 7 Enter a descriptive name for the infill.
- 8 Select Style as the infill type.
The bottom right pane changes to display a tree view of the object styles available for insertion into a curtain wall.
- 9 Select an object style.

There is a unique icon for each type of style. For example, the door style icon  and the curtain wall unit icon . These icons are also displayed next to the infill name at the top of the dialog box to help you identify the type of infill.
- 10 Specify an alignment for the infill. For more information, see the next section [Specifying an Alignment for a Curtain Wall Infill](#) on page 956.
- 11 Specify an offset for the infill. For more information, see [Specifying an Offset for a Curtain Wall Infill](#) on page 957.
- 12 Click OK.

After you create an infill definition, you can assign it to any cell in a curtain wall grid. For more information, see [Assigning Infills to Curtain Wall Cells](#) on page 969.

Specifying an Alignment for a Curtain Wall Infill

Use this procedure to align an infill so that it is centered with the baseline of the curtain wall, in front of the baseline, or behind the baseline. In Plan view, the front of a curtain wall (drawn from left to right) is below the baseline and the back is above the baseline.

NOTE To move the infill away from the baseline, see [Specifying an Offset for a Curtain Wall Infill](#) on page 957.

Specifying infill alignments

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select an infill, or create a new one.
- 7 Select an alignment: front, center, or back.
- 8 Click OK.

Specifying an Offset for a Curtain Wall Infill

Use this procedure to specify an offset for a curtain wall infill. By default, infills are centered on the curtain wall baseline. If your design requires that the infill be aligned with frame edges or some other part of the curtain wall, you can specify an offset for the infill.

You can also edit individual style-based infills directly in the drawing. The selected infill has Flip grips in both the X and Y directions so that you can change the orientation of the infill.

Specifying panel infill offsets

- 1 Click Format menu ► Style Manager.

- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select an infill, or create a new one.
- 7 Enter an offset distance.

In Plan view, positive numbers offset the infill above the baseline and negative numbers offset the infill below the baseline. The offset is also affected by the selected alignment for the infill.

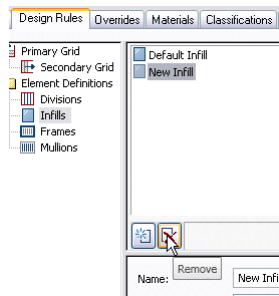

- 8 Click OK.

Removing an Infill Definition from a Curtain Wall Style

Use this procedure to delete an infill definition that you no longer need from the Infills definitions list. You cannot remove an infill definition when it is currently assigned to a cell. In addition, you cannot remove the default infill definition, but you can modify it as needed.

NOTE For information about removing an infill from a cell, see [Removing an Infill from a Curtain Wall Cell](#) on page 975.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select the unneeded infill definition, and click Remove.

- 7 Click OK.

Defining Curtain Wall Frames

All curtain wall grids, including the primary grid, can have frame definitions. The frame of the primary grid defines the outer edges of the curtain wall. The overall frame size is determined by the length and height of the primary curtain wall grid or a nested curtain wall grid. You can define a frame by specifying a width and depth or by selecting a profile.

Specifying default and profile-based frames

You create frame definitions for a specific curtain wall style. Those definitions can be assigned only to frames in curtain walls of that style. You can create as many frame definitions as you want, and then assign the definitions to the frames as needed. If you have nested grids, each grid has its own frame. There is a default frame definition that you can modify and assign as needed. Unassigned frames are not displayed. For more information, see [Assigning Definitions to Curtain Wall Frames](#) on page 977.

TIP Using Style Manager, you can copy a mullion definition and use it as a frame definition. Select the mullion definition and drag it to Frames in the left pane of the Design Rules tab.

Materials and Display Properties for Frames

If you do not use materials to control the display properties of frames, you can specify their display properties in the curtain wall style. The layer, color, linetype, and other display properties of the default frame are applied to all frames unless you create a custom display component for each definition. You can then control the display of each frame definition independently. For more information, see [Specifying the Display of Curtain Walls](#) on page 984.

Defining a Curtain Wall Frame by Width and Depth

You can define a frame by specifying its width and depth. The overall frame size is determined by the length and height of the curtain wall grid.

Specifying frame width and depth

Because curtain walls can contain multiple object styles with different frames, it is helpful to use a naming convention for grid frames that indicates the grid location or purpose within the curtain wall. For example, L3-FL1- Metal Frame can identify a metal frame for a third-level grid on Floor 1.

TIP To remove the frame edge and have the infill adjust to fill the space occupied by the frame, create a frame definition with both width and depth set to zero. Then, assign that definition to the frame edge that you want to remove. This is necessary for the infill to be mitered as it would be for a butt-glazed condition. For more information, see [Removing a Frame Edge from a Curtain Wall](#) on page 978.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.

6 Click  to create a new frame definition.

- 7 Enter a descriptive name for the frame.
- 8 Specify a width and depth for the frame.
- 9 Specify any offsets.

For more information, see [Specifying Offsets for a Curtain Wall Frame](#) on page 961.

- 10 Click OK.

After you create a frame definition, you can assign it to any frame in a curtain wall. For more information, see [Assigning Definitions to Curtain Wall Frames](#) on page 977.

Creating a Profile for a Curtain Wall Frame

Use this procedure to create a profile that you can use to define the shape of a curtain wall frame. You can then extrude the profile to create a curtain wall frame.

The height and the width of the polyline you use to create the profile define the default height and width of the curtain wall frame. The insertion point of the profile is aligned with the centroid of the frame.

- 1 Draw a closed polyline of the height and the depth needed for the resulting curtain wall frame.
- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.
- 3 Enter **c** (Centroid) for the insertion point of the profile.
The insertion point of the profile is aligned with the centroid of the frame.
- 4 Enter a name for the profile, and click OK.

You can now use the profile as a curtain wall frame. For more information, see [Defining a Curtain Wall Frame Using a Profile](#) on page 960.

Defining a Curtain Wall Frame Using a Profile

Use this procedure to create a frame element definition from a profile. If you do not want a straight edge to your frame, you can use a profile to define edges with curves, jags, or any other shape you require.

You can also use an edit in-place routine to create a frame from a profile. For more information, see [Creating a Frame or Mullion Edge from a Polyline or Profile Using In-Place Editing](#) on page 998.

Two profile-based frame examples

NOTE The insertion point of the profile is aligned with the centroid of the frame.

1 Create the profile for the frame.

For information on creating profiles for curtain wall frames, see [Creating a Profile for a Curtain Wall Frame](#) on page 960.

2 Click Format menu ► Style Manager.

3 Expand Architectural Objects, and expand Curtain Wall Styles.

4 Select a curtain wall style.

5 Click the Design Rules tab.

6 In the left pane, select Frames under Element Definitions.

7 Click New Frame.

8 Enter a descriptive name for the frame.

9 Specify a width and depth for the frame edge.

These dimensions are used to calculate the center point of the edge for aligning the profile and also to specify a boundary for the adjacent infill.

10 Select Use Profile.

NOTE The Profile options are available only if you have profiles in the current drawing.

11 Select a profile from the list.

By default, the profile is inserted using the same width and depth with which it was created.

12 To adjust the size of the profile to fit within the width or depth dimension of the frame edge, select Auto-Adjust Profile Width or Depth.

13 To mirror the profile, select to mirror along the X or Y axis.

14 To rotate the profile, specify an angle for Rotation.

15 Specify any offsets.

For more information, see [Specifying Offsets for a Curtain Wall Frame](#) on page 961.

16 Click OK.

After you create a frame definition, you can assign it to any frame in a curtain wall. For more information, see [Assigning Definitions to Curtain Wall Frames](#) on page 977.

Specifying Offsets for a Curtain Wall Frame

Use this procedure to define the distance that a curtain wall frame is from the floor line, roof line, or baseline. By default, the outside edges of the frame align with the start and end of the floor line and the start and end of the roof line. When you adjust the width of the frame, the frame expands inward. However, you can

use offsets to expand or contract the frame away from these default limits or to shift the frame away from the baseline in either the X or Y direction.

Offset	Description
X	Positive X offset moves the frame edge outward beyond the end of the curtain wall, while a negative X offset moves the frame edge inward toward the center of the curtain wall.
Y	In Plan view, a positive Y offset moves the frame edge above the baseline, while a negative Y offset moves the frame below the baseline.
Start	Negative Start offset lengthens the frame beyond the start point, while a positive Start offset shortens the frame. The start point for vertical edges is the baseline, and the start point for horizontal edges (drawn left to right) is the left side.
End	Negative End offset lengthens the frame beyond the end point, while a positive End offset shortens the frame. The end point for vertical edges is the base height, and the end point for horizontal edges (drawn left to right) is the right side.

Specifying frame offsets in the x and y directions

TIP To quickly identify the start and end of a curtain wall, select the curtain wall. The Reverse Direction grip is displayed near the center of the curtain wall and points toward the end of the curtain wall.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Select a frame definition from the list.
- 7 Specify an offset distance for the frame edge.
- 8 Click OK.

Removing a Frame Definition from a Curtain Wall Style

Use this procedure to remove a frame definition from the Frame definitions list. You cannot remove a frame definition if it is currently assigned to a frame edge, but you can remove it if it is assigned as an override to a frame edge. In addition, you cannot remove the default frame definition, but you can modify it as needed.

NOTE For information about removing a frame edge, see [Removing a Frame Edge from a Curtain Wall](#) on page 978.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Select the unneeded frame definition.
- 7 Click Remove Frame.
- 8 Click OK.

Defining Curtain Wall Mullions

All curtain wall grids, including the primary grid, can have mullion definitions. The mullion of the primary grid defines the outer edges of the curtain wall. You can define the mullions by specifying a width and depth or by selecting a profile from which the mullion is extruded.

Because curtain walls can contain multiple nested grids with different mullions, it is helpful to use a naming convention for grid mullions that indicates the level of each grid and the grid location or purpose within the curtain wall. For example, L3-FL1-Window Mullion can identify a mullion for a window in a third-level grid on Floor 1.

Specifying default and profile-based mullions

You create mullion definitions for a specific curtain wall style and those definitions can be assigned only to mullions in curtain walls of that style. You can create as many mullion definitions as you want, and then assign the definitions to mullions as needed. If you have nested grids, each grid has its own mullions. There is a default mullion definition that you can modify as needed that is used for any unassigned mullions. For more information, see [Assigning Definitions to Curtain Wall Mullions](#) on page 980.

TIP Using Style Manager, you can copy a frame definition and use it as a mullion definition. Select the frame definition and drag it to Mullions in the left pane of the Design Rules tab.

Materials and Display Properties for Mullions

If you do not use materials to control the display properties of mullions, you can specify their display properties in the curtain wall style. The layer, color, linetype, and other display properties of the default mullion are applied to all mullions unless you create a custom display component for each definition. You can then control the display of each mullion definition independently. For more information, see [Specifying the Display of Curtain Walls](#) on page 984.

Defining Curtain Wall Mullions by Width and Depth

You can define mullions by specifying a width and a depth.

Specifying mullion width and depth

TIP To remove mullions for butt glazing, create a definition with both width and depth set to zero. Then, assign that definition to the mullions that you want to remove. For more information, see [Removing Mullions from a Curtain Wall Grid](#) on page 982.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Click New Mullion.
- 7 Enter a descriptive name for the mullion.
- 8 Specify a width and depth for the mullion.
- 9 Specify the offsets you want.

For more information, see [Specifying Offsets for the Mullions of a Curtain Wall](#) on page 966.

- 10 Click OK.

After you create a mullion definition, you can assign it to any mullion in a curtain wall. For more information, see [Assigning Definitions to Curtain Wall Mullions](#) on page 980.

Creating a Profile for Curtain Wall Mullions

Use this procedure to create a profile that you can use to define the shape of a curtain wall mullion definition. You can then extrude the profile to create mullions from it.

The height and the width of the polyline you use to create the profile define the default height and width of the curtain wall mullion. The insertion point of the profile is aligned with the centroid of the mullion.

- 1 Draw a closed polyline of the height and the depth needed for the resulting curtain wall mullion.
- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.
- 3 Enter **c** (Centroid) for the insertion point of the profile.

The insertion point of the profile is aligned with the centroid of the mullion.

- 4 Enter a name for the profile, and click OK.

You can now use the profile as a curtain wall mullion. For more information, see [Defining the Mullions of a Curtain Wall Using a Profile](#) on page 965.

Defining the Mullions of a Curtain Wall Using a Profile

Use this procedure to create a mullion element definition from a profile. If you do not want a straight edge to your mullions, you can use a profile to define mullions with curves, jags, or any other shape.

You can also use an edit in-place routine to create a mullion from a profile. For more information, see [Creating a Frame or Mullion Edge from a Polyline or Profile Using In-Place Editing](#) on page 998.

NOTE The insertion point of the profile is aligned with the centroid of the mullion.

Infill alignments with default and profile-based mullions

default mullions

profile-based mullions

- 1 Create the profile to use for the mullion.
For information, see [Creating a Profile for Curtain Wall Mullions](#) on page 964.
- 2 Click Format menu ► Style Manager.
- 3 Expand Architectural Objects, and expand Curtain Wall Styles.
- 4 Select a curtain wall style.
- 5 Click the Design Rules tab.
- 6 In the left pane, select Mullions under Element Definitions.
- 7 Click New Mullion.
- 8 Enter a descriptive name for the mullion.
- 9 Specify a width and depth for the mullion.

These dimensions are used to calculate the center point of the mullion for aligning the profile, and also to specify a boundary for the adjacent infill.

10 Select Use Profile.

NOTE The Profile options are available only if you have profiles in the current drawing.

11 Select a profile from the list.

By default, the profile is inserted using the same width and depth with which it was created.

12 To adjust the size of the profile to fit within the width or depth dimension of the mullion, select Auto-Adjust Profile Width or Depth.

13 To mirror the profile, select X or Y for Mirror In.

14 To rotate the profile, specify a rotation angle for Rotation.

15 Specify any offsets.

For more information, see [Specifying Offsets for the Mullions of a Curtain Wall](#) on page 966.

16 Click OK.

After you create a mullion definition, you can assign it to any mullion in a curtain wall. For more information, see [Assigning Definitions to Curtain Wall Mullions](#) on page 980.

Specifying Offsets for the Mullions of a Curtain Wall

Use this procedure to define mullions that are offset from the start or end of the curtain wall to lengthen or shorten the edge or offset in the X or Y direction to shift the edge. For example, you might want to represent butt glazing by offsetting the mullions to be behind glass panel infills.

Offset	Description
X	For vertical mullions, a positive X offset moves the mullions toward the end of the curtain wall, while a negative X offset moves the mullions toward the start of the curtain wall. For horizontal mullions, a positive X offset moves the mullions toward the top of the curtain wall, while a negative X offset moves the mullions toward the bottom of the curtain wall.
Y	In Plan view, a positive Y offset moves the mullions above the baseline, while a negative Y offset moves the mullions below the baseline.
Start	Negative Start offset lengthens the mullions beyond the start point, while a positive Start offset shortens the mullions.
End	Negative End offset lengthens the mullions beyond the end point, while a positive End offset shortens the mullions.

Specifying mullion offsets in x and y directions

TIP To quickly identify the start and end of a curtain wall, select the curtain wall. The Reverse Direction grip is displayed near the center of the curtain wall and points toward the end of the curtain wall.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Select a mullion definition from the list.
- 7 Specify an offset distance for the X, Y, Start, or End.
- 8 Click OK.

Removing a Mullion Definition from a Curtain Wall Style

Use this procedure to remove a mullion definition from the Mullions definitions list. You cannot remove a mullion definition if it is assigned to a mullion, but you can remove it if it is assigned as an override to a mullion. In addition, you cannot remove the default mullion definition, but you can modify it as needed.

NOTE For information about removing mullions from between cells, see [Removing Mullions from a Curtain Wall Grid](#) on page 982.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Select the unneeded mullion definition from the list.
- 7 Click Remove Mullion.
- 8 Click OK.

Assigning Definitions to Curtain Wall Elements

After you've created element definitions for a curtain wall style, you can assign those definitions to each of the curtain wall element types: divisions, cell infills, frames, and mullions.

By default, one definition is assigned to all elements of a particular type. However, you can assign definitions to individual elements as well. For example, all cells in the grid are assigned the default infill. You can, however, create a new cell assignment, select a different infill, and then specify the cells to use that infill.

Assignment list

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Vertical Division	Grid	This grid division
Cell Assignments			
Default Cell Assignment	2 Inch panel	Default	All unassigned cells
Door	Standard	Location	Middle
Window	Casement Wi...	Index	1, 2, 4, 5
Frame Assignments			
Custom Corner	Profile	Location	Left, Right
Default Frame Assignment	Default Frame	Location	*NONE*
Mullion Assignments			
Default Mullion Assignment	Default Mullion	Default	All unassigned mullions
Main Mullions	12 inches Mulli...	Index	1, 3, 5
Secondary Mullions	4 inches Mullions	Index	2, 4

For more information about element definitions, see [Creating Element Definitions for a Curtain Wall Style](#) on page 943.

Assigning a Division to a Curtain Wall Grid

Use this procedure to assign a division to a curtain wall grid. A division defines the grid orientation (whether the direction of the grid cells and mullions is horizontal or vertical) and the division type (number and size of cells).

After you define a division, you can assign it to the primary grid or to nested grids. Nested grids are created by selecting Nested Grid as the cell assignment. For more information, see [Working with Nested Grids in Curtain Walls](#) on page 969.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid you want to assign a division to.

The name of the grid you select is displayed in the table under the Division Assignment row.

TIP To rename a grid, select it, and click Rename and enter a new name.

- 6 Click the Element column for that grid and select a division definition from the list.
- 7 Click OK.

Assigning Infills to Curtain Wall Cells

An infill defines the contents of a curtain wall cell. A curtain wall cell can have the default simple panel or contain a nested grid, an AEC Polygon, curtain wall unit, door, window, or door/window assembly style. The object styles you use in infills must exist in the current drawing to be added to an infill definition. Panels typically represent glazing or other plain cladding, such as stone or concrete. For more information, see [Defining Infills for Curtain Wall Cells](#) on page 954.

Cell Assignments

A cell assignment defines the infill definition used for the cells. You can use one cell assignment to assign the same infill to all cells, or you can create multiple cell assignments to assign different infills to different cells.

Cell assignments

Cell Assignments			
<input checked="" type="checkbox"/> Default: Cell Assignment	2 Inch panel	Default	All unassigned cells
<input type="checkbox"/> Door	Standard	Location	Middle
<input type="checkbox"/> Window	Casement Wi...	Index	1, 2, 4, 5

Do not assign multiple definitions to the same cell because only the last assigned definition to the cell is used.

Default Cell Assignment

The default cell assignment is used by all unassigned cells. You can modify the default assignment to be any type of infill, but you cannot delete the default cell assignment.

You may want to modify the default cell assignment to use the infill definition that occurs most frequently in your design. Any cells not assigned to other infills then use this infill definition.

Materials and Display Properties of Infills

The layer, color, linetype, and other display properties of the default infill are applied to all infills unless you assign materials to the infills you created or you create a custom display component for each definition. You can then control the display of each infill definition independently. For more information, see [Specifying the Display of Curtain Walls](#) on page 984.

Working with Nested Grids in Curtain Walls

Each curtain wall grid is one-dimensional with either a horizontal or vertical division. By nesting grids in the curtain wall style, you can create a variety of patterns from simple to complex.

Example of nested grids

Simple Primary Grids

When you nest grids, you start with one primary grid. Each cell in the primary grid can then be filled with another grid. For example, if your primary grid is horizontal and has three cells, you can nest a vertical grid in each horizontal cell to create a simple two-dimensional (2D) grid. This is the nesting configuration for the Standard curtain wall style.

Specifying cell division definitions 1

The previous illustration shows all cells in the grid with the same cell assignment—a vertical division. However, each cell in a grid is independent and can have a separate assignment. For example, the following illustration shows a three cell horizontal grid with different assignments in each cell. The bottom cell contains another horizontal division, the middle cell contains vertical divisions of varying width, and the top cell contains a vertical divisions of a fixed width.

Specifying cell division definitions 2

Multiple Nested Grids

You can continue to nest grids to create multiple levels. For example, the following illustrations show the Standard curtain wall style, which is a simple two-dimensional (2D) grid, with one horizontal cell and three vertical cells. Another grid is nested in the first cell of the secondary grid. This creates a tertiary grid. The final illustration shows the nested grids assigned to all cells.

Specifying a sequence of nested grids

Defining Nested Grids

You can define nested grids by using the Design Rules tab of the Curtain Wall Style Properties dialog box. The tree in the left pane lists the grids. There is always one primary grid. The primary grid can have one or more secondary grids. Each secondary grid can have one or more tertiary grids, and so on.

TIP To quickly create nested grids in all cells, change the default cell assignment to Nested Grid. If you want multiple levels of nesting, be sure to change the default cell assignment for each grid. For more information, see [Creating a Nested Grid in a Curtain Wall](#) on page 971.

Each grid has its own cell assignments. You assign cells to contain another grid, a panel infill, or an object such as a door or window. For more information, see [Assigning Infills to Curtain Wall Cells](#) on page 969.

Primary grid and cell assignments

Name	Element	Type	Used In
Division Assign...			
Primary Grid	Horizontal Division	Grid	This grid division
Cell Assignments			
Door	Standard Door	Location	Bottom, Top
Secondary Grid	*Nested Grid*	Default	All unassigned cells
Frame Assignm...			
Default Frame ...	Default Frame	Location	Left, Right, Top, Bot...
Mullion Assignm...			

Secondary grid and cell assignments

Name	Element	Type	Used In
Division Assign...			
Secondary Grid	Vertical Division	Grid	This grid division
Cell Assignments			
Default Cell As...	Default Infill	Default	All unassigned cells
Vertical	*Nested Grid*	Location	Start, End
Frame Assignm...			
Default Frame ...	Default Frame	Location	"NONE"
Mullion Assignm...			

Creating a Nested Grid in a Curtain Wall

Use this procedure to create a nested grid in a curtain wall. A nested grid is a grid within a grid. Each nested grid has its own division, cell assignments, frame, and mullions. By default, the frame is turned off for nested grids.

For more information, see [Working with Nested Grids in Curtain Walls](#) on page 969.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a nested grid.
- 6 Click New Cell Assignment.
 - A new cell assignment is displayed in the list of cell assignments.
- 7 Select the cell assignment in the top right frame, right-click and click Rename, and then enter a descriptive name.
- 8 Select Nested Grid in the Element column.
 - A new grid is added to the list of grids in the left pane. If you are editing the primary grid, the new grid is added at the secondary level. If you are editing a grid at the secondary level, the additional grid is placed at the tertiary level, and so on.

Creating a nested grid

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Vertical Division	Grid	This grid division
Cell Assignments			
Default Cell Assignment	Panel	Default	All unassigned c
Vertical	*Nested Grid*	Location	Start, End
Frame Assignments			
Custom Corner	*Nested Grid*	Location	Left, Right
Default Frame Assignment	2-inch Panel	Location	"NONE"
Mullion Assignments	Casement Window		
Default Mullion Assignment	Panel		
Primary Mullions	Standard Door		
Secondary Mullions	window style		
	"NONE"	Index	2, 4
	New Infill	Index	1, 3, 5
	Default Mullion		

New nested grid in tree

NOTE To rename a grid, select it in the right pane, right-click and click Rename, and enter a new name.

9 Specify the cells to contain this nested grid.

For more information, see [Specifying Which Curtain Wall Cells Use a Cell Assignment](#) on page 975.

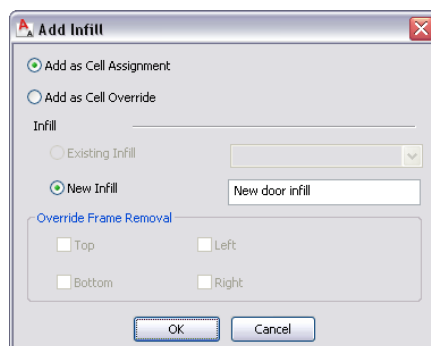

10 Click OK.

Inserting a Door, Window or Door/Window Assembly into a Curtain Wall Cell

Use this procedure to add doors, windows and door/window assemblies to a curtain wall. For more information, see [Defining Infills for Curtain Wall Cells](#) on page 954.

- 1 Open the tool palette that you want to use, and select a door, window or door/window assembly.
- 2 Select the curtain wall in which to insert the door, window or door/window assembly.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Select the curtain wall cell marker for the cell in which to insert the door, window or door/window assembly.

The Add Infill worksheet opens.

4 Select the insertion method for the door, window or door/window assembly:

If you want to...

Then...

add the door, window or door/window assembly as a cell assignment and have all curtain walls using the same style

select Add as Cell Assignment.

If you want to...	Then...
display the same object added in a corresponding cell	
add the door, window or door/window assembly exclusively to the selected curtain wall	select Add as Cell Override.
If a door, window or door/window assembly of the style you selected already exists in your drawing, Existing Infill is selected by default.	

5 Select the type of infill for the door, window or door/window assembly:

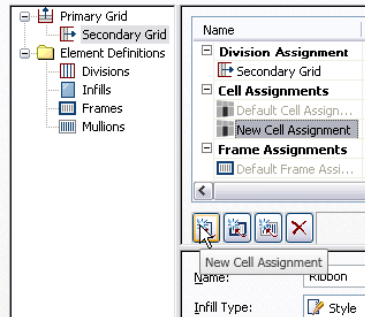

If you selected...	Then...
Add as Cell Assignment and you want to insert a door, window or door/window assembly of the existing style, Existing Infill is selected by default.	Click OK.
Add as Cell Assignment and you want to insert a door, window or door/window assembly of a different style than exists in your drawing	select New Infill, enter a name for the object and click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of the existing style and not modify the edge of the frame surrounding the object	Click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of a different style than exists in your drawing and not remove an edge of the frame surrounding the object	select New Infill, enter a name for the object and click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of the existing style and remove an edge of the frame surrounding the object	select Top, Bottom, Left, or Right for Override Frame Removal and click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of a different style than exists in your drawing and remove an edge of the frame surrounding the object	select New Infill and enter a name for the object. Then select Top, Bottom, Left, or Right for Override Frame Removal and click OK.

6 Press *ENTER*.

Filling a Curtain Wall Cell with a Simple Panel

Use this procedure to fill a curtain wall cell with a simple panel. Simple panels are generally used to represent basic cladding materials in the curtain wall, such as a stone wall panel or a concrete panel.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to put a simple panel infill.
- 6 Click New Cell Assignment.

A new cell assignment is displayed in the list of cell assignments.

- 7 Select the cell assignment in the top right pane, right-click and click Rename, and then enter a descriptive name.
- 8 Under Element, select an infill that defines a simple panel.
If you do not have a simple panel infill defined, then select New Infill and define one. For more information, see [Creating a Panel Infill for a Curtain Wall](#) on page 955.
- 9 Specify the cells to contain this simple panel.
For more information, see [Specifying Which Curtain Wall Cells Use a Cell Assignment](#) on page 975.
- 10 Click OK.

Inserting an Object into a Curtain Wall Cell

Use this procedure to insert objects, such as curtain wall units and AEC Polygons, into a curtain wall cell. Curtain wall cells can contain these objects when you create infill definitions that use them. For more information, see [Creating a Style Infill for a Curtain Wall](#) on page 956.

TIP After you insert an object in a cell, you can select that object independent of the grid, right-click, and access editing options for the object.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to insert objects.
- 6 Click New Cell Assignment.

A new cell assignment is displayed in the list of cell assignments.

- 7 Select the cell assignment in the top right frame, right-click and click Rename, and then enter a descriptive name.
- 8 Select an infill that uses an object style.
- 9 Specify the cells to contain this object.
For more information, see [Specifying Which Curtain Wall Cells Use a Cell Assignment](#) on page 975.
- 10 Click OK.

Removing an Infill from a Curtain Wall Cell

Use this procedure to remove the infill of a cell and leave the cell empty. To do this, use None as the element definition. Using None also removes any frame edges that border the cell, but it does not affect the mullions.

Removing an infill assignment from a cell

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid that contains the cells you want to assign to None.
- 6 Create a new cell assignment or select an existing cell assignment.
- 7 Select NONE under the Element column.
- 8 Specify the cells to contain the None infill.
For more information, see [Specifying Which Curtain Wall Cells Use a Cell Assignment](#) on page 975.
- 9 Click OK.

Specifying Which Curtain Wall Cells Use a Cell Assignment

When you create a cell assignment you need to specify the cells in the grid to use that assignment. There are two options for selecting cells:

- Use Location to insert the infill into the start, middle, or end cells of a vertical grid or into the bottom, middle, or top cells of a horizontal grid. If there is an even number of cells (four or more), Middle refers to the two cells in the middle of the grid. If there is an odd number of cells (three or more), Middle refers to one cell in the middle of the grid.

Specifying cell assignments by location

- Use Index to insert the infill into specific cells based on cell numbers. Cells are numbered from start to end or bottom to top. For example, typing 1, 3, 5 would place the infill in the first, third, and fifth cells.

Specifying cell assignment by index

TIP When you are trying to determine cell assignments in a grid that has both vertical and horizontal cells it is helpful to remember that each of these directions is actually in a separate grid. You can have a vertical grid with a nested horizontal grid, or the other way around. Select each grid separately to make cell assignments.

Any cells that are not assigned a specific cell assignment use the default infill.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 In the right pane, select Location or Index for Type.
- 7 Select a cell assignment:

If you select ...	Then ...
Location	click the Used In column, and click the button at the far right of the row. Select the cells you want to use this assignment, and click OK.
Index	enter the cell numbers separated by commas in the Used In column. For vertical grids, cells are numbered from start to end and for horizontal grids, cells are numbered from bottom to top.

NOTE Do not assign multiple definitions to a cell because the last definition assigned to the cell is used.

8 Click OK.

Removing an Assignment from a Curtain Wall Style
