Use this procedure to remove cell assignments, frame assignments, and mullion assignments from a curtain wall style. You cannot remove default assignments, but you can modify them to suit your needs.

NOTE Each grid requires one division assignment. Therefore, you cannot remove the division assignment, although you can change the division element used for the division assignment.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid from which you want to remove an assignment.
- 6 Select a cell assignment, frame assignment, or a mullion assignment.
- 7 Click Remove Assignment.
- 8 Click OK.

Assigning Definitions to Curtain Wall Frames

The curtain wall frame is represented by the outer edges of the primary grid. Each nested grid has its own frame that is defined separately from the primary grid frame. By default, the frames of nested grids are turned off. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

Frame Assignments

A frame assignment defines the frame definition that is used by each frame edge. You can use one frame assignment to assign the same definition to all four edges of the frame, or you can create multiple frame assignments to assign different definitions to different edges of the frame. Unassigned edges are not displayed.

Do not assign multiple definitions to the frame edge because only the last definition assigned to the edge is used.

Default Frame Assignment

There is a default frame assignment and you can select the frame edges it applies to. You can modify the default assignment to use any frame definition, but you cannot delete the default frame assignment.

Materials and Display Properties of Frames

The layer, color, linetype, and other display properties of the default frame are applied to all frame edges unless you assign materials to the frame definition or you create a custom display component for each definition. You can then control the display of each frame definition independently. For more information, see [Specifying the Display of Curtain Walls](#) on page 984.

Adding a New Frame Assignment to a Curtain Wall

Use this procedure to add a frame assignment to a curtain wall. To assign different definitions to different frame edges, you need multiple frame assignments.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a new frame assignment.
- 6 Click New Frame Assignment.

A new frame assignment is displayed in the list of frame assignments.

New frame assignment

Name	Element	Type	Used In
Division Assignment			
Cell Assignments			
Frame Assignments			
Custom Corner	Profile	Location	Left, Right
Default Frame Assignment	Default Frame	Location	*NONE*
New Frame Assignment	Custom Corner	Location	Left, Right
Mullion Assignments			

- 7 Select the frame assignment in the right pane, right-click and click Rename, and then enter a descriptive name.
- 8 Select a frame definition from the Element column.
- 9 Specify the sides of the frame to use this frame assignment.
For more information, see [Specifying Which Curtain Wall Edges Use a Frame Assignment](#) on page 979.
- 10 Click OK.

Removing a Frame Edge from a Curtain Wall

Use this procedure to remove a frame edge from a curtain wall. There are three ways to remove a frame edge:

- Set the width and depth of the edge to zero
- Leave the edge unassigned
- Specify None as an override to the edge assignment

The first two methods remove the frame edge and expand the adjacent infills into the space occupied by the edge.

Specifying a frame width and depth of zero

By specifying None as an override, the frame edge is not displayed, but the adjacent infill is not expanded into the space the edge occupied.

Overriding a frame edge definition

For information about setting the width and depth to zero, see [Defining a Curtain Wall Frame by Width and Depth](#) on page 959.

For information about leaving the edge unassigned, see [Specifying Which Curtain Wall Edges Use a Frame Assignment](#) on page 979.

For information about overriding the edge, see [Overriding Curtain Wall Frames and Mullions](#) on page 996.

Specifying Which Curtain Wall Edges Use a Frame Assignment

Use this procedure to specify edges that use a frame assignment. When you create a frame assignment, you need to specify the edges of the frame to use that assignment.

Frame edges that are not assigned a frame definition are not displayed.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 Select a frame assignment.
 - Location is the only way to specify the frame edges.
- 7 Click the Used In column, and then click the [...] button at the far right of the row.

Specifying frame location

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Horizontal Division	Grid	This grid division
Cell Assignments			
Panel	Panel Infill	Location	Start, End
Vertical	*Nested Grid*	Default	All unassigned cells
Frame Assignments			
Default Frame Assignment	Default Frame	Location	*NONE*

- 8 Select the edges that you want to use this assignment - Left, Right, Top, or Bottom - and click OK.

Assigning frames to nested grids

Do not assign multiple definitions to the same frame edge because only the last definition assigned to the edge is used.

9 Click OK.

Assigning Definitions to Curtain Wall Mullions

The mullions of a curtain wall are the edges between the grid cells. The primary grid and each nested grid have mullions that are defined separately from the other grids. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

Assign mullions to a nested grid

Mullion Assignments

A mullion assignment defines the definition used by each mullion. You can use one assignment to define all mullions, or you can create multiple assignments and assign different definitions to different mullions in any grid.

Do not assign multiple definitions to the same mullion because only the last definition assigned to the mullion is used.

Default Mullion Assignment

There is a default mullion assignment used by all unassigned mullions. You can modify the default assignment to be any mullion definition, but you cannot delete the default mullion assignment.

Adding a New Mullion Assignment to a Curtain Wall Style

Use this procedure to add a new mullion assignment to a curtain wall style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.

- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a new mullion assignment.
- 6 Click New Mullion Assignment.

A new mullion assignment is displayed in the list of mullion assignments.

New mullion assignment

Name	Element	Type	Used In
Division Assign...			
Cell Assignments			
Frame Assignm...			
Mullion Assignm...			
Default Mullion...	Default Mullion	Default	All unassigned mullions
New Mullion As...	Default Mullion	Location	Start, End
Primary Mullions	4 inch Mullions	Index	1, 3, 5
Secondary Mulli...	12 inch Mullions	Index	2, 4

- 7 Select the mullion assignment, right-click and click Rename, and then enter a descriptive name.
- 8 Select a mullion definition from the Element column.
- 9 Specify the mullions to use this assignment.

For more information, see [Specifying Which Curtain Wall Mullions Use an Assignment](#) on page 981.
- 10 Click OK.

Specifying Which Curtain Wall Mullions Use an Assignment

When you create a mullion assignment you need to specify the mullions in the grid to use that assignment. There are two options for selecting mullions:

- Use Location to assign a definition to the start, middle, or end mullions of a vertical grid or the bottom, middle, or top mullions of a horizontal grid. If there is an even number of mullions (four or more), Middle refers to the two mullions in the middle of the grid. If there is an odd number of mullions (three or more), Middle refers to the one mullion in the middle of the grid.
- Use Index to assign a definition to specific mullions based on mullion numbers. Mullions are numbered from start to end or bottom to top. For example, typing 1, 2, 3 would assign the definition to the first, second, and third mullions.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 Create a new mullion assignment or select an existing assignment.
- 7 Select Location or Index for Type.
- 8 Select a cell assignment.

If you selected ...

Then ...

Location

click the Used In column, and click the button at the far right of the row. Select the cells you want to use this cell assignment, and click OK.

If you selected ...	Then ...
Index	enter the mullion numbers separated by commas in the Used In column. For vertical grids, mullions are numbered from start to end and, for horizontal grids, mullions are numbered from bottom to top.

NOTE Do not assign multiple definitions to the same mullion because only the last definition assigned to the mullion is used.

9 Click OK.

Any mullions that are not assigned a specific mullion assignment use the default mullion definition.

Removing Mullions from a Curtain Wall Grid

Use this procedure to remove a mullion from the curtain wall. You can create a mullion definition whose edge width and depth are zero. Adjacent infills expand to fill in the space that was occupied by the mullion. This is an effective way to represent butt glazing.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Curtain Wall Styles.

3 Select a curtain wall style.

4 Click the Design Rules tab.

5 In the left pane, select the grid in which you want to remove a mullion.

6 Create a new mullion assignment and enter **0** (zero) for the width and depth.

For more information, see [Defining Curtain Wall Mullions by Width and Depth](#) on page 964.

7 Under Mullion Assignments, select the mullion definition you created for any cell edges of any mullion assignment, where you want to remove the mullions.

For more information, see [Specifying Which Curtain Wall Mullions Use an Assignment](#) on page 981.

8 Click OK.

Specifying the Materials of a Curtain Wall Style

A curtain wall consists of a number of components whose display properties can be determined by the materials assigned to each component.

When you assign materials to a curtain wall style, you assign one material to each display component of the curtain wall. For example, you assign a wood material to the frame and a glass material to the glass inset. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the curtain wall style, instead of using material display properties, you can turn off the material assignments in the display properties of the curtain wall style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in three dimensional (3D) model views and in elevations.

Curtain Wall Materials and Display Components

The following table identifies the material component that corresponds to each curtain wall component in the specified views.

Curtain Wall Component	Material Component
Plan, Plan High Detail, Plan Low Detail, Screened, Reflected Plan	
Frame Definitions	Linework
Mullion Definitions	Linework
Infill Definitions	Linework
Frame Definitions Hatch	Linework
Mullion Definitions Hatch	Linework
Infill Definitions Hatch	Linework
Model	
Frame	3D Body
Mullion	3D Body
Infill	3D Body

Assigning Materials to a Curtain Wall Style

Use this procedure to assign materials to the individual components of a curtain wall style. When you assign a material to a curtain wall component, the component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the curtain wall. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example,

the frame, mullion, and infill are physical components of a curtain wall. The cell marker is a symbolic component.

NOTE If a material assignment does not determine the display properties of a curtain wall component, you can change the display properties of the curtain wall style as described in [Specifying the Display of Curtain Walls](#) on page 984.

- 1 Open a tool palette that has a curtain wall tool.
- 2 Right-click a curtain wall tool, and click Curtain Wall Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, select the value for Material Definition, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

- 11 Click OK.

Specifying the Display of Curtain Walls

The display of a curtain wall depends on the direction from which you view the curtain wall. In Plan view, the curtain wall object is displayed as parallel lines with vertices marking the grid lines, as an architect would typically draw a curtain wall. In 3D isometric views, the curtain wall object is displayed as it would appear in the real world, with surfaces showing length, thickness, and height. You control what you want to display in each particular view.

Element Definitions and Custom Display Components

By default, the display of all infills, frames, and mullions is controlled by the display properties of the default infill, default frame, and default mullions. However, you can add individual element definitions as components with separate display properties. For example, if you define two infills called stone panel and glass panel, by default they are both controlled by the default infill display properties. However, you can add each definition as a new display component, and then control the display properties separately.

NOTE The component name in the Custom Display Component dialog box must match the name of element definition in the Design Rules tab. Otherwise the element definition does not display properly.

For more information about the display system, see [Display System](#) on page 537.

Materials and Display Properties

You can use materials to control the display of both default and custom infills, frames, and mullions. When you assign materials to the element definitions you create, you do not need to define these definitions as custom display components. For more information, see [Specifying the Materials of a Curtain Wall Style](#) on page 982.

Adding Curtain Wall Element Definitions as Display Components

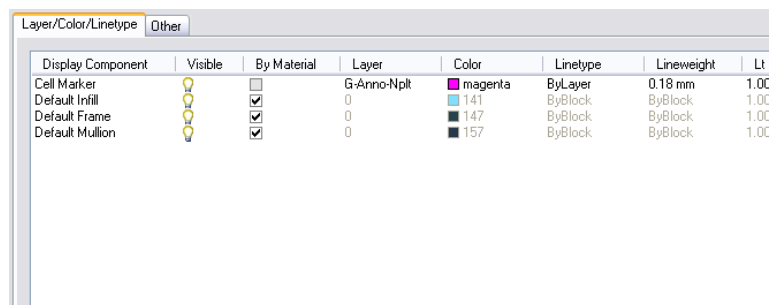

Use this procedure to add curtain wall element definitions. Before you can control the display properties of curtain wall elements according to the definition assigned to the element, you must create display components for each element definition.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select the curtain wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select Model as the display representation.

- 6 Click .

The default list of components includes only the three basic elements and cell markers.

Default Model display components for curtain walls

Display Component	Visible	By Material	Layer	Color	Linetype	Lineweight	Lt
Cell Marker		<input type="checkbox"/>	G-Anno-Nplt	magenta	ByLayer	0.18 mm	1.00
Default Infill		<input checked="" type="checkbox"/>	0	141	ByBlock	ByBlock	1.00
Default Frame		<input checked="" type="checkbox"/>	0	147	ByBlock	ByBlock	1.00
Default Mullion		<input checked="" type="checkbox"/>	0	157	ByBlock	ByBlock	1.00

- 7 Click the Other tab, and then click Add.
- 8 Select Infill, Frame, or Mullion for Component Type.
- 9 Enter a name for Component Name, or click Select Element and select an element from the list.
- 10 Click OK.
- 11 Click the Layer/Color/Linetype tab.

The element definition that you added is displayed in the list of components.

- 12 Click the Other tab to continue adding element definitions, or click OK twice.

Specifying the Layer, Color, and Linetype of a Curtain Wall Style

Use this procedure to change the following display properties of the components of a curtain wall style:

- Visibility (component is on or off)
- By Material
- Layer

- Color
- Linetype
- Lineweight
- Linetype scale

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select the curtain wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear.
- 6 Click Style Override.
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK twice.

Specifying the Hatching for Components of a Curtain Wall Style

Use this procedure to specify the hatching of the components of a curtain wall style. Curtain wall hatching is displayed only in display representations, such as Plan, that are used in Top view (Plan view) of a drawing.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select the curtain wall style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and click Style Override.
- 6 Click the Hatching tab.
- 7 Select a component, and click the setting for Pattern.
- 8 Specify the hatching for the component:

If you want to specify ...	Then ...
a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
single hatching	select User-defined for Type, and clear Double Hatch.
double hatching	select User-defined for Type, and select Double Hatch.
solid fill	select Solid Fill for Type.

- 9 Click OK.
- 10 Click the setting for Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

- 11 Click the setting for Angle, and enter the angle for the selected pattern.
- 12 Click the setting for Orientation, and specify how the hatching is oriented:

If you want to orient the hatching ...	Then ...
to the object, regardless of the object rotation	select Object.
to the World Coordinate System	select Global.

- 13 Click OK twice.

Adding Custom Graphics as a Display Component of a Curtain Wall

There may be instances where an infill, frame, or mullion requires a custom two-dimensional (2D) or three-dimensional (3D) graphic. For example, you might need a highly detailed 3D truss as the mullions or a decorative light fixture applied to an infill. In cases like these, you can create a custom block, add a display component with the block attached, and associate that component with an element definition. When you assign that definition to an element, the block is also displayed.

- 1 Draw your custom component, and save it as a block.
- 2 Select a curtain wall, right-click and click Edit Curtain Wall Style.
- 3 Click the Display Properties tab.

4 Click .

- 5 Click the Other tab.
- 6 Click Add.
- 7 Select Infill, Frame, or Mullion as the element type.
- 8 Select the specific element from the list.
- 9 Select Draw Custom Graphics.

- 10 Specify the display of the element:

If you want to ...	Then ...
display the block instead of the associated curtain wall element	select Replace Graphics.
superimpose the block over the curtain wall element so that both are displayed	clear Replace Graphics.

- 11 Click Select Block, and select the custom block that you created.
- 12 Click OK.
- 13 Specify further settings for the custom display block:

If you want to ...	Then ...
scale the block to fit a particular dimension	select Width, Height, or Depth. To prevent the block from losing its proportions, select Lock XY Ratio.
specify how the block is inserted into the grid in the X, Y, and Z directions	specify an insertion point on the X, Y, and Z planes.

If you want to ...	Then ...
mirror the block	determine if it should mirror in the X, Y, or Z direction.
offset the block from the grid	specify the offset in the X, Y, or Z direction.

14 Click OK three times.

Creating Cut Planes for a Curtain Wall

Use this procedure to specify the properties of one or more cut planes for a curtain wall style. Cut plane display properties apply only to display representations, such as Plan, that are used in Top view (Plan view) of a drawing.

To better visualize the elements of a curtain wall in Plan view, you can create cut planes. The main cut plane is where the shrinkwrap and hatching are applied. The plan display shows the components and objects in the wall as they are displayed at the height of each cut plane.

- 1 Select a curtain wall, right-click, and click Edit Curtain Wall Style.
- 2 Click the Display Properties tab.

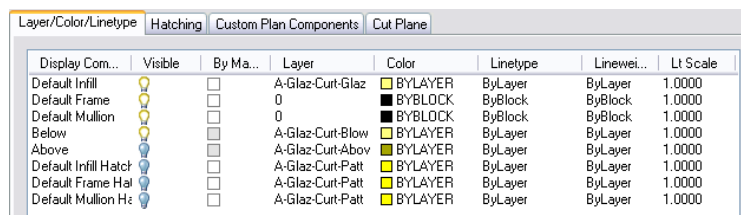

- 3 Select Plan, and click .

NOTE The Cut Plane tab is displayed only in some display representations, such as Plan.

- 4 Click the Cut Plane tab to set the cut plane to be displayed in each display representation for the curtain wall style.
- 5 Enter a value for Cut Plane Height to specify the cut plane at which hatching takes effect.
- 6 To specifically define a cut plane, click Add, and enter the height of the new cut plane.

If you add a cut plane ...	Then ...
at a height that is lower than the value for Cut Plane Height	objects are displayed using the properties specified for the Below Cut Plane component on the Layer/Color/Linetype tab.
at a height that is higher than the value for Cut Plane Height	objects are displayed using the properties specified for the Above Cut Plane component on the Layer/Color/Linetype tab.

Below and Above components

Display Com...	Visible	By Ma...	Layer	Color	Linetype	Linewei...	Lt Scale
Default Infill		<input type="checkbox"/>	A-Glaz-Curt-Glaz	BYLAYER	ByLayer	ByLayer	1.0000
Default Frame		<input type="checkbox"/>	0	BYBLOCK	ByBlock	ByBlock	1.0000
Default Mullion		<input type="checkbox"/>	0	BYBLOCK	ByBlock	ByBlock	1.0000
Below		<input type="checkbox"/>	A-Glaz-Curt-Blow	BYLAYER	ByLayer	ByLayer	1.0000
Above		<input type="checkbox"/>	A-Glaz-Curt-Abov	BYLAYER	ByLayer	ByLayer	1.0000
Default Infill Hatch		<input type="checkbox"/>	A-Glaz-Curt-Patt	BYLAYER	ByLayer	ByLayer	1.0000
Default Frame Hat		<input type="checkbox"/>	A-Glaz-Curt-Patt	BYLAYER	ByLayer	ByLayer	1.0000
Default Mullion Hat		<input type="checkbox"/>	A-Glaz-Curt-Patt	BYLAYER	ByLayer	ByLayer	1.0000

You can click Remove to delete a cut plane that you added.

- 7 Click OK twice.

Defining a Curtain Wall Style as Bounding for Associative Spaces

Use this procedure to define a curtain wall style that can bound associative spaces.

When a curtain wall style is set as bounding, by default all curtain walls that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the curtain wall style in an individual curtain wall, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall style.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Curtain Wall Style

Use this procedure to enter notes and attach reference files to a curtain wall style. You can also edit notes and edit or detach reference files from a curtain wall style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select the curtain wall style you want to change.
- 4 Click the General tab.
- 5 To add a description to the curtain wall style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Text Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to ...

Then ...

attach a reference file

click Add, select a file, and click OK.

edit the description of a reference file

select the file, and click Edit. Enter the description, and click OK.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click Delete.

- 9 Click OK.

Using Overrides in Curtain Walls

Curtain walls are geometrically complex objects that often have a large number of different elements, such as frames, panels, and window infills. The settings for these elements are defined in the curtain wall style

and can be modified using Style Manager. However, there are cases when modifying a curtain wall directly on screen is more suitable:

- You want to add custom frame or mullion edges to a curtain wall and need direct visual feedback.
- You want to create an override, like a merged infill or an irregular panel shape in only one specific place in the curtain wall.
- You want to experiment with different visuals without having to change the curtain wall style for each idea immediately.

When you have finished your onscreen edits, you have three choices:

- apply the overrides to the curtain wall you have edited.
- save the overrides to the current curtain wall style.
- create a new style for the overrides.

Overrides you can set include assigning a different definition to a selected cell, frame, or mullion, and assigning a profile to a frame or mullion edge. Note that the definition or profile must already exist in the current drawing before you can use it as an override. For example, if you want to override a cell that has a simple panel infill with an octagonal window infill, you must first define the window (octagonal) style as a valid infill in the curtain wall style. Similarly, if you want to override a frame or mullion edge assignment in the curtain wall, the curtain wall style must contain the edge profile as a frame or mullion definition.

NOTE You cannot modify a definition using the Override method. For information about modifying definitions, see [Modifying Element Definitions for Curtain Wall Styles](#) on page 1008.

Overrides do not affect the Design Rules for the curtain wall style. However, you can transfer overrides to a curtain wall style if you want all curtain walls of that style to have the same overrides.

You can view a list of overrides that are currently assigned to a curtain wall from the Overrides tab of the Curtain Wall Properties dialog box. For more information, see [Removing Curtain Wall Overrides](#) on page 1007.

NOTE Overrides are also listed on the Overrides tab in the Curtain Wall Style Properties dialog box.

Overriding Curtain Wall Infills

The cell infills of a curtain wall are set in the curtain wall style. You can, however, create overrides for these infills in cells. For example, you might want a row of glider windows for a first floor facade. In one specific position, however, you want a frosted glass window. In this case, you would set the row of glider windows in the curtain wall style, and then override the infill style in one specific cell with a frosted glass window.

Curtain wall infills can consist of simple panels, objects like windows or doors, or nested grids. You can change one infill for another, merge cells, or remove the frame from an infill altogether. This would be useful if you add a door into a grid cell and want to remove the bottom frame from that cell.

Turning on Cell Markers

Use this procedure to turn on the cell markers for each grid cell in a curtain wall. The cell markers must be on in order to select individual cells and make changes to them.

Viewing Cell Markers

- 1 Select the curtain wall for which you want to create an infill override.
- 2 Right-click, and click Infill ► Show Markers.

Merging Curtain Wall Cells

Use this procedure to merge two curtain wall cells.

NOTE To merge curtain wall cells, the cell markers need to be visible. For information on turning on cell markers, see [Turning on Cell Markers](#) on page 990.

You can only merge cells which are adjacent to each other.

In most cases you merge cells with the same infill type. The merged cell is then the same type as the original cells. For example, if you merge two solid panel infills, the resulting merged cell also has a solid panel infill. In some cases however, you might want to merge two cells that have different infill types. In that case, the infill type of the first selected cell is used for the merged cell. For example, if you want to merge a cell with a simple panel infill and a cell with a window infill, and you select the cell with the simple panel first during the merge command, the merged cell contains a simple panel infill, not a window. If you select the two cells in the opposite order, the merged cell contains a window and no simple panel infill.

Merging two cells

select cell A

select cell B

result

- 1 Select the curtain wall on which you want to merge two cells.
- 2 Right-click, and click Infill ► Merge.
- 3 Select the first cell to be merged.
- 4 Select the second cell to be merged.

The cells are merged into one.

5 Specify where you want to save the curtain wall override:

If you want to save the override ...

Then ...

only on this specific curtain wall

no further steps are necessary. The override is saved to the curtain wall. For information about how to remove an override from a curtain wall, see [Removing Curtain Wall Overrides](#) on page 1007.

to a curtain wall style

select the curtain wall, right-click, and select Design Rules ► Transfer to Object.

6 If you have chosen to save the override to a curtain wall style, select the curtain wall again, right-click and click Design Rules ► Save to Style and decide to which curtain wall style you want to save the override.

If you want to save the override ...

Then ...

to the current curtain wall style

select Transfer Merge Operations to Style, and click OK.

NOTE If you have created only a cell merge, only the Transfer Merge Operations to Style checkbox is active. If you have also created other overrides, such as a new cell assignment or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.

to a new curtain wall style

select Transfer Merge Operations to Style, and click New. Then, enter a name for the new curtain wall style, and click OK.

NOTE If you have created only a cell merge, only the Transfer Merge Operations to Style checkbox is active. If you have also created other overrides, such as a new cell assignment or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the curtain wall, where they can be removed as described in [Removing Curtain Wall Overrides](#) on page 1007, but they are not saved back to a curtain wall style.

In-Place Editing of Curtain Wall Cells

Use this procedure to edit curtain wall cells using in-place editing with the Edit Grid grip. With in-place editing, you can edit individual cells, bays, columns, or nested grids of the curtain wall directly and interactively in the drawing area, and later save the changes to the curtain wall or curtain wall style.

1 Select a curtain wall on which you want to edit cells with in-place editing.

2 Specify the mode in which to edit the curtain wall:

If you want to edit ...	Then ...
this instance of the curtain wall	right-click, and click Design Rules ► Transfer to Object.
the curtain wall style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall.

3 Click the Edit Grid grip.

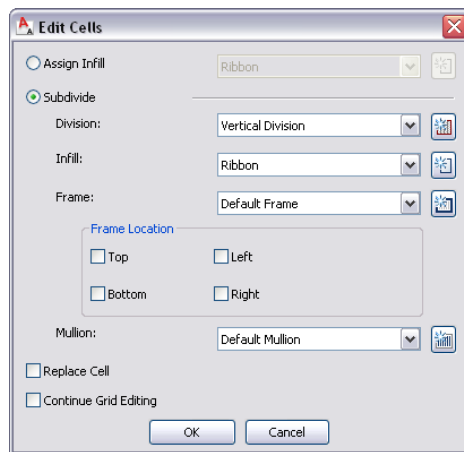

4 Enter **c** (Cell) and press ENTER.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

5 Select the individual cells, bay, column, or nested grid to modify the cell assignment by hovering over a cell or pressing TAB, and press ENTER.

Press CTRL to select multiple cells, bays, columns or nested grids.

The Edit Cells worksheet displays.

6 Edit the cell for the selected grid:

If you want to...	Then...
assign an infill to selected cells	select Assign Infill and select an infill definition. Clear Replace Cell and click OK.

If you want to...	Then...
replace the selected cells with a new infill	select Assign Infill and select an infill definition. Select Replace Cell and click OK.
create and assign a new infill to the selected cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning Infills to Curtain Wall Cells on page 969.
divide the selected cells with divisions, infills or frames	select Subdivision.
select a division for the subdivided cells	select a division definition.
create and assign a new division to the selected cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning a Division to a Curtain Wall Grid on page 968.
select an infill for the subdivided cells	select an infill definition.
create and assign a new infill to the subdivided cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning Infills to Curtain Wall Cells on page 969.
select a frame definition for the grid created after the cell is subdivided	select the frame definition and click OK.
specify the location of frames on the grid created after the cell is subdivided	select Top, Bottom, Left, Right for Frame Location and click OK.
create and assign a new frame definition for the new grid created after the cell is subdivided	click  and specify values on the Design Rules worksheet. For more information, see Adding a New Frame Assignment to a Curtain Wall on page 978.
select a mullion definition for the grid created after the cell is subdivided	select the mullion definition.
create and assign a new mullion definition to the selected grid	click  and specify values on the Design Rules worksheet. For more information, see Adding a New Mullion Assignment to a Curtain Wall Style on page 980.
replace the existing cell infill with the options selected on this worksheet	select Replace Cell.

If you want to...	Then...
continue in-place editing the grid after the cell is subdivided	select Continue Grid Editing.

- 7 Click OK.
- 8 Press ENTER.

Creating a Curtain Wall Infill Override

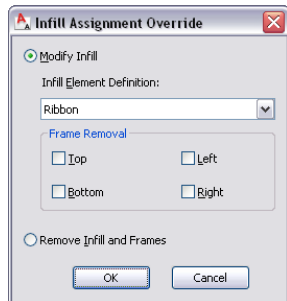

Use this procedure to override the infill of a curtain wall cell.

For example, you might have a row of simple concrete panels in your curtain wall, but want in one location a round window instead of the concrete panel. In that case, it might be simpler to use an infill override, instead of creating complex curtain wall unit definitions.

NOTE To override an infill assignment, the cell markers must be visible. For information on turning on cell markers, see [Turning on Cell Markers](#) on page 990.

To exchange an infill definition, the new infill definition must already be defined in the curtain wall style. For information on creating infill definitions, see [Defining Infills for Curtain Wall Cells](#) on page 954.

- 1 Select the curtain wall on which you want to override an infill.
- 2 Right-click, and click Infill ► Override Assignment.
- 3 Select the marker of the cell where you want to create an override, and press *ENTER*.

- 4 Create the override.

If you want to ...	Then ...
exchange the existing infill for another	select a new infill definition from the list.
remove one or more of the frames around the infill	select the frame component to be removed. You could, for example, override a cell to contain a door infill instead of a panel infill; in this case, you would want to remove the bottom frame of the cell.
remove the complete infill and its frame	select Remove Infill and Frames.

NOTE This works only for infills that border the exterior of the curtain wall.

5 Click OK.

6 Specify where you want to save the curtain wall override.

If you want to save the override ...	Then ...
only on this specific curtain wall	no further steps are necessary. The override is saved to the curtain wall. For information about how to remove an override from a curtain wall, see Removing Curtain Wall Overrides on page 1007.
to a curtain wall style	select the curtain wall, right-click, and select Design Rules ► Transfer to Object.

7 If you have chosen to save the override to a curtain wall style, select the curtain wall again, right-click and click Design Rules ► Save to Style and decide to which curtain wall style you want to save the override.

If you want to save the override ...	Then ...
to the current curtain wall style	select Transfer Cell Overrides to Style, and click OK. NOTE If you have created only an infill override, only the Transfer Cell Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.
to a new curtain wall style	select Transfer Cell Overrides to Style, and click New. Then, enter a name for the new curtain wall style, and click OK. NOTE If you have created only an infill override, only the Transfer Cell Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides remain on the curtain wall, where they can be removed as described in [Removing Curtain Wall Overrides](#) on page 1007, but they are not saved back to a curtain wall style.

Overriding Curtain Wall Frames and Mullions

You can change a selected frame edge or mullion edge by using an edge assignment override.

NOTE To exchange a frame edge or mullion edge, the new edge definition must already be defined in the curtain wall style.

Removing the edge does not affect the width of the cell. To remove the edge and have the adjacent cell resize, create an edge definition with a width and depth of zero. For more information, see [Defining a Curtain Wall Frame by Width and Depth](#) on page 959 or [Defining Curtain Wall Mullions by Width and Depth](#) on page 964.

You can also create a new edge profile by drawing a polyline or using an existing profile in the drawing. This edge profile can be interactively edited onscreen by in-place editing.

Creating a Frame or Mullion Override

Use this procedure to override an individual frame or mullion.

To exchange a frame or mullion, the new definition must already be defined in the curtain wall style. For information on creating frames and mullions, see [Defining Curtain Wall Frames](#) on page 958 and [Defining Curtain Wall Mullions](#) on page 963.

- 1 Select the curtain wall on which you want to override an edge.
- 2 Right-click, and click Frame/Mullion ► Override Assignment.
- 3 Select the frame or mullion edge you want to override.
If you selected a frame edge, the Frame Assignment Override dialog box is displayed.
If you selected a mullion, the Mullion Assignment Override dialog box is displayed.
- 4 Create the override.

If you want to ...	Then ...
exchange the existing edge for another	select a new edge definition from the list.
remove the frame or mullion edge	select Remove Edge.

- 5 Click OK.
- 6 Specify where you want to save the curtain wall override.

If you want to save the override ...	Then ...
only on this specific curtain wall	no further steps are necessary. The override is saved to the curtain wall. For information about how to remove an override from a curtain wall, see Removing Curtain Wall Overrides on page 1007.
to a curtain wall style	select the curtain wall, right-click, and select Design Rules ► Transfer to Object.

7 If you have chosen to save the override to a curtain wall style, select the curtain wall again, right-click and click Design Rules ► Save to Style and decide to which curtain wall style you want to save the override.

If you want to save the override ...

Then ...

to the current curtain wall style

select Transfer Edge Overrides to Style, and click OK.

NOTE If you have created only a frame or mullion edge override, only the Transfer Edge Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a division override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.

to a new curtain wall style

select Transfer Edge Overrides to Style, and click New. Then, enter a name for the new curtain wall style, and click OK.

NOTE If you have created only a frame or mullion edge override, only the Transfer Edge Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a division override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides remain on the curtain wall, where they can be removed as described in [Removing Curtain Wall Overrides](#) on page 1007, but they are not saved back to a curtain wall style.

Creating a Frame or Mullion Edge from a Polyline or Profile Using In-Place Editing

Use this procedure to assign a profile to a vertical edge of a frame or mullion. The curtain wall edge profile can be any profile or any closed polyline that you specify. You can use a profile edge to create a unique corner in situations where a simple miter is not sufficient.

NOTE Adjacent infills are not trimmed or expanded to accommodate the new edge. To adjust the infill, change the width of the frame edge. For more information, see [Defining a Curtain Wall Frame by Width and Depth](#) on page 959.

Overriding edge profile

1 Draw a closed polyline in the location where you want it to display in the curtain wall.

NOTE For best results, it is recommended to draw the polyline in Plan view.

2 Select the curtain wall for which you want to create a frame or mullion edge profile override.

3 Specify the mode in which to edit the curtain wall:

If you want to edit ...

Then ...

this instance of the curtain wall

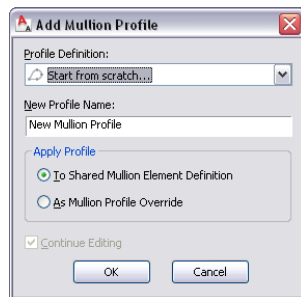

right-click, and click Design Rules ► Transfer to Object.

the curtain wall style

right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall.

4 Right-click, and click Frame/Mullion ► Add Profile.

5 Select a vertical frame or mullion edge.

6 Select a profile for the override.

If you want to create the edge profile ...

Then ...

from the polyline drawn in step 1

select Start from scratch for Profile Definition, and enter a name for New Profile Name.

from an existing profile in the drawing

select the existing profile for Profile Definition, and click Continue Editing.

7 Select whether to apply the profile to the shared edge element definition or as an edge profile override.

8 Click OK.

You are now in in-place edit mode, and can edit the profile.

9 On the In-Place Edit toolbar, click  to zoom to the profile.

10 Select the profile and edit it using Edge and Vertex grips, or by using the right-click context menu.

The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.

Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.

Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.

11 Save or discard changes to the curtain wall grid:

If you want to exit the in-place editing session ... Then ...

without saving your changes

click  on the In-Place Edit toolbar.

after saving your changes

click  on the In-Place Edit toolbar.

In-Place Editing of Edge Profiles for Curtain Walls

Use this procedure to edit profile edges using in-place editing. With in-place editing, you can edit the curtain wall directly and interactively in the drawing area and later save the changes to the profile definition.

1 Select a curtain wall that has the edge profile you want to edit with in-place editing.

2 Right-click, and click Frame/Mullion ► Edit Profile In Place.

This command is only available if you have profile-based edges in the curtain wall.

NOTE If the profile is not drawn to size, it must be converted in order for you to begin the in-place editing session. Click Yes if prompted to convert the profile to its actual size.

3 Select the edge you want to edit.

NOTE You have entered the in-place editing session now. You can see this from the magenta-colored grips and light blue hatch of the temporary in-place editing profile, as well as the faded color of all other objects in the drawing. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

4 Edit the profile:

If you want to ...	Then ...
use grips to edit the profile	move the grips as needed. The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary. Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well. Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.
add a vertex to the profile	select an Edge grip, and press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press <i>ENTER</i> .
remove a vertex from the profile	select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.
add a ring to the profile	select the profile, right-click and click Add Ring. Then, select a closed polyline, spline, ellipse, or circle for an additional ring. Specify if you want to erase the source linework, and press <i>Enter</i> .
remove a ring from a profile	select the profile, right-click and click Remove Ring. Then select the ring you want to remove. <hr/> NOTE You cannot remove the last ring from a profile. <hr/>
replace a ring on a profile	select the profile, right-click and click Replace Ring. Then, select a closed polyline, spline, ellipse, or circle for the replaced ring. Specify if you want to erase the source linework, and press <i>Enter</i> .

5 Save the changes to the profile.

If you want to ...

Then ...

change the existing profile definition to reflect the new shape

click  on the In-Place Edit toolbar.

create a new profile definition with the shape you have created

select the profile, right-click, and click Save As New Profile. Then, enter a name for the new profile and click OK. The in-place edit session is exited and the new profile definition is available in the Style Manager.

discard all changes on the profile and revert back to the previous shape

click  on the In-Place Edit toolbar.

In-Place Editing of Curtain Wall Frames and Mullions

Use this procedure to edit frames and mullions using in-place editing with the Edit Grid grip. With in-place editing, you can edit bays, columns or nested grids of the curtain wall directly and interactively in the drawing area, and later save the changes to the curtain wall or curtain wall style.

1 Select a curtain wall on which you want to edit frames or mullions with in-place editing.

2 Specify the mode in which to edit the curtain wall:

If you want to edit ...

Then ...

this instance of the curtain wall

right-click, and click Design Rules ► Transfer to Object.

the curtain wall style

right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall.

3 Click the Edit Grid grip.

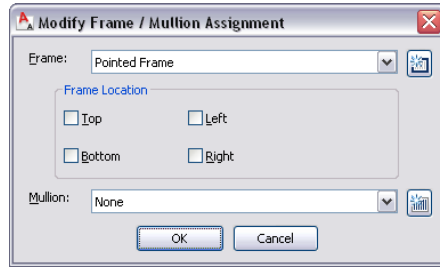

4 Enter **f** (Frame and mullion assignment) and press ENTER.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

5 Select the bay, column or nested grid to modify the frame and mullion assignment and press ENTER.

Press CTRL to select multiple bays, columns or nested grids.

The Modify Frame/Mullion Assignment worksheet displays.

6 Select a frame definition for the selected grid:

If you want to...

Then...

modify the frame of the selected grid

select a frame definition and click OK.

specify the location of the frame on the selected grid

select Top, Bottom, Left, Right for Frame Location and click OK.

create and assign a new frame definition to the selected grid

click .

For more information, see [Adding a New Frame Assignment to a Curtain Wall](#) on page 978.

7 Select the mullion definition for the selected grid:

If you want to...

Then...

modify the mullion of the selected grid

select the mullion definition and click OK.

create and assign a new mullion definition to the selected grid

click and complete the Design Rules worksheet.

For more information, see [Adding a New Mullion Assignment to a Curtain Wall Style](#) on page 980.

8 Press ENTER.

Overriding Curtain Wall Divisions

The grid of a curtain wall is made up of one or more divisions that define how the curtain wall is partitioned. Divisions can be horizontal or vertical, and can be nested in each other. For detailed information on curtain wall divisions, see [Defining Divisions for Curtain Wall Grids](#) on page 945.

You can override a division in a curtain wall, thereby changing the grid of the curtain wall.

five cell horizontal grid and three cell vertical grid before override

five cell horizontal grid and six cell vertical grid after override

Creating a Division Override

Use this procedure to create a division override on a curtain wall.

NOTE To exchange a curtain wall division, the new division definition must already be defined in the curtain wall style. For information on curtain wall divisions, see [Defining Divisions for Curtain Wall Grids](#) on page 945.

- 1 Select the curtain wall for which you want to create a division override.
- 2 Right-click, and click **Division** ► **Override Assignment**.
- 3 Select an edge of the curtain wall to determine if a horizontal or vertical division is overridden.
For example, if you want to override the primary horizontal division, you could select the bottom horizontal frame of the curtain wall.

TIP The Division Assignment Override dialog box shows you which grid type and which grid division you have selected, e.g. Selected Nested Grid: Secondary Grid, Division Element Definition: Vertical 3 Cells. If you have accidentally selected the wrong division, click **Cancel** and reselect the correct grid.

- 4 Select the appropriate division override, and click **OK**.
- 5 Specify where you want to save the curtain wall override:

If you want to save the override ...

Then ...

only on this specific curtain wall

no further steps are necessary. The override is saved to the curtain wall. For information about how to remove an override from a curtain wall, see [Removing Curtain Wall Overrides](#) on page 1007.

to a curtain wall style

select the curtain wall, right-click, and select **Design Rules** ► **Transfer to Object**.

6 If you have chosen to save the override to a curtain wall style, select the curtain wall again, right-click and click Design Rules ► Save to Style and decide to which curtain wall style you want to save the override.

If you want to save the override ...	Then ...
to the current curtain wall style	select Transfer Division Overrides to Style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Division Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or an edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.
to a new curtain wall style	select Transfer Division Overrides to Style, and click New. Then, enter a name for the new curtain wall style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Division Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or an edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes, too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides remain on the curtain wall, where they can be removed as described in [Removing Curtain Wall Overrides](#) on page 1007, but they are not saved back to a curtain wall style.

In-Place Editing of Curtain Wall Divisions

Use this procedure to edit divisions using in-place editing with the Edit Grid grip. With in-place editing, you can edit the curtain wall directly and interactively in the drawing area, and later save the changes to the curtain wall or curtain wall style. For more information, see [Division of Curtain Wall Grids](#) on page 946.

- 1 Select a curtain wall on which you want to edit divisions with in-place editing.
- 2 Specify the mode in which to edit the curtain wall:

If you want to edit ...	Then ...
this instance of the curtain wall	right-click, and click Design Rules ► Transfer to Object.
the curtain wall style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall.

- 3 Click the Edit Grid grip.
- 4 Enter **d** (Division in place) and press ENTER.

Viewing edit in-place grips for a primary division

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

Viewing edit in-place grips for adding and removing bays

5 Edit the division:

If you want to ...	Then ...
add a bay to the grid	click the Add Bay grip.
remove a bay from the grid	click the Remove Bay grip.
change the start offset of the grid	select the Start Offset grip and move it to the appropriate position.
change the end offset of the grid	select the End Offset grip and move it to the appropriate position.
change the spacing of bays	click the Auto Grid Bay Spacing grip and move it to the appropriate position.
manually edit the grid	right-click and click Convert To Manual. You can manually add and remove gridlines, change the offsets, and change the position of individual gridlines.

If you want to ...	Then ...
use a worksheet to edit the cell dimensions	click the Fixed Cell Dimension Rules grip, and edit the values in the worksheet.

6 Save or discard changes to the curtain wall grid:

If you want to exit the in-place editing session ...	Then ...
without saving your changes	click  on the In-Place Edit toolbar.
after saving your changes	click  on the In-Place Edit toolbar. If you edited the grid by instance, the changes are saved to the grid by instance, the changes are saved to the design rules for the individual grid. If you edited the curtain wall style, the Save Changes dialog box is displayed.

7 In the Save Changes dialog box, specify to which division to save the changes:

If you want to ...	Then ...
save the changes to the style in the current curtain wall division	verify the current division is selected for Save Changes to Existing Division, and click Save. The changes are made in the style and affect all curtain walls of that style in the drawing.
create an override to the style by saving the changes in a new curtain wall division	click New, enter a name for the new division override, and click OK. Click Save. The changes are saved as an override to the style, and affect only the curtain walls to which the override is applied.

Removing Curtain Wall Overrides

Use this procedure to remove curtain wall overrides either from the curtain wall or the curtain wall style.

1 Select the curtain wall.

If you want to remove an override ...	Then ...
from a curtain wall	select the curtain wall, expand Advanced in the Properties palette, and click Overrides.
from the curtain wall style	select the curtain wall, right-click and click Edit Curtain Wall Style, and then click the Overrides tab.

2 Select an override from the list and click Remove.

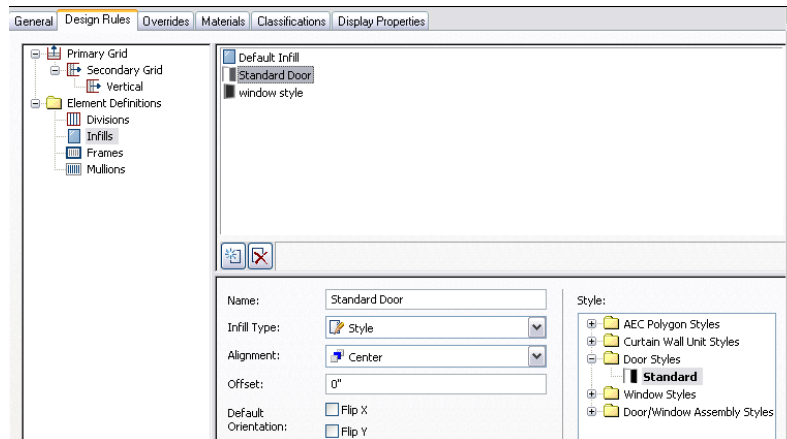

3 Click OK.

Modifying Element Definitions for Curtain Wall Styles

Use this procedure to modify existing elements in a curtain wall style. A curtain wall consists of division, infill, frame and mullion elements, all of which are defined in the design rules of the curtain wall style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select the curtain wall style that you want to change.
- 4 Click the Design Rules tab.
- 5 In the left pane, click Element Definitions.
The list of element types is displayed.

Element definitions list

6 Decide the type of elements you want to edit:

If you want to modify ...

Then ...

a division definition

click Divisions under Element Definitions. In the right pane, select the division definition you want to modify and edit it as described in [Defining Divisions for Curtain Wall Grids](#) on page 945.

an infill definition

click Infills under Element Definitions. In the right pane, select the infill definition you want to modify and edit it as described in [Defining Infills for Curtain Wall Cells](#) on page 954.

a frame definition

click Frames under Element Definitions. In the right pane, select the frame definition you want to modify and edit it as described in [Defining Curtain Wall Frames](#) on page 958.

a mullion definition

click Mullions under Element Definitions. In the right pane, select the mullion definition you want to modify and edit it as described in [Defining Curtain Wall Mullions](#) on page 963.

- 7 Click OK twice.

Editing Curtain Walls

Most relevant settings for a curtain wall are defined in the curtain wall style. These include divisions, infills, frames, and mullions. For information on modifying a curtain wall style, see [Curtain Wall Styles](#) on page 941.

You can make other changes directly to individual curtain walls. These changes affect only the curtain wall you select:

- Dimensions of a curtain wall
- Roof and floor line settings
- Interference conditions
- Cleanup settings

Methods of Editing Curtain Walls

AutoCAD Architecture offers several methods for editing curtain walls:

- You can directly edit curtain walls using grips for dimensions, base height, location, and other physical characteristics.
- You can directly edit curtain walls using the Edit Grid grip for grid divisions, cells, frames, and mullions. For more information, see [In-Place Editing of Curtain Wall Divisions](#) on page 1005, [In-Place Editing of Edge Profiles for Curtain Walls](#) on page 1000 and [Overriding Curtain Wall Infills](#) on page 990.
- You can change curtain wall settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- You can select editing commands from the context menu for a selected curtain wall.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.

Using Grips to Edit Curtain Walls

There are many different curtain wall grips. The grips that appear in your drawing when you select a curtain wall are dependent upon the design rules of the curtain wall. For more information, see [Curtain Wall Styles](#) on page 941.

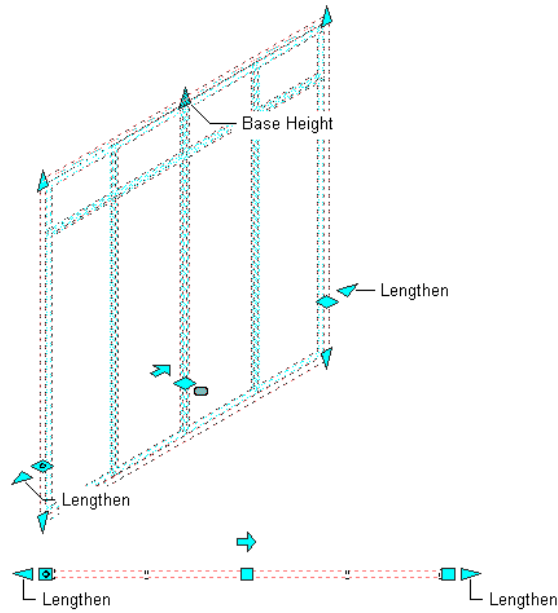

Editing Curtain Wall Dimensions

Use this procedure to change the dimensions of a curtain wall.

- 1 Select the curtain wall.
- 2 Select the grip for the dimension you want to change.

You can modify the dimensions of the length, roof line, floor line, and base height for a curtain wall.

Viewing Curtain Wall Lengthen and Base Height grips

- 3 Enter a value for the dimension and press *ENTER*, or drag the grip until the dimension value you want is displayed.

Changing the Location or Position of a Curtain Wall

Use this procedure to change the location or the position of a curtain wall with grips.

- 1 Select the curtain wall.
- 2 Select the appropriate grip to change the location of the curtain wall, its start point, or its endpoint.

Viewing Curtain Wall Start, End, Location, and Reverse Direction Grips

In Model view, the Location grip has three possible edit modes: Edit Along Object's XY Plane, Edit Along Object's YZ Plane, and Edit Along Object's XZ Plane. Press *CTRL* to cycle between modes until you are in the desired mode. The default edit mode is along the *XY* plane. In Plan view, the Location grip is restricted to movement in one plane.

3 Move the curtain wall to the desired location and click once, or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the curtain wall along a specific direction. If you enter a value for either of the dimension directions in the current edit mode and then press *TAB*, the movement of the curtain wall is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the curtain wall is constrained to the *Y* dimension direction.

Viewing Curtain Wall Location Grip

4 Right-click, and click Deselect All to turn off grips.

Changing the Base Height of a Curtain Wall

Use this procedure to change the base height of a curtain wall with grips.

1 Select the curtain wall.

2 Select the Base Height grip, move the grip until the height value you want is displayed, and click once.

NOTE As you move the grip, the original base height value is displayed in addition to the new base height and the difference between the two values.

After selecting the grip, you can also enter a new value for the base height of the curtain wall.

Changing the Length of a Curtain Wall

Use this procedure to change the length of a curtain wall with grips.

- 1 Select the curtain wall.
- 2 Select the Lengthen grip, move the grip until the length value you want is displayed, and click once.

NOTE As you move the grip, the original length value is displayed in addition to the new length and the difference between the two values.

After selecting the grip, you can also enter a new value for the length of the curtain wall.

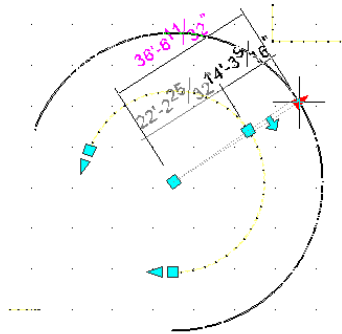

Changing the Radius of a Curtain Wall

Use this procedure to change the radius of a curved curtain wall with grips.

- 1 Select the curtain wall.

- 2 Select the Curve Radius grip, move the grip until the radius value you want is displayed, and click once.

NOTE As you move the grip, the original radius value is displayed in addition to the new radius and the difference between the two values.

After selecting the grip, you can also enter a new value for the radius of the curtain wall.

Reversing the Direction of a Curtain Wall

Use this procedure to change the direction in which a curtain wall is drawn by reversing the start point and the end point of the curtain wall with grips.

Curtain walls are drawn from the first specified point to the last point. Some commands and properties are affected by that order.

To determine the direction in which a curtain wall was drawn, select the curtain wall. The Reverse Direction grip is shaped like an arrow and points in the direction in which the curtain wall has been drawn.

- 1 Select the curtain wall for which you want to reverse the direction.
- 2 Click on the Reverse Direction grip.

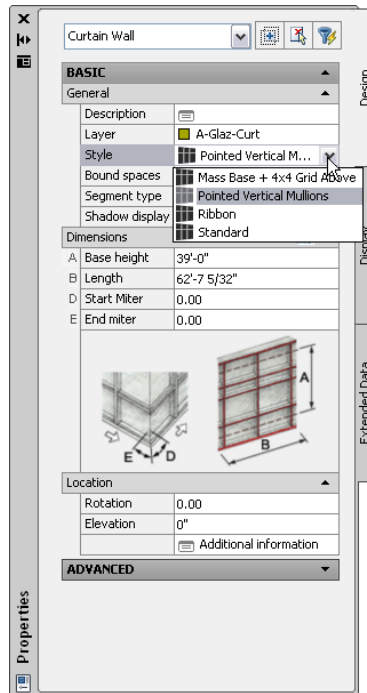

The direction of the wall is reversed, which switches the Start and End grips.

Selecting a Different Curtain Wall Style

Use this procedure to select a different style for the curtain wall on the Properties palette.

- 1 Double-click the curtain wall for which you want to change the style.
You can select multiple curtain walls and change the style for all at the same time.
- 2 On the Properties palette, scroll to the General subcategory.

3 Select a different style.

Applying the Properties of an Existing Curtain Wall

Use this procedure to apply the properties of a curtain wall tool to one or more existing curtain walls. The properties include the curtain wall style and any other settings specified in the tool you select.

1 Open the tool palette that you want to use.

If necessary, scroll to display the tool that you want to use.

2 Right-click a curtain wall tool, and click Apply Tool Properties to ► Curtain Wall.

3 Select the curtain wall(s), and press *ENTER*.

The properties of the selected curtain wall(s) match the properties of the curtain wall tool.

Changing the Dimensions of a Curtain Wall

Use this procedure to change the dimensions of a curtain wall on the Properties palette.

1 Double-click a curtain wall.

2 On the Properties palette, expand Dimensions.

3 Change the dimension:

Dimension	Description
Base Height	Height of the curtain wall from the baseline
Length	Length of a straight curtain wall from the start grip on the baseline to the end grip

Dimension	Description
Radius (curved curtain walls only)	Radius of a curved curtain wall from the start grip on the baseline to the end grip
Start Miter	Angle of all infills and horizontal edges (frame or mullion) at the start of the curtain wall: for more information about miter angles, see Mitering Curtain Walls on page 1017.
End Miter	Angle of all infills and horizontal edges (frame or mullion) at the end of the curtain wall

Changing the Curtain Wall Location Properties

Use this procedure to relocate a curtain wall by changing the coordinate values of its insertion point. The curtain wall also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the curtain wall are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the curtain wall by aligning its normal with another axis. You can also rotate the curtain wall on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Double-click the curtain wall you want to change.
- 2 Expand Location.
- 3 Click Additional information.
- 4 Specify the location of the curtain wall:

If you want to ...	Then ...
relocate the curtain wall	enter new coordinate values under Insertion Point.
locate the curtain wall on the <i>XY</i> plane	make the normal of the wall parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the curtain wall on the <i>YZ</i> plane	make the normal of the curtain wall parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the curtain wall on the <i>XZ</i> plane	make the normal of the curtain wall parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the curtain wall	enter a new value for Rotation Angle.

- 5 Click OK.

Adding an Interference Condition to a Curtain Wall

Use this procedure to add an interference condition to a curtain wall. Interference conditions use the geometry of 3D objects to create custom openings or cutouts in curtain walls. You can specify how the interference condition is applied to the curtain wall: added to the curtain wall, subtracted from the curtain wall, or ignored.

You can specify whether the interference condition applies to an infill, frame, or mullions of a curtain wall.

- 1 Place the object in the location where you want to specify the interference condition.
- 2 Select the curtain wall to which you want to add an interference condition, right-click, and click Interference ► Add.
- 3 Select the object intersecting the curtain wall, and press *ENTER*.
- 4 Specify to which curtain wall component the interference should be added:

If you want to add the interference condition ...	Then ...
to the infill	enter <i>y</i> (Yes) when prompted for the infill component.
to the frame	enter <i>y</i> (Yes) when prompted for the frame component.
to the mullion	enter <i>y</i> (Yes) when prompted for the mullion component.

- 5 Press *ENTER*.

Removing an Interference Condition from a Curtain Wall

Use this procedure to remove an object, such as a mass element, from a curtain wall that the object was added to as an interference condition.

- 1 Select the curtain wall from which you want to remove an interference object, right-click, and click Interference ► Remove.
- 2 Select the object intersecting the curtain wall, and press *ENTER*.

Mitering Curtain Walls

Use this procedure to miter the corners where curtain walls meet. The corner where adjacent curtain walls meet is not mitered by default. However, you can determine the necessary angles automatically.

The miter angle applies to all infills and horizontal edges (frame or mullion) that are adjacent to the corner. Vertical edges are not affected.

TIP If you want to create a custom corner condition between two curtain walls, you can replace the edge of one curtain wall with an AEC profile and remove the edge of the other curtain wall by using the frame override Remove Edge option. For more information, see [Overriding Curtain Wall Frames and Mullions](#) on page 996 and [Defining Curtain Wall Frames](#) on page 958.

- 1 Select one of the curtain walls, right-click, and click Set Miter Angles.
- 2 Select the other curtain wall.

If you change the angle of either curtain wall, use Set Miter Angles again to recalculate the angles.

Specifying a Miter Angle for a Curtain Wall Adjacent to Another Object

Use this procedure to manually create a mitered corner between a curtain wall and another object, such as a standard wall or a mass element. For example, if your curtain wall connects with a standard wall that is at a 60-degree angle from the curtain wall, you would set the miter angle to 30.

The miter angle applies to all infills and horizontal edges that are adjacent to the corner. Vertical edges are not affected.

TIP To quickly identify the start and end of a curtain wall, select the curtain wall. The Reverse Direction grip points toward the end of the curtain wall.

Frame miter angles for a curtain wall

- 1 Double-click the curtain wall.
- 2 Expand Dimensions.
- 3 Miter the curtain wall on the start or the end point:

If you want to miter the curtain wall ...

Then ...

at its start point

enter an angle for Start Miter, and press *ENTER*.

at its end point

enter an angle for End Miter, and press *ENTER*.

Specifying the Cut Plane Display of a Curtain Wall

Use this procedure to specify the properties of one or more cut planes for an individual curtain wall. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the curtain wall.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all curtain walls in the drawing, select Drawing default setting. To apply changes to all curtain walls of this style, select Curtain Wall Style:<style name>. For more information on styles, see [Curtain Wall Styles](#) on page 941.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object.
- 8 For Use cut plane of containing object when anchored, specify whether you want the containing object's cut plane to be used when the curtain wall is anchored to that object.
- 9 To define additional cut planes for the curtain wall, click  Manual cut planes.
- 10 On the Manual Above and Below Cut Plane Heights worksheet, click Add, and under Cut Plane, enter the height of the new cut plane.

If you add a cut plane ...	Then ...
at a height that is lower than the current cut plane	objects are displayed using the Layer/Color/Linetype properties specified for the Below Cut Plane component of the object.
at a height that is higher than the current cut plane	objects are displayed using the Layer/Color/Linetype properties specified for the Above Cut Plane component of the object.

You can click Remove to delete a cut plane that you added.

You can also access and modify these same cut plane settings through the curtain wall's context menu, as follows

- 1 Select the curtain wall you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.
- 5 Click OK twice.

Specifying the Display of Other Characteristics of a Curtain Wall

Use this procedure to specify other display properties for a curtain wall, including cell marker size, the display of miters at frame corners, and the display of custom components. If you are going to use custom graphics for a component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the curtain wall.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all curtain walls in the drawing, select Drawing default setting. To apply changes to all curtain walls of this style, select Curtain Wall Style:<style name>. For more information on styles, see [Curtain Wall Styles](#) on page 941.

- 5 If necessary, expand Object Display Properties ► Advanced.
- 6 If you want to change the size of the markers used for cells in the curtain wall grid, click Cell marker size, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)
- 7 Optionally, for Show mitres at frame corners, select Yes/No.
- 8 If you want to add or edit a custom component, for Custom model components (or for Custom plan components, if in a plan view), click .
- 9 On the Custom Model (or Plan) Components worksheet, click Add, or select one of the components in the list, and click Edit.
- 10 On the Custom Display Component worksheet, for Component Type, select Infill, Frame, or Mullion.
- 11 Enter a name for Component Name, or click Select Component, and in the Select <component type> Definition dialog, select a definition and click OK.
- 12 Select Draw Custom Graphics.
- 13 Specify the display of the element:

If you want to ...	Then ...
display the block instead of the associated curtain wall element	select Replace Graphics.
superimpose the block over the curtain wall element so that both are displayed	clear Replace Graphics.

- 14 Click Select Block, select the custom block that you created, and click OK.
- 15 Specify further settings for the custom display block:

If you want to ...	Then ...
scale the block to fit a particular dimension	select Width, Height, or Depth. To prevent the block from losing its proportions, select Lock XY Ratio.
specify how the block is inserted into the grid in the X, Y, and Z directions	specify an insertion point on the X, Y, and Z planes.
mirror the block	determine whether it should mirror in the X, Y, or Z direction.
offset the block from the grid	specify the offset in the X, Y, or Z direction.

- 16 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Curtain Wall

Use this procedure to enter notes and attach reference files to a curtain wall. You can also edit notes and edit or detach reference files from a curtain wall.

- 1 Double-click the curtain wall.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
- 4 To add a note, click the setting for Notes, and enter the text.
- 5 Click OK.
- 6 To attach a reference file, click under Reference documents, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click Open.
edit the description of a reference file	select the file, and click the description. Enter the new text, and press <i>ENTER</i> .
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 7 Click OK twice.

Changing the Roof Line and the Floor Line of a Curtain Wall

You can modify the roof and floor lines of a curtain wall to create a non-rectangular curtain wall:

- You edit vertex locations on the roof line to create steps, gables, and other roof conditions.

Modifying the roof line of a curtain wall

- You edit vertex locations on the floor lines to create steps and other floor conditions.

Modifying the floor line of a curtain wall

You can also create non-rectangular roof and floor conditions by projecting to polylines.

AutoCAD Architecture offers multiple methods of editing roof lines and floor lines. You may want to begin by graphically creating a custom roof line or floor line condition. You can then fine-tune that condition by specifying precise values in the Roof/Floor Line worksheet on the Properties palette.

Offsetting or Projecting the Roof Line of a Curtain Wall

Use this procedure to change the height or the shape of the roof line of a curtain wall:

- Offset the roof line from the current height of the curtain wall.
- Project the roof line of the curtain wall to a polyline.
- Project the roof line of the curtain wall to another object, such as a roof or stairs.

You can also create a polyline that represents the current roof line of the selected curtain wall. You can then use this polyline to change the roof line of other curtain walls.

NOTE To project the roof line to a polyline, draw the polyline first in Elevation view. For best results, the polyline should be parallel to the curtain wall. The polyline does not need to be in the same plane as the curtain wall.

1 Select a curtain wall, right-click, and click **Roof Line / Floor Line** ► **Modify Roof Line**.

The current roof line is the default value in the curtain wall style.

2 Change the roof line of the wall:

If you want to ...	Then ...
offset the roof line from the current height of the curtain wall	enter o (Offset), select the curtain walls to change, and enter an offset distance. Enter a negative value to project the roof line below the current curtain wall height.
project the roof line to a polyline	enter p (Project), select the curtain walls to change, and select the polyline.
generate a polyline of the current roof line	enter g (Generate), and select the curtain walls for the polyline to be created from.
project the roof line to another object, such as a roof or stairs	enter a (Auto-project), select the curtain walls to change, and select the object to project to. When projecting to stairs, make sure that the bottom riser or the stringer does not create a zero-height segment of curtain wall.
remove any changes to the roof line	enter r (Reset), and select the curtain walls to change.

3 Press **ENTER**.

The new roof line value is used only on the selected curtain walls. The curtain wall style is unchanged.

Offsetting or Projecting the Floor Line of a Curtain Wall

Use this procedure to change the height or the shape of the floor line of a curtain wall:

- Offset the floor line from the current baseline of the curtain wall.
- Project the floor line of the curtain wall to a polyline.
- Project the floor line of the curtain wall to another object, such as a floor slab or stairs.

You can also create a polyline that represents the current floor line of the selected curtain walls. You can then use this polyline to change the floor line of other curtain walls.

NOTE To project the floor line to a polyline, draw the polyline first in Elevation view. For best results, the polyline should be parallel to the curtain wall. The polyline does not need to be in the same plane as the curtain wall.

1 Select a curtain wall, right-click, and click **Roof Line / Floor Line** ► **Modify Floor Line**.

The current floor line is the default value in the curtain wall style.

2 Change the floor line of the curtain wall:

If you want to ...	Then ...
offset the floor line from the current baseline of the curtain wall	enter o (Offset), select the curtain walls to change, and enter an offset distance. Enter a negative value to offset the floor line below the current baseline.
project the floor line to a polyline	enter p (Project), select the curtain walls to change, and select the polyline.
generate a polyline of the current floor line	enter g (Generate), and select the curtain walls for the polyline to be created from.
project the floor line to another object, such as a floor slab or stairs	enter a (Auto-project), select the curtain walls to change, and select the object to project to.
remove any changes to the floor line	enter r (Reset), and select the curtain walls to change.

3 Press **ENTER**.

The new floor line value is used only in the selected curtain wall. The curtain wall style is unchanged.

Editing the Roof Line or the Floor Line of a Curtain Wall

Use this procedure to edit the geometry of the roof line or the floor line of a curtain wall:

- Add, modify, or remove gables.
- Add, modify, or remove steps.
- Project the roof line or the floor line to a polyline or to other objects, such as roofs, roof slabs, slabs, and stairs.
- Create custom roof line or floor line conditions by adding and adjusting vertices and edges.

- Reverse the roof line or the floor line of the curtain wall without reversing the curtain wall itself.
- Remove all changes to the roof line or the floor line of a curtain wall.

You can also edit the roof line and the floor line on the Roof/Floor Line worksheet on the Properties palette. For more information, see [Changing Vertices in the Roof Line or Floor Line of a Curtain Wall](#) on page 1029.

NOTE If you want to project the roof line or the floor line to a polyline, draw the polyline before you start this procedure.

1 Select the curtain wall that has the roof line or floor line you want to change, right-click, and click Roof/Floor Line ► Edit in Place.

A temporary profile is created for you to edit the geometry of the roof line or the floor line.

2 NOTE After you perform an editing task from the shortcut menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the menu, select the profile, and right-click to display the shortcut menu.

Edit the profile:

If you want to ...	Then ...
add a gable to the roof line or the floor line	select the profile, right-click, and click Add Gable. Select the roof line or the floor line.
add a step to the roof line or the floor line	select the profile, right-click, and click Add Step. Select the roof line or the floor line.
change the shape of the roof line or the floor line	select the profile, and use Vertex and Edge grips to adjust the shape.
add vertices to the roof line or the floor line	select the profile, right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .
remove vertices from the roof line or the floor line	select the profile, right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .
project the roof line or the floor line to a polyline	select the profile, right-click, and click Project. Select the roof line or the floor line, and select the polyline. Press <i>ENTER</i> to keep the geometry, or enter n (No) to erase it.
project the roof line or the floor line to another object, such as a stair or a roof	select the profile, right-click, and click Auto Project. Select the roof line or the floor line, and select the object.
reverse the roof line or the floor line	select the profile, right-click, and click Reverse. Select the roof line or the floor line.
restore the roof line to the base height of the curtain wall, or restore the floor line to the baseline of the curtain wall	select the profile, right-click, and click Remove. Select the roof line or the floor line.

NOTE To add a gable or a step to a roof line or a floor line that has been edited, first use the Remove option on the shortcut menu to remove an existing roof line or floor line condition.

3 Save or discard the changes:

If you want to ...

Then ...

restore the roof line and the floor line to their shape before editing

select the profile, and click

save the changes

select the profile, and click . The curtain wall uses the edited profile to define its geometry.

Changing the Roof Line and the Floor Line

Use this procedure to change the height or the shape of the roof line and the floor line using grips.

- 1 Select a curtain wall.

2 Select a Roof Line End or Floor Line End grip, move the grip to the appropriate position, and click once.

Adding a Gable to the Roof Line of a Curtain Wall

Use this procedure to add a gable to the roof line of a curtain wall. You can also add a gable on the Roof/Floor Line worksheet on the Properties palette. For more information, see [Specifying Gable Settings for a Roof Line](#) on page 1030.

NOTE This option is available only if the roof line has not been edited. After the roof line changes, you cannot add a gable using this option. To add a gable to a roof line that has been edited, see [Changing Vertices in the Roof Line or Floor Line of a Curtain Wall](#) on page 1029.

- 1 Select the curtain wall, right-click, and click Roof/Floor Line ► Edit in Place.
A temporary profile is created for you to edit the geometry of the Roof line.
- 2 Right-click, and click Add Gable.
If Add Gable is not listed on the menu, the roof line was previously edited.

3 Select the roof line.

Modifying a curtain wall roof line by adding a gable

A third vertex is added to the roof line halfway between the two ends of the roof line.

4 Continue editing the roof line or the floor line, if needed.

For more information, see [Changing the Roof Line and the Floor Line](#) on page 1025.

5 Save or discard the changes:

If you want to ...

Then ...

restore the roof line to its previous shape

select the profile, and click  .

save the changes to the roof line

select the profile, and click  .

Adding a Step to the Roof Line or Floor Line of a Curtain Wall

Use this procedure to add a step to the roof line or the floor line of a curtain wall. You can also add a step on the Roof/Floor Line worksheet on the Properties palette. For more information, see [Specifying Step Settings for a Roof Line or Floor Line](#) on page 1031.

NOTE This option is available only when the roof line or the floor line has not been edited. After the line has been changed, you cannot automatically add a step using this option. To add a step to a roof line or a floor line that has been edited, see [Changing Vertices in the Roof Line or Floor Line of a Curtain Wall](#) on page 1029.

1 Select the curtain wall, right-click, and click Roof/Floor Line ► Edit in Place.

A temporary profile is created for you to edit the geometry of the roof line or the floor line.

2 Right-click, and click Add Step.

If Add Step is not listed on the menu, the roof line or the floor line was previously edited.

3 Select the roof line or the floor line.

Modifying a curtain wall floor line by adding a step

existing curtain wall segment

modified floor line with added step

A third vertex is added to the line halfway between the two ends of the line and four feet from the line. A step is created from the selected vertex to the second vertex.

4 Continue editing the roof line or the floor line, if needed.

For more information, see [Changing the Roof Line and the Floor Line](#) on page 1025.

5 Save or discard the changes:

If you want to ...

Then ...

restore the roof line or the floor line to its previous shape

select the profile, and click

save the changes to the roof line or the floor line

select the profile, and click

Changing Vertices in the Roof Line or Floor Line of a Curtain Wall

Use this procedure to perform the following tasks:

- Add, move, or remove vertices and edges in the roof line or the floor line of a curtain wall.
- Add gables or steps to a roof line or steps to a floor line that was previously edited by adding vertices that define these conditions.
- Remove all changes to the roof line or the floor line, restoring the original base height or baseline of a curtain wall.

NOTE You can also edit vertices in a curtain wall with the curtain wall worksheets. For information, see [Specifying Vertex Settings for a Roof Line or Floor Line](#) on page 1032.

1 Select the curtain wall in which you want to edit vertices, right-click, and click Roof Line/Floor Line ► Edit in Place.

A temporary profile is created for you to edit the geometry of the roof line or the floor line.

2 Edit the vertices:

If you want to ...	Then ...
change the position of a vertex or an edge	select its grip and move it to the appropriate position.
add a vertex	select the profile, right-click, and click Add Vertex. Specify new vertices in the drawing. When you are finished adding vertices, press <i>Enter</i> .
remove a vertex	select the profile, right-click, and click Remove Vertex. Select the vertices you want to remove. Press <i>Enter</i> .
restore the original roof line or floor line	select the profile, right-click, and click Remove. Select the roof line or the floor line.

3 Save the changes to the curtain wall:

If you want to ...	Then ...
save the changes to the current curtain wall	select the profile, right-click, and click Save All Changes.
discard all changes on the curtain wall and revert back to the previous shape	select the profile, right-click, and click Discard all Changes. Changes you made to the roof line or floor line of the curtain wall are discarded.

Specifying Gable Settings for a Roof Line

Use this procedure to add a gable to the roof line of a curtain wall by adding a vertex to the roofline.

Modifying a curtain wall roof line by adding a gable

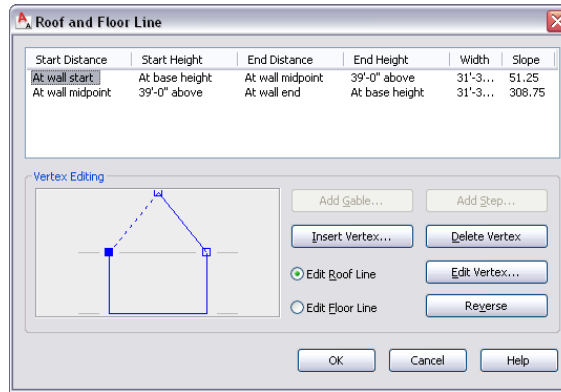

NOTE This option is available only if the roof line has not been edited. After the roof line changes, you cannot add a gable using this option. To add a gable to a roof line that has been edited, see [Changing Vertices in the Roof Line or Floor Line of a Curtain Wall](#) on page 1029.

1 Double-click the curtain wall.

- 2 Expand Advanced.
- 3 Click Roof/floor line.
- 4 Select Edit Roof Line or Edit Floor Line.
- 5 Click Add Gable.

A third vertex is added to the roof line halfway between the two ends of the roof line.

The table at the top of the dialog box displays information about each vertex in the curtain wall. You can also select the vertex to edit from the list.

- 6 Click OK.

Specifying Step Settings for a Roof Line or Floor Line

Use this procedure to add a step to the roof line or the floor line of a curtain wall.

Modifying a curtain wall roof line by adding a gable

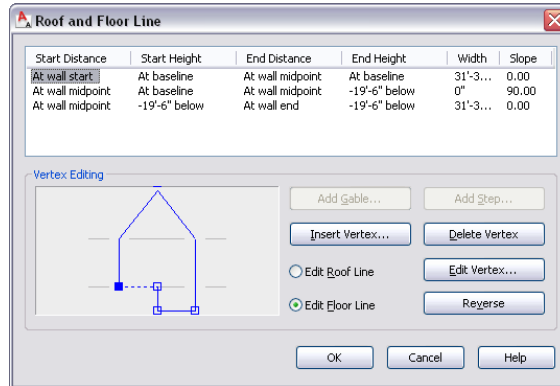

NOTE This option is available only when the roof line or the floor line has not been edited. After the line has been changed, you cannot automatically add a step using this option. To add a step to a roof line or a floor line that has been edited, see [Changing Vertices in the Roof Line or Floor Line of a Curtain Wall](#) on page 1029.

- 1 Double-click the curtain wall.
- 2 Expand Advanced.
- 3 Click Roof/floor line.
- 4 Select Edit Roof Line or Edit Floor Line.
- 5 Click Add Step.

A third vertex is added to the line halfway between the two ends of the line. A step is created from the selected vertex to the second vertex.

The table at the top displays information about each vertex in the curtain wall. You can select a vertex to edit from the list.

6 Click OK.

Specifying Vertex Settings for a Roof Line or Floor Line

Use this procedure to perform the following tasks:

- Add, move, or remove vertices in the roof line or the floor line of a curtain wall.
- Add gables or steps to a roof line or steps to a floor line that was previously edited by adding vertices that define these conditions.

- 1 Double-click the curtain wall.
- 2 Expand Advanced.
- 3 Click Roof/floor line.
- 4 Select Edit Roof Line or Edit Floor Line.

The active vertex in the illustration changes when you select a different line to edit. Any changes you make to the wall are reflected in the illustration.

5 Specify vertex settings:

If you want to ...	Then ...
add a vertex	click Insert Vertex. In the Wall Roof/Floor Line Vertex dialog box, specify the horizontal offset and vertical offset for the new vertex, specify a distance, and click OK.
move a vertex	select a vertex from the list, and then click Edit Vertex.
delete a vertex	select a vertex from the list, and then click Delete Vertex. The selected vertex is deleted, and the line automatically connects the two adjacent vertices.

6 Specify the horizontal offset.

The horizontal offset specifies the existing vertex from which to measure the placement of the next vertex and how far away from the existing vertex to place the new one. Distance is measured in the direction the curtain wall is drawn. You can enter a negative number to offset the vertex in the reverse direction.

7 Specify the vertical offset.

The vertical offset specifies the location from which to measure the height of the next vertex and how far away from the existing location to place the new vertex. You can enter a negative number to offset the vertex toward the ground.

8 Click OK twice.

Editing Objects Anchored in Curtain Walls

When you fill a curtain wall cell with an infill that contains an object, such as a door or window, you can edit that object independently from the curtain wall. For example, you can select a door from a curtain wall and edit its properties. You can edit the anchor settings for the door to change the orientation of the door and the alignment or offset of the door in relation to the curtain wall.

You can also move objects from one cell to another or release the object anchor so that the object moves independently of the curtain wall.

When you move or release an object or edit its properties, you are creating a variation from the infill cell assignment for the curtain wall style. By default, these variations (except release) are allowed to persist in the drawing when you reapply the style to a curtain wall. However, if you want these variations to be overridden when you reapply a curtain wall style, turn off the Allow Variation from Infill Element Definition option on the Anchor worksheet of the Properties palette of the object. This option is set on a per object basis.

Changing the Orientation of an Object Anchored in a Curtain Wall

Use this procedure to change the orientation of an object anchored in a curtain wall using grips.

1 Click the object in the curtain wall for which you want to change the orientation.

2 Click the appropriate Flip grip to change the X or Y direction of the object.

You can also change the orientation of an object, including the Z direction, using the Anchor worksheet found on the object's Properties palette.

Changing the Alignment of an Object Anchored in a Curtain Wall

Use this procedure to modify the alignment of an object that is anchored in a curtain wall.

1 Double-click the object in the curtain wall.

2 Expand Location, and click Anchor.

3 Click Allow Variation from Infill Element Definition.

4 Select a new alignment for the object.

For more information, see [Specifying an Alignment for a Curtain Wall Infill](#) on page 956.

5 Click OK.

Changing the Offset of an Object Anchored in a Curtain Wall

Use this procedure to change the offset of an object anchored in a curtain wall.

- 1 Double-click the object in the curtain wall.
- 2 Expand Location, and click Anchor.
- 3 Click Allow Variation from Infill Element Definition.
- 4 Specify a new offset for the object.

For more information, see [Specifying an Offset for a Curtain Wall Infill](#) on page 957.

- 5 Click OK.

Swapping Two Objects Anchored in a Curtain Wall

When you fill a curtain wall cell with an object, such as a door or window, you can swap that object with another object in the curtain wall.

- 1 Select one of the objects from the curtain wall and click Infill Anchor ► Swap Objects.
- 2 Select the object you want to swap with.

Releasing an Object Anchored in a Curtain Wall

When you fill a curtain wall cell with an object, such as a door or window, that object is anchored to the curtain wall. While the anchor is in place, the object moves when you move the curtain wall and is removed when you erase the curtain wall. If you want to move or erase an object independently from the curtain wall, you can release the anchor of the object.

NOTE You can also move or erase the object by changing the element definition for the cell that contains the object. For more information, see [Defining Infills for Curtain Wall Cells](#) on page 954.

- Select one of the objects from the curtain wall, and click Infill Anchor ► Release.

Curtain Wall Units

Curtain wall units are an important building block of curtain walls.

The Concept of Curtain Wall Units

Curtain wall units can significantly reduce the complexity of the curtain wall design and, thereby, the necessary design time.

You can think of a curtain wall unit as a “mini” curtain wall itself, which can have frames, mullions and divisions, but is normally not a standalone building object. A curtain wall unit is used in the larger context of a curtain wall. You usually assign curtain wall units to specific cells within a curtain wall grid. For more information, see [Inserting an Object into a Curtain Wall Cell](#) on page 974.

Curtain Wall Unit Styles

Curtain wall units are style-based, permitting maximum efficiency and flexibility. Curtain wall unit styles are created and edited independently from the curtain wall style. You can use a curtain wall unit style in

different curtain wall styles. For example, you can create a decorative three-tiled panel as a curtain wall unit and use that for several curtain wall styles.

Curtain Wall Units and Door/Window Assemblies

Curtain wall units and door/window assemblies are very similar in their functionality. Both can contain nested grids and be anchored as building blocks in curtain walls. A curtain wall unit usually is not used as a standalone object, whereas a door/window assembly could be.

Curtain Wall Unit Grids

Like curtain walls, curtain wall units are made up of one or more grids. Each grid has either a horizontal division or a vertical division, but you can nest the grids to create a variety of patterns.

Using curtain wall units in a curtain wall can help you limit the complexity in the curtain wall design.

Elements of Grids

Grids are the foundation of curtain walls and curtain wall units. Every grid has four element types:

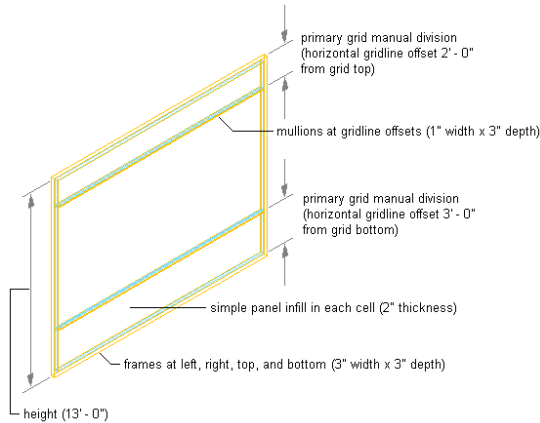

- **Divisions:** Define the direction of the grid (horizontal or vertical) and the number of cells
- **Cell Infills:** Contain another grid, a panel infill, or an object such as a window or a door
- **Frames:** Define the edge around the outside of the primary grid and nested grids
- **Mullions:** Define the edges between the cells

NOTE Division is an abstract element, in contrast to the other three element types that represent physical elements of the curtain wall unit.

Each element type is assigned a default definition that describes what elements of that type look like.

Element type	Default definitions
Divisions	Horizontal grid with two manual divisions offset from the top and bottom of the grid
Cell Infills	Cells containing simple panels
Frames	Outer edges of grid 3" wide and 3" deep
Mullions	Edges between cells 1" wide and 3" deep

Curtain wall units default element definitions

Getting Started with Curtain Wall Units

To get started with curtain wall units, draw a curtain wall unit using one of the methods described in [Creating Curtain Wall Units](#) on page 1036. Try a variety of the existing curtain wall unit styles, find a style you like and make a copy of it. Then, modify the element definitions and assignments to suit your own needs. For more information, see [Creating Element Definitions for a Curtain Wall Unit Style](#) on page 1040.

For more information about element definitions and assignments, see [Creating Element Definitions for a Curtain Wall Unit Style](#) on page 1040 and [Assigning Infills to Curtain Wall Unit Cells](#) on page 1060.

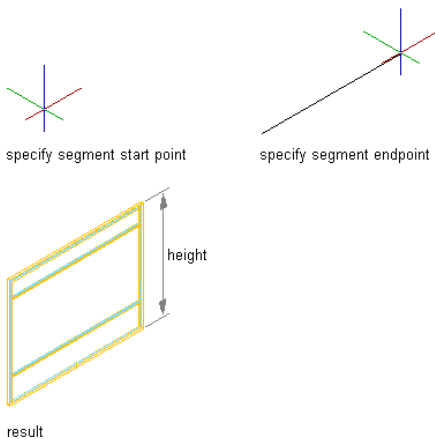

Creating Curtain Wall Units

Creating curtain wall units is similar to creating curtain walls. You specify a style, a height, and start and end points. You can also create curtain wall units by converting a 2D layout grid to a curtain wall or converting two-dimensional (2D) lines, arcs, and circles. Unlike curtain walls, you cannot create a curtain wall unit based on a curve. Curtain wall units can only be planar.

Creating a Curtain Wall Unit

Use this procedure to create a curtain wall unit.

Drawing a curtain wall unit

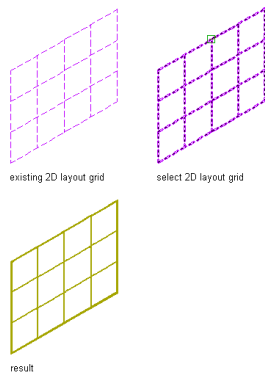

- 1 At the command line, enter **cwunit**.
- 2 Enter **a** (Add).
- 3 Select a start point and an end point.
- 4 Specify a height for the curtain wall unit.
- 5 Select a style, and click OK.

For information about curtain wall unit styles, see [Curtain Wall Unit Styles](#) on page 1039.

Converting a Layout Grid to a Curtain Wall Unit

You can create a curtain wall unit grid that is based on a 2D layout grid. If you already have 2D layout grids in a drawing, you can easily convert them to curtain wall units. Or if you are already familiar with layout grids, it is an efficient way to create a curtain wall unit, and then experiment with the curtain wall commands to learn more about them.

Converting a 2D layout grid to a curtain wall unit

When you create a curtain wall unit from a 2D layout grid, you also create a new curtain wall unit style. The divisions in the new curtain wall unit style are taken from the divisions in the layout grid.

Curtain wall unit grids are one-dimensional, divided either horizontally or vertically. To create the horizontal and vertical patterns in the 2D layout grid, the curtain wall unit uses a primary grid with a secondary grid nested inside it. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

When you create a curtain wall unit grid from a 2D layout grid, you need to decide the direction of the primary grid in the curtain wall unit. If you select horizontal, the primary grid has horizontal divisions that cross over the vertical divisions of the secondary grid. If you select vertical, the primary grid has vertical divisions that cross over the horizontal divisions of the secondary grid.

Specifying primary division directions

The horizontal and vertical lines of the 2D layout grid define the divisions for the curtain wall unit grids. The grid cells, frame, and mullions are assigned default definitions.

- 1 Create a layout grid.

For more information, see [Using Layout Grids](#) on page 1810.

- 2 At the command line, enter **cwunit**.
- 3 Enter **c** (Convert).
- 4 Enter **LA** (LayoutGrid).
- 5 Select the layout grid.
- 6 To erase the layout grid, enter **y** (Yes). To have the layout grid remain after the curtain wall unit is created, enter **n** (No).
- 7 When prompted for the primary division, enter **v** (Vertical) or **h** (Horizontal) as the orientation.
- 8 Enter a name for this new curtain wall unit style.
- 9 Click OK, and press **ENTER** to end the command.

Creating a Curtain Wall Unit with a Custom Grid

Curtain wall units contain one or more grids. You can define a custom grid with lines, arcs, and circles, and then convert that linework into a curtain wall unit.

NOTE Curtain wall unit grids are either horizontal or vertical. To create a grid pattern with horizontal and vertical cells, nested grids are used. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

You cannot modify the division definition of a custom grid created from lines, arcs, and circles. You can, however, assign a different division definition to it. For more information, see [Assigning a Division to a Curtain Wall Unit Grid](#) on page 1060.

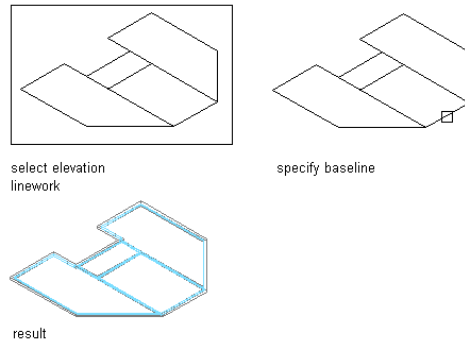

- 1 Use lines, arcs, and circles to draw a grid in the current world coordinate system (WCS).
- 2 At the command line, enter **cwunit**.
- 3 Enter **c** (Convert).
- 4 Enter **LI** (LInework).
- 5 Select the lines, arcs, or circles that define your grid.
- 6 Press **ENTER**.
- 7 Select one of the grid lines as the baseline for the curtain wall or press **ENTER** to use the line along the *X* axis as the baseline.

Converting linework to curtain walls units using the default baseline option

TIP If you draw your linework in the XY plane (in Plan view) and accept the default baseline, the resulting curtain wall unit is displayed as it is projected in the Z direction.

Converting linework to curtain walls using the specified baseline option

8 To erase the lines, enter **y** (Yes). To have the lines remain after the curtain wall unit is created, enter **n** (No).

Each enclosed area is assigned the default cell infill. The lines between the cells are assigned the default mullion definition, and the boundary around the grid is assigned the default frame definition. For more information, see [Assigning Definitions to Curtain Wall Elements](#) on page 968.

9 Select the resulting custom curtain wall unit, right-click, and click Design Rules ► Save to Style.

10 Click New to create a new curtain wall unit style.

11 Enter a name for the new curtain wall unit style.

12 Click OK twice.

Curtain Wall Unit Styles

Curtain wall units are style-based, meaning there are preset characteristics assigned to each curtain wall unit that determine its appearance and function. By changing from one style of curtain wall unit to another, you can quickly study several different design options. Any changes you make to the style are reflected throughout your building, updating all curtain walls that use that particular curtain wall unit style. You can also apply overrides to a single curtain wall unit, without changing other curtain walls of the same style.

A curtain wall unit style controls the following properties of a curtain wall:

- Element definitions
- Definition assignments for each element
- Materials for each element
- Display properties for each element
- Notes about the style and any associated reference files

To create, edit, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Creating Element Definitions for a Curtain Wall Unit Style

Element definitions determine the appearance of the four basic curtain wall unit elements. There is a different definition type for each element.

Element type	Default definitions
Divisions	Horizontal grid with two manual divisions offset from the top and the bottom of the grid
Cell Infills	Cells containing simple panels
Frames	Left, right, top, and bottom outer edges of grid 3" wide and 3" deep
Mullions	Edges between cells 1" wide and 3" deep

Each type of element can have multiple definitions. For example, you can define a division to create a horizontal grid or a vertical grid, and you can define the cells to contain a nested grid or a panel infill. To make reuse easier, you can save the element definitions, and then assign them to grids, cells, frames, or mullions as needed.

Element definitions are style-specific. When you create element definitions for a specific curtain wall unit style, those definitions are available only for curtain wall units of that style. For example, if you define a panel infill for one curtain wall unit style, that infill is not available as an option when you edit a curtain wall unit of a different style.

For information about defining the color, linetype, or layer of curtain wall elements, see [Specifying the Display of Curtain Wall Units](#) on page 1073.

Creating a Curtain Wall Unit Style

Use this procedure to create a curtain wall unit style. You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Create a new curtain wall style:

If you want to create a style ...	Then ...
with default properties	right-click Curtain Wall Unit Styles, and click New.
from an existing style	right-click the curtain wall unit style you want to copy, and click Copy. Right-click, and click Paste.
from a curtain wall, curtain wall unit, or door/window assembly in the drawing	right-click Curtain Wall Unit Styles, and click New. Right-click the new style, click Set From, and then pick a curtain wall, a curtain wall unit, or a door/window assembly.

4 Enter a name for the new curtain wall unit style, and press *Enter*.

5 Edit the new curtain wall unit style:

If you want to ...	Then ...
define the elements of a curtain wall unit style	see Defining Divisions for Curtain Wall Unit Grids on page 1041, Defining Infills for Curtain Wall Unit Cells on page 1048, Defining Curtain Wall Unit Frames on page 1051, and Defining Curtain Wall Unit Mullions on page 1055.
assign element definitions to the curtain wall unit style	see Assigning a Division to a Curtain Wall Unit Grid on page 1060, Assigning Infills to Curtain Wall Unit Cells on page 1060, Assigning Definitions to Curtain Wall Unit Frames on page 1066, and Assigning Definitions to the Mullions of a Curtain Wall Unit on page 1069.
add curtain wall element definitions as display components	see Adding Curtain Wall Unit Element Definitions as Display Components on page 1074.
specify layer, color and linetype settings for the display components of a curtain wall	see Specifying the Layer, Color, and Linetype of a Curtain Wall Unit Style on page 1074.
specify curtain wall unit hatching	see Specifying the Hatching for Components of a Curtain Wall Unit Style on page 1075.
add custom graphics as display components of a curtain wall unit style	see Adding Custom Graphics as a Display Component of a Curtain Wall Unit on page 1076.
create individual cut planes for curtain wall unit styles	see Creating Cut Planes for a Curtain Wall Unit on page 1077.
add notes and files to the style	see Attaching Notes and Files to a Curtain Wall Unit Style on page 1078.

6 Click OK.

Defining Divisions for Curtain Wall Unit Grids

The divisions of a grid define the orientation that determines the direction of the grid cells and mullions, and they define a division type that determines the number and size of cells.

NOTE Creating a nested grid is not a division rule. To create a nested grid, add a cell assignment. For more information, see [Creating a Nested Grid in a Curtain Wall Unit](#) on page 1061 and [Working with Nested Grids in Curtain Walls](#) on page 969.

You can create a variety of division definitions under different names, and then assign different divisions to each grid in your curtain wall unit. Although you can create multiple definitions, there can be only one division assignment per grid. You create division definitions for a specific curtain wall unit style and those definitions can be assigned only to grids in curtain wall units of that style.

For more information about assigning divisions to a particular grid, see [Assigning a Division to a Curtain Wall Unit Grid](#) on page 1060.

Division of Curtain Wall Unit Grids

A curtain wall unit consists of one or more grids, which are the framework for placing design elements in the curtain wall unit. The highest-level grid is the primary grid, which is also the outside edge of the curtain wall unit.

Each grid in a curtain wall unit has one division assignment that determines whether the grid is divided horizontally or vertically. The division also determines the number of cells, their size and their placement.

Within the primary grid, you can define multiple levels of grids. These grids within are called nested grids. Each subdivision of a grid is called a cell.

Creating a Division Definition for a Curtain Wall Unit

Use this procedure to create divisions for a curtain wall unit grid.

Because curtain wall units can contain multiple nested grids, it is helpful to use a naming convention for grids that indicates the level of each grid and the grid location or the purpose within the curtain wall unit. For example, L3-FL1-Stone Panels can identify a third level grid that provides a row of stone panels on Floor 1.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Click New Division.
- 7 Enter a name for this division definition.
- 8 Click either Horizontal or Vertical for Orientation.
- 9 Select one of the following division types and specify offsets if needed.

Division Type	Description
Fixed Cell Dimension	Creates a grid where the size of the individual cells is predetermined. For more information, see Specifying a Fixed Size for Cells in a Curtain Wall Unit Grid on page 1043.
Fixed Number of Cells	Creates a grid where the number of grid cells is predetermined. For more information, see Specifying a Fixed Number of Cells for a Curtain Wall Unit Grid on page 1045.
Manual	Creates a grid where the size and number of individual cells is manually determined by the user. For more information, see Manually Defining the Number and Size of Cells in a Curtain Wall Unit Grid on page 1046.

After you create a division definition, you can assign the definition to a specific grid in a curtain wall unit. For more information, see [Assigning a Division to a Curtain Wall Unit Grid](#) on page 1060.

10 When you are finished creating division definitions, click OK.

Specifying a Fixed Size for Cells in a Curtain Wall Unit Grid

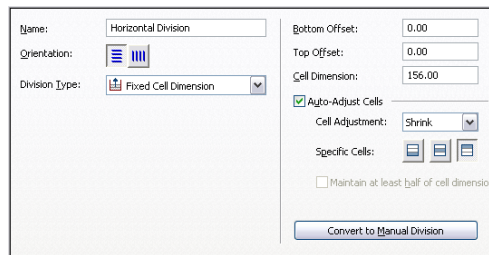

Use this procedure to define a specific size for the cells in a grid. In this case, the number of cells is determined by the length or height of the grid, depending on how the grid is divided.

When you specify a fixed cell size in a grid, you can control how the cells of the grid adjust to accommodate any leftover space. This space occurs if the length (or the height) of the curtain wall unit cannot be evenly divided by the fixed size of the cell. For more information, see [Using the Auto-Adjust Cells Option to Resize Cells in a Curtain Wall Unit Grid](#) on page 1044.

Specifying a fixed size for cells

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Fixed Cell Dimension for Division Type.

- 8 Specify a size for the cells in Cell Dimension.

If you are defining a vertical division, the cell dimension is the length of the cell from mullion to mullion. If you are defining a horizontal division, the cell dimension is the height of the cell.

- 9 To specify an offset for the grid, enter an offset distance in Start Offset or End Offset. For more information, see [Specifying an Offset for a Curtain Wall Unit Grid](#) on page 1046.

TIP The frame width is calculated as part of the cell size. Therefore, cells adjacent to the frame can appear to be a different size than the other cells. If you do not want the frame width included in the cell size, specify an offset for the grid that is equal to the frame width.

When you draw a curtain wall unit using a fixed cell dimension, there is often extra space between the last full-size cell and the end of the curtain wall unit.

10 To adjust the cells and accommodate this extra space automatically as you draw curtain wall units, select the Auto-Adjust Cells option.

11 Adjust the cells to accommodate this extra space:

If you want to ...	Then ...
add the space to grid cells	select Auto-Adjust Cells, select Grow for Cell Adjustment, and select the specific cells where the space is added. You can select any combination of specific cells.
remove the space from grid cells	select Auto-Adjust Cells, select Shrink for Cell Adjustment, and select the specific cells where the space is removed. You can select any combination of specific cells.

For information about offsets, see [Specifying an Offset for a Curtain Wall Unit Grid](#) on page 1046.

12 Click OK.

For information about assigning the division definition to a specific grid in your curtain wall unit, see [Assigning a Division to a Curtain Wall Unit Grid](#) on page 1060.

Using the Auto-Adjust Cells Option to Resize Cells in a Curtain Wall Unit Grid

Use this procedure to automatically resize cells in a grid when the result of dividing the grid by the specified cell dimension is not a whole number.

For example, if a vertical primary grid in a curtain wall unit style is 17 feet in length and you specify a fixed cell dimension of 3 feet, the grid has five cells of 3 feet each with 2 feet remaining. Using the Auto-Adjust Cells option, you can specify how the grid distributes the remaining quantity.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Styles.
- 3 Select a curtain wall unit style, right-click.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Divisions definition or create a new one.
- 7 Select Fixed Cell Dimension as the division type.
- 8 Select Auto-Adjust Cells, and specify the cell adjustment:

If you want to ...	Then ...
add the remaining space to grid cells	select Grow, and select the specific cells to which you want the space added.

If you want to ...**Then ...**

remove the remaining space from grid cells

select Shrink, and select the specific cells from which you want the space removed. You can then select Maintain at least half of cell dimension in order to control the cell shrinkage.

The cells that you do not select maintain the fixed value you specified for Cell Dimension.

Specifying a Fixed Number of Cells for a Curtain Wall Unit Grid

Use this procedure to define a specific number of cells in a grid. In this case, the size of the cells is determined by the length or height of the grid, depending on how the grid is divided.

In some cases, when you create a complex curtain wall unit grid, you might want to start with a standard grid with a fixed number of cells, and then later fine-tune that manually. You can first create a grid with fixed cell numbers and then convert that to a manual grid. For information on manual grids, see [Manually Defining the Number and Size of Cells in a Curtain Wall Unit Grid](#) on page 1046.

Specifying a fixed number of cells

vertical divisions
with four cells

horizontal divisions
with three cells

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Fixed Number of Cells for Division Type.
- 8 Specify the number of cells.
- 9 To specify an offset for the grid, enter an offset distance for Start Offset or End Offset. For more information, see [Specifying an Offset for a Curtain Wall Unit Grid](#) on page 1046.

NOTE If you want to fine-tune the initial layout with a fixed number of cells, click Convert To Manual Division and edit the grid as described in [Manually Defining the Number and Size of Cells in a Curtain Wall Unit Grid](#) on page 1046.

- 10 Click OK.

For information about assigning the division definition to a specific grid in your curtain wall unit, see [Assigning a Division to a Curtain Wall Unit Grid](#) on page 1060.

Manually Defining the Number and Size of Cells in a Curtain Wall Unit Grid

Use this procedure to manually add gridlines and specify an offset for each one when you need to create a unique grid that does not fit into any of the other division types. You can also start with a fixed cell dimension grid or a fixed number of cells grid, and then manually adjust the grid lines to suit your needs.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Manual for Division Type.
- 8 Click the Add Gridline icon to insert a grid line. Insert as many grid lines as you need. If you need to remove a grid line, select it from the table and click the Remove Gridline icon.
- 9 Under Offset in the gridline table, specify an offset distance for each grid line.

Gridline offset

Gridline	Offset	From
1	2'-6"	Grid Bottom
2	5'-0"	Grid Bottom
3	0"	Grid Middle
4	5'-0"	Grid Top
5	2'-6"	Grid Top

- 10 Under From in the grid line table, select the grid location from which the grid line is offset.

Offset grid line from option

Gridline	Offset	From
1	2'-6"	Grid Bottom
2	5'-0"	Grid Bottom
3	0"	Grid Middle
4	5'-0"	Grid Top
5	2'-6"	Grid Top

- 11 To specify an offset for the grid, enter an offset distance for Start Offset or End Offset.

For more information, see [Specifying an Offset for a Curtain Wall Unit Grid](#) on page 1046.

- 12 Click OK.

For information about assigning the division definition to a specific grid in your curtain wall, see [Assigning a Division to a Curtain Wall Unit Grid](#) on page 1060.

Specifying an Offset for a Curtain Wall Unit Grid

By default, grids cells are measured from the start and end points of the curtain wall unit baseline. The width of the grid frame is not considered in calculating the size of the cell. For example, if you draw a curtain wall unit with a 14' baseline and a 1' frame on the left and right, and you specify a fixed number of vertical cells, the cells do not appear equal in size. The first and last cells appear smaller because they include the frame. To make the cells equal in size, offset the start and end of the grid by the width of the frame.

Specifying grid offset directions

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Specify an offset for the grid:

If you want to specify the distance between ... Then ...

the start point of the curtain wall baseline and the start of the first cell in a horizontal grid enter a value for Start Offset.

the end point of the curtain wall baseline and the end of the last cell in a horizontal grid enter a value for End Offset.

the floor line of the curtain wall and the start of the first cell in a vertical grid enter a value for Bottom Offset.

the roof line of the curtain wall and the end of the top cell in a vertical grid enter a value for Top Offset.

- 8 Click OK.

Removing a Division Definition from a Curtain Wall Unit Style

Use this procedure to remove a division definition that you no longer need. You cannot remove a division definition when it is currently assigned to a grid. In addition, you cannot remove the default division definition, but you can modify it.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.

- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition that you want to remove.
- 7 Click Remove Division.
- 8 Click OK.

Defining Infills for Curtain Wall Unit Cells

An infill defines the contents of a curtain wall unit cell. A curtain wall unit cell can have the default simple panel or contain a nested grid, an AEC Polygon, door, window, or door/window assembly style. The object styles you use in infills must exist in the current drawing to be added to an infill definition. Panels typically represent glazing or other plain cladding, such as stone or concrete. For more information, see [Assigning Infills to Curtain Wall Unit Cells](#) on page 1060.

NOTE Nested grids and no infill are options you select when assigning an infill to cell. These options do not require infill definitions. For information, see [Creating a Nested Grid in a Curtain Wall Unit](#) on page 1061 and [Removing an Infill Definition from a Curtain Wall Unit Style](#) on page 1050.

You can define as many infills as you need, and then use cell assignments to specify the cells that use each infill. You can modify a default infill that is used for all unassigned cells.

NOTE Create infill definitions for a specific curtain wall unit style. Those definitions can be assigned only to grid cells in curtain wall units of that style.

Materials

Styles use the materials of the object style assigned to each panel. For example, if you specify an infill to use the Standard door/window assembly style, the materials of that infill are those designated in the door/window assembly style. Simple panels need material assigned in the curtain wall style.

If you do not use materials to control the display properties of infills, you can specify their display properties in the curtain wall unit style. The layer, color, linetype, and other display properties of the default infill are applied to all infills unless you create a custom display component for each infill definition. You can then control the display of each infill definition independently. For more information, see [Specifying the Display of Curtain Wall Units](#) on page 1073.

Creating a Panel Infill for a Curtain Wall Unit

Use this procedure to create a simple panel infill to represent basic cladding materials in the curtain wall, such as a stone wall panel, concrete panel, metal panel, or glazing infill.

Because curtain wall units can contain multiple infills, it is helpful to use a naming convention for panel infills that indicates the infill location or purpose within the curtain wall unit. For example, L3-FL1- Stone Panel can identify a stone panel in a third-level grid on Floor 1.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Click New Infill.
- 7 Enter a descriptive name for the infill.

8 Specify an alignment for the infill.

For more information, see [Specifying an Alignment for a Curtain Wall Unit Infill](#) on page 1049.

9 Specify an offset for the infill.

For more information, see [Specifying an Offset for a Curtain Wall Unit Infill](#) on page 1050.

10 Specify a thickness for the panel.

Specifying infill panel thickness

11 Click OK.

After you create an infill definition, you can assign it to any cell in a curtain wall unit grid. For more information, see [Assigning Infills to Curtain Wall Unit Cells](#) on page 1060.

Specifying an Alignment for a Curtain Wall Unit Infill

Use this procedure to align an infill so that it is centered with the baseline of the curtain wall unit, in front of the baseline, or behind the baseline. In Plan view, the front of a curtain wall unit (drawn from left to right) is below the baseline and the back is above the baseline.

NOTE To move the infill away from the baseline, see [Specifying an Offset for a Curtain Wall Unit Infill](#) on page 1050.

Specifying infill alignments

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.

3 Select a curtain wall unit style.

4 Click the Design Rules tab.

5 In the left pane, select Infills under Element Definitions.

6 Select an infill, or create a new one.

7 Select an alignment: front, center, or back.

8 Click OK.

Specifying an Offset for a Curtain Wall Unit Infill

Use this procedure to specify an offset for a curtain wall unit infill. By default, infills are centered on the curtain wall unit baseline. If your design requires that the infill be aligned with frame edges or some other part of the curtain wall unit, you can specify an offset for the infill.

Specifying panel infill offsets

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select an infill, or create a new one.
- 7 Enter an offset distance.

In Plan view, positive numbers offset the infill above the baseline and negative numbers offset the infill below the baseline. The offset is also affected by the selected alignment for the infill.

- 8 Click OK.

Removing an Infill Definition from a Curtain Wall Unit Style

Use this procedure to delete an infill definition that you no longer need from the Infills definitions list. You cannot remove an infill definition when it is currently assigned to a cell. In addition, you cannot remove the default infill definition, but you can modify it.

NOTE For information about removing an infill from a cell, see [Removing an Infill from a Curtain Wall Unit Cell](#) on page 1064.

- 1 Click Format menu ► Style Manager.

- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select the unneeded infill definition from the list.
- 7 Click Remove Infill.
- 8 Click OK.

Defining Curtain Wall Unit Frames

All curtain wall unit grids, including the primary grid, can have frame definitions. The frame of the primary grid defines the outer edges of the curtain wall unit. The overall frame size is determined by the length and height of the primary curtain wall unit grid or a nested curtain wall unit grid. You can define a frame by specifying a width and depth or by selecting a profile.

Specifying default and profile-based frames

You create frame definitions for a specific curtain wall unit style. Those definitions can be assigned only to frames in curtain wall units of that style. You can create as many frame definitions as you want, and then assign the definitions to the frames. If you have nested grids, each grid has its own frame. There is a default frame definition that you can modify and assign as needed. Unassigned frames are not displayed. For more information, see [Assigning Definitions to Curtain Wall Unit Frames](#) on page 1066.

TIP You can copy a mullion definition and use it as a frame definition. Select the mullion definition and drag it to Frames in the tree on the left side of the dialog box.

Materials and Display Properties for Frames

If you do not use materials to control the display properties of frames, you can specify their display properties in the curtain wall style. The layer, color, linetype, and other display properties of the default frame are applied to all frames unless you create a custom display component for each definition. You can then control the display of each frame definition independently. For more information, see [Specifying the Display of Curtain Wall Units](#) on page 1073.

Defining a Curtain Wall Unit Frame by Width and Depth

You can define a frame by specifying its width and depth. The overall frame size is determined by the length and height of the curtain wall unit grid.

Specifying frame width and depth

Because curtain wall units can contain multiple nested grids with different frames, it is helpful to use a naming convention for grid frames that indicates the grid location or purpose within the curtain wall unit. For example, L3-FL1- Metal Frame can identify a metal frame for a third-level grid on Floor 1.

TIP To remove the frame edge and have the infill adjust to fill the space occupied by the frame, create a frame definition with both width and depth set to zero. Then, assign that definition to the frame edge that you want to remove. This is necessary for the infill to be mitered as it would be for a butt-glazed condition. For more information, see [Removing a Frame Edge from a Curtain Wall Unit](#) on page 1067.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Click the New Frame icon to create a new frame definition.
- 7 Enter a descriptive name for the frame.
- 8 Specify a width and depth for the frame.
- 9 Specify any offsets.
For more information, see [Specifying Offsets for a Curtain Wall Unit Frame](#) on page 1054.
- 10 Click OK.

After you create a frame definition, you can assign it to any frame in a curtain wall unit. For more information, see [Assigning Definitions to Curtain Wall Unit Frames](#) on page 1066.

Creating a Profile for a Curtain Wall Unit Frame

Use this procedure to create a profile that you can use to define the shape of a curtain wall unit frame. You can then extrude the profile to create a curtain wall unit frame.

The height and the width of the polyline you use to create the profile define the default height and width of the curtain wall unit frame. The insertion point of the profile is aligned with the centroid of the frame.

- 1 Draw a closed polyline of the height and the depth needed for the resulting curtain wall unit frame.
- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.
- 3 Enter **c** (Centroid) for the insertion point of the profile.

The insertion point of the profile is aligned with the centroid of the frame.

4 Enter a name for the profile, and click OK.

You can now use the profile as a curtain wall unit frame. For more information, see [Defining a Curtain Wall Unit Frame Using a Profile](#) on page 1053.

Defining a Curtain Wall Unit Frame Using a Profile

Use this procedure to create a frame element definition from a profile. If you do not want a straight edge to your frame, you can use a profile to define edges with curves, jags, or any other shape.

Two profile-based frame examples

NOTE The insertion point of the profile is aligned with the centroid of the frame.

1 Create the profile for the frame.

For information on creating profiles for curtain wall unit frames, see [Creating a Profile for a Curtain Wall Unit Frame](#) on page 1052.

2 Click Format menu ► Style Manager.

3 Expand Architectural Objects, and expand Curtain Wall Unit Styles.

4 Select a curtain wall unit style.

5 Click the Design Rules tab.

6 In the left pane, select Frames under Element Definitions.

7 Click New Frame.

8 Enter a descriptive name for the frame.

9 Specify a width and depth for the frame edge.

These dimensions are used to calculate the center point of the edge for aligning the profile and also to specify a boundary for the adjacent infill.

10 Select Use Profile.

NOTE The Profile options are available only if you have profiles in the current drawing.

11 Select a profile from the list.

By default, the profile is inserted using the same width and depth with which it was created.

12 To adjust the size of the profile to fit within the width or depth dimension of the frame edge, select Auto-Adjust Profile Width or Depth.

13 To mirror the profile, select X or Y for Mirror In.

14 To rotate the profile, specify an angle for Rotation.

15 Specify any offsets.

For more information, see [Specifying Offsets for a Curtain Wall Unit Frame](#) on page 1054.

16 Click OK.

After you create a frame definition, you can assign it to any frame in a curtain wall unit. For more information, see [Assigning Definitions to Curtain Wall Unit Frames](#) on page 1066.

Specifying Offsets for a Curtain Wall Unit Frame

Use this procedure to define the distance that a curtain wall unit frame is from the floor line, roof line, or baseline. By default, the outside edges of the frame align with start and end of the floor line and the start and end of the roof line. When you adjust the width of the frame, the frame expands inward. However, you can use offsets to expand or contract the frame away from these default limits or to shift the frame away from the baseline in either the X or Y direction.

Offset	Description
X	Positive X offset moves the frame edge outward beyond the end of the curtain wall unit, while a negative X offset moves the frame edge inward toward the center of the curtain wall unit.
Y	In Plan view, a positive Y offset moves the frame edge above the baseline, while a negative Y offset moves the frame below the baseline.
Start	Negative Start offset lengthens the frame beyond the start point, while a positive Start offset shortens the frame. The start point for vertical edges is the baseline and, for horizontal edges (drawn left to right), it is the left side.
End	Negative End offset lengthens the frame beyond the end point, while a positive End offset shortens the frame. The end point for vertical edges is the base height and, for horizontal edges (drawn left to right), it is the right side.

Specifying frame offsets

1 Click Format menu ► Style Manager.

- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Select a frame definition from the list.
- 7 Specify an offset distance for the frame edge X, Y, Start, or End.
- 8 Click OK.

Removing a Frame Definition from a Curtain Wall Unit Style

Use this procedure to remove a frame definition from the Frame definitions list. You cannot remove a frame definition if it is currently assigned to a frame edge, but you can remove it if it is assigned as an override to a frame edge. In addition, you cannot remove the default frame definition, but you can modify it.

NOTE For information about removing a frame edge, see [Removing a Frame Edge from a Curtain Wall Unit](#) on page 1067.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Select the unneeded frame definition from the list.
- 7 Click the Remove Frame icon.
- 8 Click OK.

Defining Curtain Wall Unit Mullions

The mullions of a curtain wall unit are the edges between the grid cells. You can define the mullions by specifying a width and depth or by selecting a profile from which the mullion is extruded.

Because curtain wall units can contain multiple nested grids with different mullions, it is helpful to use a naming convention for grid mullions that indicates the grid location or purpose within the curtain wall unit. For example, L3-FL1- Panel Decorative Mullion can identify a mullion for a panel in a third-level grid on Floor 1.

Specifying default and profile-based mullions

default mullions

profile-based mullions

You create mullion definitions for a specific curtain wall unit style and those definitions can be assigned only to mullions in curtain wall units of that style. You can create as many mullion definitions as you want, and then assign the definitions to mullions as needed. If you have nested grids, each grid has its own mullions. There is a default mullion definition that you can modify as needed that is used for any unassigned mullions. For more information, see [Assigning Definitions to the Mullions of a Curtain Wall Unit](#) on page 1069.

TIP You can copy a frame definition and use it as a mullion definition. Select the frame definition and drag it to Mullions in the left pane of the dialog box.

Materials and Display Properties for Mullions

If you do not use materials to control the display properties of mullions, you can specify their display properties in the curtain wall unit style. The layer, color, linetype, and other display properties of the default mullion are applied to all mullions unless you create a custom display component for each definition. You can then control the display of each mullion definition independently. For more information, see [Specifying the Display of Curtain Wall Units](#) on page 1073.

Defining Curtain Wall Unit Mullions by Width and Depth

You can define mullions by specifying a width and a depth.

Specifying mullion width and depth

TIP To remove mullions for butt glazing, create a definition with both width and depth set to zero. Then, assign that definition to the mullions that you want to remove. For more information, see [Removing Mullions from a Curtain Wall Unit Grid](#) on page 1071.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Click New Mullion.
- 7 Enter a descriptive name for the mullion.
- 8 Specify a width and depth for the mullion.
- 9 Specify the offsets you want.
For more information, see [Specifying Offsets for the Mullions of a Curtain Wall Unit](#) on page 1059.
- 10 Click OK.

After you create a mullion definition, you can assign it to any mullion in a curtain wall unit. For more information, see [Assigning Definitions to the Mullions of a Curtain Wall Unit](#) on page 1069.

Creating a Profile for Curtain Wall Unit Mullions

Use this procedure to create a profile that you can use to define the shape of a curtain wall unit mullion definition. You can then extrude the profile to create mullions from it.

The height and the width of the polyline you use to create the profile define the default height and width of the curtain wall unit mullion. The insertion point of the profile is aligned with the centroid of the mullion.

- 1 Draw a closed polyline of the height and the depth needed for the resulting curtain wall unit mullion.
- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.
- 3 Enter c (Centroid) for the insertion point of the profile.
The insertion point of the profile is aligned with the centroid of the mullion.
- 4 Enter a name for the profile, and click OK.
You can now use the profile as a curtain wall unit mullion. For more information, see [Defining the Mullions of a Curtain Wall Unit Using a Profile](#) on page 1057.

Defining the Mullions of a Curtain Wall Unit Using a Profile

Use this procedure to create a mullion element definition from a profile. If you do not want a straight edge to your mullions, you can use a profile to define mullions with curves, jags, or any other shape.

NOTE The insertion point of the profile is aligned with the centroid of the mullion.

Infill alignments with default and profile-based mullions

1 Create the profile to use for the mullion.

For information, see [Creating a Profile for Curtain Wall Unit Mullions](#) on page 1057.

2 Click Format menu ► Style Manager.

3 Expand Architectural Objects, and expand Curtain Wall Unit Styles.

4 Select a curtain wall unit style.

5 Click the Design Rules tab.

6 In the left pane, select Mullions under Element Definitions.

7 Click the New Mullion icon to create a new mullion definition.

8 Enter a descriptive name for the mullion.

9 Specify a width and depth for the mullion.

These dimensions are used to calculate the center point of the mullion for aligning the profile and also to specify a boundary for the adjacent infill.

10 Select Use Profile.

NOTE The Profile options are available only if you have profiles in the current drawing.

11 Select a profile from the list.

By default, the profile is inserted using the same width and depth with which it was created.

12 To adjust the size of the profile to fit within the width or depth dimension of the mullion, select Auto-Adjust Profile Width or Depth.

13 To mirror the profile, select X or Y for Mirror In.

14 To rotate the profile, specify a rotation angle for Rotation.

15 Specify any offsets.

For more information, see [Specifying Offsets for the Mullions of a Curtain Wall Unit](#) on page 1059.

16 Click OK.

After you create a mullion definition, you can assign it to any mullion in a curtain wall unit. For more information, see [Assigning Definitions to the Mullions of a Curtain Wall Unit](#) on page 1069.

Specifying Offsets for the Mullions of a Curtain Wall Unit

Use this procedure to define mullions that are offset from the start or end of the curtain wall unit to lengthen or shorten the edge or offset in the X or Y direction to shift the edge. For example, you might want to represent butt glazing by offsetting the mullions to be behind glass panel infills.

Offset	Description
X	For vertical mullions, a positive X offset moves the mullions toward the end of the curtain wall unit, while a negative X offset moves the mullions toward the start of the curtain wall unit. For horizontal mullions, a positive X offset moves the mullions toward the top of the curtain wall unit, while a negative X offset moves the mullions toward the bottom of the curtain wall unit.
Y	In Plan view, a positive Y offset moves the mullions above the baseline, while a negative Y offset moves the mullions below the baseline.
Start	Negative Start offset lengthens the mullions beyond the start point, while a positive Start offset shortens the mullions.
End	Negative End offset lengthens the mullions beyond the end point, while a positive End offset shortens the mullions.

Specifying mullion offsets

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Select a mullion definition from the list.
- 7 Specify an offset distance for the X, Y, Start, or End.
- 8 Click OK.

Removing a Mullion Definition from a Curtain Wall Unit Style

Use this procedure to remove a mullion definition from the Mullions definitions list. You cannot remove a mullion definition if it is assigned to a mullion. In addition, you cannot remove the default mullion definition, but you can modify it as needed.

NOTE For information about removing mullions from between cells, see [Removing Mullions from a Curtain Wall Unit Grid](#) on page 1071.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Select the unneeded mullion definition from the list.
- 7 Click the Remove Mullion icon to remove the mullion definition.
- 8 Click OK.

Assigning a Division to a Curtain Wall Unit Grid

Use this procedure to assign a division to a curtain wall unit grid. A division defines the grid orientation (whether the direction of the grid cells and mullions is horizontal or vertical) and the division type (number and size of cells).

After you define a division, you can assign it to the primary grid or to nested grids. Nested grids are created by selecting Nested Grid as the cell assignment. For more information, see [Working with Nested Grids in Curtain Walls](#) on page 969.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid you want to assign a division to. The name of the grid you select is displayed in the table under the Division Assignment row.

TIP To rename a grid, select it, and click Rename, and enter a new name.

- 6 Click the Element column for that grid and select a division definition from the list.
- 7 Click OK.

Assigning Infills to Curtain Wall Unit Cells

An infill defines the contents of a curtain wall unit cell. A curtain wall unit cell can have the default simple panel or contain a nested grid, an AEC Polygon, door, window, or door/window assembly style. The object

styles you use in infills must exist in the current drawing to be added to an infill definition. Panels typically represent glazing or other plain cladding, such as stone or concrete. For more information, see [Defining Infills for Curtain Wall Unit Cells](#) on page 1048.

Cell Assignments

A cell assignment defines the infill definition used for the cells. You can use one cell assignment to assign the same infill to all cells, or you can create multiple cell assignments to assign different infills to different cells.

Cell assignments

Cell Assignments			
 Default Cell Assignment	2 Inch panel	Default	All unassigned cells
 Door	Standard	Location	Middle
 Window	Casement Wi...	Index	1, 2, 4, 5

Do not assign multiple definitions to the same cell because only the last definition assigned to the cell is used.

Default Cell Assignment

The default cell assignment is used by all unassigned cells. You can modify the default assignment to be any type of infill, but you cannot delete the default cell assignment.

You may want to modify the default cell assignment to use the infill definition that occurs most frequently in your design. Any cells not assigned to other infills then use this infill definition.

Materials and Display Properties of Infills

The layer, color, linetype, and other display properties of the default infill are applied to all infills unless you assign materials to the infills you created or you create a custom display component for each definition. You can then control the display of each infill definition independently. For more information, see [Specifying the Display of Curtain Wall Units](#) on page 1073.

Creating a Nested Grid in a Curtain Wall Unit

Use this procedure to create a nested grid in a curtain wall unit. A nested grid is a grid within a grid. Each nested grid has its own division, cell assignments, frame, and mullions. By default, the frame is turned off for nested grids.

For more information, see [Working with Nested Grids in Curtain Walls](#) on page 969.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a nested grid.
- 6 Click the New Cell Assignment icon.
 - A new cell assignment is displayed in the list of cell assignments.
- 7 Click New Cell Assignment, and enter a descriptive name for the assignment.
- 8 Select Nested Grid in the Element column.
 - A new grid is added to the list of grids in the tree view to the left of the dialog box. If you are editing the primary grid, the new grid is added at the secondary level. If you are editing a grid at the secondary level, the additional grid is placed at the tertiary level, and so on.

Creating a nested grid

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Vertical Division	Grid	This grid division
Cell Assignments			
Default Cell Assignment	Panel	Default	All unassigned cells
Vertical	*Nested Grid*	Location	Start, End
Frame Assignments			
Custom Corner	*Nested Grid*	Location	Left, Right
Default Frame Assignment	2-inch Panel	Location	*NONE*
Mullion Assignments			
Default Mullion Assignment	Panel	Default	All unassigned mullions
Primary Mullions	Standard Door window style	Default	All unassigned mullions
Secondary Mullions	*NONE*	Index	2, 4
	New Infill	Index	1, 3, 5
	Default Infill	Index	1, 3, 5

New nested grid in tree

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Vertical Division	Grid	This grid division
Cell Assignments			
Default Cell Assignment	Casement Wi...	Default	All unassigned cells
New Nested Grid	*Nested Grid*	Location	Start, End
Frame Assignments			
Custom Corner	Profile	Location	Left, Right
Default Frame Assignment	Default Frame	Location	*NONE*
Mullion Assignments			
Default Mullion Assignment	Default Mullion	Default	All unassigned mullions
Primary Mullions	12 inch Mullions	Index	1, 3, 5
Secondary Mullions	4 inch Mullions	Index	2, 4

NOTE To rename a grid, select it in the right pane, right-click and click Rename, and enter a new name.

9 Specify the cells to contain this nested grid.

For more information, see [Specifying Which Curtain Wall Unit Cells Use a Cell Assignment](#) on page 1065.

10 Click OK.

Inserting a Door, Window or Door/Window Assembly into a Curtain Wall Unit Cell

Use this procedure to add doors, windows and door/window assemblies to a curtain wall unit. For more information, see [Defining Infills for Curtain Wall Unit Cells](#) on page 1048.

- 1 Open the tool palette that you want to use, and select a door, window or door/window assembly.
- 2 Select the curtain wall unit in which to insert the door, window or door/window assembly.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Select the curtain wall unit cell marker for the cell in which to insert the door, window or door/window assembly.

The Add Infill worksheet displays.

4 Select the insertion method for the door, window or door/window assembly:

If you want to...	Then...
add the door, window or door/window assembly as a cell assignment and have all curtain wall units using the same style display the same object added in a corresponding cell	select Add as Cell Assignment.
add the door, window or door/window assembly exclusively to the selected curtain wall unit	select Add as Cell Override.

If a door, window or door/window assembly of the style you selected already exists in your drawing, Existing Infill is selected by default.

5 Select the type of infill for the door, window or door/window assembly:

If you selected...	Then...
Add as Cell Assignment and you want to insert a door, window or door/window assembly of the existing style, Existing Infill is selected by default.	Click OK.
Add as Cell Assignment and you want to insert a door, window or door/window assembly of a different style than exists in your drawing	select New Infill, enter a name for the object and click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of the existing style and not modify the edge of the frame surrounding the object	Click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of a different style than exists in your drawing and not remove an edge of the frame surrounding the object	select New Infill, enter a name for the object and click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of the existing style and remove an edge of the frame surrounding the object	select Top, Bottom, Left, or Right for Override Frame Removal and click OK.
Add as Cell Override and you want to insert a door, window or door/window assembly of a different style than exists	select New Infill and enter a name for the object. Then select Top, Bottom, Left, or Right for Override Frame Removal and click OK.

If you selected...

Then...

in your drawing and remove an edge of the frame surrounding the object

6 Press *ENTER*.

Filling a Curtain Wall Unit Cell with a Simple Panel

Use this procedure to fill a curtain wall unit cell with a simple panel. Simple panels are generally used to represent basic cladding materials in the curtain wall, such as a stone wall panel or a concrete panel.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to put a simple panel infill.
- 6 Click the New Cell Assignment icon.

A new cell assignment is displayed in the list of cell assignments.
- 7 Click New Cell Assignment, and enter a descriptive name for the assignment.
- 8 Under Element, select an infill that defines a simple panel.

If you do not have a simple panel infill defined, select New Infill and define one. For more information, see [Creating a Panel Infill for a Curtain Wall Unit](#) on page 1048.
- 9 Specify the cells to contain this simple panel.

For more information, see [Specifying Which Curtain Wall Unit Cells Use a Cell Assignment](#) on page 1065.
- 10 Click OK.

Removing an Infill from a Curtain Wall Unit Cell

Use this procedure to remove the infill of a cell and leave the cell empty. To do this, use None as the element definition. Using None also removes any frame edges that border the cell, but it does not affect the mullions.

Removing an infill assignment from a cell

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid that contains the cells you want to assign to None.

6 Create a new cell assignment or select an existing cell assignment.

7 Select None under the Element column.

8 Specify the cells to contain the None infill.

For more information, see [Specifying Which Curtain Wall Unit Cells Use a Cell Assignment](#) on page 1065.

9 Click OK.

Specifying Which Curtain Wall Unit Cells Use a Cell Assignment

When you create a cell assignment you need to specify the cells in the grid to use that assignment. There are two options for selecting cells:

- Use Location to insert the infill into the start, middle, or end cells of a vertical grid or into the bottom, middle, or top cells of a horizontal grid. If there is an even number of cells (four or more), Middle refers to the two cells in the middle of the grid. If there is an odd number of cells (three or more), Middle refers to one cell in the middle of the grid.

Specifying cell assignments by location

new infill assigned to start and end cells

new infill assigned to middle cells

- Use Index to insert the infill into specific cells based on cell numbers. Cells are numbered from start to end or bottom to top. For example, typing 1, 3, 5 would place the infill in the first, third, and fifth cells.

Specifying cell assignment by index

new infill assigned to cells 1 and 3

new infill assigned to cells 2 and 4

Any cells that are not assigned a specific cell assignment use the default infill.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.

3 Select a curtain wall unit style.

4 Click the Design Rules tab.

5 In the left pane, select a grid.

6 Under the Type column, select Location or Index.

7 Select a cell assignment:

If you selected ...	Then ...
Location	click the Used In column, and click the button at the far right of the row. Select the cells you want to use this assignment, and click OK.
Index	enter the cell numbers separated by commas in the Used In column. For vertical grids, cells are numbered from start to end and for horizontal grids, cells are numbered from bottom to top.

NOTE Do not assign multiple definitions to a cell because the last definition assigned to the cell is used.

8 Click OK

Removing an Assignment from a Curtain Wall Unit Style

Use this procedure to remove cell assignments, frame assignments, and mullion assignments from a curtain wall unit style. You cannot remove default assignments, but you can modify them to suit your needs.

NOTE Each grid requires one division assignment. Therefore, you cannot remove the division assignment, although you can change the division element used for the division assignment.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style, right-click, and click Edit.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid from which you want to remove an assignment.
- 6 Select a cell assignment, frame assignment, or a mullion assignment.
- 7 Click the Remove Assignment icon.
- 8 Click OK twice.

Assigning Definitions to Curtain Wall Unit Frames

The curtain wall unit frame is represented by the outer edges of the primary grid. Each nested grid has its own frame that is defined separately from the primary grid frame. By default, the frames of nested grids are turned off. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

Frame Assignments

A frame assignment defines the frame definition that is used by each frame edge. You can use one frame assignment to assign the same definition to all four edges of the frame, or you can create multiple frame assignments to assign different definitions to different edges of the frame. Unassigned edges are not displayed.

Do not assign multiple definitions to the frame edge because the last definition assigned to the edge is used.

Default Frame Assignment

There is a default frame assignment, and you can select the frame edges it applies to. You can modify the default assignment to use any frame definition, but you cannot delete the default frame assignment.

Materials and Display Properties of Frames

The layer, color, linetype, and other display properties of the default frame are applied to all frame edges unless you assign materials to the frame definition or you create a custom display component for each definition. You can then control the display of each frame definition independently. For more information, see [Specifying the Display of Curtain Wall Units](#) on page 1073.

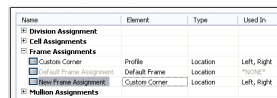

Adding a New Frame Assignment to a Curtain Wall Unit

Use this procedure to add a frame assignment to a curtain wall unit. To assign different definitions to different frame edges, you need multiple frame assignments.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a new frame assignment.
- 6 Click the New Frame Assignment icon.

A new frame assignment is displayed in the list of frame assignments.

New frame definition

Name	Element	Type	Used In
Division Assignment			
Cell Assignments			
Frame Assignments			
Custom Corner	Profile	Location	Left, Right
Default Frame	Profile	Location	Top, Bottom
New Frame Assignment	Custom Corner	Location	Left, Right
Mullion Assignments			

- 7 Click New Frame Assignment and enter a descriptive name for the assignment.
- 8 Select a frame definition from the Element column.
- 9 Specify the sides of the frame to use this frame assignment.

For more information, see [Specifying Which Curtain Wall Unit Edges Use a Frame Assignment](#) on page 1068.

- 10 Click OK.

Removing a Frame Edge from a Curtain Wall Unit

Use this procedure to remove a frame edge from a curtain wall unit. There are three ways to remove a frame edge:

- Set the width and depth of the edge to zero
- Leave the edge unassigned
- Specify None as an override to the edge assignment

The first two methods remove the frame edge and expand the adjacent infills into the space occupied by the edge.

Specifying a frame width and depth of zero

By specifying None as an override, the frame edge is not displayed, but the adjacent infill is not expanded into the space the edge occupied.

Overriding a frame edge definition

For information about setting the width and depth to zero, see [Defining a Curtain Wall Unit Frame by Width and Depth](#) on page 1052.

For information about leaving the edge unassigned, see [Specifying Which Curtain Wall Unit Edges Use a Frame Assignment](#) on page 1068.

Specifying Which Curtain Wall Unit Edges Use a Frame Assignment

Use this procedure to specify edges that use a frame assignment. When you create a frame assignment, you need to specify the edges of the frame to use that assignment.

Frame edges that are not assigned a frame definition are not displayed.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 Select a frame assignment.

Location is the only way to specify the frame edges.

- 7 Click the Used In column, and then click the [...] button at the far right of the row.

Specifying frame location

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Horizontal Division	Grid	This grid division
Cell Assignments			
Panel	Panel Infill	Location	Start, End
Vertical	*Nestled Grid*	Default	All unassigned cells
Frame Assignments			
Default Frame Assignment	Default Frame	Location	*NONE*

8 Select the edges that you want to use this assignment - Left, Right, Top, or -Bottom - and click OK.

Assigning frames to nested grids

Do not assign multiple definitions to the same frame edge because only the last definition assigned to the edge is used.

9 Click OK.

Assigning Definitions to the Mullions of a Curtain Wall Unit

The mullions of a curtain wall unit are the edges between the grid cells. The primary grid and each nested grid have mullions that are defined separately from the other grids. For more information about nested grids, see [Working with Nested Grids in Curtain Walls](#) on page 969.

Assign mullions to a nested grid

Mullion Assignments

A mullion assignment defines the definition used by each mullion. You can use one assignment to define all mullions, or you can create multiple assignments and assign different definitions to different mullions in any grid.

Do not assign multiple definitions to the same mullion because only the last definition assigned to the mullion is used.

Default Mullion Assignment

There is a default mullion assignment used by all unassigned mullions. You can modify the default assignment to be any mullion definition, but you cannot delete the default mullion assignment.

Adding a New Mullion Assignment to a Curtain Wall Unit Style

Use this procedure to add a new mullion assignment to a curtain wall unit style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a new mullion assignment.
- 6 Click New Mullion Assignment.

A new mullion assignment is displayed in the list of mullion assignments.

New mullion assignment

Name	Element	Type	Used In
Division Assignm...			
Cut Assignments			
Frame Assignm...			
Mullion Assignm...			
Default Mullion	Default Mullion	Default	All unassigned mullions
Start Mullion	Default Mullion	Location	Start, End
Primary Mullion	4 inch Mullion	Index	1, 3, 5
Secondary Mull...	12 inch Mullion	Index	2, 4

- 7 Select the mullion assignment, right-click and click Rename, and then enter a descriptive name.
- 8 Select a mullion definition from the Element column.
- 9 Specify the mullions to use this assignment.

For more information, see [Specifying Which Curtain Wall Unit Mullions Use an Assignment](#) on page 1070.

- 10 Click OK.

Specifying Which Curtain Wall Unit Mullions Use an Assignment

When you create a mullion assignment you need to specify the mullions in the grid to use that assignment. There are two options for selecting mullions:

- Use Location to assign a definition to the start, middle, or end mullions of a vertical grid or the bottom, middle, or top mullions of a horizontal grid. If there is an even number of mullions (four or more), Middle refers to the two mullions in the middle of the grid. If there is an odd number of mullions (three or more), Middle refers to the one mullion in the middle of the grid.
- Use Index to assign a definition to specific mullions based on mullion numbers. Mullions are numbered from start to end or bottom to top. For example, entering **1, 2, 3** would assign the definition to the first, second, and third mullions.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 Create a new mullion assignment or select an existing assignment.
- 7 Select Location or Index for Type.
- 8 Select a cell assignment.

If you selected ...

Location

Then ...

click the Used In column, and click the button at the far right of the row. Select the cells you want to use this assignment, and click OK.

If you selected ...

Then ...

Index

enter the mullion numbers separated by commas in the Used In column. For vertical grids, mullions are numbered start to end and for horizontal grids, mullions are numbered from bottom to top.

NOTE Do not assign multiple definitions to the same mullion because only the last definition assigned to the mullion is used.

9 Click OK.

Any mullions that are not assigned a specific mullion assignment use the default mullion definition.

Removing Mullions from a Curtain Wall Unit Grid

Use this procedure to remove a mullion from the curtain wall unit. You can create a mullion definition whose edge width and depth are zero. Adjacent infills expand to fill in the space that was occupied by the mullion. This is an effective way to represent butt glazing.

Removing mullions from a curtain wall unit grid

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.

3 Select a curtain wall unit style.

4 Click the Design Rules tab.

5 In the left pane, select the grid in which you want to remove a mullion.

6 Create a new mullion assignment and enter **0** (zero) for the width and depth.

For more information, see [Defining Curtain Wall Unit Mullions by Width and Depth](#) on page 1056.

7 Under Mullion Assignments, select the mullion definition you created for any cell edges of any mullion assignment where you want to remove the mullions.

For more information, see [Specifying Which Curtain Wall Unit Mullions Use an Assignment](#) on page 1070.

8 Click OK.

Specifying the Materials of a Curtain Wall Unit Style

A curtain wall unit consists of a number of components whose display properties can be determined by the materials assigned to each component.

When you assign materials to a curtain wall unit style, you assign one material to each display component of the curtain wall unit. For example, you assign a wood material to the frame and a glass material to the glass inset. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the curtain wall unit style, instead of using material display properties, you can turn off the material assignments in the display properties of the curtain wall unit style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in three dimensional (3D) model views and in elevations.

Curtain Wall Unit Materials and Display Components

The following table identifies the material component that corresponds to each curtain wall unit component in the specified views.

Curtain Wall Unit Component	Material Component
Plan, Plan High Detail, Plan Low Detail, Screened, Reflected Plan	
Frame Definitions	Linework
Mullion Definitions	Linework
Infill Definitions	Linework
Frame Definitions Hatch	Linework
Mullion Definitions Hatch	Linework
Infill Definitions Hatch	Linework
Model	
Frame	3D Body
Mullion	3D Body
Infill	3D Body

Assigning Materials to a Curtain Wall Unit Style

Use this procedure to assign materials to the individual components of a curtain wall unit style. When you assign a material to a curtain wall unit component, the component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the curtain wall unit. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, the frame, mullion, and infill are physical components of a curtain wall unit. The cell marker is a symbolic component.

NOTE If a material assignment does not determine the display properties of a curtain wall unit component, you can change the display properties of the curtain wall unit style as described in [Specifying the Display of Curtain Wall Units](#) on page 1073.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, select the value for Material Definition, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

- 11 Click OK.

Specifying the Display of Curtain Wall Units

The display of a curtain wall unit depends on the direction from which you view the curtain wall unit. In Plan view, the curtain wall unit is displayed as parallel lines with vertices marking the grid lines, as an architect would typically draw a curtain wall unit. In 3D isometric views, the curtain wall unit is displayed as it would appear in the real world, with surfaces showing length, thickness, and height. You control what you want to display in each particular view.

Element Definitions and Custom Display Components

By default, the display of all infills, frames, and mullions are controlled by the display properties of the default infill, default frame, and default mullions. However, you can add individual element definitions as components with separate display properties. For example, if you define two infills called stone panel and acetylene panel, by default they are both controlled by the same default infill display properties. However, you can add each definition as a new display component and control the display properties separately.

NOTE The component name in the Custom Display Component dialog box must match the name of element definition in the Design Rules tab. Otherwise the element definition does not display properly.

For more information about the display system, see [Display System](#) on page 537.

Materials and Display Properties

You can use materials to control the display of both default and custom infills, frames, and mullions. When you assign materials to the element definitions you create, you do not need to define these definitions as custom display components. For more information, see [Specifying the Materials of a Curtain Wall Unit Style](#) on page 1071.

Adding Curtain Wall Unit Element Definitions as Display Components

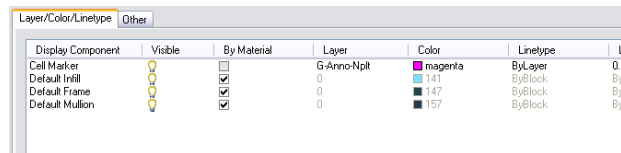

Use this procedure to add curtain wall unit element definitions. Before you can control the display properties of curtain wall unit elements according to the definition assigned to the element, you must create display components for each element definition.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select the curtain wall unit style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select Model as the display representation.

- 6 Click .

The default list of components includes only the three basic elements and cell markers.

Default Model display components for curtain wall units

Display Component	Visible	By Material	Layer	Color	Linetype	L
Cell Marker		<input type="checkbox"/>	G-Anno-Nplit	 magenta	ByLayer	0.1
Default Infill		<input checked="" type="checkbox"/>	0	 141	ByBlock	By
Default Frame		<input checked="" type="checkbox"/>	0	 147	ByBlock	By
Default Mullion		<input checked="" type="checkbox"/>	0	 157	ByBlock	By

- 7 Click the Other tab, and then click Add.
- 8 Select Infill, Frame, or Mullion for Component Type.
- 9 Enter a name for Component Name, or click Select Element and select an element from the list.
- 10 Click OK.
- 11 Click the Layer/Color/Linetype tab.
The element definition that you added is displayed in the list of components.
- 12 Click the Other tab to continue adding element definitions, or click OK twice.

Specifying the Layer, Color, and Linetype of a Curtain Wall Unit Style

Use this procedure to change the following display properties of the components of a curtain wall unit style:

- Visibility (component is on or off)
- By Material
- Layer
- Color

- Linetype
- Lineweight
- Linetype scale

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select the curtain wall unit style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear.
- 6 Click Style Override.
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK twice.

Specifying the Hatching for Components of a Curtain Wall Unit Style

Use this procedure to specify the hatching of the components of a curtain wall unit style. Curtain wall hatching is displayed only in display representations, such as Plan, that are used in Top view (Plan view) of a drawing.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select the curtain wall unit style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and click Style Override.
- 6 Click the Hatching tab.
- 7 Select a component, and click the setting for Pattern.
- 8 Specify the hatching for the component:

If you want to select ...	Then ...
a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
single hatching	select User-defined for Type, and clear Double Hatch.
double hatching	select User-defined for Type, and select Double Hatch.
solid fill	select Solid Fill for Type.

- 9 Click OK.
- 10 Click the setting for Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

- 11 Click the setting for Angle, and enter the angle for the selected pattern.
- 12 Click the setting for Orientation, and specify how the hatching is oriented:

If you want to orient the hatching ...	Then ...
to the object, regardless of the object rotation	select Object.
to the World Coordinate System	select Global.

- 13 Click OK twice.

Adding Custom Graphics as a Display Component of a Curtain Wall Unit

There may be instances where an infill, frame, or mullion requires a custom two-dimensional (2D) or three-dimensional (3D) graphic. For example, you might need a highly detailed three-dimensional truss as the mullions or a decorative light fixture applied to an infill. In cases like these, you can create a custom block, add a display component with the block attached, and associate that component with an element definition. When you assign that definition to an element, the block is also displayed.

- 1 Draw your custom component and save it as a block.
- 2 Select a curtain wall unit, right-click, and click Edit Curtain Wall Unit Style.
- 3 Click the Display Properties tab.

- 4 Click .

- 5 Click the Custom Plan Components tab.

If Model is the current display representation, the tab is called Other.

- 6 Click Add.
- 7 Select Infill, Frame, or Mullion for Component Type.
- 8 Select the specific element from the list.
- 9 Select Draw Custom Graphics.

- 10 Specify the display of the component:

If you want to ...	Then ...
display the block instead of the associated curtain wall unit element	select Replace Graphics.
superimpose the block over the curtain wall unit element so that both are displayed	clear Replace Graphics.

- 11 Click Select Block, and select the custom block that you created.

- 12 Click OK.

- 13 Specify further settings for the custom display block:

If you want to ...	Then ...
scale the block to fit a particular dimension	select Width, Height, or Depth. To prevent the block from losing its proportions, select Lock XY Ratio.

If you want to ...	Then ...
specify how the block is inserted into the grid in the X, Y, and Z directions	specify an insertion point on the X, Y, and Z planes.
mirror the block	determine if it should mirror in the X, Y, or Z direction.
offset the block from the grid	specify the offset in the X, Y, or Z direction.

14 Click OK three times.

Creating Cut Planes for a Curtain Wall Unit

Use this procedure to specify the properties of one or more cut planes for a curtain wall unit style. Cut plane display properties apply only to display representations, such as Plan, that are used in Top view (Plan view) of a drawing.

To better visualize the elements of a curtain wall unit in Plan view, you can create cut planes. The main cut plane is where the shrinkwrap and hatching are applied. The plan display shows the components and objects in the wall as they are displayed at the height of each cut plane.

- 1 Select a curtain wall unit, right-click, and click Edit Curtain Wall Unit Style.
- 2 Click the Display Properties tab.

3 Select Plan, and click .

NOTE The Cut Plane tab is displayed only in some display representations, such as Plan.

- 4 Click the Cut Plane tab to set the cut plane to be displayed in each display representation for the curtain wall unit style.
- 5 Enter a value for Cut Plane Height to specify the cut plane at which hatching takes effect.
- 6 To specifically define a cut plane, click Add, and enter the height of the new cut plane:

If you add a cut plane ...	Then ...
at a height that is lower than the value for Cut Plane Height	objects are displayed using the properties specified for the Below Cut Plane component on the Layer/Color/Linetype tab.
at a height that is higher than the value for Cut Plane Height	objects are displayed using the properties specified for the Above Cut Plane component on the Layer/Color/Linetype tab.

Below and Above components

You can click Remove to delete a cut plane that you added.

7 Click OK to exit all dialog boxes.

Defining a Curtain Wall Unit Style as Bounding for Associative Spaces

Use this procedure to define a curtain wall unit style that can bound associative spaces.

When a curtain wall unit style is set as bounding, by default all curtain wall units that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the curtain wall unit style in an individual curtain wall unit, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select a curtain wall unit style.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Curtain Wall Unit Style

Use this procedure to enter notes and attach reference files to a curtain wall unit style. You can also edit notes and edit or detach reference files from a curtain wall unit style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Curtain Wall Unit Styles.
- 3 Select the curtain wall unit style you want to change.
- 4 Click the General tab.
- 5 To add a description to the curtain wall unit style, enter the description for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 9 Click OK twice.

Using Overrides in Curtain Wall Units

Curtain wall units are subunits of geometrically complex curtain walls, which often have a large number of different elements, like frames, panels, and infills. Most of these settings are defined in the style. However, there are cases when modifying a curtain wall unit directly on screen is more suitable:

- You want to add custom frame or mullion edges to a curtain wall unit and need direct visual feedback.
- You want to create an override, like a merged infill or nested grid, in only one specific place in the curtain wall unit.
- You want to experiment with different visuals without having to change the curtain wall unit style for each idea immediately.

When you have finished your onscreen edits, you can decide if you want to

- Apply the overrides to the curtain wall unit you have edited.
- Save the overrides to the current curtain wall unit style.
- Create a new style for the overrides.

Overrides you can set include assigning a different definition to a selected cell, frame, or mullion, and assigning a profile to a frame or mullion edge. Note that the definition or profile must already exist in the current drawing before you can use it as an override.

Overrides do not affect the Design Rules for the curtain wall unit style. However, you can transfer overrides to a curtain wall unit style if you want all curtain wall units of that style to have the same overrides.

You can view a list of overrides that are currently assigned to a curtain wall unit from the Overrides tab of the Curtain Wall Unit Properties dialog box. For more information, see [Removing Curtain Wall Unit Overrides](#) on page 1096.

NOTE Overrides are also listed on the Overrides tab in the Curtain Wall Unit Style Properties dialog box.

Overriding Curtain Wall Unit Infills

The cell infills of a curtain wall unit are set in the curtain wall unit style. You can however, create overrides for these infill overrides in cells. For example, you might want a row of normal rectangular panel infills for a first floor facade. In one specific position, however, you want a decorative nested grid. In this case, you would set the row of concrete panels in the curtain wall unit style, and then override the panel at one specific place with the nested grid.

Curtain wall unit infills can consist of simple panels or nested grids. You can change one infill for another, merge cells, or remove frames from an infill altogether.

Turning on Cell Markers for Curtain Wall Units

Use this procedure to turn on the cell markers for each grid cell in a curtain wall unit. The cell markers must be on in order to select individual cells and make changes to them.

Viewing Cell Markers

- 1 Select the curtain wall unit for which you want to create an infill override.
- 2 Right-click, and click Infill ► Show Markers.

Merging Curtain Wall Unit Cells

Use this procedure to merge two curtain wall unit cells.

NOTE To merge curtain wall unit cells, the cell markers need to be visible. For information on turning on cell markers, see [Turning on Cell Markers for Curtain Wall Units](#) on page 1079.

You can only merge cells that are adjacent to each other.

In most cases, you merge cells with the same infill type. The merged cell is then of the same type as the original cells. For example, if you merge two solid panel infills, the resulting merged cell also has a solid panel infill. In some cases, however, you might want to merge two cells that have different infill types. In that case, the infill type of the first selected cell is used for the merged cell. For example, if you want to merge a cell with a simple panel infill and a cell with a nested grid, and you select the cell with the simple panel first during the merge command, the merged cell contains a simple panel infill, and not a nested grid. If you select the two cells in the opposite order, the merged cell contains a nested grid and no simple panel infill.

Merging two cells

- 1 Select the curtain wall unit on which you want to merge two cells.
- 2 Right-click, and click Infill ► Merge.
- 3 Select the first cell to be merged.

4 Select the second cell to be merged.

The cells are merged into one.

5 Specify where you want to save the curtain wall unit override.

If you want to save the override ...	Then ...
only on this specific curtain wall unit	no further steps are necessary. The override is saved to the curtain wall unit. For information about how to remove an override from a curtain wall unit, see Removing Curtain Wall Unit Overrides on page 1096.
to a curtain wall unit style	select the curtain wall unit, right-click, and select Design Rules ► Transfer to Object.

6 If you have chosen to save the override to a curtain wall unit style, select the curtain wall unit again, right-click and click Design Rules ► Save to Style and decide to which curtain wall unit style you want to save the override.

If you want to save the override ...	Then ...
to the current curtain wall unit style	<p>select Transfer Merge Operations to Style, and click OK.</p> <p>NOTE If you have created only a cell merge, only the Transfer Merge Operations to Style checkbox is active. If you have also created other overrides, such as a new cell assignment or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.</p>
to a new curtain wall unit style	<p>select Transfer Merge Operations to Style, and click New. Enter a name for the new curtain wall unit style, and click OK.</p> <p>NOTE If you have created only a cell merge, only the Transfer Merge Operations to Style checkbox is active. If you have also created other overrides, such as a new cell assignment or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.</p>

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the curtain wall unit, where they can be removed as described in [Creating a Curtain Wall Unit Infill Override](#) on page 1082, but they are not saved back to a curtain wall unit style.

Creating a Curtain Wall Unit Infill Override

Use this procedure to override the infill of a curtain wall unit cell.

For example, you might have a row of simple concrete panels in your curtain wall unit, but want in one location a nested grid instead of the concrete panel. In that case, it might be simpler to use an infill override, instead of creating a complex curtain wall unit style setting.

NOTE To override an infill assignment, the cell markers need to be visible. For information on turning on cell markers, see [Turning on Cell Markers for Curtain Wall Units](#) on page 1079.

To exchange an infill definition, the new infill definition must already be defined in the curtain wall unit style. For information on creating infill definitions, see [Defining Infills for Curtain Wall Unit Cells](#) on page 1048.

Overriding a curtain wall unit cell definition

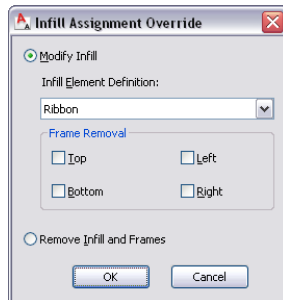

five cell horizontal grid and three cell vertical grid before override

five cell horizontal grid and six cell vertical grid after override

- 1 Select the curtain wall unit on which you want to override an infill.
- 2 Right-click, and click **Infill** ► **Override Assignments**.
- 3 Select the marker of the cell where you want to create an override.

- 4 Create the override:

If you want to ...	Then ...
exchange the existing infill for another	select a new infill definition from the list.
remove one or more of the frames around the infill	select the frame component to be removed.

NOTE To exchange an infill definition, the new infill definition must already be defined in the curtain wall unit style.

If you want to ...	Then ...
remove the complete infill and its frame	select Remove Infill and Frames.

NOTE This works only for infills that are bordering the exterior of the curtain wall unit.

5 Click OK.

6 Specify where you want to save the curtain wall unit override.

If you want to save the override ...	Then ...
only on this specific curtain wall unit	no further steps are necessary. The override is saved to the curtain wall unit. For information about how to remove an override from a curtain wall unit, see Removing Curtain Wall Unit Overrides on page 1096.
to a curtain wall unit style	select the curtain wall unit, right-click, and select Design Rules ► Transfer to Object.

7 If you have chosen to save the override to a curtain wall unit style, select the curtain wall unit again, right-click and click Design Rules ► Save to Style and decide to which curtain wall unit style you want to save the override.

If you want to save the override ...	Then ...
to the current curtain wall unit style	select Transfer Cell Overrides to Style, and click OK.
	NOTE If you have created only an infill override, only the Transfer Cell Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.
to a new curtain wall unit style	select Transfer Cell Overrides to Style, and click New. Enter a name for the new curtain wall unit style, and click OK.
	NOTE If you have created only an infill override, only the Transfer Cell Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a frame or mullion edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the curtain wall unit, where they can be removed as described in [Removing Curtain Wall Unit Overrides](#) on page 1096, but they are not saved back to a curtain wall unit style.

In-Place Editing of Curtain Wall Unit Cells

Use this procedure to edit curtain wall unit cells using in-place editing with the Edit Grid grip. With in-place editing, you can edit individual cells, bays, columns, or nested grids of the curtain wall unit directly and interactively in the drawing area, and later save the changes to the curtain wall unit or curtain wall unit style.

1 Select a curtain wall unit on which you want to edit cells with in-place editing.

2 Specify the mode in which to edit the curtain wall unit:

If you want to edit ...

Then ...

this instance of the curtain wall unit

right-click, and click Design Rules ► Transfer to Object.

the curtain wall unit style

right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall unit.

3 Click the Edit Grid grip.

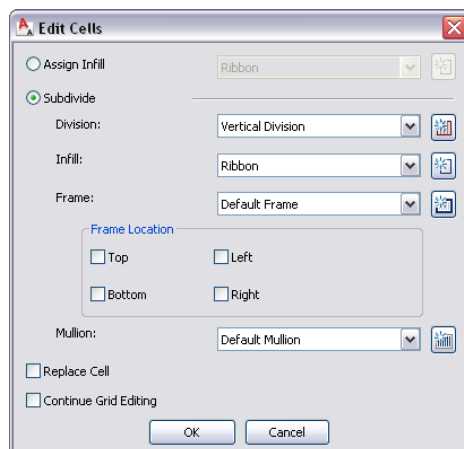

4 Enter **c** (Cell) and press ENTER.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

5 Select the individual cells, bay, column, or nested grid to modify the cell assignment by hovering over a cell or pressing TAB, and press ENTER.

Press CTRL to select multiple cells, bays, columns or nested grids.

The Edit Cells worksheet displays.

6 Edit the cell for the selected grid:

If you want to...	Then...
assign an infill to selected cells	select Assign Infill and select an infill definition. Clear Replace Cell and click OK.
replace the selected cells with a new infill	select Assign Infill and select an infill definition. Select Replace Cell and click OK.
create and assign a new infill to the selected cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning Infills to Curtain Wall Unit Cells on page 1060.
divide the selected cells with divisions, infills or frames	select Subdivision.
select a division for the subdivided cells	select a division definition.
create and assign a new division to the selected cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning a Division to a Curtain Wall Unit Grid on page 1060.
select an infill for the subdivided cells	select an infill definition.
create and assign a new infill to the subdivided cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning Infills to Curtain Wall Unit Cells on page 1060.
select a frame definition for the grid created after the cell is subdivided	select the frame definition and click OK.
specify the location of frames on the grid created after the cell is subdivided	select Top, Bottom, Left, Right for Frame Location and click OK.
create and assign a new frame definition for the new grid created after the cell is subdivided	click  and specify values on the Design Rules worksheet. For more information, see Adding a New Frame Assignment to a Curtain Wall Unit on page 1067.
select a mullion definition for the grid created after the cell is subdivided	select the mullion definition.
create and assign a new mullion definition to the selected grid	click  and specify values on the Design Rules worksheet. For more information, see Adding a New Mullion Assignment to a Curtain Wall Unit Style on page 1069.

If you want to...	Then...
replace the existing cell infill with the options selected on this worksheet	select Replace Cell.
continue in-place editing the grid after the cell is subdivided	select Continue Grid Editing.

- 7 Click OK.
- 8 Press ENTER.

Overriding Curtain Wall Unit Frames and Mullions

You can change a selected frame edge or mullion edge by using an edge assignment override.

NOTE To exchange a frame edge or mullion edge, the new edge definition must already be defined in the curtain wall unit style.

Removing the edge does not affect the width of the cell. To remove the edge and have the adjacent cell resize, create an edge definition with a width and depth of zero. For more information, see [Defining a Curtain Wall Unit Frame by Width and Depth](#) on page 1052 or [Defining Curtain Wall Unit Mullions by Width and Depth](#) on page 1056.

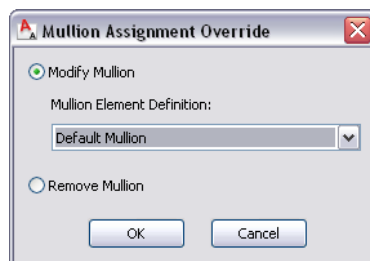

You can also create a new edge profile by drawing a polyline or using an existing profile in the drawing. This edge profile can be interactively edited onscreen using in-place editing.

Creating a Curtain Wall Unit Frame or Mullion Override

Use this procedure to override an individual frame or mullion in a curtain wall unit.

To exchange a frame or mullion, the new definition must already be defined in the curtain wall unit style. For information on creating frames and mullions, see [Defining Curtain Wall Unit Frames](#) on page 1051 and [Defining Curtain Wall Unit Mullions](#) on page 1055.

- 1 Select the curtain wall unit on which you want to override an edge.
- 2 Right-click, and click Frame/Mullion ► Override Assignment.
- 3 Select the frame or mullion edge you want to override.

4 Create the override:

If you want to ...	Then ...
exchange the existing edge for another	select a new edge definition from the list. <hr/> NOTE To exchange an edge definition, the new edge definition must already be defined in the curtain wall unit style. <hr/>
remove the frame or mullion edge	select Remove Edge.

5 Click OK.

6 Specify where you want to save the curtain wall unit override.

If you want to save the override ...	Then ...
only on this specific curtain wall unit	no further steps are necessary. The override is saved to the curtain wall unit. For information about how to remove an override from a curtain wall unit, see Removing Curtain Wall Unit Overrides on page 1096.
to a curtain wall unit style	select the curtain wall unit, right-click, and select Design Rules ► Transfer to Object.

7 If you have chosen to save the override to a curtain wall unit style, select the curtain wall unit again, right-click and click Design Rules ► Save to Style and decide to which curtain wall unit style you want to save the override.

If you want to save the override ...	Then ...
to the current curtain wall unit style	select Transfer Edge Overrides to Style, and click OK. <hr/> NOTE If you have created only a frame or mullion edge override, only the Transfer Edge Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a division override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too. <hr/>

If you want to save the override ...**Then ...**

to a new curtain wall unit style

select Transfer Edge Overrides to Style, and click New. Then, enter a name for the new curtain wall unit style, and click OK.

NOTE If you have created only a frame or mullion edge override, only the Transfer Edge Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a division override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the curtain wall unit, where they can be removed as described in [Removing Curtain Wall Unit Overrides](#) on page 1096, but they are not saved back to a curtain wall unit style.

Creating a Curtain Wall Unit Frame or Mullion Edge from a Polyline or Profile

You can assign a profile to any vertical edge of a frame or mullion. The profile can be any profile or any closed polyline that you specify. You can use a profile edge to create a unique corner in situations where a simple miter is not sufficient.

NOTE Adjacent infills are not trimmed or expanded to accommodate the new edge. To adjust the infill, change the width of the frame edge. For more information, see [Defining a Curtain Wall Unit Frame by Width and Depth](#) on page 1052.

Overriding edge profile

1 Draw a closed polyline in the location where you want it to display in the curtain wall unit.

NOTE For best results, it is recommended that you draw the polyline in Plan view.

2 Select the curtain wall unit for which you want to create a frame or mullion edge profile override.

3 Right-click, and click Frame/Mullion ► Add Profile.

4 Select a vertical frame or mullion edge.

5 Select a profile for the override:

If you want to create the edge profile ...	Then ...
from the polyline drawn in step 1	select it in the drawing, and enter a name for it. Click OK.
from an existing profile in the drawing	press <i>Enter</i> , select the profile, and click OK.

6 Specify where you want to save the curtain wall unit override.

If you want to save the override ...	Then ...
only on this specific curtain wall unit	no further steps are necessary. The override is saved to the curtain wall unit. For information about how to remove an override from a curtain wall unit, see Removing Curtain Wall Unit Overrides on page 1096.
to a curtain wall unit style	select the curtain wall unit, right-click, and select Design Rules ► Transfer to Object.

7 If you have chosen to save the override to a curtain wall unit style, select the curtain wall unit again, right-click and click Design Rules ► Save to Style and decide to which curtain wall unit style you want to save the override.

If you want to ...	Then ...
to the current curtain wall unit style	select Transfer Edge Profile Overrides to Style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Edge Profile Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a division override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.
to a new curtain wall unit style	select Transfer Edge Overrides to Style, and click New. Enter a name for the new curtain wall unit style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Edge Profile Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or a division override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the curtain wall unit, where they can be removed as described in [Removing Curtain Wall Unit Overrides](#) on page 1096, but they are not saved back to a curtain wall unit style.

In-Place Editing of Edge Profiles for Curtain Wall Units

Use this procedure to edit profile edges with in-place editing. With in-place editing, you can use edge grips to edit the profile directly and interactively on screen, and later save the changes to the profile definition.

1 Select a curtain wall unit that has the edge profile you want to edit onscreen with in-place editing.

2 Right-click, and click Frame/Mullion ► Edit Profile In Place.

This command is only available if you have profile-based edges in the curtain wall unit.

NOTE If the profile is not drawn to size, it must be converted in order for you to begin the in-place editing session. Click Yes if prompted to convert the profile to its actual size.

3 Select the edge you want to edit.

NOTE You have entered the in-place editing session now. You can see this from the magenta colored grips and light blue hatch of the temporary in-place editing profile, as well as the faded color of all other objects in the drawing. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

4 Edit the profile:

If you want to ...

Then ...

use grips to edit the profile

move the grips as needed.

The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.

Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.

Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.

add a vertex to the profile

select an Edge grip, and press *CTRL* to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press *ENTER*.

If you want to ...	Then ...
remove a vertex from the profile	select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.
add a ring to the profile	select the profile, right-click and click Add Ring. Select a closed polyline, spline, ellipse, or circle for an additional ring. Specify if you want to erase the source linework, and press <i>Enter</i> .
remove a ring from a profile	select the profile, right-click and click Remove Ring. Select the ring you want to remove. NOTE You cannot remove the last ring from a profile.
replace a ring on a profile	select the profile, right-click and click Replace Ring. Select a closed polyline, spline, ellipse, or circle for the replaced ring. Specify if you want to erase the source linework, and press <i>Enter</i> .

5 Save the changes to the profile.

If you want to ...	Then ...
change the existing profile definition to reflect the new shape	click  on the In-Place Edit toolbar.
create a new profile definition with the shape you have created	select the profile, right-click, and click Save As New Profile. Enter a name for the new profile and click OK. The in-place edit session is exited and the new profile definition is available in the Style Manager.
discard all changes on the profile and revert back to the previous shape	click  on the In-Place Edit toolbar.

In-Place Editing of Curtain Wall Unit Frames and Mullions

Use this procedure to edit frames and mullions using in-place editing with the Edit Grid grip. With in-place editing, you can edit bays, columns or nested grids of the curtain wall unit directly and interactively in the drawing area, and later save the changes to the curtain wall unit or curtain wall unit style.

- 1 Select a curtain wall unit on which you want to edit frames or mullions with in-place editing.

2 Specify the mode in which to edit the curtain wall unit:

If you want to edit ...	Then ...
this instance of the curtain wall unit	right-click, and click Design Rules ► Transfer to Object.
the curtain wall unit style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall unit.

3 Click the Edit Grid grip.

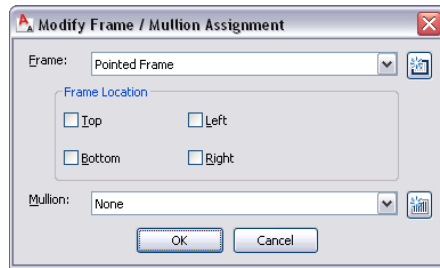

4 Enter f (Frame and mullion assignment) and press ENTER.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

5 Select the bay, column or nested grid to modify the frame and mullion assignment and press ENTER.

Press CTRL to select multiple bays, columns or nested grids.

The Modify Frame/Mullion Assignment worksheet displays.

6 Select a frame definition for the selected grid:

If you want to...	Then...
modify the frame of the selected grid	select a frame definition and click OK.
specify the location of the frame on the selected grid	select Top, Bottom, Left, Right for Frame Location and click OK.
create and assign a new frame definition to the selected grid	click  . For more information, see Adding a New Frame Assignment to a Curtain Wall on page 978.

7 Select the mullion definition for the selected grid:

If you want to...	Then...
modify the mullion of the selected grid	select the mullion definition and click OK.

If you want to...

create and assign a new mullion definition to the selected grid

Then...

click  and complete the Design Rules worksheet. For more information, see [Adding a New Mullion Assignment to a Curtain Wall Style](#) on page 980.

8 Press ENTER.

Overriding Curtain Wall Unit Divisions

The grid of a curtain wall unit is made up of one or more divisions that define how the curtain wall unit is partitioned. Divisions can be horizontal or vertical and can be nested in each other. For detailed information on curtain wall unit divisions, see [Defining Divisions for Curtain Wall Unit Grids](#) on page 1041.

You can override a division in a curtain wall unit, thereby changing the grid of the curtain wall unit.

Overriding number of Curtain Wall Unit cells

five cell horizontal grid and three cell vertical grid before override

five cell horizontal grid and six cell vertical grid after override

Creating a Curtain Wall Unit Division Override

Use this procedure to create a division override on a curtain wall unit.

NOTE To exchange a curtain wall unit division, the new division definition must already be defined in the curtain wall unit style. For information on curtain wall unit divisions, see [Defining Divisions for Curtain Wall Unit Grids](#) on page 1041.

- 1 Select the curtain wall unit for which you want to create a division override.
- 2 Right-click, and click **Division** ► **Override Assignment**.
- 3 Select an edge of the curtain wall unit to determine if a horizontal or vertical division is overridden.

For example, if you want to override the primary horizontal division, you could select the bottom horizontal frame of the curtain wall unit.

TIP The Division Assignment Override dialog box shows you which grid type and which grid division you have selected, e.g., Selected Nested Grid: Secondary Grid, Division Element Definitions: Vertical 3 Cells. If you accidentally selected the wrong division, click **Cancel** and reselect the correct grid.

- 4 Select the appropriate division override, and click **OK**.

5 Specify where you want to save the curtain wall unit override.

If you want to save the override ...	Then ...
only on this specific curtain wall unit	no further steps are necessary. The override is saved to the curtain wall unit. For information about how to remove an override from a curtain wall unit, see Removing Curtain Wall Unit Overrides on page 1096.
to a curtain wall unit style	select the curtain wall unit, right-click, and select Design Rules ► Transfer to Object.

6 If you have chosen to save the override to a curtain wall unit style, select the curtain wall unit again, right-click and click Design Rules ► Save to Style and decide to which curtain wall unit style you want to save the override.

If you want to save the override ...	Then ...
to the current curtain wall unit style	select Transfer Division Overrides to Style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Division Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or an edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.
to a new curtain wall unit style	select Transfer Division Overrides to Style, and click New. Enter a name for the new curtain wall unit style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Division Overrides to Style checkbox is active. If you have also created other overrides, such as a cell merge or an edge override, these checkboxes are available as well. If you also want to save these overrides to the style, select their checkboxes too.

NOTE If you do not want to save the override back to a style at all, right-click and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the curtain wall unit, where they can be removed as described in [Removing Curtain Wall Unit Overrides](#) on page 1096, but they are not saved back to a curtain wall unit style.

In-Place Editing of Curtain Wall Unit Divisions

Use this procedure to edit divisions using in-place editing with the Edit Grid grip. With in-place editing, you can edit the curtain wall unit directly and interactively in the drawing area and later save the changes to the curtain wall unit or curtain wall unit style.

For more information, see [Division of Curtain Wall Unit Grids](#) on page 1042.

1 Select a curtain wall unit on which you want to edit divisions with in-place editing.

2 Specify the mode in which to edit the curtain wall unit:

If you want to edit ...	Then ...
this instance of the curtain wall unit	right-click, and click Design Rules ► Transfer to Object.
the curtain wall unit style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the curtain wall unit.

3 Click the Edit Grid grip.

4 Enter d (Division in place).

Viewing edit in-place grips for a primary division

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

Viewing edit in-place grips for adding and removing bays

5 Edit the division:

If you want to ...	Then ...
add a bay to the grid	click the Add Bay grip.
remove a bay from the grid	click the Remove Bay grip.

If you want to ...	Then ...
change the start offset of the grid	select the Start Offset grip and move it to the position.
change the end offset of the grid	select the End Offset grip and move it to the position.
change the spacing of bays	click the Auto Grid Bay Spacing grip and move it to the position.
manually edit the grid	right-click and click Convert To Manual. You can manually add and remove gridlines, change the off-sets, and change the position of individual gridlines.
use a worksheet to edit the cell dimensions	click the Set Fixed Cell Dimension Rules command grip, and edit the values in the worksheet.

6 Save or discard changes to the curtain wall unit grid:

If you want to exit the in-place editing session ...	Then ...
without saving your changes	click  on the In-Place Edit toolbar.
after saving your changes	click  on the In-Place Edit toolbar. If you edited the grid by instance, the changes are saved to the design rules for the individual grid. If you edited the curtain wall unit style, the Save Changes dialog box is displayed.

7 In the Save Changes dialog box, specify to which division to save the changes:

If you want to ...	Then ...
save the changes to the style in the current curtain wall unit division	verify the current division is selected for Save Changes to Existing Division, and click Save. The changes are made in the style and affect all curtain wall units of that style in the drawing.
create an override to the style by saving the changes in a new curtain wall unit division	click New, enter a name for the new division override, and click OK. Click Save. The changes are saved as an override to the style, and affect only the curtain wall units to which the override is applied.

Removing Curtain Wall Unit Overrides

Use this procedure to remove curtain wall unit overrides either from the curtain wall unit or the curtain wall unit style.

1 Select the curtain wall unit:

If you want to remove an override ...	Then ...
from a curtain wall unit	select the curtain wall unit, right-click and click Curtain Wall Unit Properties. Click the Overrides tab.
from the curtain wall unit style	select the curtain wall unit, right-click, and click Edit Curtain Wall Unit Style. Click the Overrides tab.

2 Select an override from the list and click Remove.

3 Click OK.

Editing Curtain Wall Units

Most relevant settings for a curtain wall unit are defined in the curtain wall unit style. These include divisions, infills, frames, and mullions. For information on modifying a curtain wall unit style, see [Curtain Wall Unit Styles](#) on page 1039.

You can make other changes directly to individual curtain wall units. These changes affect only the curtain wall unit you select:

- Dimensions of a curtain wall unit
- Roof and floor line settings
- Interference conditions
- Cleanup settings

Methods of Editing Curtain Wall Units

AutoCAD Architecture offers several methods for editing curtain wall units:

- You can directly edit curtain wall units using grips for dimensions, base height, location, and other physical characteristics.
- You can directly edit curtain wall units using the Edit Grid grip for grid divisions, cells, frames, and mullions. For more information, see [In-Place Editing of Curtain Wall Unit Divisions](#) on page 1094, [In-Place Editing of Edge Profiles for Curtain Wall Units](#) on page 1090 and [Overriding Curtain Wall Unit Infills](#) on page 1079.
- You can change curtain wall unit settings on the Properties palette.
- You can select editing commands from the context menu for a selected curtain wall unit.

Using Grips to Edit Curtain Wall Units

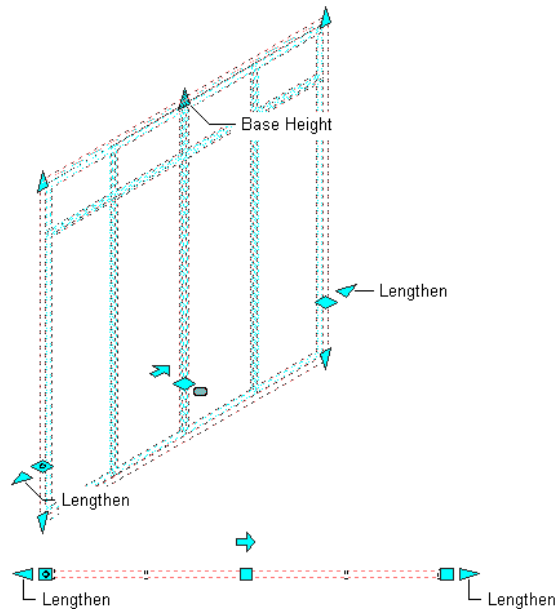

There are many different curtain wall unit grips. The grips that appear in your drawing when you select a curtain wall unit are dependent upon the design rules of the curtain wall unit. For more information, see [Curtain Wall Unit Styles](#) on page 1039.

Editing Curtain Wall Unit Dimensions

Use this procedure to change the dimensions of a curtain wall unit.

- 1 Select the curtain wall unit.
- 2 Select the grip for the dimension you want to change.
You can modify the dimensions of the height and length for a curtain wall unit.

Viewing Curtain Wall Unit Lengthen and Base Height grips

- 3 Enter a value for the dimension and press *ENTER*, or drag the grip until the dimension value you want is displayed.

Changing the Location or Position of a Curtain Wall Unit

Use this procedure to change the location or the position of a curtain wall unit with grips.

- 1 Select the curtain wall unit.
- 2 Select the appropriate grip to change the location of the curtain wall unit, its start point, or its end point.

Viewing Curtain Wall Unit Start, End, Location, and Reverse Direction Grips

In Model view, the Location grip has three possible edit modes: Edit Along XY Plane, Edit Along YZ Plane, and Edit Along ZX Plane. Press *CTRL* to cycle between modes until you are in the desired mode. The default edit mode is along the XY plane. In Plan view, the Location grip is restricted to movement in one plane.

- 3 Move the curtain wall unit to the desired location and click once, or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the Y direction when editing along the XY plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the curtain wall unit along a specific direction. If you enter a value for either of the dimension directions in the current edit mode and then press *TAB*, the movement of the curtain wall unit is constrained to the second dimension direction. When editing along the XY plane, for example, you can enter a value for X dimension, and then press *TAB*. The X dimension is locked at that value, and movement of the curtain wall unit is constrained to the Y dimension direction.

- 4 Right-click, and click Deselect All to turn off grips.

Changing the Base Height of a Curtain Wall Unit

Use this procedure to change the base height of a curtain wall unit. You can also change the base height on the Properties palette.

- 1 Select the curtain wall unit.
- 2 Select the Base Height grip, move the grip until the height value you want is displayed, and click once.

As you move the grip, the original base height value is displayed in addition to the new base height and the difference between the two values.

After selecting the grip, you can also enter a new value for the base height of the curtain wall unit.

Changing the Length of a Curtain Wall Unit

Use this procedure to change the length of a curtain wall unit. You can also change the length on the Properties palette. For more information, see [Changing the Dimensions of a Curtain Wall Unit](#) on page 1101.

- 1 Select the curtain wall unit.
- 2 Select the Lengthen grip, move the grip until the length value you want is displayed, and click once.

As you move the grip, the original length value is displayed in addition to the new length and the difference between the two values.

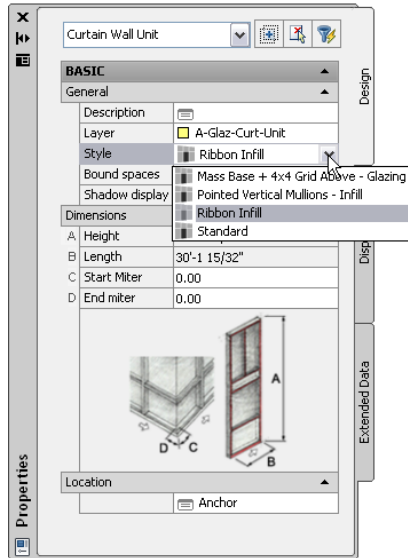

After selecting the grip, you can also enter a new value for the length of the curtain wall unit.

Selecting a Different Curtain Wall Unit Style

Use this procedure to select a different style for the curtain wall unit.

- 1 Select the curtain wall unit for which you want to change the style.
You can select multiple curtain wall units and change the style for all at the same time.
- 2 On the Properties palette, scroll to the General subcategory.

3 Select a different style.

Matching the Properties of an Existing Curtain Wall Unit

Use this procedure to apply the properties of a curtain wall unit tool to one or more existing curtain wall units. The properties include the curtain wall unit style and any other settings specified in the tool you select.

1 Open the tool palette that you want to use.

If necessary, scroll to display the tool that you want to use.

2 Right-click a curtain wall unit tool, and click Apply Tool Properties to ► Curtain Wall Unit.

3 Select the curtain wall units, and press *ENTER*.

The properties of the selected curtain wall units match the properties of the curtain wall unit tool.

Changing the Dimensions of a Curtain Wall Unit

Use this procedure to change the dimensions of a curtain wall unit.

Dimension	Description
Height	Height of the curtain wall unit from the baseline
Length	Length of a straight curtain wall unit from the start grip on the baseline to the end grip
Start Miter	Angle of all infills and horizontal edges (frame or mullion) at the start of the curtain wall unit. For more information about miter angles, see Mitering Curtain Walls on page 1017.

Dimension	Description
End Miter	Angle of all infills and horizontal edges (frame or mullion) at the end of the curtain wall unit. For more information about miter angles, see Mitering Curtain Walls on page 1017.

- 1 Select a curtain wall unit.
- 2 Expand Dimensions.
- 3 Change the dimension.

Specifying a Miter Angle for a Curtain Wall Unit Adjacent to Another Object

Use this procedure to manually create a mitered corner between a curtain wall unit and another object, such as a standard wall or a mass element. For example, if your curtain wall unit connects with a standard wall that is at 60-degree angle from the curtain wall unit, you would specify the miter angle as 30.

The miter angle applies to all infills and horizontal edges that are adjacent to the corner. Vertical edges are not affected.

TIP To quickly identify the start and end of a curtain wall unit, select the curtain wall unit. The Reverse Direction grip points toward the end of the curtain wall unit.

- 1 Select a curtain wall unit.
- 2 Expand Dimensions.
- 3 Miter the curtain wall unit on the start or the end point:

If you want to miter the curtain wall unit ...	Then ...
at its start point	enter an angle for Start Miter Angle, and press <i>ENTER</i> .
at its end point	enter an angle for End Miter Angle, and press <i>ENTER</i> .

Changing the Location of a Freestanding Curtain Wall Unit

Use this procedure to relocate a freestanding curtain wall unit by changing the coordinate values of its insertion point. The curtain wall unit also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the curtain wall unit are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the curtain wall unit by aligning its normal with another axis. You can also rotate the curtain wall unit on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Double-click the curtain wall unit you want to change.
- 2 Expand Location.
- 3 Click Additional information.
- 4 Specify the location of the curtain wall unit:

If you want to ...	Then ...
relocate the curtain wall unit	enter new coordinate values under Insertion Point.

If you want to ...	Then ...
locate the curtain wall unit on the XY plane	make the normal of the wall parallel to the Z axis: under Normal, enter 1 for Z, and enter 0 for X and Y.
locate the curtain wall unit on the YZ plane	make the normal of the curtain wall unit parallel to the X axis: under Normal, enter 1 for X and enter 0 for Y and Z.
locate the curtain wall unit on the XZ plane	make the normal of the curtain wall unit parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.
change the rotation of the curtain wall unit	enter a new value for Rotation Angle.

5 Click OK.

Modifying the Position of Anchored Curtain Wall Units

When you use a curtain wall unit as an infill for a curtain wall or a door/window assembly, the curtain wall unit is anchored to the other object. While anchored, the curtain wall unit moves when you move the curtain wall and is erased when you erase the curtain wall.

You can change the orientation, alignment, or offset of the curtain wall unit without affecting the anchor.

NOTE For information about releasing the curtain wall unit anchor so that it moves and erases independently from the curtain wall, see [Releasing an Object Anchored in a Curtain Wall](#) on page 1034.

Changing the Orientation of an Anchored Curtain Wall Unit

Use this procedure to change the orientation of an anchored curtain wall unit using grips.

- 1 Select the anchored curtain wall unit.
- 2 Click the appropriate Flip grip to change the X or Y direction of the object.
You can also change the orientation of an object, including the Z direction, using the Anchor worksheet found on the object's Properties palette.

Changing the Alignment of an Anchored Curtain Wall Unit

Use this procedure to change the alignment of a curtain wall unit anchored into a curtain wall.

- 1 Double-click the anchored curtain wall unit.
- 2 Expand Location, and click Anchor.
- 3 Click Allow Variation from Infill Element Definition.
- 4 Select a new alignment for the curtain wall unit.
For more information, see [Specifying an Alignment for a Curtain Wall Unit Infill](#) on page 1049.
- 5 Click OK.

Changing the Offset of an Anchored Curtain Wall Unit

Use this procedure to change the offset of an anchored curtain wall unit.

- 1 Double-click the anchored curtain wall unit.
- 2 Expand Location, and click Anchor.
- 3 Click Allow Variation from Infill Element Definition.
- 4 Specify a new offset for the curtain wall unit.
For more information, see [Specifying an Offset for a Curtain Wall Unit Infill](#) on page 1050.
- 5 Click OK.

Specifying the Cut Plane Display of a Curtain Wall Unit

Use this procedure to specify the properties of one or more cut planes for an individual curtain wall unit. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the curtain wall unit you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all curtain wall units in the drawing, select Drawing default setting. To apply changes to all curtain wall units of this style, select Curtain Wall Unit Style:<style name>. For more information on styles, see [Curtain Wall Unit Styles](#) on page 1039.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object.
- 8 For Use cut plane of containing object when anchored, specify whether you want the containing object's cut plane to be used when the curtain wall unit is anchored to that object.
- 9 To define additional cut planes for the curtain wall unit, click  Manual cut planes.
- 10 On the Manual Above and Below Cut Plane Heights worksheet, click Add, and under Cut Plane, enter the height of the new cut plane.

If you add a cut plane ...	Then ...
at a height that is lower than the current cut plane	objects are displayed using the Layer/Color/Linetype properties specified for the Below Cut Plane component of the object.
at a height that is higher than the current cut plane	objects are displayed using the Layer/Color/Linetype properties specified for the Above Cut Plane component of the object.

You can click Remove to delete a cut plane that you added.

You can also access and modify these same cut plane settings through the curtain wall unit's context menu, as follows

- 1 Select the curtain wall unit you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.
- 5 Click OK twice.

Specifying the Display of Other Characteristics of a Curtain Wall Unit

Use this procedure to specify other display properties for a curtain wall unit, including cell marker size, the display of miters at frame corners, and the display of custom components. If you are going to use custom graphics for a component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the curtain wall unit.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all curtain wall units in the drawing, select Drawing default setting. To apply changes to all curtain wall units of this style, select Curtain Wall Unit Style:<style name>. For more information on styles, see [Curtain Wall Styles](#) on page 941.

- 5 If necessary, expand Object Display Properties ► Advanced.
- 6 If you want to change the size of the markers used for cells in the curtain wall grid, click Cell marker size, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)
- 7 Optionally, for Show mitres at frame corners, select Yes/No.
- 8 If you want to add or edit a custom component, for Custom model components (or Custom plan components, if in a plan view), click .
- 9 On the Custom Model (or Plan) Components worksheet, click Add, or select one of the components in the list, and click Edit.
- 10 On the Custom Display Component worksheet, for Component Type, select Infill, Frame, or Mullion.
- 11 Enter a name for Component Name, or click Select Component, and in the Select <component type> Definition dialog, select a definition, and click OK.
- 12 Select Draw Custom Graphics.
- 13 Specify the display of the element:

If you want to ...	Then ...
display the block instead of the associated curtain wall unit element	select Replace Graphics.

If you want to ...	Then ...
superimpose the block over the curtain wall unit element so that both are displayed	clear Replace Graphics.

14 Click Select Block, select the custom block that you created, and click OK.

15 Specify further settings for the custom display block:

If you want to ...	Then ...
scale the block to fit a particular dimension	select Width, Height, or Depth. To prevent the block from losing its proportions, select Lock XY Ratio.
specify how the block is inserted into the grid in the X, Y, and Z directions	specify an insertion point on the X, Y, and Z planes.
mirror the block	determine if it should mirror in the X, Y, or Z direction.
offset the block from the grid	specify the offset in the X, Y, or Z direction.

16 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Curtain Wall Unit

Use this procedure to enter notes and attach reference files to a curtain wall unit. You can also edit notes and edit or detach reference files from a curtain wall unit.

1 Double-click the curtain wall unit.

2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

4 To add a note, click the setting for Notes, and enter the text.

5 Click OK.

6 Click under Reference documents, and attach, edit, or detach a reference file:

If you want to ...	Then ...
attach a reference file	click Add, select a file, and click Open.
edit the description of a reference file	select the file, and click the description. Enter the new text, and press <i>ENTER</i> .
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

7 Click OK twice.

Facet Deviation

The smoothness (tessellation) of curved curtain wall edges is controlled by the FACETDEV variable. Specify the facet deviation to set the number of facets to display on curved objects. This must be set before converting a polyline to a curtain wall.

The facet deviation is available only on the command line by typing **-AecFacetDev**.

The number you set as the facet deviation defines the maximum distance from the chord to the arc, the chord being an edge that is created from faceting the curve, to the true mathematical arc. The facet deviation has a range of greater than zero (0) and no upper limit.

The minimum number of facets is 8. For example, when you create a cylinder mass element with a 1' radius, and specify a FACETDEV value of 1', the cylinder has 8 faces.

Door and Window Assemblies

20

Door and window assemblies provide a mechanism for creating door and window compounds for inserting in walls and curtain walls.

Door and Window Assemblies

Door/window assemblies provide a grid or framework for inserting objects such as windows and doors. With this framework, you can create complex window and door assemblies, which can then be inserted in standard walls or used as repeated elements in curtain walls.

assembly added to curtain wall segment

assembly added to wall segment

Door/Window Assembly Grids

Door/window assemblies are made up of 1 or more grids. Each grid has either a horizontal division or a vertical division, but you can nest the grids to create a variety of patterns from simple to complex.

vertical divisions

horizontal divisions

nested grids

TIP Using a door/window assembly in a curtain wall can help you avoid the complexities of too many nested grids in the curtain wall.

Elements of Grids

Grids are the foundation of curtain walls, curtain wall units, and door/window assemblies. Every grid has four element types:

- **Divisions:** Define the direction of the grid (horizontal or vertical) and the number of cells
- **Cell Infills:** Contain another grid, a panel infill, or an object such as a window or a door
- **Frames:** Define the edge around the outside of the primary grid and nested grids
- **Mullions:** Define the edges between the cells

NOTE Division is an abstract element, in contrast to the other three element types that represent physical elements of the door/window assembly.

Each element type is assigned a default definition that describes what elements of that type look like.

Element type	Default definitions
Divisions	Vertical divisions with a fixed cell dimension of 3'
Cell Infills	Cells containing simple panels with a 2" thickness
Frames	Outer edges of grid 3" wide and 3" deep

Element type	Default definitions
Mullions	Edges between cells 1" wide and 3" deep

You can create new element definitions and assign those definitions within the door/window assembly. For example, you can create multiple infill definitions and then assign different infills to specific cells in the grid. Likewise, you can create multiple frame definitions and then assign a different definition to each frame edge (top, bottom, left, right). This is also true for mullion definitions.

Experimenting with Door/Window Assembly Designs

The templates provided with AutoCAD Architecture offer door/window assembly styles. Looking at these styles and experimenting with them makes it easier to understand door/window assembly behavior and create your own door/window assembly designs.

For more information about element definitions and assignments, see [Creating Element Definitions for a Door and Window Assembly Style](#) on page 1122 and [Assigning Definitions to Door and Window Assembly Elements](#) on page 1146.

Door and Window Assembly Endcaps

Door and window assemblies that are anchored in a wall can have endcap styles applied to them. The endcap shapes for wall openings are defined in the wall style and are a property of the wall. For information on setting an opening endcap style in a wall, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

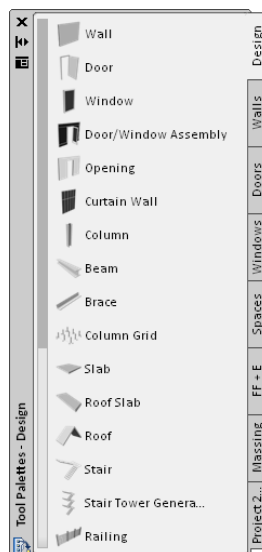

Using Door and Window Assembly Tools to Create Door and Window Assemblies

Door/window assemblies are planar and defined by an insertion point, as opposed to curtain walls, which have a baseline that can be curved or straight. You can create a door/window assembly based on a 2D layout grid or on a combination of lines, arcs, and circles.

To create a door/window assembly for use in a standard wall, you draw the wall first. You can then insert the door/window assembly and modify the door/window assembly elements as needed.

To create a door/window assembly for use in a curtain wall, insert the door/window assembly in space. Modify the element definitions and assignments as needed. Save your changes as a new door/window assembly style, and then assign that style to cells in your curtain wall grid. For more information, see [Inserting an Object into a Curtain Wall Cell](#) on page 974.

Tool palettes provided with AutoCAD Architecture let you quickly place door/window assemblies by selecting a door/window assembly tool with a specific door/window assembly style and other predefined properties. When you place door/window assemblies using door/window assembly tools, you can use the default settings of the tool, or you can change settings for the door/window assembly properties. You can also use door/window assembly tools to convert linework to door/window assemblies and to apply the settings of a door/window assembly tool to existing door/window assemblies.

The following palettes contain one or more door/window assembly tools:

Tool Palette	Door/Window Assembly Tools
Design palette in the Sample Palette catalog	Standard door/window assembly style and default settings for other door/window assembly properties
Design Tool Catalog ► Doors and Windows ► Door and Window Assemblies	a large number of door and window assembly styles for many design uses
custom tool palettes created by your CAD manager	door/window assembly styles and properties that your CAD manager customized for your projects or office standards

When you place door/window assemblies using door/window assembly tools, you can use the default settings of the tool, or you can change settings for any door/window assembly properties that are not controlled by the style.

Creating a Door and Window Assembly

Use this procedure to add a new door/window assembly that has the properties specified in the door/window assembly tool that you select. To specify settings when you add a door/window assembly, see [Creating a Door and Window Assembly with User-Specified Settings](#) on page 1114.

- 1 Open the tool palette that contains the door/window assembly tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After you select it, you can move or hide the Properties palette to expose more of the drawing area.

If necessary, scroll to display the tool that you want to use.

- 2 Select a wall, or press *ENTER* and then specify the insertion point of the door/window assembly.
- 3 Continue adding door/window assemblies, and then press *ENTER*.

Creating a Door and Window Assembly with User-Specified Settings

Use this procedure to add a door/window assembly with settings that you specify.

1 Open the tool palette that contains the door/window assembly tool you want to use, and select it.

(You may have to scroll to display the desired tool.)

2 On the Properties palette, expand Basic, and expand General.

3 Select a style.

4 Under Bound Spaces, specify if this door and window assembly can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this door and window assembly can be used as bounding object for associative spaces.
- No: this door and window assembly cannot be used as bounding object for associative spaces.
- By style: this door and window assembly will use the bounding settings from the door and window assembly style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

5 Expand Dimensions.

6 Modify the dimensions of the door/window assembly:

If you want to specify...	Then...
the length of the door/window assembly	enter a value for Length.
the height of the door/window assembly	enter a value for Height.
the rise of the door/window assembly	enter a value for Rise.
start and end miters	enter miter values for Start miter angle and End miter angle.

7 Expand Location.

8 Modify the location properties of the door/window assembly:

If you want to specify...	Then...
the position of the door/window assembly	select Unconstrained or Offset/Centered for Position along the wall. <hr/> NOTE If you selected Offset/Centered, enter a value for the Automatic offset.
the vertical alignment of the door/window assembly	select Head or Sill for Vertical Alignment.
the head height of the door/window assembly	enter a value for Head height.
the sill height of the door/window assembly	enter a values for Sill height.

If you want to specify...**Then...**

the rotation reference angle of the door/window assembly enter a value for Rotation.

Vertical alignment controls how you place the door/window assembly in the wall and how the door/window assembly responds to modifications in height. The Sill height and Head height options allow you to determine the working point on the door/window assembly. You can place the working point at the sill or at the head. The vertical alignment value determines the location of the working point vertically in the wall.

Modifications to the door/window assembly height respect the working point. For example, if you specify the working point of the window as sill, the vertical alignment as 0", and the door/window assembly height as 7'-0", the height in the wall where the top of the door/window assembly is placed is 7'-0". If you modify the height of the window to 6'-8", the window sill remains at 0", and the top of the door/window assembly becomes 6'-8". The sill working point is maintained.

If you specify the working point as the door/window assembly head, the Vertical Alignment value as 7'-0", and the door/window assembly height as 7'-0", the height in the wall where the top of the door/window assembly is placed is 7'-0". If you modify the height of this door/window assembly to 6'-8", the door/window assembly head remains at 7'-0" and the window sill becomes 4". The head working point is maintained.

TIP You can move or hide the Properties palette to expose more of the drawing area.

- 9** In the drawing area, select a wall, or press *ENTER* and then specify the insertion point of the door/window assembly.
- 10** Continue adding door/window assemblies, and press *ENTER*.

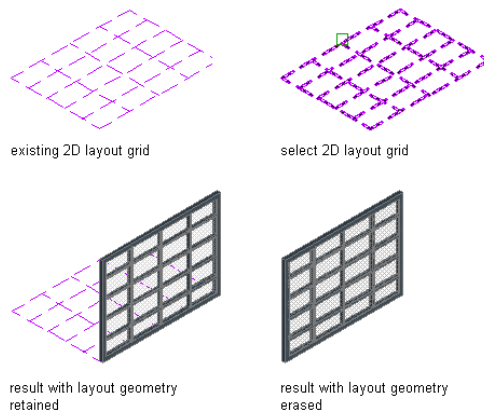

Creating a Door and Window Assembly from a Layout Grid

Use this procedure to create a door/window assembly based on a 2D layout grid. If you already have 2D layout grids in a drawing, you can easily convert them to door/window assemblies. Or, if you are already familiar with layout grids, it is an efficient way to create a door/window assembly and then experiment with the door/window assembly commands to learn more about them. For more information, see [Using Layout Grids](#) on page 1810.

NOTE Only rectangular layout grids can be converted to a door/window assemblies.

When you create a door/window assembly from a 2D layout grid, you also create a new door/window assembly style. The divisions in the new door/window assembly style are taken from the divisions in the layout grid.

- 1 Open the tool palette that contains the door/window assembly tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click a door/window assembly tool, and click Apply Tool Properties to ► Layout Grid.
- 3 Select the layout grid to convert.
- 4 When prompted to erase the original geometry, press *ENTER* to keep the layout grid, or enter *y* (Yes) to erase it.
- 5 Press *ENTER* to specify horizontal as the orientation for the primary division, or enter *v* to specify vertical.
- 6 Enter a name for the door/window assembly style, and click OK.

- 7 If necessary, edit the properties of the door/window assembly in the Properties palette.

Creating a Door and Window Assembly from Doors, Windows and Openings

Use this procedure to convert doors, windows, and openings to a door/window assembly that has the properties of the door/window assembly tool you select. You can edit the properties of the door/window assembly after you create it.

NOTE When you create a door/window assembly from a collection of doors, windows and openings, you create a single assembly from each object selected. For more information about how to create an assembly from a specific configuration, see [Creating a Door and Window Assembly from an Elevation Sketch](#) on page 1117.

- 1 Open the tool palette that contains the door/window assembly tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click a door/window assembly tool, and click Apply Tool Properties to ► Door, Opening, Window.

3 Select the door, window or opening to convert.

4 Edit the properties of the door/window assembly in the Properties palette, if necessary.

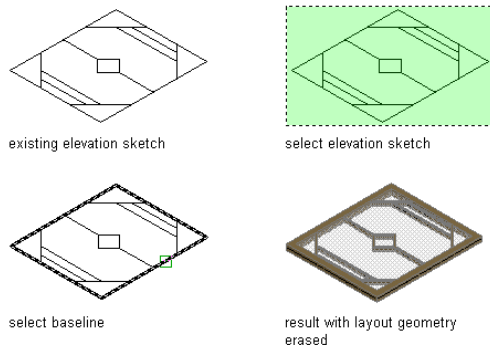

Creating a Door and Window Assembly from an Elevation Sketch

Use this procedure to create a sketch of a custom grid with lines, arcs, and circles, and then convert that linework into a door/window assembly.

NOTE You cannot modify the division definition of a custom grid created from lines, arcs, and circles. You can, however, assign a different division definition to it. For more information, see [Assigning a Division to a Door and Window Assembly Grid](#) on page 1146.

NOTE Door/window assembly grids are either horizontal or vertical. To create a grid pattern with horizontal and vertical cells, nested grids are used. For more information about nested grids, see [Working with Nested Grids in Door and Window Assemblies](#) on page 1148.

- 1 Use lines, arcs, and circles to draw a grid in the world coordinate system (WCS).
- 2 Right-click a door/window assembly tool, and click Apply Properties to ► Elevation Sketch.
- 3 Select the linework of your sketch, and press *ENTER*.
- 4 You have the option of either selecting a baseline for the door/window assembly or accepting the default baseline. Select one of the grid lines as the baseline for the door/window assembly.

Or press *ENTER* to use the line along the *X* axis as the default baseline.

TIP If you draw your linework in the *XY* plane (in Plan view) and accept the default baseline, the resulting door/window assembly is displayed from the *Z* direction.

5 To erase the lines, enter **y** (Yes). To have the lines remain after the door/window assembly is created, enter **n** (No).

If there is a style applied to the door/window assembly tool, the new custom style is based on the existing style. The infill, mullion, and frame definitions are those of the existing style. You can modify the style without having to create a new one from scratch. For more information, see [Assigning Definitions to Door and Window Assembly Elements](#) on page 1146.

6 Select the resulting custom door/window assembly, right-click, and click Design Rules ► Save to Style.

7 Click New to create a new door/window assembly style.

8 Enter a name for the new door/window assembly style.

9 Click OK twice.

Creating a Door and Window Assembly Tool

Use this procedure to create a door/window assembly tool and add it to a tool palette. You may want to create your own door/window assembly tools if you are placing multiple door/window assemblies of specific styles that have the same properties.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a door/window assembly in the drawing	select the door/window assembly, and drag it to the tool palette.
create a tool from a door/window assembly style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.

If you want to...	Then...
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

- 3 Right-click the new tool, and click Properties.
- 4 Enter a name for the tool.
- 5 Click the setting for Description, enter a description of the tool, and click OK.
- 6 Expand Basic, and expand General.
- 7 Click the setting for Description, enter a description of the door/window assembly created from this tool, and click OK.
- 8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.
- 9 Select a style.
- 10 Select the drawing file containing the style used for this door/window assembly.
- 11 Under Bound Spaces, define if this door and window assembly tool can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this door and window assembly tool can be used as bounding object for associative spaces.
- No: this door and window assembly tool cannot be used as bounding object for associative spaces.
- By style: this door and window assembly tool will use the bounding settings from the door and window assembly style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

- 12 Expand Dimensions.
- 13 Modify the dimensions of the door/window assembly

If you want to specify...	Then...
the length of the door/window assembly	enter a value for Length.
the height of the door/window assembly	enter a value for Height.
the rise of the door/window assembly	enter a value for Rise.
start and end miters	enter miter values for Start miter angle and End miter angle.

- 14 Expand Location.

15 Modify the location properties of the door/window assembly:

If you want to...

Then...

specify the position of the door/window assembly

select Unconstrained or Offset/Center for Position along the wall.

NOTE If you selected Offset/Centered, enter a value for the Automatic offset.

specify the head height of the door/window assembly

enter a value for Head height.

specify the sill height of the door/window assembly

enter a value for Sill height.

16 Click OK.

Door and Window Assembly Styles

Door/window assemblies are style-based, meaning there are preset characteristics assigned to each door/window assembly that determine its appearance and function. By changing from one style of door/window assembly to another, you can quickly study several different design options. Any changes you make to the style are reflected throughout your building, updating all door/window assemblies of that particular style. You can also apply overrides to a single door/window assembly, without changing other door/window assemblies of the same style.

A door/window assembly style controls the following properties of a door/window assembly:

- Element definitions
- Definition assignments for each element
- Materials for each element

- Display properties for each element
- Default dimensions
- Notes about the style and any associated reference files

To create, edit, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Process Overview: Creating a Door and Window Assembly Style

When you create a door/window assembly style, you assign characteristics to any or all elements of a door/window assembly and save them as a named style. In this way, you standardize the appearance of all door/window assemblies that use the style. When you modify a style, all door/window assemblies in your drawing that use the style are updated to reflect the changes. There are eight general steps for creating a door/window assembly style:

- 1 Define divisions for the door/window assembly grid.
For information on defining door/window assembly grid definitions, see [Division of Door and Window Assembly Grids](#) on page 1125.
- 2 Define the infill for the cells of the door/window assembly.
For information on creating infills, see [Defining Infills for Door and Window Assembly Cells](#) on page 1132.
- 3 Define the door/window assembly frame, including using profiles and specifying offsets.
For information on defining a frame for a door/window assembly, see [Defining Door and Window Assembly Frames](#) on page 1137.
- 4 Define the mullions for the door/window assembly, including using profiles and specifying offsets.
For information on ways to define mullions, see [Defining Door and Window Assembly Mullions](#) on page 1142.
- 5 Assign the element definitions you created:

If you want to assign...	Then see...
a division to a door/window assembly grid	Assigning a Division to a Door and Window Assembly Grid on page 1146.
infills to door/window assembly cells	Assigning Infills to Door and Window Assembly Cells on page 1147.
definitions to door/window assembly frames	Assigning Definitions to Door and Window Assembly Frames on page 1156.
definitions to door/window assembly mullions	Assigning Definitions to the Mullions of a Door and Window Assembly on page 1158.

- 6 Specify the materials of the door/window assembly style.
For information on specifying materials, see [Specifying the Materials of a Door and Window Assembly Style](#) on page 1161.

- 7 Specify the display properties of the door/window assembly, including layer, color, linetype, and hatching.
For information on specifying the display properties of a door/window assembly, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.
- 8 Attach notes and reference documents to the door/window assembly style.
For information on attaching notes and files, see [Attaching Notes and Files to a Door and Window Assembly Style](#) on page 1167.

Tips for Working Efficiently with Door and Window Assembly Styles

Use these suggestions to work with door/window assembly styles efficiently and productively.

- Name grids and elements very clearly to identify where they are used and what they are. For example, use the name L3-FL1-H to represent a third-level grid used on the first floor and that is horizontally divided. Incorporating this suggestion makes it easier to ensure that you are using elements correctly.
- Use the element definition that is applied most often as the default element definition. For example, if most cells are stone panels, define the default infill as the stone panel. This panel is then used in every cell that is not specifically assigned to another infill. Apply this rule to the default frame, mullion, and division.
- Name the styles for doors, windows, curtain wall units, AEC Polygons, and curtain walls to indicate where they are used and what they are.
- Remember that you can use cell and edge overrides to define special conditions not accounted for in the door/window assembly style.

Creating Element Definitions for a Door and Window Assembly Style

Element definitions determine the appearance of the four basic door/window assembly elements. There is a different definition type for each element.

Definition	Sample definitions
Divisions	Horizontal grid with six cells
Cell Infills	Cells contain windows
Frames	Outer edge of grid is 6" wide

Definition**Sample definitions**

Mullions

Edges between cells are 4" wide

Each type of element can have multiple definitions. For example, you can define the divisions to create a horizontal grid or a vertical grid and you can define the cells to contain a nested grid or a door/window assembly. To make reuse easier, you can save the element definitions and then assign them to grids, cells, frames, or mullions as needed.

Element definitions are style-specific. When you create element definitions for a specific door/window assembly style, those definitions are available only for door/window assemblies of that style. For example, if you define a door/window assembly infill for one door/window assembly style, that infill is not available as an option when you edit a door/window assembly of a different style.

Creating a Door and Window Assembly Style

Use this procedure to create a door/window assembly style. You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style. You can also create a door/window assembly tool based on the newly created door/window assembly style. When you use the tool to add door/window assemblies, each door/window assembly has the style specific to the tool.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Create a new door/window assembly style:

If you want to...	Then...
create a style with default properties	right-click Door/Window Assembly Styles, and click New.
create a style from an existing style	right-click the door/window assembly style you want to copy, and click Copy. Right-click, and click Paste.
create a style from a curtain wall, curtain wall unit, or door/window assembly in the drawing	right-click Door/Window Assembly Styles, and click New. Right-click the new style, click Set From, and then pick a curtain wall, a curtain wall unit, or a door/window assembly.

- 4 Enter a name for the new door/window assembly style, and press *ENTER*.

5 Edit the new door/window assembly style:

If you want to...	Then...
define the elements of a door/window assembly style	see Creating a Division Definition for a Door and Window Assembly on page 1125, Defining Infills for Door and Window Assembly Cells on page 1132, Defining Door and Window Assembly Frames on page 1137, and Defining Door and Window Assembly Mullions on page 1142.
assign element definitions to the door/window assembly style	see Assigning Definitions to Door and Window Assembly Elements on page 1146, Assigning a Division to a Door and Window Assembly Grid on page 1146, Assigning Infills to Door and Window Assembly Cells on page 1147, Assigning Definitions to Door and Window Assembly Frames on page 1156, and Assigning Definitions to the Mullions of a Door and Window Assembly on page 1158.
add door/window assembly element definitions as display components	see Adding Door and Window Assembly Element Definitions as Display Components on page 1163.
specify layer, color and linetype settings for the display components of a door/window assembly	see Specifying the Layer, Color, and Linetype of a Door and Window Assembly Style on page 1163.
specify door/window assembly hatching	see Specifying the Hatching for Components of a Door and Window Assembly Style on page 1164.
add custom graphics as display components of a door/window assembly style	see Adding Custom Graphics as a Display Component of a Door and Window Assembly on page 1165.
create individual cut planes for door/window assembly styles	see Creating Cut Planes for a Door and Window Assembly on page 1166.
specify the materials of the door/window assembly style	see Specifying the Materials of a Door and Window Assembly Style on page 1161.
add notes and files to the style	see Attaching Notes and Files to a Door and Window Assembly Style on page 1167.

6 When you finish specifying the properties of the door/window assembly style, click OK.

7 If you want to assign the style to a door/window assembly tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Door and Window Assembly Tool](#) on page 1118.

8 Click OK.

Division of Door and Window Assembly Grids

A door/window assembly consists of one or more grids, which are the framework for placing design elements in the door/window assembly. The highest-level grid is the primary grid, which is also the outside edge of the door/window assembly.

Each grid in a door/window assembly has one division assignment that determines whether the grid is divided horizontally or vertically. The division also determines the number of cells, their size, and their placement.

Within the primary grid, you can define multiple levels of grids. These grids within the primary grid are called nested grids. Each subdivision of a grid is called a cell.

You can create a variety of division definitions under different names and then assign different divisions to each grid in your door/window assembly. Although you can create multiple definitions, there can be only one division assignment per grid. You create division definitions for a specific door/window assembly style and those definitions can be assigned only to grids in door/window assemblies of that style. For more information about assigning divisions to a particular grid, see [Assigning a Division to a Door and Window Assembly Grid](#) on page 1146.

Creating a Division Definition for a Door and Window Assembly

Use this procedure to create divisions for a door/window assembly grid.

Because door/window assemblies can contain multiple nested grids, it is helpful to use a naming convention for grids that indicates the level of each grid and the grid location or the purpose within the door/window assembly. For example, L3-FL1-Stone Panels identifies a third level grid that provides a row of stone panels on Floor 1.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Click New Division.
- 7 Enter a name for this division definition.
- 8 Select either Vertical orientation  or Horizontal orientation .

9 Select one of the following division types and specify offsets if needed:

Division Type	Description
Fixed Cell Dimension	Creates a grid where the size of the individual cells is predetermined. For more information, see Specifying a Fixed Size for Cells in a Door and Window Assembly Grid on page 1126.
Fixed Number of Cells	Creates a grid where the number of grid cells is predetermined. For more information, see Specifying a Fixed Number of Cells for a Door and Window Assembly Grid on page 1129.
Manual	Creates a grid where the size and number of individual cells is manually determined by the user. For more information, see Manually Defining the Number and Size of Cells in a Door and Window Assembly Grid on page 1129.

After you create a division definition, you can assign the definition to a specific grid in a door/window assembly. For more information, see [Assigning a Division to a Door and Window Assembly Grid](#) on page 1146.

10 When you are finished creating division definitions, click OK.

Specifying a Fixed Size for Cells in a Door and Window Assembly Grid

Use this procedure to define a specific size for the cells in a grid. In this case, the number of cells is determined by the length or height of the grid, depending on how the grid is divided.

When you specify a fixed cell size in a grid, you can control how the cells of the grid adjust to accommodate any leftover space. This space occurs if the length (or the height) of the door/window assembly cannot be evenly divided by the fixed size of the cell. For more information, see [Using the Auto-Adjust Cells Option](#) on page 1127.

fixed cell size vertical grid

fixed cell size horizontal grid

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.

7 Select Fixed Cell Dimension for Division Type.

8 Specify a size for the cells in Cell Dimension.

If you are defining a vertical grid, the cell dimension is the length of the cell from mullion to mullion. If you are defining a horizontal grid, the cell dimension is the height of the cell.

9 To specify an offset for the grid, specify an offset distance in Bottom Offset or Top Offset.

TIP The frame width is calculated as part of the cell size. Therefore, cells adjacent to the frame can appear to be a different size than the other cells. If you do not want the frame width included in the cell size, specify an offset for the grid that is equal to the frame width.

When you draw a door/window assembly using a fixed cell dimension, there is often extra space between the last full-size cell and the end of the door/window assembly.

For more information about grid offsets, see [Specifying an Offset for a Door and Window Assembly Grid](#) on page 1130.

10 Adjust the cells to accommodate this extra space:

If you want to...

Then...

add the space to grid cells

select Auto-Adjust Cells, select Grow for Cell Adjustment, and select the specific cells where the space is to be added. You can select any combination of Specific Cells.

remove the space from grid cells

select Auto-Adjust Cells, select Shrink for Cell Adjustment, and select the specific cells where the space is to be removed. You can select any combination of Specific Cells.

11 Click OK.

For information about assigning the division definition to a specific grid in your door/window assembly, see [Assigning a Division to a Door and Window Assembly Grid](#) on page 1146.

Using the Auto-Adjust Cells Option

Use this procedure to automatically resize cells in a grid when the result of dividing the grid by the specified cell dimension is not a whole number. You can adjust the size of cells by specifying a cell or combination of cells to grow or shrink according to your layout.

For example, if a vertical primary grid in a door/window assembly style is 17 feet in length and you specify a fixed cell dimension of 3 feet, the grid has five cells of 3 feet each with 2 feet remaining. Using the Auto-Adjust Cells option, you can specify how the grid distributes the remaining quantity.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Door/Window Assembly Styles.

- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Divisions definition or create a new one.
- 7 Select Fixed Cell Dimension as the division type.

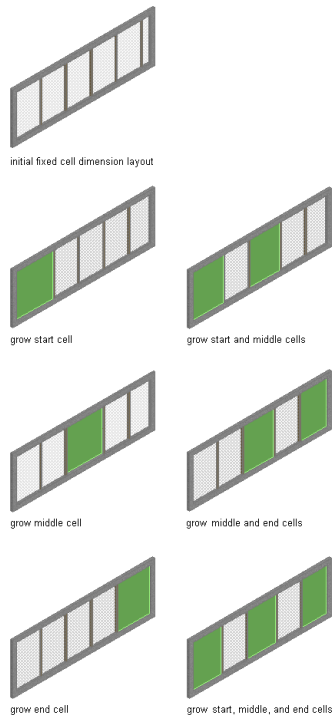

Auto-Adjusting Cells by Growing

- 8 Select Auto-Adjust Cells, and specify the cell adjustment:

If you want to...	Then...
add the remaining space to grid cells	select Grow, and select the specific cells to which you want the space added.
remove the remaining space from grid cells	select Shrink, and select the specific cells from which you want the space removed. You can then select Maintain at least half of cell dimension in order to control the cell shrinkage.

The cells that you do not select maintain the fixed value you specified for Cell Dimension.

You can auto-adjust the grid divisions by specifying the start, middle, or end cell, or any combination of those cells, to receive the cell growth. The size of each cell depends on which combination of cells you specify. In the following illustration, all of the possible cell growth combinations for an example door/window assembly are shown, with highlighted cells in green.

Specifying a Fixed Number of Cells for a Door and Window Assembly Grid

Use this procedure to define a specific number of cells in a grid. In this case, the size of the cells is determined by the length or height of the grid, depending on how the grid is divided.

Specifying a fixed number of cells for Door/Window Assembly grids

four cell vertical grid

three cell horizontal grid

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Fixed Number of Cells for Division Type.
- 8 Enter the desired number of cells in Number of Cells.
- 9 Specify an offset distance for Start Offset or End Offset.

For more information, see [Specifying an Offset for a Door and Window Assembly Grid](#) on page 1130.

TIP The frame width is calculated as part of the cell size. Therefore, cells adjacent to the frame can appear to be a different size than the other cells. If you do not want the frame width included in the cell size, specify an offset for the grid that is equal to the frame width.

For information about assigning the division definition to a specific grid in your door/window assembly, see [Assigning a Division to a Door and Window Assembly Grid](#) on page 1146.

Manually Defining the Number and Size of Cells in a Door and Window Assembly Grid

Use this procedure to manually add gridlines and specify an offset for each one when you need to create a unique grid that does not fit into any of the other division types. You can also start with a fixed cell dimension grid or a fixed number of cells grid and then manually adjust the gridlines to suit your needs.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.
- 6 Select a Division definition or create a new one.
- 7 Select Manual for Division Type.

8 Click  to add a gridline.

Insert as many grid lines as you need. If you need to remove a grid line, select it from the table,

and then click .

9 Under Offset in the grid line table, specify an offset distance for each grid line.

Gridline	Offset	From
1	2'-0"	Grid Start
2	4'-0"	Grid Start
3	6'-0"	Grid Start

10 Under From in the grid line table, select the grid location from which the grid line is offset.

Gridline	Offset	From
1	2'-0"	Grid Start
2	4'-0"	Grid Start
3	6'-0"	Grid Start

Grid Start
 Grid Middle
 Grid End

11 Specify an offset distance in Bottom Offset or Top Offset.

For more information, see [Specifying an Offset for a Door and Window Assembly Grid](#) on page 1130.

12 Click OK.

For information about assigning the division definition to a specific grid in your door/window assembly, see [Assigning a Division to a Door and Window Assembly Grid](#) on page 1146.

Specifying an Offset for a Door and Window Assembly Grid

By default, grids cells are measured from the start and end points of the door/window assembly baseline (for horizontal divisions) or in the baseline to the base height (for vertical divisions). The width of the grid frame is not considered in calculating the size of the cell. For example, if you draw a door/window assembly with a 14 ft. baseline and a 1 ft. frame on the left and right, and you specify a fixed number of vertical cells, the cells do not appear equal in size. The first and last cells appear smaller because they include the frame.

To make the cells equal in size, offset the start and end of the grid by the width of the frame.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Divisions under Element Definitions.

6 Select a Division definition or create a new one.

7 Specify an offset for the grid.

If you want to specify the distance between... Then...

the start point of the door/window assembly baseline and the start of the first cell in a horizontal grid enter a value for Start Offset.

the end point of the door/window assembly baseline and the end of the last cell in a horizontal grid enter a value for End Offset.

the baseline of the door/window assembly and the start of the bottom cell in a vertical grid enter a value for Bottom Offset.

the base height of the door/window assembly and the end of the top cell in a vertical grid enter a value for Top Offset.

8 Click OK.

Removing a Division Definition from a Door and Window Assembly Style

Use this procedure to remove a division definition that you no longer need. You cannot remove a division definition that is currently assigned to a grid. In addition, you cannot remove the default division definition, but you can modify it.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Door/Window Assembly Styles.

3 Select a door/window assembly style.

4 Click the Design Rules tab.

5 In the left pane, select Divisions under Element Definitions.

6 Select the division definition that you want to remove.

7 Right-click and click Remove, or click .

8 Click OK.

Defining Infills for Door and Window Assembly Cells

An infill defines the contents of a door/window assembly cell. A door/window assembly cell can have the default simple panel or contain a nested grid, an AEC Polygon, curtain wall unit, door or window style. The object styles you use in infills must exist in the current drawing to be added to an infill definition. Panels typically represent glazing or other plain cladding, such as stone or concrete.

NOTE Nested grids and no infill are options you select when assigning an infill to a cell. They do not require infill definitions. For more information, see [Creating a Nested Grid for a Door and Window Assembly](#) on page 1150 and [Removing an Infill from a Door and Window Assembly](#) on page 1153.

You can define as many infills as you need and then use cell assignments to specify the cells that use each infill. A default infill, which you can modify, is used for all unassigned cells. For more information about cell assignments, see [Assigning Definitions to Door and Window Assembly Elements](#) on page 1146.

NOTE Create infill definitions for a specific door/window assembly style. Those definitions can be assigned only to grid cells in door/window assemblies of that style.

Materials

Styles use the materials of the object style assigned to each panel. For example, if you specify an infill to use the Standard door style, the materials of that infill are those designated in the door style.

Simple panels need materials assigned in the door/window assembly style.

If you do not use materials to control the display properties of infills, you can specify their display properties in the door/window assembly style. The layer, color, linetype, and other display properties of the Default Infill are applied to all infills unless you create a custom display component for each infill definition. Then you can control the display of each infill definition independently. For more information, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.

Creating a Panel Infill for a Door and Window Assembly

Use this procedure to create a simple panel infill to represent basic cladding materials in the door/window assembly, such as a stone wall panel, concrete panel, metal panel, or glazing infill.

Because door/window assemblies can contain multiple infills, it is helpful to use a naming convention for panel infills that indicates the infill location or purpose within the door/window assembly. For example, L3-FL1- Stone Panel identifies a stone panel in a third-level grid on Floor 1.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Click New Infill.
- 7 Enter a descriptive name for the infill.
- 8 Select Simple Panel for Infill Type.
- 9 Select an alignment for the infill.

For more information, see [Specifying an Alignment for a Door and Window Assembly Infill](#) on page 1134.

- 10 Specify an offset for the infill.

For more information, see [Specifying an Offset for a Door and Window Assembly Infill](#) on page 1135.

- 11 Specify a thickness for the panel.
- 12 Click OK.

After you create an infill definition, you can assign it to any cell in a door/window assembly grid. For more information, see [Assigning Infills to Door and Window Assembly Cells](#) on page 1147.

Creating an Infill for Inserting an Object into a Door and Window Assembly

Use this procedure to create a style infill to insert objects into a door/window assembly. You can insert doors, windows, curtain wall units, and AEC Polygons by defining a specific style of that object as an infill.

TIP After you insert an object in a cell, you can select that object independent of the grid and access editing options for the object.

Because door/window assemblies can contain multiple infills, it is helpful to use a naming convention for panel infills that indicates the infill location or purpose within the door/window assembly. For example, L3-FL1-Stone Panel identifies a stone panel in a third-level grid on Floor 1.

NOTE The object styles you use in infills must exist in the current drawing to be added to an infill definition.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Click New Infill.
- 7 Enter a descriptive name for the infill.
- 8 Select Style for Infill Type.
The right side of the dialog box changes to display a tree view of the object styles available for insertion into a door/window assembly.
- 9 Select an object style.

There is a unique icon for each type of style. For example, the door style icon  and the curtain wall unit icon . These icons also are displayed next to the infill name at the top of the dialog box to help you identify the type of infill.
- 10 Select an alignment for the infill.
For more information, see [Specifying an Alignment for a Door and Window Assembly Infill](#) on page 1134.
- 11 Specify an offset for the infill.
For more information, see [Specifying an Offset for a Door and Window Assembly Infill](#) on page 1135.
- 12 Click OK.

After you create an infill definition, you can assign it to any cell in a door/window assembly grid. For more information, see [Assigning Infills to Door and Window Assembly Cells](#) on page 1147.

Specifying an Alignment for a Door and Window Assembly Infill

Use this procedure to align an infill so that it is centered with the baseline of the door/window assembly, in front of the baseline, or behind the baseline. In Plan view, the front of a door/window assembly (drawn from left to right) is below the baseline and the back is above the baseline.

Specifying Door/Window Assembly panel infill alignments

NOTE To move the infill away from the baseline, see [Specifying an Offset for a Door and Window Assembly Infill](#) on page 1135.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select an infill or create a new one.
- 7 Select an alignment: front, center, or back.
- 8 Click OK.

Specifying an Offset for a Door and Window Assembly Infill

Use this procedure to specify an offset for a door/window assembly infill. By default, infills are centered on the door/window assembly baseline. If your design requires that the infill be aligned with frame edges or some other part of the door/window assembly, you can specify an offset for the infill.

You can also edit individual style-based infills directly in the drawing. The selected infill has Flip grips in both the *X* and *Y* directions so that you can change the orientation of the infill.

Specify Door/Window Assembly infill panel offsets

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Door/Window Assembly Styles.

3 Select a door/window assembly style.

4 Click the Design Rules tab.

5 In the left pane, select Infills under Element Definitions.

6 Select an infill or create a new one.

7 Enter an offset distance.

In plan view, positive numbers offset the infill above the baseline and negative numbers offset the infill below the baseline. The offset is also affected by the selected alignment for the infill.

8 Click OK.

Removing an Infill Definition from a Door and Window Assembly Style

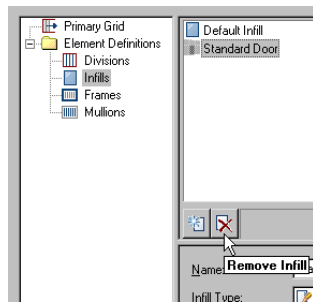

Use this procedure to delete an infill definition that you no longer need. However, you cannot remove an infill definition that is currently assigned to a cell in the primary grid or any nested grid. Also, you cannot remove the default infill definition, but you can modify it as needed.

NOTE For information about removing an infill from a cell, see [Removing an Infill from a Door and Window Assembly](#) on page 1153.

Removing panel infill from a Door/Window Assembly

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Infills under Element Definitions.
- 6 Select the unneeded infill definition, and click Remove Infill.

- 7 Click OK.

Defining Door and Window Assembly Frames

All door/window assembly grids, including the primary grid, can have frame definitions. The door/window assembly frame is represented by the outer edges of a grid. The overall frame size is determined by the length and height of the door/window assembly grid. You can define a frame by specifying a width and depth or by selecting a profile.

Specifying Door/Window Assembly frame width and depth

You create frame definitions for a specific door/window assembly style. Those definitions can be assigned only to frames in door/window assemblies of that style. You can create as many frame definitions as you want and then assign the definitions to the frame edges as needed. If you have nested grids, each grid has its own frame. There is a default frame definition that you can modify and assign as needed. Unassigned frame edges are not displayed. For more information, see [Assigning Definitions to Door and Window Assembly Frames](#) on page 1156.

TIP Using Style Manager, you can copy a mullion definition and use it as a frame definition. Select the mullion definition and drag it to Frames in the left pane.

Materials and Display Properties for Frames

If you do not use materials to control the display properties of frames, you can specify their display properties in the door/window assembly style. The layer, color, linetype, and other display properties of the default frame are applied to all frames unless you create a custom display component for each definition. You can then control the display of each frame definition independently. For more information, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.

NOTE You create frame definitions for a specific door/window assembly style and those definitions can be assigned only to frames in door/window assemblies of that style.

Defining a Door and Window Assembly Frame by Width and Depth

Use this procedure to define a frame by specifying its width and depth. The overall frame size is determined by the length and height of the door/window assembly grid.

Because door/window assemblies can contain multiple styles with different frames, it is helpful to use a naming convention for grid frames that indicates the grid location or purpose within the door/window assembly. For example, L3-FL1- Metal Frame identifies a metal frame in a third-level grid on Floor 1.

TIP To remove the frame edge and have the infill adjust to fill the space occupied by the frame, create a frame definition with both width and depth set to zero. Then assign that definition to the frame edge that you want to remove. This is necessary for the infill to be mitered as it would be for a butt-glazed condition. For more information, see [Removing a Frame Edge from a Door and Window Assembly](#) on page 1158.

Specifying a Door/Window Assembly frame width and depth of zero

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.

- 6 Click  to create a new frame definition.
- 7 Enter a descriptive name for the frame.
- 8 Specify a width and depth for the frame.
- 9 Specify any offsets.

For more information, see [Specifying Offsets for a Door and Window Assembly Frame](#) on page 1140.

- 10 Click OK.

After you create a frame definition, you can assign it to any frame in a door/window assembly. For more information, see [Assigning Definitions to Door and Window Assembly Frames](#) on page 1156.

Creating a Profile for a Door and Window Assembly Frame

Use this procedure to create a profile that you can use to define the shape of a door/window assembly frame. You can then extrude the profile to create a door/window assembly frame.

The height and the width of the polyline you use to create the profile define the default height and width of the door/window assembly frame. The insertion point of the profile is aligned with the centroid of the frame.

- 1 Draw a closed polyline of the height and the depth needed for the resulting door/window assembly frame.
- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.
- 3 Enter **c** (Centroid) for the insertion point of the profile.
The insertion point of the profile is aligned with the centroid of the frame.
- 4 Enter a name for the profile, and click OK.
You can now use the profile as a door/window assembly frame. For more information, see [Defining a Door and Window Assembly Frame Using a Profile](#) on page 1139.

Defining a Door and Window Assembly Frame Using a Profile

Use this procedure to create a frame element definition from a profile. If you do not want a straight edge to your frame, you can use a profile to define edges with curves, jags, or any other shape you require.

You can also use an edit in-place routine to create a frame from a profile. For more information, see [Creating a Frame or Mullion Edge from a Polyline or Profile Using In-Place Editing](#) on page 1176.

It is helpful to use a naming convention for profiles that indicates the grid location or purpose within the door/window assembly. For example, L3-FL1- Metal Frame identifies a metal frame in a third-level grid on Floor 1.

Specifying default and profile-based Door/Window Assembly frames

NOTE The insertion point of the profile is aligned with the centroid of the frame.

- 1 Create the profile to use for the frame.
For more information, see [Creating a Profile for a Door and Window Assembly Frame](#) on page 1139.
- 2 Click Format menu ► Style Manager.
- 3 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 4 Select a door/window assembly style.
- 5 Click the Design Rules tab.
- 6 In the left pane, select Frames under Element Definitions.
- 7 Create a new frame definition.
- 8 Enter a descriptive name for the frame.
- 9 Specify a width and depth for the frame edge.
These dimensions are used to calculate the center point of the edge for aligning the profile and also to specify a boundary for the adjacent infill.
- 10 Select Use Profile.

NOTE The Profile options are available only when you have profiles in the current drawing.

- 11 Select a profile from the list.
By default, the profile is inserted using the same width and depth with which it was created.
- 12 To adjust the size of the profile to fit within the width or depth dimension of the frame edge, select Auto-Adjust Profile Width or Depth.
- 13 To mirror the profile along the X or Y axis, select X or Y for Mirror In.
- 14 To rotate the profile, specify a rotation angle.
- 15 Specify any offsets.
For more information, see the next section [Specifying Offsets for a Door and Window Assembly Frame](#) on page 1140.
- 16 Click OK.

After you create a frame definition, you can assign it to any frame in a door/window assembly. For more information, see [Assigning Definitions to Door and Window Assembly Frames](#) on page 1156.

Specifying Offsets for a Door and Window Assembly Frame

Use this procedure to define the distance that a door/window assembly frame is from the floor line, roof line, or baseline. By default, the outside edges of the frame align with start and end of the baseline and the start and end of the base height. When you adjust the width of the frame, the frame expands inward. However, you can use offsets to expand or contract the frame away from these default limits or to shift the frame away from the baseline in either the X or Y direction.

Offset	Description
X	Positive X offset moves the frame edge outward beyond the end of the door/window assembly, while a negative X offset moves the frame edge inward toward the center of the door/window assembly.

Offset	Description
Y	In Plan view, a positive Y offset moves the frame edge above the baseline, while a negative Y offset moves the frame below the baseline.
Start	Negative Start offset lengthens the frame beyond the start point, while a positive Start offset shortens the frame. The start point for vertical edges is the baseline, and the start point for horizontal edges (drawn left to right) is the left side.
End	Negative End offset lengthens the frame beyond the end point, while a positive End offset shortens the frame. The end point for vertical edges is the base height, and the end point for horizontal edges (drawn left to right) is the right side.

TIP To quickly identify the start and end of a door/window assembly, select the door/window assembly. The Reverse Direction grip is displayed near the center of the door/window assembly and points toward the end of the door/window assembly.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Select a frame definition from the list.
- 7 Specify an offset distance for the frame edge: X, Y, Start, or End.
- 8 Click OK.

Removing a Frame Definition from a Door and Window Assembly Style

Use this procedure to remove a frame definition that you no longer need. You cannot remove a frame definition if it is currently assigned to a frame edge, but you can remove it if it is assigned as an override to a frame edge. Also, you cannot remove the default frame definition, but you can modify it as needed.

NOTE For information about removing a frame edge, see [Removing a Frame Edge from a Door and Window Assembly](#) on page 1158.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Frames under Element Definitions.
- 6 Select the unneeded frame definition from the list.
- 7 Click Remove Frame.
- 8 Click OK.

Defining Door and Window Assembly Mullions

All door/window assembly grids, including the primary grid, can have mullion definitions. The mullions of a door/window assembly are the edges between the grid cells. You can define the mullions by specifying a width and depth or by selecting a profile from which the mullion is extruded.

Because door/window assemblies can contain multiple nested grids with different mullions, it is helpful to use a naming convention for grid mullions that indicates the grid location or purpose within the door/window assembly. For example, L3-FL1- Window Mullion identifies a mullion for a window in a third-level grid on Floor 1.

Specifying default and profile-based Door/Window Assembly mullions

You create mullion definitions for a specific door/window assembly style and those definitions can be assigned only to mullions in door/window assemblies of that style. You can create as many mullion definitions as you want and then assign the definitions to mullions as needed. If you have nested grids, each grid has its own mullions. A default mullion definition, which you can modify and assign as needed, is used for any unassigned mullions. For more information, see [Assigning Definitions to the Mullions of a Door and Window Assembly](#) on page 1158.

TIP Using Style Manager, you can copy a frame definition and use it as a mullion definition. Select the frame definition and drag it to Mullions in the left pane.

Materials and Display Properties for Mullions

If you do not use materials to control the display properties of mullions, you can specify their display properties in the door/window assembly style. The layer, color, linetype, and other display properties of the default mullion are applied to all mullions unless you create a custom display component for each definition. You can then control the display of each mullion definition independently. For more information, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.

Defining Door and Window Assembly Mullions by Width and Depth

Use this procedure to define mullions by specifying a width and a depth.

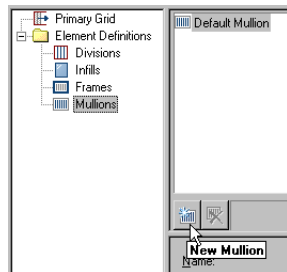

Because door/window assemblies can contain multiple nested grids with different mullions, it is helpful to use a naming convention for grid mullions that indicates the grid location or purpose within the door/window assembly. For example, L3-FL1- Window Mullion identifies a mullion for a window in a third-level grid on Floor 1.

Specifying Door/Window Assembly mullion width and depth

TIP To remove mullions for butt glazing, create a definition with both width and depth set to zero. Then assign that definition to the mullions that you want to remove. For more information, see [Removing Mullions from a Door and Window Assembly Grid](#) on page 1160.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Click New Mullion.

- 7 Enter a descriptive name for the mullion definition.
- 8 Specify a width and depth for the mullion definition.
- 9 Specify any offsets.
For more information, see [Specifying Offsets for the Mullions of a Door and Window Assembly](#) on page 1145.
- 10 Click OK.

After you create a mullion definition, you can assign it to any mullion in a door/window assembly. For more information, see [Assigning Definitions to the Mullions of a Door and Window Assembly](#) on page 1158.

Creating a Profile for Door and Window Assembly Mullions

Use this procedure to create a profile that you can use to define the shape of a door/window assembly mullion definition. You can then extrude the profile to create mullions from it.

The height and the width of the polyline you use to create the profile define the default height and width of the door/window assembly mullion. The insertion point of the profile is aligned with the centroid of the mullion.

- 1 Draw a closed polyline of the height and the depth needed for the resulting door/window assembly mullion.
- 2 Select the polyline, right-click, and click Convert to ► Profile Definition.

3 Enter **c** (Centroid) for the insertion point of the profile.

The insertion point of the profile is aligned with the centroid of the mullion.

4 Enter a name for the profile, and click OK.

You can now use the profile as a door/window assembly mullion. For more information, see [Defining the Mullions of a Door and Window Assembly Using a Profile](#) on page 1144.

Defining the Mullions of a Door and Window Assembly Using a Profile

Use this procedure to create a mullion element definition from a profile. If you do not want a straight edge to your mullions, you can use a profile to define mullions with curves, jags, or any other shape.

You can also use an edit in-place routine to create a mullion from a profile. For more information, see [Creating a Frame or Mullion Edge from a Polyline or Profile Using In-Place Editing](#) on page 1176.

Because door/window assemblies can contain multiple nested grids with different mullions, it is helpful to use a naming convention for grid mullions that indicates the grid location or purpose within the door/window assembly. For example, L3-FL1- Window Mullion identifies a mullion for a window in a third-level grid on Floor 1.

NOTE The insertion point of the profile is aligned with the centroid of the mullion.

1 Create the profile to use for the mullion.

For more information, see [Creating a Profile for Door and Window Assembly Mullions](#) on page 1143.

2 Click Format menu ► Style Manager.

3 Expand Architectural Objects, and expand Door/Window Assembly Styles.

4 Select a door/window assembly style.

5 Click the Design Rules tab.

6 In the left pane, select Mullions under Element Definitions.

7 Click New Mullion.

8 Enter a descriptive name for the mullion definition.

9 Specify a width and depth for the mullion definition.

These dimensions are used to calculate the center point of the mullion for aligning the profile, and also to specify a boundary for the adjacent infill.

10 Select Use Profile.

NOTE The Profile options are available only when you have profiles in the current drawing.

11 Select a profile from the list.

By default, the profile is inserted using the same width and depth with which it was created.

12 To adjust the size of the profile to fit within the width or depth dimension of the mullion, select Auto-Adjust Profile Width or Depth.

13 To mirror the profile along the X or Y axis, select X or Y for Mirror In.

14 To rotate the profile, specify a rotation angle.

15 Specify any offsets.

For more information, see [Specifying Offsets for the Mullions of a Door and Window Assembly](#) on page 1145.

16 Click OK.

After you create a mullion definition, you can assign it to any mullion in a door/window assembly. For more information, see [Assigning Definitions to the Mullions of a Door and Window Assembly](#) on page 1158.

Specifying Offsets for the Mullions of a Door and Window Assembly

Use this procedure to define mullions that are offset from the start or end of the door/window assembly to lengthen or shorten the edge or offset in the X or Y direction to shift the edge. For example, you might want to represent butt glazing by offsetting the mullions to be behind glass panel infills.

Offset	Description
X	For vertical mullions, a positive X offset moves the mullions toward the end of the door/window assembly, while a negative X offset moves the mullions toward the start of the door/window assembly. For horizontal mullions, a positive X offset moves the mullions toward the top of the door/window assembly, while a negative X offset moves the mullions toward the bottom of the door/window assembly.
Y	In Plan view, a positive Y offset moves the mullions above the baseline, while a negative Y offset moves the mullions below the baseline.
Start	Negative Start offset lengthens the mullions beyond the start point, while a positive Start offset shortens the mullions.
End	Negative End offset lengthens the mullions beyond the end point, while a positive End offset shortens the mullions.

TIP To quickly identify the start and end of a door/window assembly, select the door/window assembly. The Reverse Direction grip is displayed near the center of the door/window assembly and points toward the end of the door/window assembly.

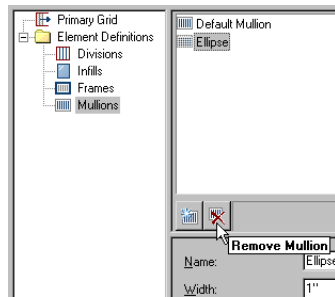

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Select a mullion definition from the list.
- 7 Specify an offset distance for the X, Y, Start, or End.
- 8 Click OK.

Removing a Mullion Definition from a Door and Window Assembly Style

Use this procedure to remove a mullion definition that you no longer need. You cannot remove a mullion definition if it is assigned to a mullion, but you can remove it if it is assigned as an override to a mullion. Also, you cannot remove the Default Mullion definition, but you can modify it as needed.

NOTE For information about removing mullions from between cells, see [Removing Mullions from a Door and Window Assembly Grid](#) on page 1160.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select Mullions under Element Definitions.
- 6 Select the unneeded mullion definition from the list.
- 7 Click Remove Mullion.

- 8 Click OK.

Assigning Definitions to Door and Window Assembly Elements

After you've created element definitions for a door/window assembly style, you can assign those definitions to each of the door/window assembly element types: divisions, cell infills, frames, and mullions.

By default, one definition is assigned to all elements of a particular type. However, you can assign definitions to individual elements as well. For example, all cells in the grid are assigned the default infill. But you can create a new cell assignment, select a different infill, and then specify the cells to use that infill.

Assignment list

Name	Element	Type	Used in
Division Assign...			
Primary Grid	Transom	Grid	This grid division
Cell Assignments			
Default Cell As...	*NONE*	Default	All unassigned cells
Doors			
Standard Door	Location	Start	
Frame Assignm...			
Custom Corner	Profile	Location	Left, Right, Top, Bot...
Default Frame ...	Default Frame	Location	Left, Right
Mullion Assignm...			
Default Mullion ...	Default Mullion	Default	All unassigned mullions
Secondary Mull...	Ellipse	Index	2, 4

For more information about element definitions, see [Creating Element Definitions for a Door and Window Assembly Style](#) on page 1122.

Assigning a Division to a Door and Window Assembly Grid

Divisions define the grid orientation (whether the direction of the grid cells and mullions is horizontal or vertical) and the division type (number and size of cells).

After you define a division, you can assign it to the primary grid or to nested grids. Nested grids are created by selecting Nested Grid as the cell assignment. For more information, see [Working with Nested Grids in Door and Window Assemblies](#) on page 1148.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid you want to assign rules to.
The name of the grid you select is displayed in the table under the Division Assignment row.

TIP To rename a grid, select it, click Rename, and enter a new name.

- 6 Click the Element column for that grid and select a division definition from the list.
- 7 Click OK.

Assigning Infills to Door and Window Assembly Cells

An infill defines the contents of a door/window assembly cell. A door/window assembly cell can have the default simple panel or contain a nested grid, an AEC Polygon, curtain wall unit, door or window style. The object styles you use in infills must exist in the current drawing to be added to an infill definition. Panels typically represent glazing or other plain cladding, such as stone or concrete.

Specifying Door/Window Assembly infill definitions

Cell Assignments

A cell assignment defines the infill definition used for cells. You can use one cell assignment to assign the same infill to all cells, or you can create multiple cell assignments to assign different infills to different cells.

Name	Element	Type	Used In
Division Assignment			
Secondary Grid	Vertical Division	Grid	This grid division
Cell Assignments			
Default Cell Assignment	2 Inch panel	Default	All unassigned cells
Door	Standard	Location	Middle
Window	Casement Wi...	Index	1, 2, 4, 5

Do not assign multiple definitions to the same cell. If you do, the last definition assigned to the cell is used.

Default Cell Assignment

The default cell assignment used by all unassigned cells. You can modify the default assignment to be any type of infill, but you cannot delete the default cell assignment.

You may want to modify the default cell assignment to use the infill definition that occurs most frequently in your design. Any cells not assigned to other infills then use this infill definition.

Materials and Display Properties of Infills

The layer, color, linetype, and other display properties of the default infill are applied to all infills unless you assign materials to the infills you created or you create a custom display component for each definition. Then you can control the display of each infill definition independently. For more information, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.

Working with Nested Grids in Door and Window Assemblies

Each door/window assembly grid is one dimensional with either a horizontal or vertical division. By nesting grids in the door/window assembly style, you can create a variety of patterns from simple to complex.

Specifying Door/Window Assembly nested grid locations

nested grid in start cell

nested grid in all cells

Simple Primary Grids

When you nest grids, you start with one primary grid. Then each cell in the primary grid can be filled with another grid. For example, the following illustration has a horizontal primary grid with four cells. You can nest a vertical grid in each horizontal cell to create a simple 2D grid.

Specifying Door/Window Assembly cell divisions 1

The previous illustration shows all cells in the grid with the same cell assignment—a vertical division. But each cell in a grid is independent and can have a separate assignment. For example, the following illustration shows one cell in the primary grid that contains another horizontal grid, the next cell contains a vertical grid with three divisions, and the next cell contains a vertical grid with six divisions.

Specifying Door/Window Assembly cell divisions 2

Multiple Nested Grids

You can continue to nest grids to create multiple levels. For example, the following illustrations show the Standard door/window assembly style grid, the same grid with a nested grid in one cell of the secondary grid, and the same grid again with nested grids in all cells of the secondary grid.

Specifying a nested grid in a door/window assembly

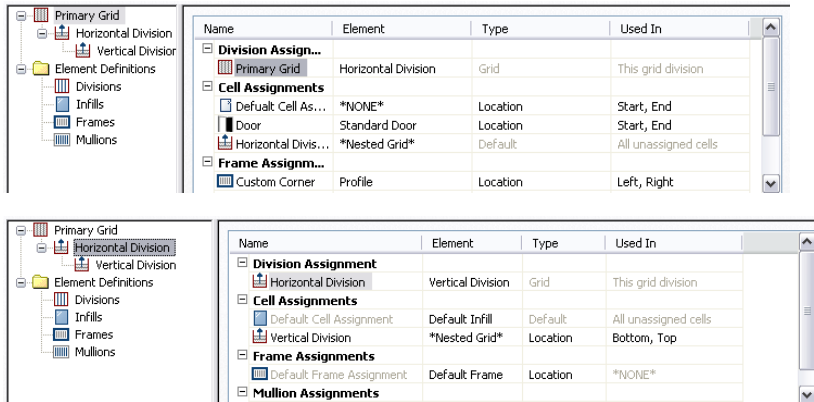

Defining Nested Grids

You can define nested grids on the Design Rules tab of the Door/Window Assembly Style Properties dialog box. The tree on the left side of the tab lists the grids. There is always one primary grid. The primary grid can have one or more secondary grids. Each secondary grid can have one or more tertiary grids and so on.

TIP To quickly create nested grids in all cells, change the default cell assignment to Nested Grid. If you want multiple levels of nesting, be sure to change the default cell assignment for each grid. For more information, see [Creating a Nested Grid for a Door and Window Assembly](#) on page 1150.

Each grid has its own cell assignments. You assign cells to contain another grid, a panel infill, or an object such as a door or window. For more information, see [Assigning Infills to Door and Window Assembly Cells](#) on page 1147.

Creating a Nested Grid for a Door and Window Assembly

Use this procedure to create a nested grid, which is a grid within a grid. Each nested grid has its own division rules, cell assignments, frame, and mullions. By default, the frame is off for nested grids.

For more information, see [Working with Nested Grids in Door and Window Assemblies](#) on page 1148.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a nested grid.
- 6 In the left pane, select the grid in which you want to create a new cell assignment.
- 7 Click New Cell Assignment.
 - A new cell assignment is displayed in the list of cell assignments.
- 8 Right-click the default name, click Rename, and enter a descriptive name for the assignment.
- 9 Select Nested Grid in the Element column.

A new grid is added to the list of grids in the left pane of the dialog box. If you are editing the primary grid, the new grid is added at the secondary level. If you are editing a grid at the secondary level, the additional grid is placed at the tertiary level, and so on.

Creating a nested grid

New nested grid in tree

NOTE To rename a grid, select it in the right pane, right-click, and click Rename, and enter a new name.

10 Specify the cells to contain this nested grid.

For more information, see [Specifying Which Door and Window Assembly Cells Use a Cell Assignment](#) on page 1154.

11 Click OK.

Filling a Door and Window Assembly Cell with a Simple Panel

Use this procedure to fill a door/window assembly cell with a simple panel. Simple panels are generally used to represent basic cladding materials in the door/window assembly, such as a stone wall panel or a concrete panel.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Door/Window Assembly Styles.

3 Select a door/window assembly style.

4 Click the Design Rules tab.

5 In the left pane, select the grid in which you want to assign a simple panel.

6 Click New Cell Assignment.

A new cell assignment is displayed in the list of cell assignments.

7 Right-click the default name, click Rename, and enter a descriptive name for the assignment.

8 Select an infill that defines a simple panel.

9 Specify the cells to contain this simple panel.

For more information, see [Specifying Which Door and Window Assembly Cells Use a Cell Assignment](#) on page 1154.

10 Click OK.

Inserting a Door or Window into a Door and Window Assembly

Use this procedure to add doors and windows to door/window assemblies. For more information, see [Defining Infills for Door and Window Assembly Cells](#) on page 1132.

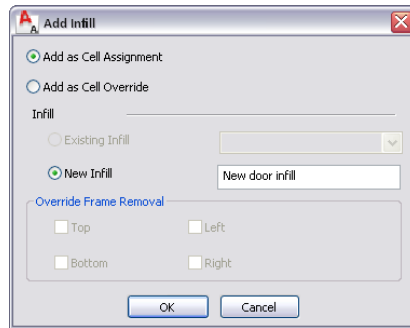

1 Open the tool palette that you want to use, and select a door, window or door/window assembly.

2 Select the door/window assembly in which to insert the door or window.

You can move or hide the Properties palette to expose more of the drawing area.

3 Select the door/window assembly cell marker for the cell in which to insert the door or window.

The Add Infill worksheet displays.

4 Select the insertion method for the door or window:

If you want to...

Then...

add the door or window as a cell assignment and have all door/window assemblies using the same style display the same object added to a corresponding cell

select Add as Cell Assignment.

add the door or window exclusively to the selected door/window assembly

select Add as Cell Override.

If a door or window of the style you selected already exists in your drawing, Existing Infill is selected by default.

5 Select the type of infill for the door or window:

If you selected...

Then...

Add as Cell Assignment and you want to insert a door or window of the existing style, Existing Infill is selected by default.

Click OK.

Add as Cell Assignment and you want to insert a door or window of a different style than exists in your drawing

select New Infill, enter a name for the object and click OK.

Add as Cell Override and you want to insert a door or window of the existing style and not modify the edge of the frame surrounding the object

Click OK.

Add as Cell Override and you want to insert a door or window of a different style than exists in your drawing and not remove an edge of the frame surrounding the object

select New Infill, enter a name for the object and click OK.

Add as Cell Override and you want to insert a door or window of the existing

select Top, Bottom, Left, or Right for Override Frame Removal and click OK.

If you selected...	Then...
style and remove an edge of the frame surrounding the object	
Add as Cell Override and you want to insert a door or window of a different style than exists in your drawing and remove an edge of the frame surrounding the object	select New Infill and enter a name for the object. Then select Top, Bottom, Left, or Right for Override Frame Removal and click OK.

6 Press *ENTER*.

Inserting an Object into a Door and Window Assembly Cell

Use this procedure to insert objects, such as doors, windows, curtain wall units, and AEC Polygons, into a door/window assembly cell. Door/window assembly cells can contain these objects when you create infill definitions that use them. For more information, see [Creating an Infill for Inserting an Object into a Door and Window Assembly](#) on page 1134.

TIP After you insert an object in a cell, you can select that object independent of the grid, and access editing options for the object. For more information, see [Editing Objects Anchored in Door and Window Assemblies](#) on page 1196.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to insert objects.
- 6 Click New Cell Assignment.
A new cell assignment is displayed in the list of cell assignments.
- 7 Right-click the default name, click Rename, and then enter a descriptive name for the assignment.
- 8 Select an infill that uses an object style.
- 9 Specify the cells to contain this object.
For more information, see [Specifying Which Door and Window Assembly Cells Use a Cell Assignment](#) on page 1154.
- 10 Click OK.

Removing an Infill from a Door and Window Assembly

Use this procedure to remove the infill of a cell and leave the cell empty. To do this, use None as the element definition. Using None also removes any frame edges that border the cell, but it does not affect the mullions.

Removing infill from a Door/Window Assembly cell

To remove the infill of a cell

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid that contains the cells you want to assign to None.
- 6 Select an existing cell assignment or create a new one.
- 7 Select None under the Element column.
- 8 Specify the cells to contain the None infill.

For more information, see [Specifying Which Door and Window Assembly Cells Use a Cell Assignment](#) on page 1154.

- 9 Click OK.

Specifying Which Door and Window Assembly Cells Use a Cell Assignment

When you create a cell assignment you need to specify the cells in the grid to use that assignment. There are two options for selecting cells:

- Use Location to insert the infill into the start, middle, or end cells of a vertical grid or into the bottom, middle, or top cells of a horizontal grid. If there is an even number of cells (four or more), Middle refers to the two cells in the middle of the grid. If there is an odd number of cells (three or more), Middle refers to one cell in the middle of the grid.

Specifying Door/Window Assembly infill by location

- Use Index to insert the infill into specific cells based on cell numbers. Cells are numbered from start to end or bottom to top. For example, typing 1, 2, 3 would place the infill in the first, second and third cells.

Specifying Door/Window Assembly Infill by Index

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 Select a cell assignment:

If you selected...	Then...
--------------------	---------

Location

click the Used In column, and click the button at the far right of the row. Select the cells you want to use this assignment, and click OK.

Index

enter the cell numbers separated by commas in the Used In column. For vertical grids, cells are numbered from start to end and for horizontal grids, cells are numbered from bottom to top.

NOTE Do not assign multiple definitions to a cell. If you do, the last definition assigned to the cell is used.

- 7 Click OK.

Any cells that are not assigned a specific cell assignment use the default infill.

Removing an Assignment from a Door and Window Assembly Style

Use this procedure to remove cell assignments, frame assignments, and mullion assignments from a door/window assembly style. You cannot remove default assignments, but you can modify them to suit your needs.

NOTE Each grid requires one division assignment, therefore you cannot remove the division assignment. You can change the division element used for the division assignment.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid from which you want to remove an assignment.

- 6 Select a cell assignment, frame assignment, or a mullion assignment.
- 7 Click Remove Assignment.
- 8 Click OK.

Assigning Definitions to Door and Window Assembly Frames

The door/window assembly frame is represented by the outer edges of the primary grid. Each nested grid has its own frame that is defined separately from the primary grid frame. By default, the frames of nested grids are turned off. For more information about nested grids, see [Working with Nested Grids in Door and Window Assemblies](#) on page 1148.

Frame Assignments

A frame assignment defines the frame definition used by each frame edge. You can use one frame assignment to assign the same definition to all four edges of the frame, or you can create multiple frame assignments to assign different definitions to different edges of the frame. Unassigned edges are not displayed.

Default Frame Assignment

Do not assign multiple definitions to the frame edge. If you do, the last definition assigned to the edge is used.

There is a default frame assignment and you can select the frame edges it applies to. You can modify the default assignment to use any frame definition, but you cannot delete the default frame assignment.

Materials and Display Properties of Frames

The layer, color, linetype, and other display properties of the default frame are applied to all frame edges unless you assign materials to the frame definition or create a custom display component for each definition. Then you can control the display of each frame definition independently. For more information, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.

Adding a New Frame Assignment to a Door and Window Assembly Grid

Use this procedure to add a frame assignment to a door/window assembly. To assign different definitions to different frame edges, you need multiple frame assignments.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a new frame assignment.
- 6 Click New Frame Assignment.

A new frame assignment is displayed in the list of frame assignments.

Name	Element	Type	Used In
[-] Division Assignment			
[-] Cell Assignments			
[-] Frame Assignments			
Custom Corner	Profile	Location	Left, Right
Default Frame Assignment	Default Frame	Location	"NONE"
New Frame Assignment	Default Frame	Location	Left, Right
[-] Mullion Assignments			

- 7 Right-click the default name, click Rename, and then enter a descriptive name.

8 Under Element, select a frame definition.

9 Specify the sides of the frame to use this frame assignment.

For more information, see [Specifying Which Door and Window Assembly Edges Use a Frame Assignment](#) on page 1157.

10 Click OK.

Specifying Which Door and Window Assembly Edges Use a Frame Assignment

When you create a frame assignment, you need to specify the edges of the frame to use that assignment.

Frame edges that are not assigned a frame definition are not displayed.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Door/Window Assembly Styles.

3 Select a door/window assembly style.

4 Click the Design Rules tab.

5 In the left pane, select a grid.

6 Select a frame assignment.

Location is the only way to specify the frame edges.

7 Click the Used In column, and then click the [...] button at the far right of the row.

Name	Element	Type	Used In
Division Assign...			
Primary Grid	Default Division	Grid	This grid division
Cell Assignments			
Default Cell As...	**NONE*	Default	All unassigned cells
Doors	New Infill	Location	Bottom, Top
Horizontal Divis...	**Nestled Grid*	Location	Bottom, Top
Frame Assignm...			
Custom Corner	Profile	Location	Left, Right
Default Frame...	Default Frame	Location	Left, Right, Top, Bot...
Mullion Assignm...			
Default Mullion ...	Default Mullion	Default	All unassigned mullions

8 Select the edges that you want to use this assignment - Left, Right, Top, or Bottom - and click OK.

Specifying different Door/Window Assemblies frame definitions

NOTE Do not assign multiple definitions to the same frame edge because only the last definition assigned to the edge is used.

9 Click OK.

Removing a Frame Edge from a Door and Window Assembly

Use this procedure to remove a frame edge from a door/window assembly. There are three ways to remove a frame edge:

- Set the width and depth of the edge to zero.
- Leave the edge unassigned.
- Specify None as an override to the edge assignment.

The first two methods remove the frame edge and expand the adjacent infills into the space occupied by the edge.

By specifying None as an override, the frame edge is not displayed, but the adjacent infill is not expanded into the space the edge occupied.

For information about setting the width and depth to zero, see [Defining a Door and Window Assembly Frame by Width and Depth](#) on page 1138.

For information about leaving the edge unassigned, see [Specifying Which Door and Window Assembly Edges Use a Frame Assignment](#) on page 1157.

For information about overriding the edge, see [Creating a Frame or Mullion Override](#) on page 1175.

Assigning Definitions to the Mullions of a Door and Window Assembly

The mullions of a door/window assembly are the edges between the grid cells. The primary grid and each nested grid have mullions that are defined separately from the other grids. For more information about nested grids, see [Working with Nested Grids in Door and Window Assemblies](#) on page 1148.

Specifying mullions for Door/Window Assembly nested grids

Mullion Assignments

A mullion assignment defines the definition used by each mullion. You can use one assignment to define all mullions, or you can create multiple assignments and assign different definitions to different mullions in any grid.

Do not assign multiple definitions to the same mullion because only the last definition assigned to the mullion is used.

Default Mullion Assignment

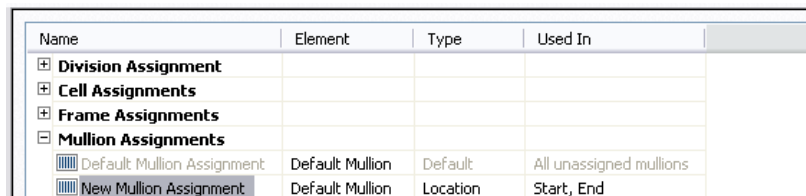

There is a default mullion assignment used by all unassigned mullions. You can modify the default assignment to be any mullion definition, but you cannot delete the default mullion assignment.

Adding a New Mullion Assignment to a Door and Window Assembly Style

Use this procedure to add a new mullion assignment to a door/window assembly style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to create a new mullion assignment.
- 6 Click New Mullion Assignment.

A new mullion assignment is displayed in the list of mullion assignments.

Name	Element	Type	Used In
+	Division Assignment		
+	Cell Assignments		
+	Frame Assignments		
-	Mullion Assignments		
Default Mullion Assignment	Default Mullion	Default	All unassigned mullions
New Mullion Assignment	Default Mullion	Location	Start, End

- 7 Right-click the default name, click Rename, and then enter a descriptive name.
- 8 Under Element, select a mullion definition.
- 9 Specify the mullions to use this assignment.
For more information, see [Specifying Which Door and Window Assembly Mullions Use an Assignment](#) on page 1159.
- 10 Click OK.

Specifying Which Door and Window Assembly Mullions Use an Assignment

When you create a mullion assignment you need to specify the mullions in the grid to use that assignment. There are two options for selecting mullions:

- Use Location to assign a definition to the start, middle, or end mullions of a vertical grid or the bottom, middle, or top mullions of a horizontal grid. If there is an even number of mullions (four or more), Middle refers to the two mullions in the middle of the grid. If there is an odd number of mullions (three or more), Middle refers to the one mullion in the middle of the grid.
- Use Index to assign a definition to specific mullions based on mullion numbers. Mullions are numbered from left to right or bottom to top. For example, typing 1, 2, 3 would assign the definition to the first, second, and third mullions.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select a grid.
- 6 Select an existing mullion assignment or create a new one.

7 Select a mullion assignment:

If you selected...	Then...
Location	click the Used In column, and click the button at the far right of the row. Select the mullions you want to use this assignment, and click OK.
Index	enter the mullion numbers separated by commas in the Used In column. For vertical grids, mullions are numbered from start to end and, for horizontal grids, mullions are numbered from bottom to top.

NOTE Do not assign multiple definitions to the same mullion because only the last definition assigned to the mullion is used.

8 Click OK.

Any mullions that are not assigned a specific mullion assignment use the default mullion definition.

Removing Mullions from a Door and Window Assembly Grid

Use this procedure to remove a mullion from the door/window assembly. You can create a mullion definition whose edge width and depth are zero. Adjacent infills expand to fill in the space that was occupied by the mullion. This is an effective way to represent butt glazing.

Removing a mullion from Door/Window Assembly grid

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the Design Rules tab.
- 5 In the left pane, select the grid in which you want to remove a mullion.
- 6 Create a new mullion assignment, and enter **0** (zero) for the width and depth.
For more information, see [Defining Door and Window Assembly Mullions by Width and Depth](#) on page 1142.
- 7 Under Mullion Assignments, select the mullion definition you created for mullion edges of any mullion assignment where you want to remove the mullions.
For more information, see [Specifying Which Door and Window Assembly Mullions Use an Assignment](#) on page 1159.
- 8 Click OK.

Specifying the Materials of a Door and Window Assembly Style

A door/window assembly consists of a number of components whose display properties can be determined by the materials assigned to each component.

When you assign materials to a door/window assembly style, you assign one material to each display component of the door/window assembly. For example, you assign a wood material to the frame and a glass material to the glass inset. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the door/window assembly style, instead of using material display properties, you can turn off the material assignments in the display properties of the door/window assembly style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in three dimensional (3D) model views and in elevations.

Door and Window Assembly Materials and Display Components

The following table identifies the material component that corresponds to each door/window assembly component in the specified views.

Door/Window Assembly Component	Material Component
Plan, Plan High Detail, Plan Low Detail, Screened, Reflected Plan	
Default Infill	Linework
Default Frame	Linework
Default Mullion	Linework
Default Infill Hatch	Linework
Default Frame Hatch	Linework
Default Mullion Hatch	Linework
Model	
Default Infill	3D Body
Default Frame	3D Body
Default Mullion	3D Body

Assigning Materials to a Door and Window Assembly Style

Use this procedure to assign materials to the individual components of a door/window assembly style. When you assign a material to a door/window assembly component, the component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the door/window assembly. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, the frame, mullion, and infill are physical components of a door/window assembly. The cell marker is a symbolic component.

NOTE If a material assignment does not determine the display properties of a door/window assembly component, you can change the display properties of the door/window assembly style as described in [Specifying the Display of Door and Window Assemblies](#) on page 1162.

- 1 Open a tool palette that has a door/window assembly tool.
- 2 Right-click a door/window assembly tool, and click Door/Window Assembly Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, select the value for Material Definition, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

- 11 Click OK.

Specifying the Display of Door and Window Assemblies

The display of a door/window assembly depends on the direction from which you view the door/window assembly. In plan view, the door/window assembly object is displayed as parallel lines with vertices marking the grid lines, as an architect would typically draw a door/window assembly. In 3D view, the door/window assembly object is displayed as it would appear in the real world, with surfaces showing length, thickness, and height. You control what you want to display in each particular view.

Element Definitions and Custom Display Components

By default, the display of all infills, frames, and mullions is controlled by the display properties of the default infill, default frame, and default mullion. However, you can add individual element definitions as components with separate display properties. For example, if you define two infills called stone panel and glass panel,

by default they are both controlled by the default infill display properties. But you can add each definition as a new display component and then control the display properties separately.

NOTE The component name in the Custom Display Component dialog box must match the name of element definition in the Design Rules tab. Otherwise, the element definition does not display properly.

For more information about the display system, see [Display System](#) on page 537.

Materials and Display Properties

You can use materials to control the display of both default and custom infills, frames, and mullions. When you assign materials to the element definitions you create, you do not need to define these definitions as custom display components. For more information, see [Specifying the Materials of a Door and Window Assembly Style](#) on page 1161.

Adding Door and Window Assembly Element Definitions as Display Components

Use this procedure to add door/window assembly element definitions. Before you can control the display properties of door/window assembly elements according to the definition assigned to the element, you must create display components for each element definition.

- 1 Select a door/window assembly, and click Edit Door/Window Assembly Style.
- 2 In the Door/Window Assembly Style Properties dialog box, click the Display Properties tab.
- 3 Click Edit Display Properties.
- 4 Click the Other tab, and then click Add.

NOTE If you click the Custom Plan Components tab, the Custom Display Component dialog box is similar, except that you do not specify the Z insertion point and Z offset for the custom graphic.

- 5 Select Infill, Frame, or Mullion for Component Type.
- 6 Enter a name for Component Name, or click Select Element and select an element from the list.
- 7 Click OK.
- 8 Click the Layer/Color/Linetype tab.
The element definition that you added is displayed in the list of components.
- 9 Click the Other tab to continue adding element definitions, or click OK twice.

Specifying the Layer, Color, and Linetype of a Door and Window Assembly Style

Use this procedure to change the following display properties of the components of an individual door/window assembly:

- Visibility (component is on or off)
- By Material
- Layer
- Color

- Linetype
- Lineweight
- Linetype scale

- 1 Select the door/window assembly you want to change, right-click, and click Edit Door/Window Assembly Style.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and click Style Override.
- 4 Click the Layer/Color/Linetype tab.
- 5 Select the component to change, and select a different setting for the property.
- 6 Click OK twice.

Specifying the Hatching for Components of a Door and Window Assembly Style

Use this procedure to specify the hatching of the components of an individual door/window assembly. Door/window assembly hatching is displayed only in display representations, such as Plan, that are used in the Top view (Plan view) of a drawing.

- 1 Select the door/window assembly you want to change, right-click, and click Edit Door/Window Assembly Style.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and click Style Override.
- 4 Click the Hatching tab.
- 5 Select a component, and click the setting for Pattern.
- 6 Select the hatching for the component:

If you want to select...	Then...
a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
single hatching	select User-defined for Type, and clear Double Hatch.
double hatching	select User-defined for Type, and select Double Hatch.
solid fill	select Solid Fill for Type.

- 7 Click OK.
- 8 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.
- 9 Click Angle, and enter the angle for the selected pattern.

10 Click Orientation, and specify how the hatching is oriented:

If you want to orient the hatching...	Then...
to the object, regardless of the object rotation	select Object.
to the World Coordinate System	select Global.

11 Click OK twice.

Adding Custom Graphics as a Display Component of a Door and Window Assembly

There may be instances where an infill, frame, or mullion requires a custom 2D or 3D graphic. For example, you might need a highly detailed three-dimensional truss as the mullions or a decorative light fixture applied to an infill. In cases like these, you can create a custom block, add a display component with the block attached, and associate that component with an element definition. When you assign that definition to an element, the block is also displayed.

1 Draw your custom component, and save it as a block.

2 Select a door/window assembly, right-click, and click Edit Door/Window Assembly Style.

3 Click the Display Properties tab.

4 Click  .

5 Click the Custom Plan Components tab.

If Model, Sill Plan, or Sill Plan Screened is the current display representation, the tab is called Other.

6 Click Add.

7 Select Infill, Frame, or Mullion as the element type.

8 Select the specific element from the list.

9 Select Draw Custom Graphics.

10 Specify the display of the element:

If you want to...	Then...
display the block instead of the associated door/window assembly element	select Replace Graphics.
superimpose the block over the door/window assembly element so that both are displayed	clear Replace Graphics.

11 Click Select Block and select the custom block that you created.

12 Click OK.

13 Specify further settings for the custom display block:

If you want to...	Then...
scale the block to fit a particular dimension	select Width, Height, or Depth. To prevent the block from losing its proportions, select Lock XY Ratio.

If you want to...	Then...
mirror the block	determine if it should mirror in the X, Y, or Z direction.
specify how the block is inserted into the grid in the X, Y, and Z directions	specify an insertion point on the X, Y, and Z planes.
offset the block from the grid	specify the offset in the X, Y, or Z direction.

14 Click OK three times.

Creating Cut Planes for a Door and Window Assembly

Use this procedure to specify the properties of one or more cut planes for a door/window assembly style. Cut plane display properties apply only to display representations, such as Plan, that are used in Top view (Plan view) of a drawing.

To better visualize the elements of a door/window assembly in plan view, you can create cut planes. The main cut plane is where the shrinkwrap and hatching are applied. The plan display shows the components of the door/window assembly as they are displayed at the height of each cut plane.

- 1 Select a door/window assembly, right-click, and click Edit Door/Window Assembly Style.
- 2 Click the Display Properties tab.
- 3 Select Plan, and click .

NOTE The Cut Plane tab is displayed only in some display representations, such as Plan.

- 4 Click the Cut Plane tab to set the cut plane to be displayed in each display representation for the door/window assembly style.
- 5 Enter a value for Cut Plane Height to specify the cut plane at which hatching takes effect.
- 6 To specifically define a cut plane, click Add, and enter the height of the new cut plane:

If you add a cut plane...	Then...
at a height that is lower than the value for Cut Plane Height	objects are displayed using the properties specified for the Below Cut Plane component on the Layer/Color/Linetype tab.
at a height that is higher than the value for Cut Plane Height	objects are displayed using the properties specified for the Above Cut Plane component on the Layer/Color/Linetype tab.

7 Click OK twice.

Defining a Door and Window Assembly Style as Bounding for Associative Spaces

Use this procedure to define a door and window assembly style that can bound associative spaces.

When a door and window assembly style is set as bounding, by default all door and window assemblies that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the object style in the object settings, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Door and Window Assembly Style

Use this procedure to enter notes and attach reference files to a door/window assembly. You can also edit notes and edit or detach reference files from a door/window assembly.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door/Window Assembly Styles.
- 3 Select a door/window assembly style.
- 4 Click the General tab.
- 5 To add a description to the door/window assembly, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Text Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...**Then...**

attach a reference file

click Add, select a file, and click OK.

edit the description of a reference file

select the file, and click Edit. Enter the description, and click OK.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click Delete.

-
- 9 Click OK.

Using Overrides in Door and Window Assemblies

Door/window assemblies are geometrically complex objects that often have a large number of different elements, such as frames, panels, and window infills. The settings for these elements are defined in the door/window assembly style and can be modified using Style Manager. However, there are cases when modifying a door/window assembly directly on screen is more suitable:

- You want to add custom frame or mullion edges to a door/window assembly and need direct visual feedback.
- You want to create an override, like a merged infill or an irregular panel shape in only one specific place in the door/window assembly.
- You want to experiment with different visuals without having to change the door/window assembly style for each idea immediately.

When you have finished your onscreen edits, you can decide if you want to

- apply the overrides to the door/window assembly you have edited.
- save the overrides to the current door/window assembly style.
- create a new style for the overrides.

NOTE You cannot modify a definition using the Override method. For information about modifying definitions, see [Modifying Element Definitions for Door and Window Assembly Styles](#) on page 1185.

Overrides do not affect the door/window assembly design rules. However, you can transfer overrides to a door/window assembly style when you want all door/window assemblies of that style to have the same overrides.

You can view a list of overrides that are currently assigned to a door/window assembly from the Overrides tab of the Door/Window Assembly Properties dialog box. For more information, see [Creating a Division Override](#) on page 1181.

NOTE Overrides are also listed on the Overrides tab in the Door/Window Assembly Style Properties dialog box.

Overriding Door and Window Assembly Infills

The cell infills of a door/window assembly are set in the door/window assembly style. You can, however, create overrides for these infills in cells. For example, you might want a row of glider windows for a first floor facade. In one specific position, however, you want a frosted glass window. In this case, you would set the row of glider windows in the door/window assembly style, and then override the infill style in one specific cell with a frosted glass window.

Door/window assembly infills can consist of simple panels, objects like windows or doors, or nested grids. You can change one infill for another, merge cells, or remove the frame from an infill altogether. This would be useful if you add a door into a grid cell and want to remove the bottom frame from that cell.

Turning on Cell Markers

Use this procedure to turn on the cell markers for each grid cell in a door/window assembly. The cell markers must be on in order to select individual cells and make changes to them.

Viewing Door/Window Assembly cell markers

- 1 Select the door/window assembly for which you want to create an infill override.
- 2 Right-click, and click Infill ► Show Markers.

Merging Door and Window Assembly Cells

Use this procedure to merge two door/window assembly cells.

NOTE To merge door/window assembly cells, the cell markers need to be visible. For information on turning on cell markers, see [Turning on Cell Markers](#) on page 1168.

You can only merge cells that are adjacent to each other.

In most cases, you merge cells with the same infill type. The merged cell is then of the same type as the original cells. For example, if you merge two solid panel infills, the resulting merged cell also has a solid panel infill. In some cases however, you might want to merge two cells that have different infill types. In that case, the infill type of the first selected cell is used for the merged cell. For example, if you want to merge a cell with a simple panel infill and a cell with a window infill, and you select the cell with the simple panel first during the merge command, the merged cell contains a simple panel infill, not a window. If you select the two cells in the opposite order, the merged cell contains a window and no simple panel infill.

Merging two Door/Window Assembly cells

select cell A

select cell B

result

- 1 Select the door/window assembly on which you want to merge two cells.
- 2 Right-click, and click Infill ► Merge.
- 3 Select the first cell to be merged.
- 4 Select the second cell to be merged.

The cells are merged into one.

5 Specify where you want to save the door/window assembly override:

If you want to save the override...	Then...
only on this specific door/window assembly	no further steps are necessary. The override is saved to the door/window assembly. For information about how to remove an override from a door/window assembly, see Creating a Division Override on page 1181.
save the override to a door/window assembly style	select the door/window assembly, right-click, and select Design Rules ► Transfer to Object.

6 If you chose to save the override to a door/window assembly style, select the door/window assembly again, right-click, and click Design Rules ► Save to Style. Then choose the door/window assembly style in which to save the override.

If you want to...	Then...
save the override to the current door/window assembly style	select Transfer Merge Operations to Style, and click OK. NOTE If you have created only a cell merge, only the Transfer Merge Operations to Style check box is active. If you have also created other overrides, such as a new cell assignment or a frame or mullion edge override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.
save the override to a new door/window assembly style	select Transfer Merge Operations to Style, and click New. Then, enter a name for the new door/window assembly style, and click OK. NOTE If you have created only a cell merge, only the Transfer Merge Operations to Style check box is active. If you have also created other overrides, such as a new cell assignment or a frame or mullion edge override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.

NOTE If you do not want to save the override back to a style at all, right-click, and click Design Rules ► Revert to Style Design Rules. The overrides still remain on the door/window assembly, where they can be removed as described in [Creating a Division Override](#) on page 1181, but they are not saved back to a door/window assembly style.

Creating a Door and Window Assembly Infill Override

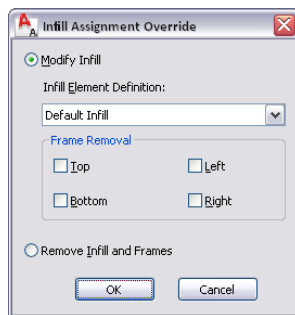

Use this procedure to override the infill of a door/window assembly cell.

For example, you might have a row of simple concrete panels in your door/window assembly, but want in one location a round window instead of the concrete panel. In that case, it might be simpler to use an infill override, instead of creating complex door/window assembly definitions.

NOTE To override an infill assignment, the cell markers must be visible. For information on turning on cell markers, see [Turning on Cell Markers](#) on page 1168.

To exchange an infill definition, the new infill definition must already be defined in the curtain wall style. For information on creating infill definitions, see [Defining Infills for Door and Window Assembly Cells](#) on page 1132.

- 1 Select the door/window assembly on which you want to override an infill.
- 2 Right-click, and click **Infill** ► **Override Assignment**.
- 3 Select the marker of the cell(s) where you want to create an override, and press **ENTER**.

- 4 Create the override:

If you want to...

Then...

exchange the existing infill for another

select a new infill definition from the list.

remove one or more of the frames around the infill

select the frame component to be removed. You could, for example, override a cell to contain a door infill instead of a panel infill; in this case, you would want to remove the bottom frame of the cell.

remove the complete infill and its frame

select Remove Infill and Frames.

NOTE This works only for infills that border the exterior of the door/window assembly.

- 5 Click OK.

- 6 Specify where you want to save the door/window assembly override:

If you want to...

Then...

save the override only on this specific door/window assembly

no further steps are necessary. The override is saved to the door/window assembly. For information about

If you want to...	Then...
save the override to a door/window assembly style	<p>how to remove an override from a door/window assembly, see Creating a Division Override on page 1181.</p> <p>select the door/window assembly, right-click, and select Design Rules ► Transfer to Object.</p>
<p>7 If you have chosen to save the override to a door/window assembly style, select the door/window assembly again, right-click, and click Design Rules ► Save to Style and decide to which door/window assembly style you want to save the override.</p>	
If you want to...	Then...
save the override to the current door/window assembly style	<p>select Transfer Cell Overrides to Style, and click OK.</p> <p>NOTE If you have created only an infill override, only the Transfer Cell Overrides to Style check box is active. If you have also created other overrides, such as a cell merge or a frame or mullion edge override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.</p>
save the override to a new door/window assembly style	<p>select Transfer Cell Overrides to Style, and click New. Then, enter a name for the new door/window assembly style, and click OK.</p> <p>NOTE If you have created only an infill override, only the Transfer Cell Overrides to Style check box is active. If you have also created other overrides, such as a cell merge or a frame or mullion edge override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.</p>
<p>NOTE If you do not want to save the override back to a style at all, right-click, and click Design Rules ► Revert to Style Design Rules. The overrides remain on the door/window assembly, where they can be removed as described in Creating a Division Override on page 1181, but they are not saved back to a door/window assembly style.</p>	

In-Place Editing of Door and Window Assembly Cells

Use this procedure to edit door/window assembly cells using in-place editing with the Edit Grid grip. With in-place editing, you can edit individual cells, bays, columns, or nested grids of the door/window assembly directly and interactively in the drawing area, and later save the changes to the door/window assembly or door/window assembly style.

- 1 Select a door/window assembly on which you want to edit cells with in-place editing.

2 Specify the mode in which to edit the door/window assembly:

If you want to edit ...	Then ...
this instance of the door/window assembly	right-click, and click Design Rules ► Transfer to Object.
the door/window assembly style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the door/window assembly.

3 Click the Edit Grid grip.

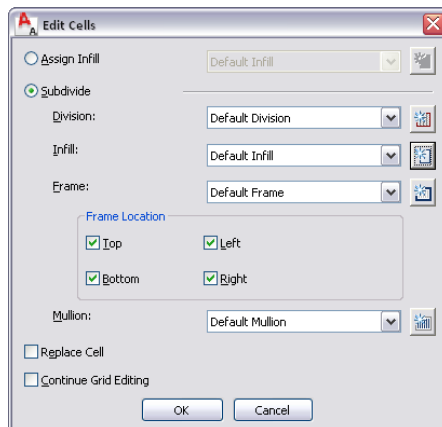

4 Enter c (Cell) and press ENTER.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

5 Select the individual cells, bay, column, or nested grid to modify the cell assignment by hovering over a cell or pressing TAB, and press ENTER.

Press **CTRL** to select multiple cells, bays, columns or nested grids.

The Edit Cells worksheet displays.

6 Edit the cell for the selected grid:

If you want to...	Then...
assign an infill to selected cells	select Assign Infill and select an infill definition. Clear Replace Cell and click OK.
replace the selected cells with a new infill	select Assign Infill and select an infill definition. Select Replace Cell and click OK.
create and assign a new infill to the selected cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning Infills to Door and Window Assembly Cells on page 1147.

If you want to...	Then...
divide the selected cells with divisions, infills or frames	select Subdivision.
add a division to the subdivided cells	select a division definition.
create and assign a new division to the selected cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning a Division to a Door and Window Assembly Grid on page 1146.
select an infill for the subdivided cells	select an infill definition.
create and assign a new infill to the subdivided cells	click  and specify values on the Design Rules worksheet. For more information, see Assigning Infills to Door and Window Assembly Cells on page 1147.
select a frame definition for the grid created after the cell is subdivided	select the frame definition and click OK.
specify the location of frames on the grid created after the cell is subdivided	select Top, Bottom, Left, Right for Frame Location and click OK.
create and assign a new frame definition for the new grid created after the cell is subdivided	click  and specify values on the Design Rules worksheet. For more information, see Adding a New Frame Assignment to a Door and Window Assembly Grid on page 1156.
select a mullion definition for the grid created after the cell is subdivided	select the mullion definition.
create and assign a new mullion definition to the selected grid	click  and specify values on the Design Rules worksheet. For more information, see Adding a New Mullion Assignment to a Door and Window Assembly Style on page 1159.
replace the existing cell infill with the options selected on this worksheet	select Replace Cell.
continue in-place editing the grid after the cell is subdivided	select Continue Grid Editing.

7 Click OK.

8 Press *ENTER*.

Overriding Door and Window Assembly Frames and Mullions

You can change a selected frame edge or mullion edge by using an edge assignment override.

NOTE To exchange a frame edge or mullion edge, the new edge definition must already be defined in the door/window assembly style.

Removing the edge does not affect the width of the cell. To remove the edge and have the adjacent cell resize, create an edge definition with a width and depth of zero. For more information, see [Defining a Door and Window Assembly Frame by Width and Depth](#) on page 1138 or [Defining Door and Window Assembly Mullions by Width and Depth](#) on page 1142.

You can also create a new edge profile by drawing a polyline or using an existing profile in the drawing. This edge profile can be interactively edited onscreen by in-place editing.

Creating a Frame or Mullion Override

Use this procedure to select a different element definition for a selected frame edge or mullion by using an edge assignment override.

To exchange a frame or mullion, the new definition must already be defined in the door/window assembly style. For information on creating frames and mullions, see [Defining Door and Window Assembly Frames](#) on page 1137 and [Defining Door and Window Assembly Mullions](#) on page 1142.

Overriding a Door/Window Assembly frame definition

- 1 Select the door/window assembly on which you want to override an edge.
- 2 Right-click, and click Frame/Mullion ► Override Assignment.
- 3 Select the frame or mullion edge you want to override.
- 4 Create the override:

If you want to...	Then...
exchange the existing edge for another	select a new edge definition from the list.
remove the frame or mullion edge	select Remove.

- 5 Click OK.

- 6 Specify where you want to save the door/window assembly override:

If you want to...	Then...
save the override only on this specific door/window assembly	no further steps are necessary. The override is saved to the door/window assembly. For information about

If you want to...	Then...
save the override to a door/window assembly style	<p>how to remove an override from a door/window assembly, see Creating a Division Override on page 1181.</p> <p>select the door/window assembly, right-click, and select Design Rules ► Transfer to Object.</p>
<p>7 If you have chosen to save the override to a door/window assembly style, select the door/window assembly again, right-click, and click Design Rules ► Save to Style and decide to which door/window assembly style you want to save the override.</p>	
If you want to...	Then...
save the override to the current door/window assembly style	<p>select Transfer Edge Overrides to Style, and click OK.</p> <p>NOTE If you have created only a frame or mullion edge override, only the Transfer Edge Overrides to Style check box is active. If you have also created other overrides, such as a cell merge or a division override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.</p>
save the override to a new door/window assembly style	<p>select Transfer Edge Overrides to Style, and click New. Then, enter a name for the new door/window assembly style, and click OK.</p> <p>NOTE If you have created only a frame or mullion edge override, only the Transfer Edge Overrides to Style check box is active. If you have also created other overrides, such as a cell merge or a division override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.</p>
<p>NOTE If you do not want to save the override back to a style at all, right-click, and click Design Rules ► Revert to Style Design Rules. The overrides remain on the door/window assembly, where they can be removed as described in Creating a Division Override on page 1181, but they are not saved back to a door/window assembly style.</p>	

Creating a Frame or Mullion Edge from a Polyline or Profile Using In-Place Editing

Use this procedure to assign a profile to a vertical edge of a frame or mullion. The profile can be any profile or any closed polyline that you specify. You can use a profile edge to create a unique corner in situations where a simple miter is not sufficient.

NOTE Adjacent infills are not trimmed or expanded to accommodate the new edge. To adjust the infill, change the width of the frame edge. For more information, see [Defining a Door and Window Assembly Frame by Width and Depth](#) on page 1138.

1 Draw a closed polyline in the location where you want it to display in the door/window assembly.

NOTE For best results, it is recommended to draw the polyline in Plan view.

2 Select the door/window assembly for which you want to create a frame or mullion edge profile override.

3 Right-click, and click Frame/Mullion ► Add Profile.

4 Specify the mode in which to edit the door/window assembly:

If you want to edit...

Then...

this instance of the door/window assembly

right-click, and click Design Rules ► Transfer to Object.

the door/window assembly style

right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the door/window assembly.

5 Right-click, and click Frame/Mullion ► Add Profile.

6 Select a vertical frame or a mullion edge.

7 Select a profile for the override:

If you want to create the edge profile from... Then...

the polyline drawn in step 1

select Start from scratch for Profile Definition, and enter a name for New Profile Name.

an existing profile in the drawing

select the existing profile for Profile Definition.

8 Select whether to apply the profile to the shared edge element definition or as an edge profile override.

9 Click OK.

You are now in in-place edit mode, and can edit the profile. For more information, see [In-Place Editing of Edge Profiles for Door/Window Assemblies](#) on page 1178.

10 On the In-Place Edit toolbar, click  to zoom to the profile.

11 Select the profile and edit it using Edge and Vertex grips, or by using the right-click shortcut menu.

12 Save or discard changes to the door/window assembly grid:

If you want to exit the in-place editing session...

Then...

without saving your changes

click  on the In-Place Edit toolbar.

If you want to exit the in-place editing session...	Then...
--	----------------

after saving your changes

click  on the In-Place Edit toolbar.

In-Place Editing of Edge Profiles for Door/Window Assemblies

Use this procedure to edit profile edges using in-place editing. With in-place editing, you can edit the door/window assembly directly and interactively in the drawing area and later save the changes to the profile definition.

- 1 Select the door/window assembly that has the edge profile you want to edit onscreen with in-place editing.
- 2 Right-click, and click Frame/Mullion ► Edit Profile in Place.
This command is only available if you have profile-based edges in the door/window assembly.

NOTE If the profile is not drawn to size, it must be converted in order for you to begin the in-place editing session. Click Yes if prompted to convert the profile to its actual size.

- 3 Select the edge you want to edit.

NOTE You have entered the in-place editing session now. You can see this from the magenta-colored grips and light blue hatch of the temporary in-place editing profile, as well as the faded color of all other objects in the drawing. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

- 4 Edit the profile:

If you want to...	Then...
--------------------------	----------------

use grips to edit the profile

move the grips as needed.

The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.

Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.

Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.

If you want to...	Then...
add a vertex to the profile	select an Edge grip, and press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press <i>ENTER</i> .
remove a vertex from the profile	select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.
add a ring to the profile	select the profile, right-click, and click Add Ring. Then, select a closed polyline, spline, ellipse, or circle for an additional ring. Specify if you want to erase the source linework, and press <i>Enter</i> .
remove a ring from a profile	select the profile, right-click, and click Remove Ring. Then select the ring you want to remove. NOTE You cannot remove the last ring from a profile.
replace a ring on a profile	select the profile, right-click, and click Replace Ring. Then, select a closed polyline, spline, ellipse, or circle for the replaced ring. Specify if you want to erase the source linework, and press <i>Enter</i> .

5 Save the changes to the profile:

If you want to...	Then...
change the existing profile definition to reflect the new shape	click  on the In-Place Edit toolbar.
create a new profile definition with the shape you have created	select the profile, right-click, and click Save As New Profile. Then, enter a name for the new profile and click OK. The in-place edit session is exited and the new profile definition is available in the Style Manager.
discard all changes on the profile and revert back to the previous shape	click  on the In-Place Edit toolbar.

In-Place Editing of Door and Window Assembly Frames and Mullions

Use this procedure to edit frames and mullions using in-place editing with the Edit Grid grip. With in-place editing, you can edit bays, columns or nested grids of the door/window assembly directly and interactively in the drawing area, and later save the changes to the door/window assembly or door/window assembly style.

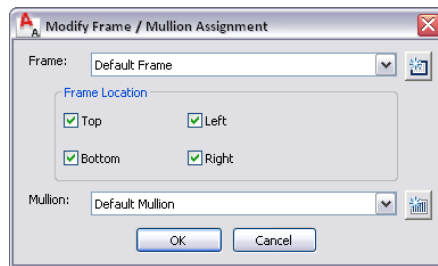

- 1 Select a door/window assembly on which you want to edit frames or mullions with in-place editing.
- 2 Specify the mode in which to edit the door/window assembly:

If you want to edit ...	Then ...
this instance of the door/window assembly	right-click, and click Design Rules ► Transfer to Object.
the door/window assembly style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the door/window assembly.

- 3 Click the Edit Grid grip.
- 4 Enter **f** (Frame and mullion assignment) and press *ENTER*.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

- 5 Select the bay, column or nested grid to modify the frame and mullion assignment and press *ENTER*.
Press *CTRL* to select multiple bays, columns or nested grids.
The Modify Frame/Mullion Assignment worksheet displays.

- 6 Select a frame definition for the selected grid:

If you want to...	Then...
modify the frame of the selected grid	select a frame definition and click OK.
specify the location of the frame on the selected grid	select Top, Bottom, Left, Right for Frame Location and click OK.
create and assign a new frame definition to the selected grid	click  . For more information, see Adding a New Frame Assignment to a Door and Window Assembly Grid on page 1156.

7 Select the mullion definition for the selected grid:

If you want to...

Then...

modify the mullion of the selected grid

select the mullion definition and click OK.

create and assign a new mullion definition to the selected grid

click  and complete the Design Rules worksheet.

For more information, see [Adding a New Mullion Assignment to a Door and Window Assembly Style](#) on page 1159.

8 Press *ENTER*.

Overriding Door and Window Assembly Divisions

The grid of a door/window assembly is made up of one or more divisions that define how the door/window assembly is partitioned. Divisions can be horizontal or vertical, and can be nested in each other. For detailed information on door/window assembly divisions, see [Creating a Division Definition for a Door and Window Assembly](#) on page 1125.

You can override a division in a door/window assembly, thereby changing the grid of the door/window assembly.

Overriding a Door/Window Assembly cell division definition

five cell horizontal grid and three cell vertical grid before override

five cell horizontal grid and six cell vertical grid after override

Creating a Division Override

Use this procedure to create a division override on a door/window assembly.

NOTE To exchange a door/window assembly division, the new division definition must already be defined in the door/window assembly style. For information on door/window assembly divisions, see [Division of Door and Window Assembly Grids](#) on page 1125.

- 1 Select the door/window assembly for which you want to create a division override.
- 2 Right-click, and click **Division** ► **Override Assignment**.
- 3 Select an edge of the door/window assembly to determine if a horizontal or vertical division is overridden.
For example, if you want to override the primary horizontal division, you could select the bottom horizontal frame of the door/window assembly.

TIP The Division Assignment Override dialog box shows you which grid type and which grid division you have selected, e.g. Selected Nested Grid: Secondary Grid, Division Element Definition: Vertical 3 Cells. If you have accidentally selected the wrong division, click Cancel and reselect the correct grid.

4 Select the division to override, and click OK.

5 Specify where you want to save the door/window assembly override:

If you want to save the override...	Then...
only on this specific door/window assembly	no further steps are necessary. The override is saved to the door/window assembly. For information about how to remove an override from a door/window assembly, see Removing Door and Window Assembly Overrides on page 1184.
to a door/window assembly style	select the door/window assembly, right-click, and select Design Rules ► Transfer to Object.

6 If you have chosen to save the override to a door/window assembly style, select the door/window assembly again, right-click, and click Design Rules ► Save to Style and decide to which door/window assembly style you want to save the override.

If you want to...	Then...
save the override to the current door/window assembly style	select Transfer Division Overrides to Style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Division Overrides to Style check box is active. If you have also created other overrides, such as a cell merge or a edge override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.
save the override to a new door/window assembly style	select Transfer Division Overrides to Style, and click New. Then, enter a name for the new door/window assembly style, and click OK. NOTE If you have created only a profile edge override, only the Transfer Division Overrides to Style check box is active. If you have also created other overrides, such as a cell merge or a edge override, these check boxes are available as well. If you also want to save these overrides to the style, select their check boxes too.

NOTE If you do not want to save the override back to a style at all, right-click, and click Design Rules ► Revert to Style Design Rules. The overrides remain on the door/window assembly, where they can be removed as described in [Removing Door and Window Assembly Overrides](#) on page 1184, but they are not saved back to a door/window assembly style.

In-Place Editing of Door and Window Assembly Divisions

Use this procedure to edit divisions using in-place editing with the Edit Grid grip. With in-place editing, you can edit the door/window assembly directly and interactively in the drawing area, and later save the changes to the door/window assembly or door/window assembly style. For more information, see [Division of Door and Window Assembly Grids](#) on page 1125.

1 Select a door/window assembly on which you want to edit divisions onscreen with in-place editing.

2 Specify the mode in which to edit the door/window assembly:

If you want to...	Then...
edit this instance of the door/window assembly	right-click, and click Design Rules ► Transfer to Object.
edit the door/window assembly style	right-click, and click Design Rules ► Revert to Style Design Rules. If this option is not available, the design rules are already style-based for the door/window assembly.

3 Click the Edit Grid grip.

4 Enter **d** (Division in place) and press *ENTER*.

For example, if you want to edit the primary grid, select an edge on the outer door/window assembly frame.

NOTE You have entered the in-place editing session now. You can see this from the faded color of all objects in the drawing, as well as from the different grips at your disposal. Note that while you are in the in-place editing session, you have only limited editing access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

Viewing Edit In Place grips

5 Edit the division:

If you want to...	Then...
add a bay to the grid	click the Add Bay grip.
remove a bay from the grid	click the Remove Bay grip.
change the start offset of the grid	select the Start Offset grip and move it to the appropriate position.

If you want to...	Then...
change the end offset of the grid	select the End Offset grip and move it to the appropriate position.
change the spacing of bays	click the Auto Grid Bay Spacing grip and move it to the appropriate position.
manually edit the grid	right-click, and click Convert To Manual. You can manually add and remove gridlines, change the offsets, and change the position of individual gridlines.
use a worksheet to edit the cell dimensions	click the Set Fixed Cell Dimension Rules command grip, and edit the values in the worksheet.

6 Save or discard changes to the door/window assembly grid:

If you want to...	Then...
exit the in-place editing session without saving your changes	click  on the In-Place Edit toolbar.
exit the in-place editing session after saving your changes	click  on the In-Place Edit toolbar. If you edited the grid by instance, the changes are saved to the design rules for the individual grid. If you edited the door/window assembly style, the Save Changes dialog box is displayed.

7 In the Save Changes dialog box, specify to which division to save the changes:

If you want to...	Then...
save the changes to the style in the current door/window assembly division	verify the current division is selected for Save Changes to Existing Division, and click Save. The changes are made in the style and affect all door/window assemblies of that style in the drawing.
create an override to the style by saving the changes in a new door/window assembly division	click New, enter a name for the new division override, and click OK. Click Save. The changes are saved as an override to the style, and affect only the door/window assemblies to which the override is applied.

Removing Door and Window Assembly Overrides

Use this procedure to remove door/window assembly overrides either from the door/window assembly or the door/window assembly style.

1 Select the door/window assembly:

If you want to...

Then...

remove an override from a door/window assembly

select the door/window assembly, expand Advanced in the Properties palette, and click Overrides.

remove an override from the door/window assembly style

select the door/window assembly, right-click, and click Edit Door/Window Assembly Style. Then click the Overrides tab.

2 Select an override from the list and click Remove.

3 Click OK.

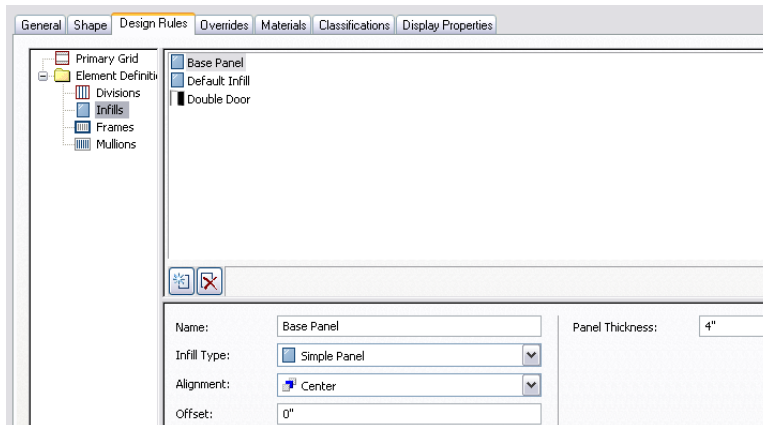

Modifying Element Definitions for Door and Window Assembly Styles

You can modify element definitions using the Design Rules tab of the Door/Window Assembly Style Properties dialog box. You can access these definitions from the assignments list and from the definitions list:

- **From the assignments list:** Select a grid from the tree view to display the assignments list. Then select an assignment that uses that definition. Make your changes below the assignment list.

- **From the definitions list:** Select an element type from the tree view to display all definitions for that element type. Select a definition and make your changes below the definitions list.

Any changes you make, including changes to the definition name, overwrite the existing definition. To create a new definition from the assignments list, select New from the Element list. To create a new definition from the definitions list, click the New Division icon, the New Infill icon, the New Frame icon, or the New Mullion icon.

Editing Door and Window Assemblies

Most relevant settings for a door/window assembly are defined in the door/window assembly style. These settings include divisions, infills, frames, and mullions. For information on modifying a door/window assembly style, see [Door and Window Assembly Styles](#) on page 1120.

You can make other changes directly to individual door/window assemblies, which affect only the door/window assembly you select:

- The dimensions of a door/window assembly
- Interference conditions
- Cleanup settings

Methods of Editing Door and Window Assemblies

AutoCAD Architecture offers several methods for editing door/window assemblies:

- You can directly edit door/window assemblies using grips for dimensions and other physical characteristics.
- You can directly edit door/window assemblies using the Edit Grid grip for grid divisions, cells, frames, and mullions. For more information, see [In-Place Editing of Door and Window Assembly Divisions](#) on page 1183, [In-Place Editing of Edge Profiles for Door/Window Assemblies](#) on page 1178, and [Overriding Door and Window Assembly Infills](#) on page 1168.
- You can change door/window assembly settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- You can select editing commands from the shortcut menu for a selected door/window assembly.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.

NOTE For information about changing the elements within a door/window assembly, see [Using Overrides in Door and Window Assemblies](#) on page 1168. For information about changing the display of the door/window assemblies, see [Specifying the Display of Door and Window Assemblies](#) on page 1162.

Using Grips to Edit Door and Window Assemblies

There are many different door/window assembly grips. The grips that appear in your drawing when you select a door/window assembly are dependent upon the design rules of the door/window assembly.

Editing Door/Window Assembly Dimensions

Use this procedure to change the dimensions of a door/window assembly.

- 1 Select the door/window assembly.
- 2 Select the grip for the dimension you want to change.
You can modify the dimensions of the base height and width for a door/window assembly.

Viewing Door/Window Assembly Grips

3 Move the grip until the dimension value you want is displayed, and click once, or enter a value.

Changing the Location of a Door/Window Assembly

Use this procedure to change the location or the position of a door/window assembly with grips.

- 1 Select the door/window assembly.
- 2 Select and hold the Location grip:

If you want to move the door/window assembly...

Then...

along the length of the wall

drag the cursor to the new location.

within the width of the wall

press *CTRL*, and drag the cursor to the new location.

vertically

press *CTRL* twice, and drag the cursor to the new location.

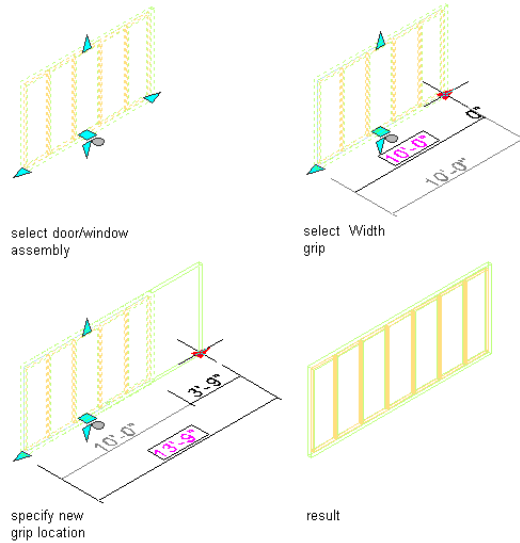

Changing the Width of a Door and Window Assembly

Use this procedure to change the width of a door/window assembly with grips.

- 1 Select the door/window assembly.
- 2 Select the Width grip, move the grip until the width value you want is displayed, and click once.

NOTE As you move the grip, the original width value is displayed in addition to the new width and the difference between the two values.

Using grips the change the width of a Door/Window Assembly

After selecting the grip, you can also enter a value to be added to or subtracted from the width of the door/window assembly, depending on the direction in which you move the grip.

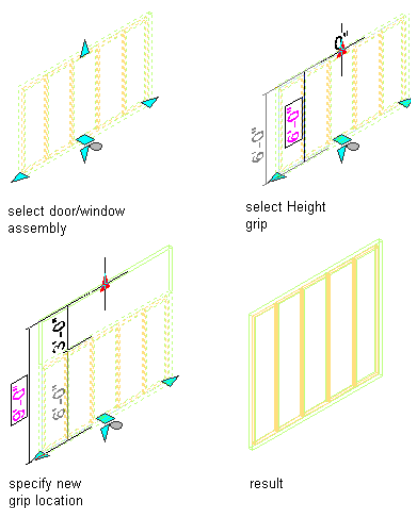

Changing the Height of a Door and Window Assembly

Use this procedure to change the height of a door/window assembly with grips.

- 1 Select the door/window assembly.
- 2 Select the Height grip, move the grip until the height value you want is displayed, and click once.

NOTE As you move the grip, the original height value is displayed in addition to the new height and the difference between the two values.

Using grips to change the height of a Door/Window Assembly

After selecting the grip, you can also enter a value to be added to or subtracted from the height of the door/window assembly, depending on the direction in which you move the grip.

Changing the Location Properties of a Door and Window Assembly

Use this procedure to change the location properties of a door/window assembly. Location properties include vertical alignment, head height, sill height, and rotation.

Location Property	Description
Vertical alignment	Specifies whether to measure the vertical height of the window to the sill or head
Head height	The head height of the window
Sill height	The sill height of the window
Rotation	Reference angle for the object

- 1 Double-click the door/window assembly.
- 2 Expand Location.
- 3 Change the location properties.
- 4 Select Additional information to display the Location worksheet, where you can change additional location properties, such as coordinate system, insertion point, and normal.

Selecting a Different Door and Window Assembly Style

Use this procedure to select a different style for a door/window assembly.

- 1 Double-click the door/window assembly for which you want to change the styles.
You can select multiple door/window assemblies and change the style for all at the same time.
- 2 Expand General.
- 3 Select a different style.

Matching the Properties of an Existing Door and Window Assembly

Use this procedure to apply the properties of a door/window assembly tool to one or more existing door/window assemblies. The properties include the door/window assembly style and any other settings specified in the tool you select.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a door/window assembly tool, and click Apply Tool Properties to ► Door/Window Assembly.
- 3 Select the door/window assemblies, and press *ENTER*.
The properties of the selected door/window assemblies match the properties of the door/window assembly tool.

Changing the Door and Window Assembly Dimensions

Use this procedure to change the dimensions of a door/window assembly.

- 1 Double-click a door/window assembly.
- 2 Expand Dimensions.
- 3 Change the dimensions:

Dimension	Description
Length	The distance from the start point to the end point of the door/window assembly baseline.
Height	The distance from the baseline to the top of the door/window assembly, including any rise.
Rise	The distance from the base height to the top of the door/window assembly.
Start Miter	Angle of all infills and horizontal edges (frame or mullion) at the start of the door/window assembly. For more information about miter angles, see Mitering Door and Window Assemblies on page 1192.
End Miter	Angle of all infills and horizontal edges (frame or mullion) at the end of the door/window assembly.

Changing the Shape of a Door and Window Assembly

Use this procedure to change the shape of a door/window assembly. There are several predefined shapes for door/window assemblies. You can use any of these shapes or use an AEC profile as the shape. For more information about profiles, see [Creating a Profile for a Door and Window Assembly Frame](#) on page 1139.

- 1 Select a door/window assembly, right-click, and click Edit Door/Window Assembly Style.
- 2 Click the Shape tab.
- 3 Select a shape from the Predefined list or select Use Profile, and select an existing AEC Profile as the shape.
- 4 Click OK.

Changing the Location of a Freestanding Door and Window Assembly

You can relocate an existing door/window assembly by changing the coordinate values of its insertion point. The door/window assembly also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the door/window assembly are parallel to the XY plane, its normal is parallel to the Z axis. You can change the orientation of the door/window assembly by aligning its normal with another axis. You can also rotate the door/window assembly on its plane by changing the rotation angle.

For more information about the world coordinate system, see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

1 Double-click the door/window assembly.

2 Expand Location.

3 Click Additional information.

4 Specify the location of the door/window assembly:

If you want to...	Then...
relocate the door/window assembly	enter new coordinate values under Insertion Point.
locate the door/window assembly on the <i>XY</i> plane	make the normal of the door/window assembly parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the door/window assembly on the <i>YZ</i> plane	make the normal of the door/window assembly parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> , and enter 0 for <i>Y</i> and <i>Z</i> .
locate the door/window assembly on the <i>XZ</i> plane	make the normal of the door/window assembly parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the door/window assembly	enter a new value for Rotation Angle.

5 Click OK.

Adding an Interference Condition to a Door and Window Assembly

Use this procedure to add an interference condition to a door/window assembly. Interference conditions use the geometry of 3D objects to create custom openings or cutouts in door/window assemblies. You can specify how the interference condition is applied to the door/window assembly: added to the door/window assembly, subtracted from the door/window assembly, or ignored.

1 Place the object in the location where you want to specify the interference condition.

2 Select the door/window assembly to which you want to add an interference condition, right-click, and click Interference ► Add.

3 Select the object intersecting the door/window assembly, and press *ENTER*.

4 Specify to which door/window assembly component the interference should be added:

If you want to add the interference condition...	Then...
to the infill	enter y (Yes) when prompted for the infill component.
to the frame	enter y (Yes) when prompted for the frame component.
to the mullion	enter y (Yes) when prompted for the mullion component.

5 Press *ENTER*.

Removing an Interference Condition from a Door and Window Assembly

Use this procedure to remove an object, such as a mass element, from a door/window assembly that the object was added to as an interference condition.

- 1 Select the door/window assembly from which you want to remove an interference object, right-click, and click Interference ► Remove.
- 2 Select the object intersecting the door/window assembly, and press *ENTER*.

Mitering Door and Window Assemblies

Use this procedure to miter the corners where door/window assemblies meet. The corner where adjacent door/window assemblies meet is not mitered by default. However, you can automatically determine the necessary angles.

The miter angle applies to all infills and horizontal edges (frame or mullion) that are adjacent to the corner. Vertical edges are not affected.

TIP If you want to create a custom corner condition between two door/window assemblies, you can replace the edge of one door/window assembly with an AEC profile and remove the edge of the other door/window assembly by using the frame override Remove Edge option. For more information, see [Overriding Door and Window Assembly Frames and Mullions](#) on page 1175 and [Defining Door and Window Assembly Frames](#) on page 1137.

- 1 Select one of the door/window assemblies, right-click, and click Set Miter Angles.
- 2 Select the other door/window assembly.
If you change the angle of either door/window assembly, use Set Miter Angles again to recalculate the angles.

Specifying a Miter Angle for a Door and Window Assembly Adjacent to Another Object

Use this procedure to manually create a mitered corner between a door/window assembly and another object, such as a standard wall or a mass element. For example, if your door/window assembly connects with a standard wall that is at a 60-degree angle from the door/window assembly, you would set the miter angle to 30.

The miter angle is applied to all infills and horizontal edges that are adjacent to the corner. Vertical edges are not affected.

- 1 Double-click the door/window assembly.
- 2 Expand Dimensions.
- 3 Miter the door/window assembly on the start or the end point:

If you want to miter the door/window assembly...

Then...

at its start point

enter an angle for Start Miter, and press *ENTER*.

at its end point

enter an angle for End Miter, and press *ENTER*.

Specifying the Cut Plane Display of a Door and Window Assembly

Use this procedure to specify the properties of one or more cut planes for an individual door and window assembly. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the door and window assembly you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all door and window assemblies in the drawing, select Drawing default setting. To apply changes to all assemblies of this style, select Door/Window Assembly Style:<style name>. For more information on styles, see [Door and Window Assembly Styles](#) on page 1120.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)
- 8 For Use cut plane of containing object when anchored, specify whether you want the containing object's cut plane to be used when the assembly is anchored to that object.

- 9 To define additional cut planes for the assembly, click  Manual cut planes.
- 10 On the Manual Above and Below Cut Plane Heights worksheet, click Add, and under Cut Plane, enter the height of the new cut plane.

If you add a cut plane ...	Then ...
at a height that is lower than the current cut plane	objects are displayed using the Layer/Color/Linetype properties specified for the Below Cut Plane component of the object.
at a height that is higher than the current cut plane	objects are displayed using the Layer/Color/Linetype properties specified for the Above Cut Plane component of the object.

You can click Remove to delete a cut plane that you added.

You can also access and modify these same cut plane settings through the assembly's context menu, as follows

- 1 Select the door and window assembly you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 4 If necessary, click .

- 5 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.
- 6 Click OK twice.

Specifying the Display of Sills for a Door and Window Assembly

Use this procedure to change the sill dimensions for a door and window assembly in the Sill Plan display representation.

- 1 Double-click the door and window assembly.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all door and window assemblies in the drawing, select Drawing default setting. To apply changes to all assemblies of this style, select Door/Window Assembly Style:<style name>. For more information on styles, see [Door and Window Assembly Styles](#) on page 1120.

- 5 For Display representation, select Sill Plan.

- 6 If necessary, expand Object Display Properties ► Advanced, and click  Sill dimensions.

- 7 On the Sill Dimensions worksheet, enter the sill extension and depth dimensions.

Sill components A and B are for the outside of the door and window assembly. Sill components C and D are for the interior side.

- 8 Click OK.
- 9 On the Display component drop-down list, click the light bulb icons for individual sill components to turn visibility on or off as desired.

You can also access and modify sill dimensions and visibility settings through the door and window assembly's context menu, as follows:

- 1 Select the door and window assembly you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 4 If necessary, click .

- 5 Click the Other tab.

Door and window assembly sill dimensions

- 6 Under Sill Dimensions, enter the sill extension and depth dimensions.

- 7 On the Layer/Color/Linetype tab, under Visible, click the icons to turn on visibility for individual sill display components as necessary.
- 8 Click OK twice.

Specifying the Display of Other Characteristics of a Door and Window Assembly

Use this procedure to specify other display properties for an individual door and window assembly, including cell marker size, the display of miters at frame corners, and the display of custom components. If you are going to use custom graphics for a component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the door and window assembly.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all door and window assemblies in the drawing, select Drawing default setting. To apply changes to all assemblies of this style, select Door/Window Assembly Style:<style name>. For more information on styles, see [Door and Window Assembly Styles](#) on page 1120.

- 5 If necessary, expand Object Display Properties ► Advanced.
- 6 If you want to change the size of the markers used for cells in the door/window assembly, click Cell marker size, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new size.)
- 7 Optionally, for Show mitres at frame corners, select Yes/No.
- 8 If you want to add or edit a custom component, for Custom model components (or Custom plan components, if in a plan view), click .
- 9 On the Custom Model (or Plan) Components worksheet, click Add, or select one of the components in the list, and click Edit.
- 10 On the Custom Display Component worksheet, for Component Type, select Infill, Frame, or Mullion.
- 11 Enter a name for Component Name, or click Select Component, and in the Select <component type> Definition dialog, select a definition and click OK.

- 12 Select Draw Custom Graphics.

- 13 Specify the display of the element:

If you want to ...	Then ...
display the block instead of the associated door/window assembly element	select Replace Graphics.
superimpose the block over the door/window assembly element so that both are displayed	clear Replace Graphics.

- 14 Click Select Block, select the custom block that you created, and click OK.

15 Specify further settings for the custom display block:

If you want to ...	Then ...
scale the block to fit a particular dimension	select Width, Height, or Depth. To prevent the block from losing its proportions, select Lock XY Ratio.
specify how the block is inserted into the grid in the X, Y, and Z directions	specify an insertion point on the X, Y, and Z planes.
mirror the block	determine if it should mirror in the X, Y, or Z direction.
offset the block from the grid	specify the offset in the X, Y, or Z direction.

16 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Door and Window Assembly

Use this procedure to enter notes and attach reference files to a door/window assembly. You can also edit notes and edit or detach reference files from a door/window assembly.

- 1 Double-click the door/window assembly.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
For more information about adding hyperlinks, “Add Hyperlinks to a Drawing” in AutoCAD Help.
- 4 To add a note, click the setting for Notes, and enter the text.
- 5 Click OK.
- 6 To attach a reference file, click under Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click Open.
edit the description of a reference file	select the file, and click the description. Enter the new text, and press <i>ENTER</i> .
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

7 Click OK twice.

Editing Objects Anchored in Door and Window Assemblies

When you fill a door/window assembly cell with an infill that contains an object, such as a door or window, you can edit that object independently from the door/window assembly. For example, you can select a door

from a door/window assembly and edit its properties. You can edit the anchor settings for the door to change the orientation of the door and the alignment or offset of the door in relation to the door/window assembly.

You can also move objects from one cell to another or release the object anchor so that the object moves independently of the door/window assembly.

When you move or release an object or edit its properties, you are creating a variation from the infill cell assignment for the door/window assembly style. By default, these variations (except release) are allowed to persist in the drawing when you reapply the style to a door/window assembly. However, if you want these variations to be overridden when you reapply a door/window assembly style, turn off the Allow Variation from Infill Element Definition option on the Anchor worksheet of the object's Properties palette. This option is set on a per object basis.

Changing the Orientation of an Object Anchored in a Door and Window Assembly

Use this procedure to change the orientation of an object anchored in a door/window assembly using grips.

- 1 Click the object in the door/window assembly for which you want to change the orientation.
- 2 Click the appropriate Flip grip to change the X or Y direction of the object.

You can also change the orientation of an object, including the Z direction, using the Anchor worksheet found on the object's Properties palette.

Changing the Alignment of an Object Anchored in a Door and Window Assembly

Use this procedure to modify the alignment of an object that is anchored in a door/window assembly.

- 1 Double-click the object in the door/window assembly.
- 2 Expand Location, and click Anchor.
- 3 Click Allow Variation from Infill Element Definition.
- 4 Select a new alignment for the object.

For more information, see [Specifying an Alignment for a Door and Window Assembly Infill](#) on page 1134.

- 5 Click OK.

Changing the Offset of an Object Anchored in a Door and Window Assembly

Use this procedure to change the offset of an object anchored in a door/window assembly.

- 1 Double-click the object in the door/window assembly.
- 2 Expand Location, and click Anchor.
- 3 Click Allow Variation from Infill Element Definition.
- 4 Specify a new offset for the object.

For more information, see [Specifying an Offset for a Door and Window Assembly Infill](#) on page 1135.

5 Click OK.

Swapping Two Objects Anchored in a Door and Window Assembly

When you fill a door/window assembly cell with an object, such as a door or window, you can swap that object with another object in the door/window assembly.

- 1 Select one of the objects from the door/window assembly and click Infill Anchor ► Swap Objects.
- 2 Select the object you want to swap with.

Releasing an Object Anchored in a Door and Window Assembly

When you fill a door/window assembly cell with an object, such as a door or window, that object is anchored to the door/window assembly. While the anchor is in place, the object moves when you move the door/window assembly and is removed when you erase the door/window assembly. If you want to move or erase an object independently from the door/window assembly, you can release the anchor.

NOTE You can also move or erase the object by changing the element definition for the cell that contains the object. For more information, see [Defining Infills for Door and Window Assembly Cells](#) on page 1132.

- Select one of the objects from the door/window assembly and click Infill Anchor ► Release.

AEC Polygons

21

An AEC Polygon is a two-dimensional (2D) area object that can be used as infill for structures such as curtain walls and layout grids. You can use a True Color display representation to assign a solid fill to the edges and interiors of AEC Polygons, making these objects useful for conceptual rendering.

AEC Polygons

An AEC Polygon is a two-dimensional (2D) area object that can be used as infill for structures such as curtain walls and layout grids. You can use a True Color display representation to assign a solid fill to the edges and interiors of AEC Polygons, making these objects useful for conceptual rendering.

AEC Polygons and Curtain Walls

Curtain walls provide a framework for inserting objects such as panels, windows, and doors. You can use curtain walls to model structures such as the following:

- Large scale curtain walls
- Storefronts with components
- Assemblies of custom-shaped doors and windows

In AutoCAD Architecture, a curtain wall object consists of one or more grids. Each grid contains cells that can be filled by a panel, or by an object such as a window or door. AEC Polygons are ideally suited to create panel infills for curtain walls.

Curtain wall with AEC Polygon infill assignment

curtain wall
with default
infill panel

curtain wall
with AEC
polygon infill

A curtain wall can include curtain wall units. Curtain wall units are similar to curtain walls except that their grid cells can contain only panel infills, and not objects. Curtain wall units are designed to represent complex elements that are repeated within the main curtain wall. You can use AEC Polygons to fill the grids in a curtain wall unit.

Paving and Tiling Patterns

You can use AEC Polygons to create intricate paving and tiling patterns in a drawing. Using the join, subtract, trim, and split functions of AEC Polygons, and by creating AEC Polygons from profiles and polylines, you can create complex and irregular polygon outlines. By adding edges and hatch patterns to the AEC Polygons, you can display a realistic tiling and paving look.

AEC Polygon Style Components

You can use AEC Polygon styles to define the look and edge widths of a polygon. You can use the edges to display framing components of infill panels, or to represent a shadow. Framing components can have different dimensions, casting shadows with different widths along the edges. When you render the curtain wall, you can depict different sun angles with different edge widths.

AEC Polygon components

Polylines and Profiles

Using straight line segments, you can create a freehand AEC Polygon by drawing a closed contour of the object.

Creating an AEC Polygon

To define complex and curved shapes, either convert an existing polyline into an AEC Polygon or use a profile definition as the source of the AEC Polygon.

Converting a polyline to an AEC Polygon

Converting a complex polyline to an AEC Polygon

True Color Display

AEC Polygons have a True Color display representation. When you attach AEC Polygons as infill panels to curtain walls, you can use the True Color display representation to create a conceptual rendering of the curtain wall.

Using AEC Polygon Tools to Create AEC Polygons

Tools provided with AutoCAD Architecture let you quickly place AEC Polygons by selecting an AEC Polygon tool with a specific AEC Polygon style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can also use AEC Polygon tools to create new AEC Polygons by applying tool properties to existing closed polylines.

An AEC Polygon tool is included in the AutoCAD Architecture Stock Tool catalog supplied with the Content Browser. For information about using the Content Browser, see [Understanding the Content Browser](#) on page 121.

Custom palettes created by your CAD manager or other users may also contain AEC Polygon tools with styles and properties customized for your projects or office standards.

Creating an AEC Polygon

Use this procedure to create a new AEC Polygon.

You create an AEC Polygon from straight line segments. The AEC Polygon must have a minimum of three sides and must not intersect itself. The style that you select controls the width and the justification of the AEC Polygon edges. The justification determines whether the edges are displayed inside, outside, or centered on the AEC Polygon vertices.

- 1 Open a tool palette containing an AEC Polygon tool, and select the tool.

To use the AEC Polygon tool supplied in the AutoCAD Architecture Stock Tool catalog, open the Content Browser and navigate to Helper Tools in the Stock Tool catalog; then drag the AEC Polygon to the drawing area. For more information on using a catalog tool, see [Using a Tool in the AutoCAD Architecture 2009 Workspace](#) on page 147.

- 2 Specify the start point of the AEC Polygon.
- 3 Specify further points to define the AEC Polygon.

NOTE You must specify enough points to create at least three sides for the AEC Polygon.

- 4 Enter **c** (Close) to close the AEC Polygon.

Creating an AEC Polygon

Creating an AEC Polygon with User-Specified Settings

Use this procedure to create an AEC Polygon with settings that you specify.

- 1 Open a tool palette containing an AEC Polygon tool, and select the tool.
To use the AEC Polygon tool supplied in the AutoCAD Architecture Stock Tool catalog, open the Content Browser and navigate to Helper Tools in the Stock Tool catalog; then drag the AEC Polygon to the drawing area. For more information on using a catalog tool, see [Using a Tool in the AutoCAD Architecture 2009 Workspace](#) on page 147.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Specify the start point of the AEC Polygon.
- 4 Specify further points to define the AEC Polygon.

NOTE You must specify enough points to create at least three sides for the AEC Polygon.

- 5 Enter **c** (Close) to close the AEC Polygon.

Creating an AEC Polygon from a Polyline

Use this procedure to create an AEC Polygon from a closed polyline in a drawing.

When you create an AEC Polygon by converting a closed polyline in your drawing, the object that you convert can be created from a combination of line and arc segments. The polyline must have a minimum of three sides and must not intersect itself. After you convert the polyline to an AEC Polygon, the width and justification of the AEC Polygon edges are set by the style that you select for the AEC Polygon.

- 1 Draw a polyline in your drawing.
- 2 Open a palette containing an AEC Polygon tool, right-click the tool, and click Apply Tool Properties to ► Closed Polyline.
- 3 Select the polyline that you created in step 1, and press **ENTER**.
- 4 Enter **y** (Yes) to erase the polyline after creating the AEC Polygon, or **n** (No) to keep the polyline in the drawing.
- 5 Press **ENTER**.

Converting a polyline to an AEC Polygon

Creating an AEC Polygon from a Profile

Use this procedure to create an AEC Polygon from a profile definition in a drawing.

The profile definition that you convert can be created from a combination of line and arc segments. The profile definition must have a minimum of three sides and must not intersect itself. After you create an AEC Polygon from the profile definition, the width and justification of the AEC Polygon edges are set by the style that you select for the AEC Polygon. For additional information, see [In-Place Editing of Profile-Based Objects and Components](#) on page 106.

- 1 At the Command prompt, enter **aecpolygon**.
- 2 Enter **c** (Convert) and press *ENTER*.
- 3 Enter **pr** (Profile) and press *ENTER*.
- 4 Select the desired profile definition and click OK.
- 5 Select the insertion point for the new AEC Polygon.
- 6 Press *ENTER*.

Converting a profile to an AEC Polygon

Creating an AEC Polygon Tool

Use this procedure to create an AEC Polygon tool and add it to a tool palette. You may want to create your own AEC Polygon tools if you are placing multiple AEC Polygons of specific styles that have the same properties.

You can use any of the following methods to create an AEC Polygon tool:

- Drag an AEC Polygon with the desired properties to a tool palette.
- Drag an AEC Polygon style from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Copy an existing AEC Polygon tool, and then customize the properties of the new tool.
- Drag an AEC Polygon tool from a tool catalog in the Content Browser to a tool palette, and then customize the properties of the tool.

1 Open the tool palette on which you want to create a tool.

2 Create the tool:

If you want to...	Then...
create a tool from an AEC Polygon in the drawing	select the AEC Polygon and drag it to the tool palette.
create a tool from an AEC Polygon style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy under Multi-Purpose Objects, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current palette	right-click the tool, click Copy, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the tool catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tool's tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic and expand General.

7 Enter a description of the AEC Polygon that you can create using this AEC Polygon tool.

8 Specify a layer key and any layer key overrides, if you do not want to use the layer assignments specified in the layer key style used in the drawing.

9 Select an AEC Polygon style.

10 For Style location, select the drawing file containing the style used for this AEC Polygon, or select Browse and use a standard file selection dialog box to select the file.

11 Click OK.

Editing AEC Polygons

You can change the location of an AEC Polygon, adjust the width and justification of its edges, and change how it is displayed in your drawing. You can also redefine the geometry of an AEC Polygon or define how AEC Polygons interact with each other. You can join two AEC Polygons, create a hole in an AEC Polygon by subtracting the area of another one, create an AEC Polygon from the intersection of two others, divide or trim an AEC Polygon, and add or remove its vertices.

AutoCAD Architecture offers several methods for editing AEC Polygons:

- You can directly edit AEC Polygons using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the

application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.

- You can change AEC Polygon settings on the Properties palette.
- You can select editing commands from the shortcut menu for a selected AEC Polygon.

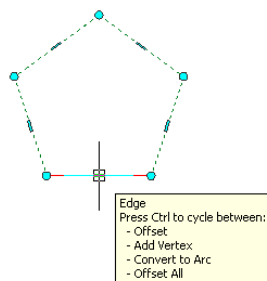

Using Grips to Edit AEC Polygons

Use this procedure to change the shape and size of an AEC Polygon in your current drawing by using grips.

Changing the edge of an AEC Polygon

- 1 Select the AEC Polygon you want to change.
- 2 Select an Edge grip.

Viewing the AEC Polygon Edge grip tooltip

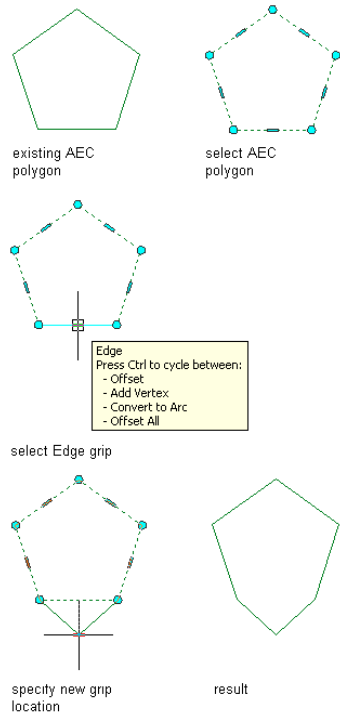

The Edge grip has four edit modes: Offset, Add Vertex, Convert to Arc, and Offset All. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the AEC Polygon and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.

Offsetting the edge of an AEC Polygon using its Edge grip

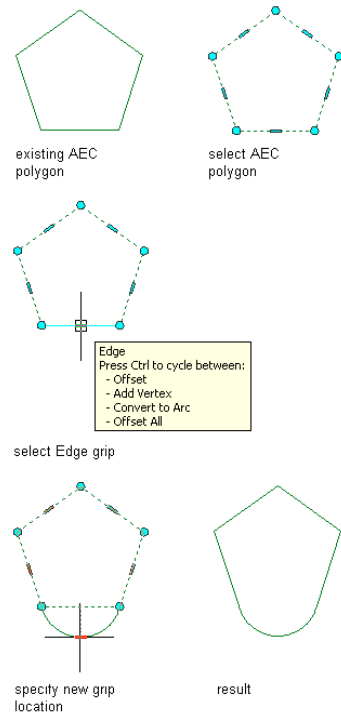

Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.

Adding a vertex to the edge of an AEC Polygon using its Edge grip

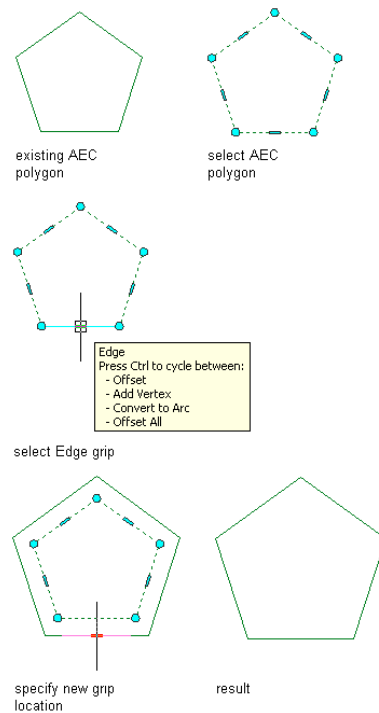

Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.

Converting the edge of an AEC Polygon to an arc using its Edge grip

Offset All moves all edges of an AEC Polygon at an identical distance. When you drag one edge, all other edges are repositioned accordingly. This option is very useful for regular resizing operations, like scaling an AEC Polygon.

Offsetting all the edges of an AEC Polygon using its Edge grip

3 Specify the new edge location:

If you want to...	Then...
offset the edge	move the edge to the desired location and click, or enter a value and press <i>ENTER</i> .
add a vertex and create an edge	press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press <i>ENTER</i> .
change the selected edge to an arc	press <i>CTRL</i> twice to switch to the Convert to Arc edit mode. Stretch the midpoint to the desired location and click, or enter a value and press <i>ENTER</i> .
offset all edges at an identical distance	press <i>CTRL</i> three times to switch to the Offset All edit mode. Move the selected edge to the desired location for all edges and click, or enter a value and press <i>ENTER</i> .

You can press *CTRL* to toggle among the edit modes.

4 Right-click, and click Deselect All to turn off grips.

Changing the vertex of an AEC Polygon

- 1 Select an existing AEC Polygon.
- 2 Select the Vertex grip for the vertex you want to change.

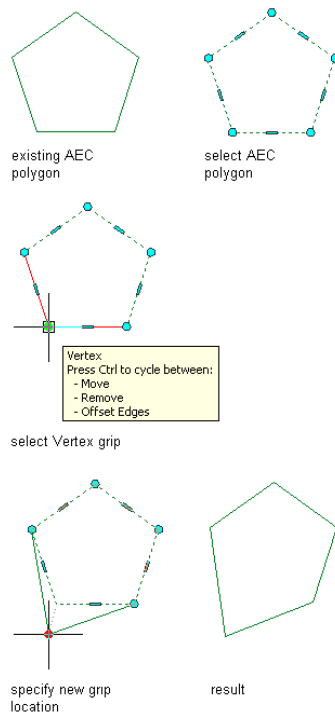

Viewing the AEC Polygon Vertex grip tooltip

The Vertex grip has three edit modes:

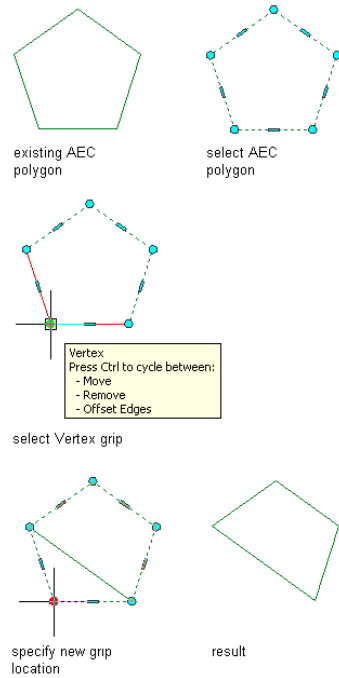

- **Move:** This is the default mode. Use this mode to move the selected vertex in any direction. The neighboring segments are stretched, as necessary.

Moving the vertex of an AEC Polygon using its Vertex grip

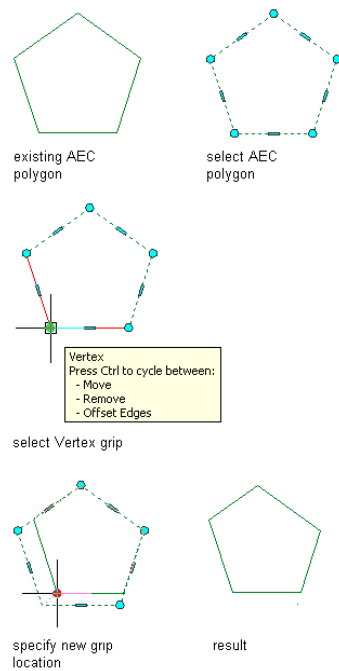

- **Remove:** Use this mode to remove a vertex. The neighboring segments are replaced with a line.

Removing the vertex of an AEC Polygon using its Vertex grip

- **Offset Edges:** Use this edit mode to move a vertex and the adjacent edges of the AEC Polygon with it.

Offsetting the edges of an AEC Polygon using its Vertex grip

3 Edit the vertex as necessary:

If you want to...	Then...
move the vertex	move the vertex to the desired location and click; or enter a value, and press <i>ENTER</i> .
remove the vertex	press <i>CTRL</i> to switch to the Remove Vertex edit mode, and click to confirm the removal.
move the vertex and the adjacent edges	press <i>CTRL</i> twice to switch to the Offset Edges edit mode. Move the vertex to the desired location, and click; or enter a value, and press <i>ENTER</i> .

4 Right-click, and click Deselect All to turn off grips.

Changing the AEC Polygon Style

Use this procedure to change the style of one or more AEC Polygons. The style controls the width and justification of the AEC Polygon edges. The justification determines whether the edges are displayed inside, outside, or centered on the vertices of the AEC Polygon. The style can also control the display properties of the AEC Polygon.

- 1 Double-click the AEC Polygon you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select an AEC Polygon style.

Merging Two AEC Polygons

Use this procedure to merge two or more AEC Polygons in a drawing. When you merge two AEC Polygons that overlap each other, their common boundary is combined to form the boundary of the merged AEC Polygon.

NOTE When you merge one AEC Polygon with another, the properties of the merged AEC Polygon are identical to the properties of the first selected AEC Polygon.

- 1 Create two overlapping AEC Polygons. For more information, see [Creating an AEC Polygon](#) on page 1201.
- 2 Select one of the AEC Polygons to be merged, right-click, and click AEC Modify Tools ► Merge.
- 3 Select the AEC Polygon to merge with the first AEC Polygon.

NOTE You can merge only those AEC Polygons that lie on the same Z-plane. Two AEC Polygons with different Z-positions in the same coordinate system cannot be merged.

- 4 Enter **y** (Yes) to erase the second AEC Polygon, or **n** (No) to leave the AEC Polygon in the drawing.

Merging two overlapping AEC Polygons

Creating a Hole in an AEC Polygon

Use this procedure to subtract AEC Polygons from one another in order to create a hole in an AEC Polygon. This would be useful, for example, for creating a complex pattern for a curtain wall infill.

Subtracting an AEC Polygon from an AEC Polygon

To perform a subtraction operation, you need to select AEC Polygons that intersect one another. You can choose whether to keep the subtracted AEC Polygon in the drawing as a separate unit. For example, you may want to keep the AEC Polygon if you need to subtract the same shape from other AEC Polygons.

- 1 Create an AEC Polygon from which to subtract a hole. For more information, see [Creating an AEC Polygon](#) on page 1201.
- 2 Create a second, smaller AEC Polygon to represent the area to be subtracted from the larger AEC Polygon.
You can draw the second AEC Polygon within or overlapping the area of the first AEC Polygon, or you can draw it in another location and then move it onto the larger AEC Polygon.
- 3 Select the larger AEC Polygon, right-click, and click AEC Modify Tools ► Subtract.
- 4 Select the smaller AEC Polygon to subtract from the larger AEC Polygon.
- 5 Enter **y** (Yes) to erase the subtracted AEC Polygon, or **n** (No) to leave the AEC Polygon in the drawing.

Creating AEC Polygons from the Intersection of Other AEC Polygons

Use this procedure to create a new AEC Polygon from the overlapping portion of two intersecting AEC Polygons. You can choose whether to retain the original geometry after creating the new intersection AEC Polygon.

Intersecting AEC Polygons with original geometry erased

Intersecting AEC Polygons with original geometry retained

- 1 Create two overlapping AEC Polygons. For more information, see [Creating an AEC Polygon](#) on page 1201.
- 2 Select the first overlapping AEC Polygon, right-click, and click AEC Modify Tools ► Crop.
- 3 Select the second overlapping AEC Polygon.
- 4 Enter **y** (Yes) to erase the original AEC Polygons, or **n** (No) to leave the AEC Polygons in the drawing.

Trimming an AEC Polygon

Use this procedure to trim a side from an AEC Polygon by defining a trim line through an existing AEC Polygon.

Trimming an AEC Polygon

- 1 Select the AEC Polygon to be trimmed, right-click, and click AEC Modify Tools ► Trim.
- 2 Specify a start point for the trim line. This line cuts through the AEC Polygon, creating the area to trim and the area to retain.
- 3 Specify an endpoint for the trim line.
- 4 Select the side of the AEC Polygon to be trimmed.

Dividing an AEC Polygon

Use this procedure to divide an AEC Polygon into two separate AEC Polygons by defining a division line through it.

Dividing an AEC Polygon

- 1 Select the AEC Polygon to be divided, right-click, and click AEC Modify Tools ► Divide.
- 2 Specify a start point for the division line.

NOTE You can specify only a start point and endpoint for your division line. You cannot specify additional points.

- 3 Specify an endpoint for the division line.

The AEC Polygon is divided by the line that you defined.

Adding a Vertex to an AEC Polygon

You can add a vertex to an existing AEC Polygon to change its shape. A vertex is the location where the edges of the AEC Polygon meet.

Adding a vertex to an AEC Polygon

1 Select the AEC Polygon for which to add a vertex, right-click, and click Vertex ► Add.

2 Select the point in your drawing to add the new vertex.

Line segments are drawn from the two existing vertices of the AEC Polygon closest to the point that you selected to form the new vertex.

3 Press *ENTER*.

Removing a Vertex from an AEC Polygon

You can remove a vertex from an existing AEC Polygon to change its shape.

Removing a vertex from an AEC Polygon

1 Select the AEC Polygon from which to remove a vertex, right-click, and click Vertex ► Remove.

2 Select the vertex you want to remove.

3 Press *ENTER*.

Converting an AEC Polygon to a Polyline

Use this procedure to convert an existing AEC Polygon to a polyline. When you create a polyline from an AEC Polygon that contains a hole, each ring of the AEC Polygon is converted into an individual polyline.

1 Select the AEC Polygon from which to create a polyline, right click and click Convert To ► Polyline.

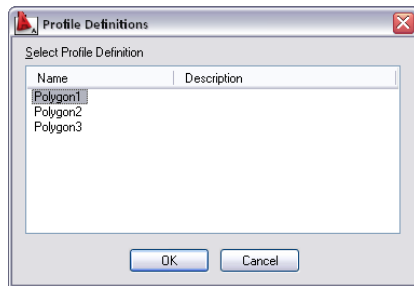

- 2 When prompted to erase the original geometry, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.

Converting an AEC Polygon to a Profile

Use this procedure to convert an existing AEC Polygon to a profile definition. You can create a new profile definition or overwrite an existing profile definition. Then, use the profile definition you create with objects that are profile based or have profile-based components, such as the soffit of a roof slab. For detailed information, see the sections for the individual objects.

- 1 Select the AEC Polygon from which to create a profile definition, right click and click Convert To ► Profile.
- 2 Specify the insertion point of the resulting profile, or press *ENTER* to use the centroid as the insertion point.
- 3 Enter *n* (New) to create a new profile definition, or *e* (Existing) to replace an existing profile.
- 4 Enter a name for the new profile definition, or select from the existing profile definitions on the Profile Definitions worksheet and click OK.

Profile Definitions worksheet

The existing profile definition you select is replaced by the one you are creating from an AEC Polygon.

Changing the Rotation of an AEC Polygon

Use this procedure to change the rotation of an AEC Polygon.

- 1 Double-click the AEC Polygon whose rotation you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Enter a value for Rotation.

Changing the Elevation of an AEC Polygon

Use this procedure to change the elevation of an AEC Polygon.

- 1 Double-click the AEC Polygon for which to change the elevation.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Enter a value for Elevation.

Changing the Location of an AEC Polygon

Use this procedure to relocate an AEC Polygon by changing the coordinate values of its insertion point. You can also move an AEC Polygon by cutting and pasting it.

AEC Polygons are oriented with respect to the WCS or the current UCS. For example, if the top and bottom of an AEC Polygon are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the AEC Polygon by aligning its normal with another axis. You can also rotate the AEC Polygon on its plane by changing the rotation angle. For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD help.

- 1 Double-click the AEC Polygon you want to move.
- 2 On the Properties palette, expand Location.
- 3 Click Additional information.
- 4 Specify the location of the AEC Polygon:

If you want to...	Then...
relocate the AEC Polygon	enter new coordinate values under Insertion Point.
locate the AEC Polygon on the <i>XY</i> plane	make the normal of the AEC Polygon parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the AEC Polygon on the <i>YZ</i> plane	make the normal of the AEC Polygon parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the AEC Polygon on the <i>XZ</i> plane	make the normal of the AEC Polygon parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the AEC Polygon	enter a new value for Rotation Angle.

- 5 Click OK.

Specifying Fill Properties for the True Color Display Representation of an AEC Polygon

Use this procedure to specify the fill properties for an AEC Polygon in the True Color display representation, which is used for high-resolution renderings.

NOTE Make sure that you do not use the True Color display representation and the Model display representation of an AEC Polygon simultaneously in one view. The Interior Fill and Edge Fill components of the Model display representation would be drawn on top of the Interior Fill and Edge Fill components of the True Color display representation. It is recommended that you create separate views for regular viewing and True Color renderings.

- 1 Double-click the AEC Polygon you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all AEC Polygons in the drawing, select Drawing default setting. To apply changes to all AEC Polygons of this style, select AEC Polygon Style:<style name>. For more information on styles, see [AEC Polygon Styles](#) on page 1219.

5 For Display representation, select True Color

NOTE The True Color display representation is not turned on for any display sets by default. If it is not included on the drop-down list, click Format menu ► Display Manager, expand Representations by Object ► AEC Polygon, and then select the display set for the current display configuration and any others for which you want this display representation turned on.

6 If necessary, expand Object Display Properties ► Advanced, and click  Fill properties.

7 Specify the fill properties:

If you want...

Then...

a True Color fill for the outer part of the AEC Polygon

in the Exterior panel, select Edge Fill, and then select a color for Edge Color, or click Other to choose a different color.

a True Color fill for the inner part of the AEC Polygon

in the Interior panel, select Interior Fill, and then select a color for Interior Color, or click Other to choose a different color.

NOTE If the edge dimensions of the AEC Polygon are set to 0, the edge fill is not displayed.

8 Click OK.

You can also access and modify these same settings through the AEC Polygon's context menu, as follows:

1 Select the AEC Polygon, right-click, and click Edit Object Display.

2 Click the Display Properties tab.

3 Select the True Color display representation, and select Object Override.

4 If necessary, click .

5 On the Fill Properties tab, adjust the settings as needed.

6 Click OK twice.

Attaching Hyperlinks, Notes, or Files to an AEC Polygon

Use this procedure to attach hyperlinks, enter notes, or attach reference files to an AEC Polygon. You can also edit notes and edit or detach reference files from an AEC Polygon.

1 Double-click the AEC Polygon to which to attach information.

2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click  next to Hyperlink, and specify the link.

For more information about adding hyperlinks, see “Add Hyperlinks in a Drawing” in AutoCAD help.

4 To add or edit a note, click  next to Notes, enter text, and click OK.

5 To attach, detach, or edit a reference file, click  to Reference documents, and then do any of the following:

If you want to...

Then...

attach a reference file

click , select a file, and click Open.

edit the description of a reference file

enter text under Description.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click .

6 Click OK.

AEC Polygon Styles

An AEC Polygon style is a group of properties that determines the appearance and other characteristics of AEC Polygons. AEC Polygon styles control the following parameters:

- default dimensions, including edge width and justification
- default display properties for the interior and edges of the AEC Polygon
The display properties of an AEC Polygon allow you to hatch its interior and edges, or fill its edges and interior with a solid color fill.
- masking capability

Creating Tools from AEC Polygon Styles

You can create an AEC Polygon tool from any AEC Polygon style. You can drag the style from the Style Manager onto a tool palette. You can then specify default settings for any AEC Polygon created with that tool. For more information, see [Using AEC Polygon Tools to Create AEC Polygons](#) on page 1201.

Managing AEC Polygon Styles

To create, copy, or edit styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information, see [Style Manager](#) on page 589.

Creating an AEC Polygon Style

Use this procedure to create an AEC Polygon style. You can create a new style using default style properties, or by copying an existing style. After you create a style, you edit its properties to customize the characteristics of the style.

1 Click Format menu ► Style Manager.

2 Expand Multi-Purpose Objects, and expand AEC Polygon Styles.

3 Create an AEC Polygon style:

If you want to...	Then...
create a style with default properties	right-click AEC Polygon Styles, and click New.
create a style from an existing style	right-click the AEC Polygon style you want to copy, and click Copy. Right-click, and click Paste.

4 To rename the new AEC Polygon style, right-click the style, and click Rename.

5 Enter a name for the new AEC Polygon style, and press *ENTER*.

6 Edit the style properties of the new AEC Polygon style:

If you want to...	Then...
change the edge width and edge alignment	see Changing the Width and Justification of the AEC Polygon Edges on page 1220.
add an AEC Polygon as a background mask	see Masking Underlying Objects with AEC Polygons on page 1221.
change the Layer/Color/Linetype properties	see Specifying the Layer, Color, and Linetype of an AEC Polygon Style on page 1223.
change the AEC Polygon interior and exterior hatching	see Specifying the Hatching of an AEC Polygon Style on page 1223.
change the colors of the True Color display representation	see Setting the Colors of the True Color Display Representation on page 1224.
add notes and files to the style	see Attaching Notes and Files to an AEC Polygon Style on page 1225.
add classifications to an AEC Polygon style	see Adding Classifications to an AEC Polygon Style on page 1225.

7 If you want to create an AEC Polygon tool from the new style, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating an AEC Polygon Tool](#) on page 1203.

8 Click OK.

Changing the Width and Justification of the AEC Polygon Edges

Use this procedure to change the width and justification of the edges of an AEC Polygon in the AEC Polygon style. The justification determines whether the edges are displayed inside, outside, or centered on the vertices of the AEC Polygon.

Justifying AEC Polygon edges

- 1 Open a tool palette containing an AEC Polygon tool.
- 2 Right-click an AEC Polygon tool, and click AEC Polygon Styles.
- 3 Select the AEC Polygon style.
- 4 Click the Dimensions tab.
- 5 To change the width of the AEC Polygon edges, enter a new value for Edge Width.
- 6 Change the justification of the AEC Polygon edges as desired:

If you want to...

Then ...

display the edges inside the AEC Polygon vertices

select In for Justify.

display the edges centered within the vertices of the AEC Polygon

select Center for Justify.

display the edges outside the AEC Polygon vertices

select Out for Justify.

- 7 Click OK.

Masking Underlying Objects with AEC Polygons

Use this procedure to change an AEC Polygon style to mask a background. This style property also determines if masking break marks display correctly in your drawings. For more information about working with break marks, see [The Basic Annotation Tool](#) on page 2381.

- 1 Select an AEC Polygon, right-click and click Edit AEC Polygon Style.
- 2 Click the Other tab.
- 3 Select Use Background Mask.
- 4 Click OK.

All AEC Polygons of this style use a background mask in the current drawing.

Specifying the Display Properties of an AEC Polygon Style

In most cases, you want the appearance of AEC Polygons that belong to the same style to be consistent throughout a drawing. To achieve this, you specify the display properties of the AEC Polygons in each AEC Polygon style:

- The layer, color, and linetype of AEC Polygon components

■ The hatching used for the components of the AEC Polygon

AEC Polygon components

Display components in Model view

Component	Description
Interior Edge	Inner edge of the AEC Polygon. NOTE When the edge dimensions are set to 0, the interior edge is the only edge of the AEC Polygon.
Exterior Edge	Outer edge of the AEC Polygon. NOTE When the edge dimensions are set to 0, the exterior edge is not displayed in the AEC Polygon.
Interior Hatch	Hatch component of the inner part of the AEC Polygon. NOTE When the edge dimensions are set to 0, the interior hatch is the only hatch of the AEC Polygon.
Edge Hatch	Hatch component of the outer part of the AEC Polygon. NOTE When the edge dimensions are set to 0, the edge hatch is not displayed in the AEC Polygon.
Interior Fill	The fill component of the inner part of the AEC Polygon. This component is displayed only in rendered views. Make sure that for each rendered view you use either the Interior Fill and Edge Fill components of the Model display representation or the Interior Fill and Edge Fill components of the True Color display representation. If you use both display representations simultaneously, the fills are drawn on top of each other. For detailed information, see Setting the Colors of the True Color Display Representation on page 1224.
Edge fill	The fill component of the outer part of the AEC Polygon. This component is displayed only in rendered views. Make sure that for each rendered view you use either the Interior Fill and Edge Fill components of the Model display representation or the Interior Fill and Edge Fill components of the True Color display representation. If you use both display representations simultaneously, the fills are drawn on top of each other. For detailed information, see Setting the Colors of the True Color Display Representation on page 1224.

Display components in Model view

Component	Description
-----------	-------------

NOTE When the edge dimensions have been set to 0, the edge fill is not displayed in a rendered AEC Polygon.

Specifying the Layer, Color, and Linetype of an AEC Polygon Style

Use this procedure to change the following display properties of an AEC Polygon style:

- Visibility (component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype Scale
- Plot Style

Materials cannot be assigned to AEC Polygons. Note that you can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

- 1 Open a tool palette containing an AEC Polygon tool.
- 2 Right-click an AEC Polygon tool, and click AEC Polygon Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the Model display representation, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK twice.

Specifying the Hatching of an AEC Polygon Style

Use this procedure to specify the hatching of an AEC Polygon style.

- 1 Open a tool palette containing an AEC Polygon tool.
- 2 Right-click an AEC Polygon tool, and click AEC Polygon Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which changes should appear, and select Style Override.
- 6 If necessary, click  .

- 7 Click the Hatching tab.
- 8 Click the setting for Pattern.
- 9 Select the hatching pattern:

If you want to...	Then...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

TIP Mask blocks do not hide the True Color representation of AEC Polygons, but you can use hatching to work around this. Use the Model representation of the AEC Polygon, set the hatch to Solid, and select the appropriate True Color for the hatch.

- 10 Click OK.
- 11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.
- 12 Click Angle, and enter the angle for the selected pattern.
- 13 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the AEC Polygon, regardless of the object's rotation	select object.
orient the hatching to the World Coordinate System	select global.

- 14 Click OK twice.

Setting the Colors of the True Color Display Representation

Use this procedure to set the colors of the AEC Polygon with True Color display representations. Use True Color display representation for high-resolution renderings.

NOTE Make sure that you do not use the True Color display representation and the Model display representation of an AEC Polygon simultaneously in one view. The Interior Fill and Edge Fill components of the Model display representation would be drawn on top of the Interior Fill and Edge Fill components of the True Color display representation. It is recommended that you create separate views for regular viewing and True Color renderings.

- 1 Open a tool palette containing an AEC Polygon tool.
- 2 Right-click an AEC Polygon tool, and click AEC Polygon Styles.
- 3 Select the style you want to edit.

- 4 Click the Display Properties tab.
- 5 Select the True Color display representation, and select Style Override.

6 If necessary, click  .

7 Specify the fill properties:

If you want...	Then...
a True Color fill for the outer part of the AEC Polygon	select Edge Fill, and select a color for Edge Color, or click Other to choose a different color.
a True Color fill for the inner part of the AEC Polygon	select Interior Fill, and select a color for Interior Color, or click Other to choose a different color.

NOTE If the edge dimensions of the AEC Polygon are set to 0, the edge fill is not displayed.

8 Click OK twice.

Attaching Notes and Files to an AEC Polygon Style

Use this procedure to enter notes and attach reference files to an AEC Polygon style. You can also edit notes and edit or detach reference files from an AEC Polygon style.

- 1 Open a tool palette containing an AEC Polygon tool.
- 2 Right-click an AEC Polygon tool, and click AEC Polygon Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the AEC Polygon, enter it under Description.
- 6 Click Notes.
- 7 To add or edit a note, click the Notes tab, and enter the note.
- 8 To attach, edit, or detach a reference file, click the Reference Docs tab:

If you want to...	Then...
attach a reference file	click Add, select a file, and click open. Click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
change the reference file	double-click the reference file to start its application. Close the application when you are finished editing.
detach a reference file	select the file name, and click Delete.

9 Click OK twice.

Adding Classifications to an AEC Polygon Style

Use this procedure to specify classifications for any classification definition applied to an AEC Polygon style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1** Open a tool palette containing an AEC Polygon tool.
- 2** Right-click an AEC Polygon tool, and click AEC Polygon Styles.
- 3** Select the style that you want to change.
- 4** Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to AEC Polygon styles.
- 5** For each classification definition, select the classification you want applied to the current AEC Polygon style.
- 6** Click OK.

Doors

22

A door is an AEC object that interacts with walls and door and window assemblies. You can also create freestanding doors for door-type drawings.

Doors

A door is an AEC object that interacts with walls and door and window assemblies. You can also create freestanding doors for door-type drawings.

Creating Doors

You can create doors using the typical design parameters for style, standard size, width and height, threshold height, and head height. You can choose styles with glass shapes that receive standard muntins patterns, and create your own custom glass shapes from profiles.

Door Styles

AutoCAD Architecture provides ready-to-use door styles. The design rules of a door style determine the default dimensions of doors and the door shape and type

- The door shape determines the geometry of the door panel, such as rectangular, half-round, and arch. You can also create custom door shapes from profiles.
- The door type determines the number of panels and the method of opening the door, such as single, double, bifold, pocket, revolving, and overhead.

You can define standard sizes in a door style and then select the size you want to use when you place the door in a drawing.

Anchoring Doors

After a door is placed in a wall or door and window assembly, the door is constrained to the object and cannot move outside it.

Doors can also be anchored to specific locations in walls or door and window assemblies, so that when the wall or door and window assembly moves or changes size, the location of the door in that object remains constant.

Door Dimensions

Some door dimensions depend on the shape and type specified in the door style.

Rise is the height from the top of the rectangular portion of a door to the peak of the door opening for Gothic, Arch, and Peak Pentagon door shapes.

Leaf specifies the door size for pairs of Uneven, Uneven-Dhung, and Uneven Opposing door types. For more information about leaf, see [Changing the Door Leaf](#) on page 1241.

Door Endcaps

Doors that are anchored in a wall can have endcap styles applied to them. The endcap shapes for wall openings are defined in the wall style and are a property of the wall. For information on setting an opening endcap style in a wall, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

Vertical Alignment of Doors

You use vertical alignment settings to control the placement of the door in the wall, the location of the working point vertically in the wall, and how the door responds to modifications in height. To determine the working point on the door, use the threshold and head height settings. You can place the working point at the sill or at the head. For example, if you specify the vertical alignment as 0" and the door height as 7'-0", the door opening height is 7'-0". If you next specify the height of the door as 6'-8", the door threshold remains at 0" and the door opening height becomes 6'-8".

For the door head working point, if you specify the vertical alignment as 7'-0" and the door height as 7'-0", the door opening height is 7'-0". If you specify the door height as 6'-8", the door head remains at 7'-0" and the door threshold becomes 4".

Materials in Doors

You can assign materials to a door. Materials are displayed in wireframe and working shade views, or when rendered. Materials have specific settings for individual components of a door, such as the panel, the stop, the frame, or a glass inset.

Doors in Wireframe, Hidden, Realistic, and Conceptual Visual Style representations

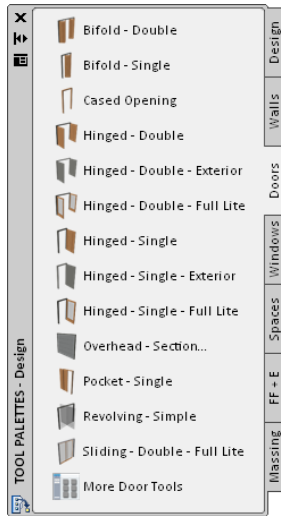

AutoCAD Architecture provides predefined materials for common design purposes, which contain settings for doors. You can use the predefined materials "as is," or modify them for your special designs. You can also create your own materials. Styles provided with the software have appropriate materials already assigned to them. For more information, see [About Door Display Components and Materials](#) on page 1265.

Using Door Tools to Create Doors

Tools provided with AutoCAD Architecture let you quickly place doors by selecting a door tool with a specific door style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can also use door tools to create new doors by applying tool properties to existing door/window assemblies, openings, and windows.

Tool palette containing door tools

The following palettes contain one or more door tools:

Palette	Tools
Design	Contains a door tool for the Standard door style and default settings for other door properties
Doors	Contains door tools for sample door styles, with default properties appropriate for each door style
Custom tool palettes created by your CAD manager	Contain door tools with styles and properties customized for your projects or office standards

Door tools are also included in the AutoCAD Architecture Stock Tool catalog supplied with the Content Browser. For information about using the Content Browser, see [Understanding the Content Browser](#) on page 121.

You can use the default settings of a door tool, or you can change settings for any door properties that are not controlled by the style.

Creating a Door

Use this procedure to add a door that has the properties specified in the door tool that you select. To specify settings when you add a door, see [Creating a Door with User-Specified Settings](#) on page 1230.

- 1 Open the tool palette that contains the door tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

- 2 Select a wall or door and window assembly in which to insert the door, or press *ENTER* to add a freestanding door.
- 3 Specify the insertion point for the door.
- 4 Continue adding doors, and press *ENTER*.

Creating a Door with User-Specified Settings

Use this procedure to create any of the following, with settings that you specify:

- Freestanding doors
- Doors in walls

Adding a door to a wall

- 1 Open the tool palette that you want to use, and select a Door tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a door style.
- 4 Under Bound Spaces, define if this door can be used as a bounding object for associative spaces.
You can select three options here:
 - Yes: this door can be used as bounding object for associative spaces.
 - No: this door cannot be used as bounding object for associative spaces.
 - By style: this door will use the bounding settings from the door style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

5 Expand Dimensions.

6 Specify a door size:

If you want to...	Then...
use a standard door size	click Standard Sizes, and then select a door size.
use a custom door size	enter values for Width and Height.

7 Enter values for Rise and Leaf (if applicable to selected style and door type).

8 Enter a value for Swing angle or Opening percent. (Zero indicates a closed door.)

9 Expand Location.

10 If you are placing the door in a wall, specify the door position:

If you want to...	Then...
position the door at a specific distance between the edge of the opening and the end of a wall segment	select Offset/Center for Position along wall, and enter a value for Automatic offset.
center the door on a wall segment	select Offset/Center for Position along wall, and specify a point near the center of the wall segment.
position the door anywhere along the wall	click Position along wall, and select Unconstrained.

11 Specify whether you want the door to be aligned vertically by threshold height or by head height:

If you want to...	Then...
align the door by threshold height	select Threshold for Vertical alignment, and enter a value for Threshold height.
align the door by head height	select Head for Vertical alignment, and enter a value for Head height.

12 Specify the insertion point for a door in a wall or for a freestanding door:

If you want to...	Then...
insert a door in a wall	select the wall, and specify an insertion point along the wall.
insert a freestanding door	press <i>ENTER</i> , and specify an insertion point and a rotation angle for the door.

TIP There are 2 command line options that make the insertion of a door in a specific location easier: You can switch the insertion point of the door from hinge (default) to center and latch by entering **CY** (cycle measure to) once or twice on the command line. You can also measure the insertion point of a door in relation to a specified point in the drawing - for example the frame of another door - by entering **RE** (Reference point on) and then selecting the point from which the distance should be measured.

13 Continue to place doors, and press *ENTER* when you are finished.

Creating a Door in a Door and Window Assembly

Use this procedure to insert a door into a door and window assembly.

- 1 Open the tool palette that you want to use, and select a Door tool.
If necessary, scroll the tool palette to display the tool you want to use.
- 2 Select a door and window assembly to insert the door into.
- 3 Select the grid cell on the door and window assembly into which you want to insert the door.
- 4 Commence adding the door to the door and window assembly, as described in [Inserting a Door or Window into a Door and Window Assembly](#) on page 1151.

Creating a Door from Door/Window Assemblies, Openings, and Windows

Use this procedure to convert a door/window assembly, opening, or window to a door that has the properties of the door tool you select. You can edit these properties after creating the door.

- 1 Open the tool palette that contains the door tool that you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click a door tool, and click Apply Tool Properties to ► Door/Window Assembly, Opening, Window.
- 3 Select the door/window assembly, window, or opening to convert, and press *ENTER*.
- 4 Edit the properties of the door in the Properties palette, if needed.

Creating a Door Tool

Use this procedure to create a door tool and add it to a tool palette. You may want to create your own door tools if you are placing multiple doors of specific styles that have the same properties.

For example, you are creating an office floor plan that contains two custom door styles: single solid doors for offices, and solid double doors for conference rooms. To work efficiently, you can create a door tool for each style. You can then select the appropriate tool to place doors in each type of room.

You can use any of the following methods to create a door tool:

- Drag a door that has the properties you want to a tool palette.
- Drag a door style from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Copy an existing tool, and then customize the properties of the new tool.
- Drag a tool from a tool catalog in the Content Browser, and then customize the properties of the tool. For information about using the Content Browser to create a tool, see [Using Tool Catalog Items in AutoCAD Architecture 2009](#) on page 146.

- 1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a door in the drawing	select the door and drag it to the tool palette.
create a tool from a door style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current palette	right-click the tool, click Copy. Right-click, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Enter a description of the tool.

8 If you do not want to use the default layer key for doors, select a layer key.

9 If you want to override the default layer name for doors, select a layer override.

10 Select a door style.

11 For Style location, select the drawing file containing the style used for this door, or select Browse and use a standard file selection dialog box to select the file.

12 Under Bound Spaces, define if this door tool can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this door tool can be used as bounding object for associative spaces.
- No: this door tool cannot be used as bounding object for associative spaces.
- By style: this door tool will use the bounding settings from the door style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

13 Expand Dimensions.

14 Specify a door size:

If you want to...	Then...
use a standard door size	click Standard Sizes, and then select a door size.
use a custom door size	enter values for Width and Height.

15 Specify how the door width and height are measured:

If you want to...	Then...
measure to the outside of the door frame	select Outside of frame for Measure to.
measure to the inside of the door frame	select Inside of frame for Measure to.

16 Enter a value for Swing angle or Opening percent. (Zero indicates a closed door.)

17 Expand Location.

18 Specify the door's position in a wall:

If you want to...	Then...
position the door at a specific distance between the edge of the opening and the end of a wall segment	select Offset/Center for Position along wall, and enter a value other than zero for Automatic offset.
center the door in a wall segment	select Offset/Center for Position along wall, and enter zero for Automatic offset.
freely position the door anywhere in the wall	click Position along wall, and select Unconstrained.

19 Enter a value for head height.

20 Enter a value for threshold height.

21 Click OK.

Editing Doors

After you create a door, you can change the size, height, width, rise, leaf, and opening. You can also move the door within the wall, flip the hinge or swing, and change the swing opening.

You can change the properties of a door by changing its style or its dimensions, moving its anchor location, or specifying the endcap conditions.

AutoCAD Architecture offers several methods for editing doors:

- You can edit doors directly using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- You can change door settings on the Properties palette.
- You can select editing commands from the context menu for a selected door.

Using Grips to Edit Doors

You can use grips to modify the following door properties:

- Dimensions (width and height)

For overhead doors, the width determines the opening cut in the wall. The width dimensions extend beyond the frame opening because the door rides behind the opening.

- Location in a wall
- Hinge side (left or right)
- Swing direction
- Rise
 - Rise applies to Peak Pentagon, Arch, and Gothic door shapes. For more information, see [Specifying the Design Rules of a Door Style](#) on page 1261.

Refer to the illustrations and steps in this topic to use door grips to edit doors.

Editing the Dimensions of a Door with Standard Sizes

1 Select the door.

Door dimension grips

2 Select the grip for the dimension you want to change.

Initially the grip is set to constrain the sizing to one of the standard values defined for the door's style. For example, if you select the width grip, the grip is set to constrain the width to one of the standard values defined for the door's style.

Standard height door with width grip selected

The **CTRL** key acts as a toggle between standard and custom sizing.

A series of tick marks indicates the standard sizes for the selected dimension. As you move the grip, it snaps to each tick mark and displays the measurement at that mark.

The size and color of the grip tick marks indicate whether setting a standard value for the dimension will result in a standard door size. For example, if the height of the door is set to a non-standard value, then even if you set the door width to a standard value for that door's style, the door is still not a standard size. Long grey tick marks indicate that a standard size is possible; short red marks indicate that another dimension is already set to a non-standard value.

3 Resize the dimension as necessary:

If you want to...	Then...
change the dimension using a standard size	move the grip until the value you want is displayed, and then click.
change the dimension using a non-standard size	press <i>CTRL</i> , and either move the grip until the value you want is displayed, and then click, or enter a value.

Changing a door width

existing wall and door

select door

select Width grip

Standard Width
Press Ctrl to toggle between:
- Standard width
- Custom width

verify initial door width

Set width to standard size
Long gray marks - Current height is standard
Short red marks - Current height is non-standard

specify new grip location

result

Changing a door height

Editing the Dimensions of a Door with Nonstandard Sizes

- 1 Select the door.
- 2 Select the grip for the dimension you want to change.
- 3 Either move the grip until the dimension value you want is displayed, and then click, or enter a value.

Moving a Door Anchored to a Wall

- 1 Select the door.
- 2 Select the Location grip.

Door location and flip grips

Moving a Freestanding Door

- 1 Select the door.
- 2 Select the Location grip.
- 3 Move the door to the desired location, and click once.

Changing the Hinge Side of a Door

- 1 Select the door.
- 2 Select the Flip grip to reverse the side of the door where hinges are located.

Flipping a door hinge

Changing the Swing Direction of a Door

- 1 Select the door.

2 Select the Flip grip to reverse the swing direction of the door.

Flipping a door swing

Changing the Rise of a Door

1 Select the door.

2 Select the Rise grip.

Changing a door rise

3 Either move the grip until the rise value you want is displayed, and then click, or enter a value.

Changing the Door Style

Use this procedure to change the style for a door or group of doors.

- 1 Select one or more doors, and double-click one of them.
- 2 On the Properties palette, click Style, and select a door style from the drop-down list.

Changing the Door Leaf

Use this procedure to change the leaf value for a door or group of doors.

Leaf applies to Uneven, Uneven-Dhung, and Uneven Opposing door types. For more information, see [Specifying the Design Rules of a Door Style](#) on page 1261.

- 1 Select the doors you want to change, and double-click one of them.
- 2 Expand Basic, and expand Dimensions.
- 3 Enter a value for Leaf Width, or click Leaf Width and then click  to pick points on the screen to specify the width.

Changing a door leaf

Changing How Door Width Is Measured

Use this procedure to change how the width of doors is measured.

Changing how a door width is measured also affects the dimensions of the opening.

- 1 Select the doors you want to change, and double-click one of them.

Specifying door frame measurements

measuring to
inside of frame

measuring to
outside of frame

- 2 Expand Basic, and expand Dimensions.

- 3 Specify the location to which door width is measured:

If you want to...

Then...

size the doors to the inside frame

select Inside of frame for Measure to.

size the doors to the outside frame

select Outside of frame for Measure to.

Changing the Door Swing Angle or Opening Percent

Use this procedure to change the swing angle or opening percent of a door or group of doors.

A door with a swing angle of zero is closed. The swing angle for overhead doors moves the door panel vertically, with graphics above the door head disappearing. The swing display moves with the panel.

NOTE Defining the opening percent in display properties overrides this setting.

- 1 Select the doors you want to change, and double-click one of them.
- 2 Expand Basic, and expand Dimensions.
- 3 Enter a value for Swing angle or Opening percent.

Changing a door swing angle

Changing the Vertical Alignment of a Door

Use this procedure to change the vertical alignment of a door or group of doors.

- 1 Select the doors you want to change, and double-click one of them.
- 2 Expand Basic, and expand Location.
- 3 Specify whether you want the door to be aligned vertically by threshold height or by head height:

If you want to...	Then...
align the doors by threshold height	select Threshold for Vertical alignment, and enter a value for Threshold height.
align the doors by head height	select Head for Vertical alignment, and enter a value for Head height.

Moving a Door Along a Wall

Use this procedure to change the location of one or more doors along a wall by offsetting the doors from a reference location.

This feature is useful when you want to position a door at a specified distance from another object. For example, you may want to specify an exact distance between a series of doors along a wall.

- 1 Select the doors you want to move, right-click, and click Reposition Along Wall.

A marker indicates the current location within the opening: left jamb, center of door, or right jamb.

Repositioning a door along a wall

existing wall and door

select door

select Location grip

Location
Press Ctrl to cycle between:
- Move along
- Move within
- Move vertically

verify initial door location

Move along length

specify new grip location

result

2 Specify how to measure the offset:

If you want to...

Then...

measure the offset from
the center of the door

select a point near the
center of the door.

If you want to...	Then...
measure the offset from the left or right jamb	select a point on the jamb of the door you want to measure from.

3 Select a point to measure to (the reference point).

You can select a point along the wall.

4 Specify the distance between the points you selected:

If you want to...	Then...
move the door to the reference point	enter 0.
move the door a specified distance from the reference point	enter a value for the offset distance.
specify the distance as a measurement between two points, such as the distance between the centers of two doors that are correctly positioned	select the two points measuring the distance.

Moving a Door Within a Wall

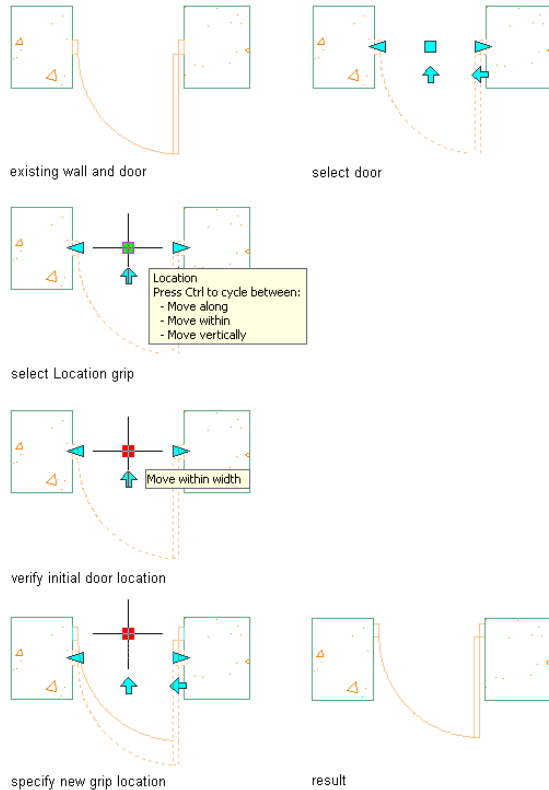

Use this procedure to move one or more doors within a wall by offsetting the doors from a reference location.

This feature allows you to align doors within the thickness of a wall. You can set an offset distance from any point within a wall, or center the doors between the faces of a wall. You can select doors, windows, or openings, and reposition them at the same time. If you select more than one object, you can select only one side to offset.

1 Select the doors you want to move, right-click, and click Reposition Within Wall.

A marker indicates the current location within the opening. This may be the center of the frame, the interior face of the frame, or the exterior face of the frame.

Repositioning a door within a wall

2 Specify how to measure the offset:

If you want to...

Then...

center the doors between the faces of the wall

select a point near the center of the door jamb.

offset the doors from the interior or exterior face

select a point on the side of the face you want to measure from.

3 Select a point to measure to.

4 Specify the offset distance from the selected point:

If you want to...

Then...

center the doors between the faces of the wall

use the Midpoint osnap to select the midpoint of the end of the wall.

move the doors to the reference point

enter 0.

move the doors a specified distance

enter a value for the offset distance.

specify the distance as a measurement between two points

select the two points measuring the distance.

Using Anchors to Change the Horizontal Position of a Door

Use this procedure to change the horizontal position of doors along a wall to which the doors are anchored.

Door position along the X axis parameters

- 1 Select the doors you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the X axis:

If you want to...

Then...

use the start of the wall as your reference point

under Position Along (X), select Start of wall (curve) for From.

use the midpoint of the wall as your reference point

under Position Along (X), select Midpoint of wall (curve) for From.

use the end of the wall as your reference point

under Position Along (X), select End of Wall (curve) for From.

- 5 Enter the distance from the reference point at which to place the doors.
Use a negative value to measure from endpoint to start point.

- 6 Select the position of the doors to measure to:

If you want to...

Then...

measure to the start edge of the doors

select Start Edge of object for To.

measure to the center of the doors

select Center of object for To.

measure to the end edge of the doors

select End Edge of object for To.

7 Click OK.

Using Anchors to Change the Vertical Position of a Door

Use this procedure to change the vertical position of doors in a wall to which the doors are anchored.

Door position along the Z axis parameters

1 Select the doors you want to change, and double-click one of them.

2 On the Properties palette, expand Basic, and expand Location.

3 Click Anchor.

4 Select the reference point for the anchor along the Z axis:

If you want to...

Then...

use the bottom of the wall height as your reference point

select Bottom of wall (curve) height for From.

use the center of the wall height as your reference point

select Center of wall (curve) height for From.

use the top of the wall height as your reference point

select Top of wall (curve) height for From.

5 Enter the distance from the reference point at which to place the doors.

Use a negative value to measure from endpoint to start point.

6 Select the position of the doors to measure to:

If you want to...

Then...

measure to the bottom of the doors

select Threshold (Bottom) of object for To.

measure to the center of the doors

select Center of object for To.

If you want to...	Then...
measure to the top of the doors	select Head (Top) of object for To.

7 Click OK.

Using Anchors to Change the Position of a Door Within a Wall

Use this procedure to change the position of doors horizontally within a wall to which the doors are anchored.

Door position along the Y axis parameters

- 1 Select the doors you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the Y axis:

If you want to...	Then...
use the left edge of the wall as your reference point	select Left edge of wall (curve) width for From.
use the center of the wall as your reference point	select Center of wall (curve) width for From.
use the right edge of the wall as your reference point	select Right edge of wall (curve) width for From.

- 5 Enter the distance from the reference point at which to place the doors.
Use a negative value to measure from endpoint to start point.

- 6 Select the position of the doors to measure to:

If you want to...	Then...
measure to the front of the doors	select Front for To.
measure to the center of the doors	select Center for To.
measure to the back of the doors	select Back for To.

7 Click OK.

Changing the Orientation of a Door to a Wall

Use this procedure to change the vertical orientation of doors in a wall to which the doors are anchored.

- 1 Select the doors you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Enter the *X* and *Z* rotation angles of the doors.
- 5 Indicate if you want to reverse the flip direction of the doors in the *X*, *Y*, and *Z* axes:

If you want to...	Then...
reverse the direction the doors open to	select Flip X.
reverse the side of the wall the doors open to	select Flip Y.
reverse the top and bottom of the doors	select Flip Z.

6 Click OK.

Moving a Door to a Different Wall

Use this procedure to move a door from one wall to another.

- 1 Select the door you want to move, right-click, and click Wall Anchor ► Set Wall.
- 2 Select the wall to move the door to.

Releasing a Door from a Wall

Use this procedure to release doors from the wall to which they are anchored.

- Select the doors you want to release, right-click, and click Wall Anchor ► Release.

Changing the Opening Endcap Assigned to a Door

Use this procedure to change the opening endcap style assigned to doors.

NOTE Each opening endcap style generally is created for use with a specific wall style. Changing the opening endcap style used for individual doors may cause the wall to display a defect marker.

For more information, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

- 1 Select the doors whose endcaps you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Expand Endcaps.
- 4 Select the opening endcap style.

Changing the Location of a Freestanding Door

Use this procedure to relocate a freestanding door by changing the coordinate values of its insertion point. The door also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the door are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the door by aligning its normal with another axis. You can also rotate the door on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use World and User Coordinate Systems in 3D” in AutoCAD Help.

- 1 Double-click the door you want to move.
- 2 On the Properties palette, expand Basic, then expand Location and click Additional Information.
- 3 In the Location dialog box, specify the door's location:

If you want to...	Then...
relocate the door	enter new coordinate values under Insertion Point.
locate the door on the <i>XY</i> plane	make the normal of the door parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the door on the <i>YZ</i> plane	make the normal of the door parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the door on the <i>XZ</i> plane	make the normal of the door parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the door	enter a new value for Rotation Angle.

- 4 Click OK.

Changing the Cut Plane Setting for a Door

Use this procedure to specify whether a selected door will use the cut plane of the containing object when anchored to that object in the current display representation. Note that cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Cut Plane.
- 7 For Use cut plane of containing object when anchored, select Yes or No.

Specifying the Display of Muntins Blocks for a Door

Use this procedure to specify the display of muntins for an individual door in model and elevation views.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and for Muntins, click  (the number in parentheses indicates the number of muntins blocks currently attached to the door).
- 7 If you want to turn off the display of muntins blocks for this door without removing them, select Disable Muntins Blocks.
- 8 Specify whether to add, edit, or remove a block:

If you want to...	Then...
add a new muntins block	click Add.
edit an existing muntins block	select the block to edit, and click Edit.
remove an existing muntins block	select the block, click Remove, and click OK.

- 9 For Name, enter a name for the new block or edit the existing one as applicable.
- 10 The rest of the parameters on the Muntins Block worksheet vary according to the type of door and type of pattern selected for the lights. For detailed instructions on specifying these parameters for a particular pattern, refer to the pattern-specific topic as listed under [Creating Muntins in a Door Style](#) on page 1274. When the worksheet parameters are set as desired, click OK.
- 11 If you want your changes to apply only to the current display representation, clear Automatically Apply to Other Display Representations. (If this option is not selected, you will be prompted to identify the other display representations to which you want your changes applied.)
- 12 Click OK.

Reversing the Handing for a Door in an Elevation View

Use this procedure to specify whether to reverse the current handing of a selected door in the Elevation display representation.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.
- 7 For Reverse handing, select Yes or No.

Specifying the Swing Display for a Door

Use this procedure to specify whether to display the swing of a selected door as a straight line in the current display representation.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.
- 7 For Straight swing, select Yes or No.

Specifying the Panel Display for a Door

Use this procedure to specify whether to display the panel of a selected door as a single line in the Plan High Detail display representation.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, verify that Plan High Detail is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.
- 7 For Single line panel, select Yes or No.

Specifying the Display of Frames for a Door

Use this procedure to change the frame display for a door in the Plan High Detail display representation.

- 1 Double-click the door

- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, select Plan High Detail.
- 6 If necessary, expand Object Display Properties ► Advanced, and click  Frame display.
- 7 On the Frame Display worksheet, under Type, select Standard, L-Shaped, or U-Shaped.
- 8 For A-Extension, enter a value to indicate the distance you want the frame to extend parallel to the containing object.
- 9 For B-Extension, if you selected a type other than Standard, enter a value to indicate the distance you want to extend the frame perpendicular to the containing object.
- 10 Click OK.

You can also access and modify frame display settings through the door's context menu, as follows:

- 1 Select the door you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the Plan High Detail display representation, and select Object Override.
The display representation in bold is the current display representation.

- 4 If necessary, click  .
- 5 Click the Frame Display tab.
- 6 Adjust the settings as desired, and click OK twice.

Specifying the Threshold Dimensions for a Door

Use this procedure to specify threshold dimensions for a selected door in the Threshold Plan display representation.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, select Threshold Plan.
- 6 If necessary, expand Object Display Properties ► Advanced, and click  Threshold dimensions.
- 7 Enter the desired distance values for each of the Extension and Depth parameters.
- 8 Click OK.

Specifying the Threshold Symbol for a Door

Use this procedure to specify the threshold symbol to be displayed for a selected door in the Threshold Symbol Plan display representation.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, select Threshold Symbol Plan.

NOTE The Threshold Symbol Plan display representation is not turned on for any display sets by default. If it is not included on the drop-down list, click Format menu ► Display Manager, expand Representations by Object ► Door, and then select the Plan display set and any others for which you want this display representation turned on.

- 6 If necessary, expand Object Display Properties ► Advanced, and click  Symbol.
- 7 Select the desired symbol setting. (The currently selected setting is illustrated in the view panel on the worksheet.)
- 8 Click OK.
- 9 If the selected symbol is not visible in the drawing, select the value for Display component, and click the lightbulb icon for Threshold Symbol to turn on visibility for this component.
- 10 Click elsewhere on the Properties palette to close the list and display the symbol in the drawing.

Specifying the Display of Custom Block Components of a Door

Use this procedure to specify the display of custom block components for an individual door in a particular display representation. If you are going to use custom graphics for a new component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the door.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all doors in the drawing, select Drawing default setting. To apply changes to all doors of this style, select Door Style:<style name>. For more information on styles, see [Door Styles](#) on page 1258.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and for Custom block display, click  (the number in parentheses indicates the number of blocks currently attached to the door).
- 7 If you want to turn off the display of custom blocks for this door without removing them, select Disable Custom Blocks.

8 Specify whether to add, edit, or remove a block component:

If you want to...	Then...
add a new block component	click Add, and then click Select Block, select the block, and click OK.
edit an existing block component	select the component to edit, and click Edit.
remove an existing block component	select the block, click Remove, and click OK.

9 Specify whether you want to scale to fit the block component to the object by width, depth, and height, or to lock the *XY* ratio:

If you want to...	Then...
set the block scale to the width of the object	select Width.
set the block scale to the depth of the object	select Depth.
set the block scale to the height of the object	select Height.
scale the whole block equally, so that one direction is scaled to fit another of the scale criteria	select Lock to XY Ratio.
scale the block to its original size	clear all options under Scale to Fit.

10 Specify whether to mirror the block in the *X*, *Y*, or *Z* direction:

If you want to create a mirror of the block...	Then...
in the <i>X</i> direction	select Mirror <i>X</i> .
in the <i>Y</i> direction	select Mirror <i>Y</i> .
in the <i>Z</i> direction	select Mirror <i>Z</i> .

11 Specify the *X*, *Y*, and *Z* location of the insertion point.

12 Specify an insertion offset of the block in the *X*, *Y*, and *Z* directions.

13 Specify whether the component is for the door frame, door glass, or door leaf component:

NOTE Frame, glass, and leaf components are not all available in all display representations.

If you want to add the block...	Then...
to the inside or outside of the frame	select Frame Component, and select either Outside or Inside.

If you want to add the block...**Then...**

to all door glass (or panel) components or a single door glass (or panel) component

click Glass Component (or Panel Component), and click either All or Single. If you select Single, enter the component number.

NOTE In the case of glass components, if you specified Depth for Scale to Fit, the depth is scaled to the glass thickness. You can scale to the door panel thickness instead by selecting Scale Depth to Panel Thickness.

14 Click OK twice.

Attaching Hyperlinks, Notes, and Files to a Door

Use this procedure to enter notes and attach reference files to a door. You can also edit notes and edit or detach reference files from a door.

- 1 Double-click the door to which to attach notes or files.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
For more information, see “Add Hyperlinks to a Drawing” in AutoCAD Help.
- 4 To add a note, click  next to Notes, enter text, and click OK.
- 5 To attach, detach, or edit a reference file, click  next to Reference documents, and then do any of the following:

If you want to...**Then...**

attach a reference file

click , select a file, and click Open.

edit the description of a reference file

enter text under Description.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click .

6 Click OK.

Door Styles

A door style is a group of properties assigned to a door that determines the appearance and characteristics of the door.

You can use door styles to represent standard door types for specific jobs and drawings or for your office standards. When you create or modify a door style, the doors using the style have the settings and characteristics of the style. Templates provided with AutoCAD Architecture contain door styles for many typical doors. You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

Creating Tools from Door Styles

To create a door tool from any door style, you drag the style from the Style Manager onto a tool palette. You can then specify default settings for doors created with that tool. For more information, see [Using Door Tools to Create Doors](#) on page 1229.

Managing Door Styles

To create, edit, copy, or purge door styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture in which to work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Creating a Door Style

Use this procedure to create a door style.

You can create a style with default style properties, or you can create a style by copying an existing one. After you create the style, you edit its properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door Styles.
- 3 Create a door style:

If you want to...	Then...
create a style with default properties	right-click Door Styles, and click New.
create a style from an existing style	right-click the door style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new door style, and press *ENTER*.
- 5 Edit the properties of your new door style:

If you want to...	Then...
enter a description of the style	click the General tab, and enter a description.
change dimension properties of the style	see Specifying the Dimensions of a Door Style on page 1260.
change design rules of the style	see Specifying the Design Rules of a Door Style on page 1261.
change the standard door sizes of the style	see Specifying the Standard Sizes of a Door Style on page 1262.

If you want to...	Then...
assign materials to the components of the door style	see Assigning Materials to a Door Style on page 1266 and Turning on Materials for a Door Style on page 1269.
add classifications to a door style	see Adding Classifications to a Door Style on page 1267.
specify the display properties of the style	see Specifying the Display Properties of a Door Style on page 1268.
change the appearance of the display components of the style	see Changing the Layer, Color, and Linetype of Door Components on page 1268.
add components to the style	see Adding Components to a Door Style on page 1269.
remove components from the style	see Removing Custom Components from a Door Style on page 1271.
turn off components in the style	see Turning Off Custom Components in a Door Style on page 1271.
display a straight door swing from the style	see Displaying a Straight Door Swing on page 1272.
override the opening percentage in the style	see Specifying the Opening Percentage for Display Representations in a Door on page 1272.
change the threshold in the style	see Changing the Door Threshold in a Door Style on page 1272.
add muntins to the style	see Creating Muntins in a Door Style on page 1274.
add notes, files, or documents to the style	see Attaching Notes and Files to a Door Style on page 1274.

6 If you want to assign the style to a door tool, drag the style from the Style Manager to a tool palette.
 You can later rename the tool and specify other properties for it as described in [Creating a Door Tool](#) on page 1232.

7 Click OK.

Specifying the Dimensions of a Door Style

Use this procedure to change the default dimensions of a door style.

- 1** Open a tool palette that has a door tool.
- 2** Right-click a door tool, and click Door Styles.
- 3** Select the style you want to edit.

4 Click the Dimensions tab.

Changing door style dimensions

5 Change dimension values:

If you want to...	Then...
change the frame width and depth	under Frame, enter values for Width and Depth.
set the frame width to the wall thickness	under Frame, select Auto-Adjust to Width of Wall.
change the stop dimensions	under Stop, enter values for Width and Depth.
change the door thickness	enter a value for Door Thickness.
change the glass thickness	enter a value for Glass Thickness.

6 Click OK.

Specifying the Design Rules of a Door Style

Use this procedure to specify the shape and the type of door for a door style.

Door shapes are named geometrical descriptions of a door. You can select predefined and custom door shapes, or create your own shape from profiles. For more information, see [Creating a Custom Door Shape](#) on page 1262.

The door type describes the type of opening for the door, such as bifold or pocket.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Design Rules tab.
- 5 Select a door shape:

If you want to...	Then...
use a predefined door shape	under Shape, click Predefined, and select a shape.
use a custom door shape	under Shape, click Use Profile, and select a profile.

6 Select a door type.

7 Click OK.

Specifying the Standard Sizes of a Door Style

Use this procedure to create standard door sizes in a door style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Standard Sizes tab, and add, change, or remove door-size values:

If you want to...	Then...
create standard sizes	click Add. Under Standard Sizes, enter values for Description, Width, Height, Rise, and Leaf.
change a size	select the size, and click Edit. Enter new values for Width, Height, Rise, and Leaf.
delete a size	select a size, and click Remove.

The description can be used to identify standard door sizes in door schedules. For example, you can specify a manufacturer's size or model code for Description.

Rise is available for Arch, Gothic, and Peak Pentagon door shapes. Leaf controls the width of Uneven, Uneven-Dhung, and Uneven-Opposing door types. For more information on door types and shapes, see [Specifying the Design Rules of a Door Style](#) on page 1261.

5 Click OK.

Creating a Custom Door Shape

Use this procedure to create a profile that you can use to define a custom door shape in a door style. To create a custom door shape that includes glazing, see [Creating a Void for Door Muntins](#) on page 1276.

- 1 Draw a closed polyline in the shape you want.
- 2 Select the polyline, right-click, and click Convert To ► Profile Definition.
- 3 Specify the insertion point of the profile.
The insertion point is not used for doors.
- 4 Enter **n** (New).
- 5 Enter a name for the profile, and click OK.

Replacing the Door Shape in a Door Style

Use this procedure to replace a predefined shape in a door style with a custom shape created from a profile.

- 1 Select a door that uses the style you want to modify, right-click, and click Add Profile.
- 2 Specify the profile to use for the custom shape:

If you want to...

Then...

use a predefined door shape

select a profile for Profile Definition, and click OK. For information about creating a profile, see [Creating a Custom Door Shape](#) on page 1262.

use a predefined door shape, but modify it

select a profile for Profile Definition, select Continue Editing, and click OK. For information about modifying the shape, see [Editing the Geometry of a Door Style](#) on page 1263.

create a custom shape

select Start from scratch for Profile Definition, enter a name for the new profile, and click OK. For information about modifying the default shape, see [Editing the Geometry of a Door Style](#) on page 1263.

Editing the Geometry of a Door Style

Use this procedure to edit the geometry of the profile used to define a door style. You can also add a profile to a door style that does not currently use a profile to define its shape.

1 Add a door that has the style you want to change.

2 Add or edit a profile:

If you want to...	Then...
add an existing profile to the style	select the door, right-click, and click Add Profile. Select the name of the profile, and click OK.
create a profile and add it to the style	select the door, right-click, and click Add Profile. Select Start from scratch for Profile Definition, enter a name for the new profile, and click OK. A rectangular profile is created for you to edit to define the required geometry.
edit the existing profile for the style	select the door, right-click, and click Edit Profile in Place.

3 If you receive a message that the profile is not drawn to size, click Yes.

The area of the door defined by the profile is selected and hatched in the drawing.

4 **NOTE** After you perform an editing task from the context menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select the profile, and right-click to display the context menu.

Edit the profile as necessary:

If you want to...	Then...
change the shape of the perimeter of the profile or its rings	select the profile, and use edge or vertex grips to adjust the shape. The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary. Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well. Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.
add vertices to the profile	select an Edge grip, and press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press <i>ENTER</i> .
remove vertices from the profile	select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.

If you want to...	Then...
replace an existing ring of the profile with new geometry	select the profile, right-click, and click Replace Ring. Select the ring to replace, and select the new geometry. Press <i>ENTER</i> to keep the geometry, or enter n (No) to erase it.
add a ring to the profile	select the profile, right-click, and click Add Ring. Select the geometry to define the ring. Press <i>ENTER</i> to keep the geometry, or enter n (No) to erase it.
remove a ring from the profile	select the profile, right-click, and click Remove Ring. Select the ring to remove, and press <i>ENTER</i> .

5 Save or discard the changes:

If you want to...	Then...
restore the profile to its original shape	select the profile and click  .
save the changes to the current profile	select the profile, and click  . The door style uses the edited profile to define its geometry. Any other objects or styles that use this profile are also updated with the edited geometry.
save the changes to a new profile definition	select the profile, right-click, and click Save as New Profile. Enter a name for the new profile definition, and click OK. The door uses the new profile to define its geometry. Any doors of this style are updated with the new geometry. Other styles or objects that use the original profile are not affected.

About Door Display Components and Materials

A door object consists of a number of components whose display properties can be determined by the materials assigned to each component.

You assign one material to each display component of the door. For example, you assign a wood material to the frame and a glass material to the glass inset. You assign materials to door components in each display representation in which the materials are to be used.

To use the display properties of the door object or the door style, instead of using material display properties, you can turn off the material assignments in the display properties of the door or the door style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in 3D model views and elevations.

For a complete list of material components and their descriptions, see [Material Components and Display Properties](#) on page 610.

The following table lists door components that can be displayed using materials assigned to them, and identifies the material component of each.

Door Component	Material Component
Plan, Plan High Detail, Reflected	
Door Panel	Linework
Frame	Linework
Stop	Linework
Plan Low Detail	
Panel	Linework
Model	
Door Panel	3D Body
Frame	3D Body
Stop	3D Body
Glass	3D Body
Elevation	
Door Panel	2D Section/Elevation Linework
Frame	2D Section/Elevation Linework
Stop	2D Section/Elevation Linework
Glass	2D Section/Elevation Linework

Assigning Materials to a Door Style

Use this procedure to assign materials to the individual components of a door style. Components use the display properties of the material. For more information, see [About Door Display Components and Materials](#) on page 1265.

You can specify the materials used to display the following components of a door style:

- Frame

- Stop
- Panel
- Glass
- Muntin

NOTE If a material assignment does not determine the display properties of a door component, you can change the display properties of the door style as described in [Specifying the Display Properties of a Door Style](#) on page 1268.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Click the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make apply to all objects that are assigned the material.

- 11 Click OK.

Adding Classifications to a Door Style

Use this procedure to specify classifications for definitions applied to a door style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style that you want to change.
- 4 Click the Classifications tab.
The default setting for classification definitions is Unspecified. If no classification definitions are listed, none are applied to door styles.
- 5 For each classification definition, select the classification you want to apply to the current door style.
- 6 Click OK.

Specifying the Display Properties of a Door Style

In most cases, you want the appearance of doors that belong to the same style to be consistent throughout a drawing. To achieve this, you specify the following display properties of the doors in each door style:

- The layer, color, and linetype of door components
- The hatching used with each component
- The cut plane height and the display of components relative to the cut plane
- Other specific door display information, such as the shape of the door swing

You can also use materials to control the display properties of the physical components of a door. Symbolic components, such as the door swing, are not controlled by materials. For more information about using materials in doors, see [About Door Display Components and Materials](#) on page 1265.

Changing the Layer, Color, and Linetype of Door Components

Use this procedure to change the following properties of the display components of a door style:

- Visibility (display component is on or off)
- By material (material assigned to the display component determines its layer properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538. Note also, that if a material assignment determines the properties of components in the door style, you can change the properties of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Assigning Materials to a Door Style](#) on page 1266.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Turning on Materials for a Door Style

Use this procedure to turn on material assignments for individual display representations in a door style.

For more information about using materials to control the display of door components, see [About Door Display Components and Materials](#) on page 1265.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for each component to be controlled by the material. The By Material check box is unavailable for components that cannot be assigned a material.
When you select By Material for a display component, all other settings in the dialog are unavailable. Since the display properties are now taken from the material definition, you can no longer set them directly in the display properties of the door style.
- 9 Click OK.

Using Custom Blocks to Create Door Components

You can add custom blocks for components, such as door hardware, to the display components, or to replace the default display components. For example, you can replace a simple door leaf with a custom six-panel door leaf in which the custom component is to appear. You can have a different custom block for each display representation.

When you add a custom block, you can specify rules for positioning and scaling the new component. Each custom block also appears in the display properties component list so that you can control its layer, color, and linetype. For more information on adding custom blocks, see [Adding Components to a Door Style](#) on page 1269.

If you create a custom block from mass elements, you can use the material assignments of the mass elements to determine the display properties of the custom block.

Be sure to set the properties of objects used to create your custom blocks to ByBlock. Otherwise, you cannot control these objects through the display properties. For more information about ByBlock, see “Use Layers to Manage Complexity” in AutoCAD Help.

Adding Components to a Door Style

Use this procedure to add or edit custom block components in the display representation of door styles.

- 1 Create a block for the component to add to the door style.
Create the block in the same plane as the door that you use to represent the style. For more information about custom blocks, see [Using Custom Blocks to Create Door Components](#) on page 1269.
- 2 Open a tool palette that has a door tool.
- 3 Right-click a door tool, and click Door Styles.

- 4 Select the style you want to edit.
- 5 Click the Display Properties tab.
- 6 Select the display representation in which to display the changes, and select Style Override.

7 If necessary, click  .

8 Click the Other tab.

9 Specify whether to add or edit a block component:

If you want to...	Then...
add a new block component	click Add.
edit an existing block component	select the component to edit, and click Edit. Proceed to step 11.

10 Click Select Block.

11 Select the block to use, and click OK.

12 Specify whether to scale to fit the block component to the object by width, depth, or height, or to lock the XY ratio:

If you want to...	Then...
set the block scale to the width of the object	select Width.
set the block scale to the depth of the object	select Depth.
set the block scale to the height of the object	select Height.
scale the whole block equally, so that one direction is scaled to fit another of the scale criteria	select Lock to XY Ratio.
scale the block to its original size	clear all options under Scale to Fit.

13 Specify whether to mirror the block in the X, Y, or Z direction:

If you want to...	Then...
create a mirror of the block in the X direction	select Mirror X.
create a mirror of the block in the Y direction	select Mirror Y.
create a mirror of the block in the Z direction	select Mirror Z.

14 Specify the X, Y, and Z location of the insertion point.

15 Specify an insertion offset of the block in the X, Y, and Z directions.

16 Specify whether the component is for the door frame, leaf or glass:

If you want to...	Then...
add the block to the inside or outside of the frame	click Frame Component, and click either Outside or Inside.

If you want to...	Then...
add the block to all leaf components or to a single leaf component	click Leaf Component, and click either All or Single. If you select Single, enter the component number.
add the block to all glass components or to a single glass component	click Glass Component, and click either All or Single. If you select Single, enter the component number.

NOTE If you specified Depth for Scale to Fit, the depth will be scaled to the glass thickness. You can scale to the door panel thickness instead by selecting Scale Depth to Panel Thickness.

17 Leaf and glass components are not available in some display representations.

Click OK three times.

Turning Off Custom Components in a Door Style

Use this procedure to turn off custom blocks in a door style.

You can turn off the display of component blocks without removing them from the style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to turn off the display of the door component, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select Disable Custom Blocks.
- 9 Click OK.

Removing Custom Components from a Door Style

Use this procedure to remove components from a door style.

Removing component blocks from a door style deletes them from the style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation from which to remove the door component, and select Style Override.
- 6 If necessary, click  .

- 7 Click the Other tab.
- 8 Select the component to remove, and click Remove.
- 9 Click OK.

Displaying a Straight Door Swing

Use this procedure to display the door swing as a straight line in a door style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display a straight door swing, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select Straight Swing.
- 9 Click OK.

Specifying the Opening Percentage for Display Representations in a Door

Use this procedure to override the opening percentage in the display representation of a door style. For example, you can specify that a door is displayed closed in model and elevation representations, but open in plan representations.

NOTE This setting overrides other door opening percent settings. If the opening percent is specified here, the opening percent entered on the Properties palette when you add or modify doors is ignored.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to override the opening percent, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select Override Open Percent.
- 9 Enter a value for the opening percent.
- 10 Click OK.

Changing the Door Threshold in a Door Style

Use this procedure to display a door threshold and change its dimensions in threshold display representations.

You can turn on threshold display representations in addition to door display representations.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select Threshold Plan, and select Style Override.
- 6 If necessary, click .
- 7 Click the Other tab.
- 8 Under Threshold Dimensions, enter the threshold extension and depth dimensions.
Component A is the swing side of the door. Component B is the other side.
- 9 Click the Layer/Color/Linetype tab.
- 10 Under Visible, click the icons to turn on visibility.
- 11 Click OK.

Changing the Door Threshold Symbol in a Door Style

Use this procedure to specify the symbol indicating a threshold that appears in a door opening for the door style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select Threshold Symbol Plan, and select Style Override.
- 6 If necessary, click .
- 7 Click the Other tab.
- 8 Select the type of symbol you want to display in the door opening.
- 9 Click the Layer/Color/Linetype tab.
- 10 Under Visible, click the icon to turn on visibility.
- 11 Click OK.

Defining a Door Style as Bounding for Associative Spaces

Use this procedure to define a door style that can bound associative spaces.

When a door style is set as bounding, by default all doors that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the door style in an individual door, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door Styles.
- 3 Select a door style.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.

6 Click OK.

Attaching Notes and Files to a Door Style

Use this procedure to enter notes and attach reference files to a door style. You can also edit reference files attached to the style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the door, enter the description under Description.
- 6 Click Notes.
- 7 To add or edit a note, click the Notes tab, and enter the note.
- 8 To attach, edit, or detach a reference file, click the Reference Docs tab:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Click OK when you finish editing.
detach a reference file	select the file name, click Delete, and click OK.

9 Click OK.

Creating Muntins in a Door Style

Door muntins are secondary framing members that hold multiple lights in door glass. AutoCAD Architecture provides an easy way to create muntins with different layout patterns.

Door muntins are available in the following patterns that you can customize into different styles:

- Rectangular
- Diamond
- Prairie 9 Lights
- Prairie 12 Lights
- Starburst
- Sunburst

Starburst and Sunburst patterns are a combined-rectangular pattern with a half-round or quarter-round spoked top. They can be used for half- and quarter-round door glass as well as rectangular door glass. The other patterns are primarily rectangular but fit into half-round glass. You can make up custom glass shapes by creating profiles from polylines and adding them to a new door style.

Door muntin components

Process Overview: Creating Door Muntins

You must have a void for the glass in the door in order to add muntins. Sample content provided with the software includes several door styles that already have glass and can receive muntins. The door style description indicates whether the style has glass. You can create door styles with a glazing void to receive muntins.

The process of creating a door style with door glass and muntins has three steps:

- 1 Create a void for door glass and muntins.

You create a profile from two concentric polylines that define the door shape and the door glass.

Concentric closed polylines for a door profile

- 2 Add glass to a door style.

You apply the profile with a void to a door style so that the style has glass for doors to receive muntins.

Door style created from a profile

- 3 Add muntins to the door style.

Door glass with muntins

Creating a Void for Door Muntins

Use this procedure to create a profile of a door with a void for glass to receive muntins. This is the first step for adding muntins to door styles that do not have glass.

The profile is made up of concentric, closed polylines. The outer polyline, or ring, becomes the door shape, and the inner polyline becomes the void for the glass. You can create multiple voids by adding more inner polylines. Voids for glazing must be entirely within the polyline representing the door shape. The polylines are proportional in size and shape to each other and also to the individual doors created from the door style.

You can draw these polylines anywhere in the drawing and use any convenient scale relative to your final door and glass size. One method for sizing the polylines relative to the door is to draw them by snapping to an existing door, and then move them to the side.

Concentric closed polylines for a door profile

- 1 Draw concentric, closed polylines representing the door and the glass that receives the muntin pattern.
- 2 Select the polylines, right-click, and click Convert To ► Profile Definition.
- 3 Select the outermost polyline.
- 4 Enter **a** (Add ring).
- 5 Select an inner polyline.
- 6 Repeat steps 3 and 4 as needed to add more voids to the profile.
- 7 Specify the insertion point of the profile.
- 8 Enter **n** (New), enter a name for the profile, and click OK.

To add the profile to a door style, see [Adding Glass to a Door Style](#) on page 1276.

Adding Glass to a Door Style

Use this procedure to create a door style with glass for doors to accept muntin patterns.

The drawing must contain a profile that defines the door style and the void for the door glass. For more information about creating such a profile, see [Creating a Void for Door Muntins](#) on page 1276.

Door profile with a void for glass

Door style created from the profile

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Door Styles.
- 3 Create a door style:

If you want to...	Then...
create a style with default properties	right-click Door Styles, and click New.
create a style from an existing style	right-click the Door style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Select the new door style, right-click, and click Rename.
- 5 Enter a name for the new door style, and press *ENTER*.
- 6 Select the new door style.
- 7 Click the Design Rules tab.
- 8 Under Shape, select Use Profile, and select a profile that defines a door style containing a void for door glass.
- 9 Click the Standard Sizes tab.
- 10 Add new sizes to the style.
For more information about adding standard sizes to a door style, see [Specifying the Standard Sizes of a Door Style](#) on page 1262.
- 11 Click OK.

The door style now contains glass. You can now add muntins to a door style.

Adding Rectangular or Diamond Muntins to a Door Style

Use this procedure to add rectangular or diamond muntins to a door style that contains glass.

You add muntins by editing the display properties of the door style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and apply them to all display representations of that door style. You add the muntins block to glass components of the door style in display properties. Each muntins block becomes a display component of the door style.

Rectangular door glass with rectangular muntins

Gothic door glass with diamond muntins

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.

NOTE A door style must contain glass to receive muntins. For more information about adding glass to a door style, see [Adding Glass to a Door Style](#) on page 1276.

- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the door style contains multiple glass components, specify whether you want to apply muntins to all glass components or to one glass component in the door:

If you want to...

Then...

attach muntins to all glass components

under Glass Component, select All.

If you want to...**Then...**

apply muntins to an individual glass component

under Glass Component, select Single, and specify the index number. Lights are indexed counterclockwise, starting from the lower-left corner.

Muntins applied to all or one glass component**11** Enter a value for the width of all muntins.**12** Enter a value for the depth of all muntins.**Specifying muntin width and depth****13** Clean up the muntin intersections:

If you want to...**Then...**

convert the muntin intersections to corners

under Muntin, select Clean Up Joints.

convert all the muntins to one body with the joints cleaned up

under Muntin, select Convert to Body.

Specifying muntin cleanup joints

cleanup muntin joints on

cleanup muntin joints off

Converting muntins to a body

muntins with
joint cleanup

muntins converted
to body

hidden line view

14 Under Lights, select a pattern:

If you want to...

Then...

use a rectangular pattern

select Rectangular for pattern.

use a diamond pattern

select Diamond for pattern.

15 Enter a value for Lights High to specify the number of light rows in the vertical direction.

16 Enter a value for Lights Wide to specify the number of light columns in the horizontal direction.

Values for lights high and lights wide

two lights
high by two
lights wide

three lights
high by three
lights wide

four lights
high by four
lights wide

17 Click OK.

18 Add other muntins:

If you want to...

Then...

add muntins to another glass component in the door style

repeat this procedure from step 8.

add muntins to another display representation

click OK, and repeat this procedure from step 5.

add muntins to all display representations of the selected door style

select Automatically Apply to Other Display Representations and Object Overrides.

19 When you finish adding muntins to the door style, click OK three times.

After you add a muntins block to a door style, you can assign a material, such as wood sash, and specify the display properties, such as color and linetype. For more information, see [Assigning Materials to a Door Style](#) on page 1266 and [Changing the Layer, Color, and Linetype of Door Components](#) on page 1268.

Adding Prairie-Lights Muntins to a Door Style

Use this procedure to add prairie-9-lights or prairie-12-lights muntins to a door style that contains glass.

You add muntins by editing the display properties of the door style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and apply them to all display representations of that door style. You add the muntins block to glass components of the door style in display properties. Each muntins block becomes a display component of the door style.

Rectangular door glass with prairie-9-lights muntins

Rectangular door glass with prairie-12-lights muntins

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.

NOTE A door style must contain glass to receive muntins. For more information about adding glass to a door style, see [Adding Glass to a Door Style](#) on page 1276.

- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the door style contains multiple glass components, specify whether you want to apply muntins to all glass components or to one glass component in the door:

If you want to...	Then...
attach muntins to all glass components	under Glass Component, select All.
apply muntins to an individual glass component	under Glass Component, select Single, and specify the index number. Lights are indexed counterclockwise, starting from the lower-left corner.

Muntins applied to all or one glass component

- 11 Enter a value for the width of all muntins.
- 12 Enter a value for the depth of all muntins.

Specifying muntin width and depth

13 Clean up the muntin intersections:

If you want to...

Then...

convert the muntin intersections to corners

under Muntin, select Clean Up Joints.

convert all the muntins to one body with the joints cleaned up

under Muntin, select Convert to Body.

Specifying muntin cleanup joints

cleanup muntin joints on

cleanup muntin joints off

Converting muntins to a body

14 Under Lights, select a pattern:

If you want to...

Then...

use a nine-light prairie pattern

select Prairie-9-Lights for Pattern.

use a twelve-light prairie pattern

select Prairie-12-Lights for Pattern.

15 Enter a value for Edge X Offset to specify the horizontal distance of the muntins from the edges of the glass.

16 Enter a value for Edge Y Offset to specify the vertical distance of the muntins from the edges of the glass.

Specifying edge X and Y offsets

17 Click OK.

18 Add other muntins:

If you want to...

Then...

add muntins to another glass component in the door style

repeat this procedure from step 8.

add muntins to another display representation

click OK, and repeat this procedure from step 5.

If you want to...	Then...
add muntins to all display representations of the selected door style	select Automatically Apply to Other Display Representations and Object Overrides.

19 When you finish adding muntins to the door style, click OK three times.

After you add a muntins block to a door style, you can assign a material, such as wood sash, and specify the display properties, such as color and linetype. For more information, see [Assigning Materials to a Door Style](#) on page 1266 and [Changing the Layer, Color, and Linetype of Door Components](#) on page 1268.

Adding Starburst Muntins to a Door Style

Use this procedure to add starburst muntins to a door style that contains glass.

You add muntins by editing the display properties of the door style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and apply them to all display representations of that door style. You add the muntins block to glass components of the door style in display properties. Each muntins block becomes a display component of the door style.

Half-round door glass with starburst muntins

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.

NOTE A door style must contain glass to receive muntins. For more information about adding glass to a door style, see [Adding Glass to a Door Style](#) on page 1276.

- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the door style contains multiple glass components, specify whether you want to apply muntins to all glass components or to one glass component in the door:

If you want to...	Then...
attach muntins to all glass components	under Glass Component, select All.

If you want to...**Then...**

apply muntins to an individual glass component

under Glass Component, select Single, and specify the index number. Lights are indexed counterclockwise, starting from the lower-left corner.

Muntins applied to all or one glass component

11 Enter a value for the width of all muntins.

12 Enter a value for the depth of all muntins.

Specifying muntin width and depth

13 Clean up the muntin intersections:

If you want to...**Then...**

convert the muntin intersections to corners

under Muntin, select Clean Up Joints.

convert all the muntins to one body with the joints cleaned up

under Muntin, select Convert to Body.

20 Click OK.

21 Add other muntins:

If you want to...	Then...
add muntins to another glass component in the door style	repeat this procedure from step 8.
add muntins to another display representation	click OK, and repeat this procedure from step 5.
add muntins to all display representations of the selected door style	select Automatically Apply to Other Display Representations and Object Overrides.

22 When you finish adding muntins to the door style, click OK three times.

After you add a muntins block to a door style, you can assign a material, such as wood sash, and specify the display properties, such as color and linetype. For more information, see [Assigning Materials to a Door Style](#) on page 1266 and [Changing the Layer, Color, and Linetype of Door Components](#) on page 1268.

Adding Sunburst Muntins to a Door Style

Use this procedure to add sunburst muntins to a door style that contains glass.

You add muntins by editing the display properties of the door style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and apply them to all display representations of that door style. You add the muntins block to glass components of the door style in display properties. Each muntins block becomes a display component of the door style.

Quarter-round door glass with sunburst muntins and closed hub

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.

NOTE A door style must contain glass to receive muntins. For more information about adding glass to a door style, see [Adding Glass to a Door Style](#) on page 1276.

- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the door style contains multiple glass components, specify whether you want to apply muntins to all glass components or to one glass component in the door:

If you want to...	Then...
attach muntins to all glass components	under Glass Component, select All.
apply muntins to an individual glass component	under Glass Component, select Single, and specify the index number. Lights are indexed counterclockwise, starting from the lower-left corner.

Muntins applied to all or one glass component

- 11 Under Shape, select Half Round or Quarter Round.
- 12 Enter a value for the width of all muntins.
- 13 Enter a value for the depth of all muntins.

Specifying muntin width and depth

14 Clean up the muntin intersections:

If you want to...

Then...

convert the muntin intersections to corners

under Muntin, select Clean Up Joints.

convert all the muntins to one body with the joints cleaned up

under Muntin, select Convert to Body.

Specifying muntin cleanup joints

cleanup muntin joints on

cleanup muntin joints off

Converting muntins to a body

15 Under Lights, select Sunburst for pattern.

16 Enter a value for Lights High to specify the number of light rows in the vertical direction, exclusive of the spoked lights.

17 Enter a value for Lights Wide to specify the number of light columns in the horizontal direction.

Count the columns as though they continue around the hub. For a half-round sunburst, five apparent columns are counted as two. For a quarter-round sunburst, three apparent columns are also counted as two.

18 Enter a value for Spokes to specify the number of radial muntin spokes.

Specifying the number of radial muntin spokes

19 Under Hub Style, select Closed for no hub light, or select Open for a hub light.

Specifying closed and open hubs

20 Enter a value for Radius to specify the radius for the hub.

Specifying hub radius

21 Specify where to place the hub:

If you want to...	Then...
place the hub at the bottom of a half-round shape	under Hub Center, select Bottom Center.
place the hub at the top of a half-round shape	under Hub Center, select Top Center.
place the hub at the bottom left of a quarter-round shape	under Hub Center, select Bottom Left.
place the hub at the bottom right of a quarter-round shape	under Hub Center, select Bottom Right.
place the hub at the top left of a quarter-round shape	under Hub Center, select Top Left.
place the hub at the top right of a quarter-round shape	under Hub Center, select Top Right.

Specifying hub placement of quarter-round shape

22 Click OK.

23 Add other muntins:

If you want to...	Then...
add muntins to another glass component in the door style	repeat this procedure from step 8.
add muntins to another display representation	click OK, and repeat this procedure from step 5.
add muntins to all display representations of the selected door style	select Automatically Apply to Other Display Representations and Object Overrides.

24 When you finish adding muntins to the door style, click OK three times.

After you add a muntins block to a door style, you can assign a material, such as wood sash, and specify the display properties, such as color and linetype. For more information, see [Assigning Materials to a Door Style](#) on page 1266 and [Changing the Layer, Color, and Linetype of Door Components](#) on page 1268.

Editing a Door Muntins Block in a Door Style

Use this procedure to edit the muntins settings for a door style.

After you create a muntins block, you can change its settings by editing the display properties of the door style for each display representation, such as Model or Elevation. You can edit the muntins for display representations individually. You can also edit the muntins for a single display representation and apply the changes to all display representations of that door style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.

5 Select the display representation in which to display the changes, and click .

6 Click the Muntins tab.

7 Select the muntins block to edit.

8 Click Edit.

9 Edit any of the settings.

For more information on settings, refer to the door muntins type in [Creating Muntins in a Door Style](#) on page 1274.

10 Select Automatically Apply to Other Display Representations and Object Overrides to apply edits to all display representations of the selected door style.

Clear this setting to apply edits to only the selected display representation.

11 When you finish editing the door muntins block in the door style, click OK three times.

You can edit the display properties, such as color and linetype, for the muntins block. For more information, see [Changing the Layer, Color, and Linetype of Door Components](#) on page 1268.

You can also edit the material applied to the muntins. For more information, see [Assigning Materials to a Door Style](#) on page 1266.

Turning Off the Display of Muntins in a Door Style

Use this procedure to turn off the display of muntins in a door style. You can turn off the display of door muntins without removing them from the style.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to turn off the display of door muntins, and click .
- 6 Click the Muntins tab.
- 7 Select Disable Muntins Blocks.
- 8 Select Automatically Apply to Other Display Representations and Object Overrides to turn off muntins block(s) for all display representations of the selected door style.
Clear this setting to turn off muntins block(s) for only the selected display representation.
- 9 Click OK two times.

Removing a Door Muntins Block from a Door Style

Use this procedure to remove muntins from a door style.

When you remove muntins blocks from a door style, they are deleted. To turn off muntins without deleting them, see [Turning Off the Display of Muntins in a Door Style](#) on page 1295.

- 1 Open a tool palette that has a door tool.
- 2 Right-click a door tool, and click Door Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation for which to remove door muntins, and click .
- 6 Click the Muntins tab.
- 7 Select the muntins block to remove.
- 8 Click Remove.
- 9 Repeat steps 7 and 8 to remove multiple muntins blocks.
- 10 Select Automatically Apply to Other Display Representations and Object Overrides to remove muntins block(s) from all display representations of the selected door style.
Clear this setting to remove muntins block(s) from only the selected display representation.
- 11 When you finish removing muntins blocks from the door style, click OK two times.

Windows

23

A window is an AEC object that interacts with walls and door and window assemblies. After a window is placed in a wall or door and window assembly, the window is constrained to the object and cannot move outside it. Windows can be anchored to specific locations in walls or door and window assemblies; when the wall or door and window assembly moves or changes size, the location of the window in that object stays constant. Windows can also be freestanding objects.

Windows

A window is an AEC object that interacts with walls and door and window assemblies. After a window is placed in a wall or door and window assembly, the window is constrained to the object and cannot move outside it. Windows can be anchored to specific locations in walls or door and window assemblies; when the wall or door and window assembly moves or changes size, the location of the window in that object stays constant. Windows can also be freestanding objects.

Creating Windows

You can create windows using all of the typical design parameters for style, standard size, width and height, threshold height, head height, and vertical alignment. You can choose styles with glass shapes that receive standard muntins patterns, and create your own custom glass shapes from profiles.

Working with Window Styles

Templates provided with AutoCAD Architecture contain ready-to-use window styles. The design rules of a window style determine the default dimensions of windows created from the style. The window style also determines the window shape and the window type:

- The window shape determines the geometry of the window frame, such as rectangular, half round, and arch. You can also create custom window shapes from profiles.
- The window type determines the number of panels and the method of opening the window, such as glider, pass-through, hopper, or picture.

You can also define standard sizes in a window style and then select the size you want to use when you place the window in a drawing.

Anchoring Windows

After a window is placed in a wall or door and window assembly, the window is constrained to the object and cannot move outside it.

Windows can also be anchored to specific locations in walls or door and window assemblies that when the wall or door and window assembly moves or changes size, the location of the window in that object stays constant.

Window Dimensions

Some window dimensions depend on the window shape and type specified in the window style.

Rise is the height from the top of the rectangular portion of a window to the peak of the window opening for Gothic, Arch, and Peak Pentagon window shapes.

Vertical Alignment of Windows

To control how you place the window in the wall, the location of the working point vertically in the wall, and how the window responds to modifications in height, use the vertical alignment settings. To determine the working point on the window, use the threshold and head height settings. You can place the working point at the sill or at the head.

The threshold height is maintained. For example, if you specify the vertical alignment as 0" and the window height as 7'-0", the window opening height is 7'-0". If you next specify the height of the window as 6'-8", the window threshold remains at 0" and the window opening height becomes 6'-8".

The window head work point is maintained. For example, if you specify the vertical alignment as 7'-0" and the window height as 7'-0", the window opening height is 7'-0". If you specify the window height as 6'-8", the window head remains at 7'-0" and the window threshold becomes 4".

Materials in Windows

In AutoCAD Architecture, you can assign materials to a window. These materials then are displayed in wireframe or rendered views. Materials have specific settings for individual components of a window, such as the frame, the sash, or the muntins. For more information, see [Material Components and Display Properties](#) on page 610.

Window in 2D wireframe and rendered views

AutoCAD Architecture provides a large number of predefined materials for all common design purposes, which contain settings for windows. You can use these predefined materials, or modify them to your special designs. You can also create your own materials. If you create a material that should specifically be used only for windows, it is recommended that you name it accordingly; for example, Window - Wood Frame or Window Sill - Marble. For more information, see [Creating and Editing Material Definitions](#) on page 624.

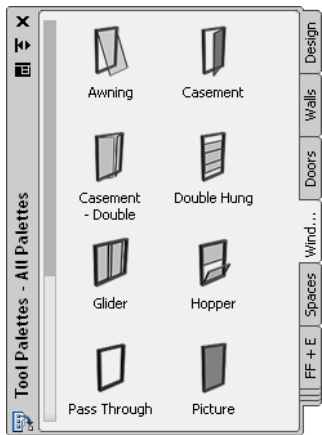

Window Endcaps

Windows that are anchored in a wall can have endcap styles applied to them. The endcap shapes for wall openings are defined in the wall style and are a property of the wall. For information on setting an opening endcap style in a wall, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

Using Window Tools to Create Windows

Tools provided with AutoCAD Architecture let you quickly place windows by selecting a window tool with a specific window style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can also use window tools to create new windows by applying tool properties to existing door/window assemblies, openings and doors.

Tool palette containing window tools

The following palettes contain one or more window tools:

Tool palette...	Contains...
Design	a window tool for the Standard window style and default settings for other window properties
Windows	a window tool for sample window styles, with default properties appropriate for each window style
Custom tool palettes created by your CAD manager	window tools with window styles and properties that are customized for your projects or office standards

When you place windows using windows tools, you can use the default settings of the tool, or you can change settings for any windows properties that are not controlled by the style.

Creating a Window

Use this procedure to add a new window that has the properties specified in the window tool that you select. To specify settings when you add a window, see [Creating a Window with User-Specified Settings](#) on page 1300.

- 1 Open the tool palette that you want to use, and select a window tool.

If necessary, scroll the palette to display the tool that you want to use.

2 Select a wall or door and window assembly in which to insert the window, or press *ENTER* to add a freestanding window.

You can move or hide the Properties palette to expose more of the drawing area.

3 Specify the insertion point of the window.

4 Continue adding windows, and press *ENTER*.

Creating a Window with User-Specified Settings

Use this procedure to create any of the following, with settings that you specify:

- Freestanding windows
- Windows in walls

Adding a window to a wall

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

1 Open the tool palette that you want to use, and select a Window tool.

If necessary, scroll the tool palette to display the tool you want to use.

2 On the Properties palette, expand Basic, and expand General.

3 Select a window style.

4 Under Bound Spaces, define if this window can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this window can be used as bounding object for associative spaces.
- No: this window cannot be used as bounding object for associative spaces.

- By style: this window will use the bounding settings from the window style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

5 Expand Dimensions.

6 Specify a window size:

If you want to...	Then...
use a standard window size	click Standard Sizes, and then select a window size.
use a custom window size	enter values for Width and Height.

7 Enter a value for Rise, if applicable to the selected style and window type.

8 Specify where the window width and height are measured to:

If you want to measure to...	Then...
the outside of the window frame	Select Outside of frame for Measure to.
the inside of the window frame	Select Inside of frame for Measure to.

9 Enter a value for Opening percent or Swing angle.

Zero indicates a closed window.

10 Expand Location.

11 If you are placing the window in a wall, specify the position of the window:

If you want to...	Then...
position the window at a specific distance between the edge of the opening and the end of a wall segment	select Offset/Center for Position along wall, and enter a value for Automatic offset.
center the window on a wall segment	select Offset/Center for Position along wall, and specify a point near the center of the wall segment.
position the window anywhere along the wall	click Position along wall, and select Unconstrained.

12 Specify whether you want the window aligned vertically by sill height or by head height:

If you want to align the window...	Then...
by sill height	select Sill for Vertical alignment, and enter a value for Sill height.
by head height	select Head for Vertical alignment, and enter a value for Head height.

13 Specify the insertion point for a freestanding window or a window in a wall:

If you want to insert...

Then...

a freestanding window

press *ENTER*, and specify an insertion point and a rotation angle for the window.

the window in a wall

select the wall and specify an insertion point along the wall.

TIP There are 2 command line options that make the insertion of a window in a specific location easier: You can switch the insertion point of the window from left (default) to center and right by entering **CY** (cycle measure to) once or twice on the command line. You can also measure the insertion point of a window in relation to a specified point in the drawing - for example the frame of a door - by entering **RE** (Reference point on) and then selecting the point from which the distance should be measured.

14 Continue to place windows by selecting window styles and specifying insertion points, or press *ENTER* to end the command.

Creating a Window in a Door and Window Assembly

Use this procedure to insert a window into a door and window assembly.

- 1 Open the tool palette that you want to use, and select a Window tool.
If necessary, scroll the tool palette to display the tool you want to use.
- 2 Select a door and window assembly to insert the window into.
- 3 Select the grid cell on the door and window assembly into which you want to insert the window.
- 4 Commence adding the window to the door and window assembly, as described in [Inserting a Door or Window into a Door and Window Assembly](#) on page 1151.

Creating a Window from Doors, Door/Window Assemblies and Openings

Use this procedure to convert a door, door/window assembly, or opening to a window that has the properties of the window tool you select. You can edit these properties after creating the window.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a window tool, and click Apply Tool Properties to ► Door, Door/Window Assembly, Opening.
- 3 Select the door or window assembly, opening, or door to convert, and press *ENTER*.
- 4 Edit the properties of the window in the Properties palette, if needed.

Creating a Window Tool

Use this procedure to create a window tool and add it to a tool palette. You may want to create your own window tools if you are placing multiple windows of specific styles with additional properties that you want to be the same each time you add a window of each type.

For example, you are creating an office floor plan that contains two custom window styles: fixed casement for conference rooms and operable casement for offices. To work efficiently, you can create a window tool for each style. You can then select the appropriate tool to place windows in offices and conference rooms.

You can use any of the following methods to create a window tool:

- Drag a window that has the properties you want to a tool palette.
- Drag a window style from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Copy an existing tool, and then customize the properties of the new tool.
- Drag a tool from a tool catalog in the Content Browser, and then customize the properties of the tool. For information about using the Content Browser to create a tool, see [Using Tool Catalog Items in AutoCAD Architecture 2009](#) on page 146.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a window in the drawing	select the object, and drag it to the tool palette.
create a tool from a window style in the Style Manager.	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK.
copy a tool in the current palette	right-click the tool, click Copy, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tool's tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Enter a description of the tool.

8 If you do not want to use the default layer key for windows, select a layer key.

9 If you want to override the default layer name for windows, select a layer override.

10 Select a window style.

11 For Style location, select the drawing file containing the style used for this window, or select Browse and use a standard file selection dialog box to select the file.

12 Under Bound Spaces, define if this window tool can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this window tool can be used as bounding object for associative spaces.
- No: this window tool cannot be used as bounding object for associative spaces.
- By style: this window tool will use the bounding settings from the window style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

13 Expand Dimensions.

14 Specify a window size:

If you want to...	Then...
use a standard window size	click Standard Sizes, and then select a window size.
use a custom window size	enter values for Width and Height.

15 Specify where the window width and height are measured to:

If you want to measure to...	Then...
the outside of the window frame	Select Outside of frame for Measure to.
the inside of the window frame	Select Inside of frame for Measure to.

16 Enter a value for Rise, if applicable to the selected style and window type.

17 Enter a value for the Opening percent or Swing angle.

Zero indicates a closed window.

NOTE Defining the opening percent in display properties overrides this setting on the Tool Properties palette. For more information, see [Specifying the Display Properties of a Window Style](#) on page 1335.

18 Expand Location.

19 Specify the position of the window when it is placed in a wall:

If you want to...	Then...
position the window at a specific distance between the edge of the opening and the end of a wall segment	select Offset/Center for Position along wall, and enter a value for Automatic offset.
center the window on a wall segment	select Offset/Center for Position along wall, and specify a point near the center of the wall segment
position the window anywhere along the wall	click Position along wall, and select Unconstrained.

20 Enter a value for the head height.

21 Enter a value for the sill height.

22 Click OK.

Editing Windows

After you create a window, you can change the size, height, width, rise, and opening. You can also move the window within the wall, flip the hinge or swing, and change the swing opening.

You can change the properties of existing windows in your drawing by changing the window style, changing the dimensions of the window, moving the anchor location of the window, and specifying the endcap conditions of the window.

AutoCAD Architecture offers several methods for editing windows:

- You can directly edit windows using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- You can change window settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- You can select editing commands from the shortcut menu for a selected window.

Using Grips to Edit Windows

You can use grips to modify the following window properties:

- Dimensions (width and height)
- Location in a wall
- Hinge side (left- or right-hand)
- Swing direction
- Rise
Rise applies to Peak Pentagon, Arch, and Gothic window shapes. For more information, see [Specifying the Design Rules of a Window Style](#) on page 1331.

Refer to the illustrations and steps in this topic to use window grips to edit windows.

Editing the Dimensions of a Window That Has Standard Sizes

- 1 Select the window.

Window Dimension Grips

2 Select the grip for the dimension you want to change.

The grip is initially set to constrain the sizing to one of the standard values defined for the style of window. For example, if you select the width grip, the grip is set to constrain the width to one of the standard values defined for that style of window.

Standard height window with width grip selected

The *CTRL* key acts as a toggle between standard and custom sizing.

A series of tick marks indicates the standard sizes for the selected dimension. As you move the grip, it snaps to each tick mark and displays the measurement at that mark.

The size and color of the grip tick marks indicate whether setting a standard value for the dimension results in a standard window size. For example, if the height of the window is set to a non-standard value, the window is still not a standard size even if you set the window width to one of the standard width values for that window style. Long grey tick marks indicate that a standard size is possible; short red marks indicate that another dimension is already set to a non-standard value.

3 Resize the dimension:

If you want to change the dimension...

Then...

using a standard size

move the grip until the value you want is displayed, and click once.

If you want to change the dimension...**Then...**

using a non-standard size

press *CTRL*, and either move the grip until the value you want is displayed and then click once, or else enter a value.

Changing a window width

existing wall and window

select window

select Width grip

verify initial window width

specify new grip location

result

Changing a window height

existing wall and window

select window

select Height grip

Custom Height
Press Ctrl to toggle between:
- Standard height
- Custom height

verify initial window head height

Set height to standard size
Long gray marks - Current width and rise are standard
Short red marks - Current width or rise is non-standard

specify new grip location

result

Editing the Dimensions of a Window That Does Not Have Standard Sizes

- 1 Select the window.
- 2 Select the grip for the dimension you want to change.
- 3 Either move the grip until the dimension value you want is displayed and then click once, or else enter a value.

Moving a Window Anchored to a Wall

- 1 Select the window.
- 2 Select the Location grip.

Window Location and Flip Grips

- 3 With the grip selected, press the *CTRL* key to switch the direction of movement. You can move along the wall, within the wall, and vertically.
- 4 Move the grip until the window is in the desired location, and click once.

Moving a Freestanding Window

- 1 Select the window.
- 2 Select the Location grip.
- 3 Move the window to the appropriate location, and click once.

Changing the Hinge Side of a Window

- 1 Select the window.
- 2 Select the Flip grip to reverse the side of the window that hinges are located on.

Flipping a window hinge

Changing the Swing Direction of a Window

- 1 Select the window.
- 2 Select the Flip grip to reverse the swing direction of the window.

Flipping a window swing

Changing the Rise of a Window

- 1 Select the window.
- 2 Select the Rise grip.

Changing a window rise

3 Move the grip until the rise value you want is displayed and click once, or enter a value.

Changing the Window Style

Use this procedure to change the style for a window or group of windows.

- 1 Select one or more windows, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a window style.

Changing How Window Width is Measured

Use this procedure to change how the width of a window or windows is measured.

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Dimensions.

Specifying window frame measurement

3 Specify the location to which window width is measured:

If you want to size the windows...

Then...

to the inside frame

select Inside of frame for Measure to.

to the outside frame

select Outside of frame for Measure to.

Changing the Window Swing Angle or Opening Percent

Use this procedure to change the swing angle or opening percent of a window or group of windows.

A window with an opening percent of zero is closed.

NOTE Defining the opening percent in display properties overrides this setting on the Properties palette. For more information, see [Specifying the Display Properties of a Window Style](#) on page 1335.

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Dimensions.
- 3 Enter a value for Swing angle or Opening percent.

Changing a window swing angle

Changing the Vertical Alignment of a Window

Use this procedure to change the vertical alignment of a window or group of windows.

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Specify whether you want the window aligned vertically by sill height or by head height:

If you want to align the windows...	Then...
by sill height	select Sill for Vertical alignment, and enter a value for Sill height.
by head height	select Head for Vertical alignment, and enter a value for Head height.

Moving a Window Along a Wall

Use this procedure to change the location of one or more windows along a wall by offsetting the windows from a reference location.

This feature is useful when you want to position a window at a specified distance from another object. For example, you may want to specify an exact distance between a series of windows along a wall.

NOTE If the defect marker appears in the wall after you move a window, the window is too close to other objects in the wall or to the end of the wall for the endcaps to fit. Adjust the position of the window until the defect marker disappears.

- 1 Select the window you want to move, right-click, and click Reposition Along Wall.
A marker indicates the current location within the opening.

2 Specify where to measure the offset from:

If you want to measure the offset...	Then...
from the center of the window	select a point near the center of the window.
from an end of the window	select a point on the end of the window you want to measure from.

3 Select a point to measure to (the reference point).

You can select a point along the wall.

4 Specify the distance between the points you selected:

If you want to...	Then...
move the window to the reference point	enter 0.
move the window a specified distance from the reference point	enter a value for the offset distance.
specify the distance as a measurement between two points, such as the distance between the centers of two windows that are correctly positioned	select the two points measuring the distance.

Repositioning a window along a wall

existing wall and window

select window

Location
Press Ctrl to cycle between:
- Move along
- Move within
- Move vertically

select Location grip

Move along length

verify initial Window location

specify new grip location

result

Moving a Window Within a Wall

Use this procedure to move one or more windows within a wall by offsetting the windows from a reference location.

This feature allows you to align windows within the thickness of a wall. You can set an offset distance from any point within a wall, or center the windows between the faces of a wall. You can select doors, windows, and openings and reposition them at the same time. If you select more than one object, you can select only one side to offset.

1 Select the windows you want to move, right-click, and click **Reposition Within Wall**.

A marker indicates the current location within the opening. This may be the center of the frame, the interior face of the frame, or the exterior face of the frame.

2 Specify where to measure the offset from:

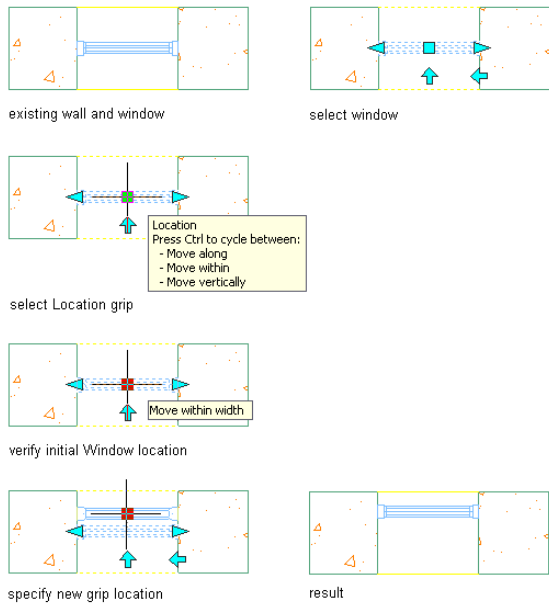

If you want to...	Then...
center the windows between the faces of the wall	select a point near the center of the window.
offset the windows from the interior or exterior face	select a point on the side of the face you want to measure from.

3 Select a point to measure to.

4 Specify the offset distance from the selected point:

If you want to...	Then...
center the windows between the faces of the wall	use the Midpoint osnap to select the midpoint of the end of the wall.
move the windows to the reference point	enter 0.
move the windows a specified distance	enter a value for the offset distance.
specify the distance as a measurement between two points	select the two points measuring the distance.

Repositioning a window within a wall

Using Anchors to Change the Horizontal Position of a Window

Use this procedure to change the horizontal position of windows along a wall to which the windows are anchored.

Window position along the X axis parameters

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the X axis:

If you want to...	Then...
use the start of the wall as the reference point	under Position Along (X), select Start of wall for From.
use the midpoint of the wall as the reference point	under Position Along (X), select Midpoint of wall for From.
use the end of the wall as the reference point	under Position Along (X), select End of wall for From.

- 5 Enter the distance from the reference point at which to place the windows.
Use a negative value to measure from endpoint to start point.

- 6 Select the position of the windows to measure to:

If you want to measure to...	Then...
the start edge of the windows	select Start Edge of object for To.
the center of the windows	select Center of object for To.
the end edge of the windows	select End Edge of object for To.

7 Click OK.

Using Anchors to Change the Vertical Position of a Window

Use this procedure to change the vertical position of windows in a wall to which the windows are anchored.

Window position along the Z axis parameters

z-axis wall parameters

z-axis window parameters

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the Z axis:

If you want to...	Then...
-------------------	---------

use the bottom of the wall height as the reference point

under Position Along (Z), select Bottom of wall height for From.

use the center of the wall height as the reference point

under Position Along (Z), select Center of wall height for From.

use the top of the wall height as the reference point

under Position Along (Z), select Top of wall height for From.

- 5 Enter the distance from the reference point at which to place the windows.
Use a negative value to measure from endpoint to start point.

- 6 Select the position of the windows to measure to:

If you want to measure to...	Then...
------------------------------	---------

the bottom of the windows

select Sill (Bottom) of object for To.

If you want to measure to...	Then...
the center of the windows	select Center of object for To.
the top of the windows	select Head (Top) of object for To.

7 Click OK.

Using Anchors to Change the Position of a Window Within a Wall

Use this procedure to change the position of windows horizontally within a wall to which the windows are anchored.

Window position along the Y axis parameters

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the Y axis:

If you want to...	Then...
use the left edge of the wall as your reference point	select Left edge of wall width for From.
use the center of the wall as your reference point	select Center of wall width for From.
use the right edge of the wall as your reference point	select Right edge of wall width for From.

- 5 Enter the distance from the reference point at which to place the windows.
Use a negative value to measure from endpoint to start point.

- 6 Select the position of the windows to measure to:

If you want to measure to...	Then...
the front of the windows	select Front of object for To.
the center of the windows	select Center of object for To.
the back of the windows	select Back of object for To.

7 Click OK.

Changing the Orientation of a Window to a Wall

Use this procedure to change the vertical orientation of windows in a wall to which the windows are anchored.

- 1 Select the windows you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Enter the X and Z rotation angles of the windows.
- 5 Indicate if you want to reverse the flip direction of the windows in the X, Y, and Z axes:

If you want to reverse...	Then...
the direction the windows open to	select Flip X.
the side of the wall the windows open to	select Flip Y.
the top and bottom of the windows	select Flip Z.

6 Click OK.

Changing the Opening Endcap Assigned to a Window

Use this procedure to change the opening endcap style assigned to windows.

NOTE Each opening endcap style is generally created for use with a specific wall style. Changing the opening endcap style used for individual windows may cause the wall to display a defect marker.

For more information, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

- 1 Select the windows whose endcaps you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Expand Endcaps.
- 4 Select the opening endcap style.

Changing the Location of a Freestanding Window

Use this procedure to relocate a freestanding window by changing the coordinate values of its insertion point. The window also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the window are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the window by aligning its normal with another axis. You can also rotate the window on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Double-click the window you want to move.
- 2 On the Properties palette, expand Basic, expand Location, and click Additional Information.

3 In the Location dialog box, specify the window location:

If you want to...	Then...
relocate the window	enter new coordinate values under Insertion Point.
locate the window on the XY plane	make the normal of the window parallel to the Z axis: under Normal, enter 1 for Z, and enter 0 for X and Y.
locate the window on the YZ plane	make the normal of the window parallel to the X axis: under Normal, enter 1 for X and enter 0 for Y and Z.
locate the window on the XZ plane	make the normal of the window parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.
change the rotation of the window	enter a new value for Rotation Angle.

4 Click OK.

Changing the Cut Plane Setting for a Window

Use this procedure to specify whether a selected window will use the cut plane of the containing object when anchored to that object in the current display representation. Note that cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the window.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that ***NONE*** is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all windows in the drawing, select Drawing default setting. To apply changes to all windows of this style, select Window Style:<style name>. For more information on styles, see [Window Styles](#) on page 1326.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Cut Plane.
- 7 For Use cut plane of containing object when anchored, select Yes or No.

Specifying the Display of Muntins Blocks for a Window

Use this procedure to specify the display of muntins for an individual window in model and elevation views.

- 1 Double-click the window.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that ***NONE*** is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all windows in the drawing, select Drawing default setting. To apply changes to all windows of this style, select Window Style:<style name>. For more information on styles, see [Window Styles](#) on page 1326.

5 For Display representation, verify that the desired display representation is selected.

6 If necessary, expand Object Display Properties ► Advanced, and for Muntins, click  (the number in parentheses indicates the number of muntins blocks currently attached to the window).

7 If you want to turn off the display of muntins blocks for this window without removing them, select Disable Muntins Blocks.

8 Specify whether to add, edit, or remove a block:

If you want to...	Then...
add a new muntins block	click Add.
edit an existing muntins block	select the block to edit, and click Edit.
remove an existing muntins block	select the block, click Remove, and click OK.

9 For Name, enter a name for the new block or edit the existing one as applicable.

10 The rest of the parameters on the Muntins Block worksheet vary according to the type of window and type of pattern selected for the lights. For detailed instructions on specifying these parameters for a particular pattern, refer to the pattern-specific topic as listed under [Creating Muntins in a Window Style](#) on page 1341. When the worksheet parameters are set as desired, click OK.

11 If you want your changes to apply only to the current display representation, clear Automatically Apply to Other Display Representations. (If this option is not selected, you will be prompted to identify the other display representations to which you want your changes applied.)

12 Click OK.

Specifying the Display of Sills for a Window

Use this procedure to change the sill dimensions for a window in the Sill Plan display representation.

1 Double-click the window.

2 Click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all windows in the drawing, select Drawing default setting. To apply changes to all windows of this style, select Window Style:<style name>. For more information on styles, see [Window Styles](#) on page 1326.

5 For Display representation, select Sill Plan.

6 If necessary, expand Object Display Properties ► Advanced, and click  Sill dimensions.

7 On the Sill Dimensions worksheet, enter the sill extension and depth dimensions.

Sill components A and B are for the outside of the opening. Sill components C and D are for the interior side.

8 Click OK.

9 On the Display component drop-down list, click the light bulb icons for individual sill components to turn visibility on or off as desired.

You can also access and modify sill dimensions and visibility settings through the window's context menu, as follows:

- 1 Select the window you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 4 If necessary, click .
- 5 Click the Other tab.

Window sill dimensions

- 6 Under Sill Dimensions, enter the sill extension and depth dimensions.
- 7 On the Layer/Color/Linetype tab, under Visible, click the icons to turn on visibility for individual sill display components as necessary.
- 8 Click OK twice.

Reversing the Handing for a Window in an Elevation View

Use this procedure to specify whether to reverse the current handing of a selected window in the Elevation display representation.

- 1 Double-click the window.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all windows in the drawing, select Drawing default setting. To apply changes to all windows of this style, select Window Style:<style name>. For more information on styles, see [Window Styles](#) on page 1326.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.
- 7 For Reverse handing, select Yes or No.

Specifying the Display of Frames for a Window

Use this procedure to change the frame display for a window in the Plan High Detail display representation.

- 1 Double-click the window.
- 2 Click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all windows in the drawing, select Drawing default setting. To apply changes to all windows of this style, select Window Style:<style name>. For more information on styles, see [Window Styles](#) on page 1326.

5 For Display representation, select Plan High Detail.

6 If necessary, expand Object Display Properties ► Advanced, and click  Frame display.

7 On the Frame Display worksheet, under Type, select either Standard or Offset.

8 For A-Extension, enter a value to indicate the distance you want the frame to extend.

9 Click OK.

You can also access and modify frame display settings through the window's context menu, as follows:

1 Select the window you want to change, right-click, and click Edit Object Display.

2 Click the Display Properties tab.

3 Select the Plan High Detail display representation, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click  .

5 Click the Frame Display tab.

6 Adjust the settings as desired, and click OK twice.

Specifying the Display of Custom Block Components of a Window

Use this procedure to specify the display of custom block components for an individual window in a particular display representation. If you are going to use custom graphics for a new component, draw the component and save it as a block before you start this procedure.

1 Double-click the window.

2 Click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all windows in the drawing, select Drawing default setting. To apply changes to all windows of this style, select Window Style:<style name>. For more information on styles, see [Window Styles](#) on page 1326.

5 For Display representation, verify that the desired display representation is selected.

6 If necessary, expand Object Display Properties ► Advanced, and for Custom block display, click

 (the number in parentheses indicates the number of blocks currently attached to the window).

7 If you want to turn off the display of custom blocks for this window without removing them, select Disable Custom Blocks.

8 Specify whether to add, edit, or remove a block component:

If you want to...	Then...
add a new block component	click Add, and then click Select Block, select the block, and click OK.
edit an existing block component	select the component to edit, and click Edit.
remove an existing block component	select the block, click Remove, and click OK.

9 Specify whether you want to scale to fit the block component to the object by width, depth, and height, or to lock the *XY* ratio:

If you want to...	Then...
set the block scale to the width of the object	select Width.
set the block scale to the depth of the object	select Depth.
set the block scale to the height of the object	select Height.
scale the whole block equally, so that one direction is scaled to fit another of the scale criteria	select Lock to XY Ratio.
scale the block to its original size	clear all options under Scale to Fit.

10 Specify whether to mirror the block in the *X*, *Y*, or *Z* direction:

If you want to create a mirror of the block...	Then...
in the <i>X</i> direction	select Mirror <i>X</i> .
in the <i>Y</i> direction	select Mirror <i>Y</i> .
in the <i>Z</i> direction	select Mirror <i>Z</i> .

11 Specify the *X*, *Y*, and *Z* location of the insertion point.

12 Specify an insertion offset of the block in the *X*, *Y*, and *Z* directions.

13 Specify whether the component is for the window frame or window glass component:

NOTE Both frame and glass components are not available in all display representations.

If you want to add the block...	Then...
to the inside or outside of the frame	select Frame Component, and select either Outside or Inside.

If you want to add the block...	Then...
to all window glass components or a single window glass component	click Window Component, and click either All or Single. If you select Single, enter the component number.
<p>NOTE If you specified Depth for Scale to Fit, the depth is scaled to the glass thickness. You can scale to the window panel thickness instead by selecting Scale Depth to Panel Thickness.</p>	

14 Click OK twice.

Attaching Hyperlinks, Notes, and Files to a Window

Use this procedure to enter notes and attach reference files to a window. You can also edit notes and edit or detach reference files from a window.

- 1 Double-click the window you want to attach notes or files to.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
- 4 To add a note, click  next to Notes, enter text, and click OK.
- 5 Click  next to Reference documents, and then attach, detach, or edit a reference file:

If you want to...	Then...
attach a reference file	click  , select a file, and click Open.
edit the description of a reference file	enter text under Description.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

6 Click OK.

Window Styles

A window style is a group of properties assigned to a window that determines the appearance and other characteristics of the window.

You can use window styles to represent standard window types for specific jobs and drawings or for office standards. When you create or modify a window style, the windows using the style have the settings and characteristics of the style. Templates provided with AutoCAD Architecture contain window styles for many standard windows. You can create your own window styles and window types for custom windows.

Each window you create has a window style associated with it. The window style controls window properties such as dimensions, design rules, and standard sizes for windows. Style control means that when you change a window style, the windows in the current drawing that use that style change globally.

The design rules are window-style properties that determine the predefined or custom shape and window type. Window shapes such as Arch, Gothic, Rectangular, and Round are the geometric configurations of the window. Custom shapes, such as Hinged-Single-Full Lite, are available for particular window types, for example a Single Casement window type. Window types, such as Awning, Pass Through, or Casement, describe window opening characteristics of closure, swing, and hinging.

You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

Creating Tools from Window Styles

You can create a window tool from any window style. You can drag the style from the Style Manager onto a tool palette. You can then specify default settings for any window created with that tool. For more information, see [Using Window Tools to Create Windows](#) on page 1299.

Creating a Window Style

Use this procedure to create a window style.

You can create a new style with default style properties, or you can create a new style by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Window Styles.
- 3 Create a window style:

If you want to create a new style...	Then...
with default properties	right-click Window Styles, and click New.
from an existing style	right-click the window style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new window style, and press *ENTER*.

- 5 Edit the style properties of your new window style:

If you want to...	Then...
enter a description of the style	click the General tab, and enter a description.
change dimension properties of the style	see Specifying the Dimensions of a Window Style on page 1328.
change the design rules of the style	see Specifying the Design Rules of a Window Style on page 1331.
change the standard window sizes of the style	see Specifying the Standard Sizes of a Window Style on page 1329.

If you want to...	Then...
assign materials to the components of the window style,	see Assigning Materials to a Window Style on page 1334 and Turning on Materials for a Window Style on page 1336.
add classifications to a window style	see Adding Classifications to a Window Style on page 1335.
specify the display properties of the style	see Specifying the Display Properties of a Window Style on page 1335.
change the appearance of the display components in the style	see Changing the Layer, Color, and Linetype of Window Components on page 1335.
add custom block components to the style	see Adding Components to a Window Style on page 1337.
turn off components in the style	see Turning Off Components in a Window Style on page 1338.
remove components from the style	see Removing Components from a Window Style on page 1339.
override the opening percentage from the style	see Specifying the Opening Percentage for a Window Style on page 1339.
change the sill from the style	see Specifying the Display of Window Sills in a Window Style on page 1340.
add muntins to the style	see Creating Muntins in a Window Style on page 1341.
add notes, files, or documents to the style	see Attaching Notes and Files to a Window Style on page 1341.

6 If you want to assign the style to a window tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Window Tool](#) on page 1303.

7 Click OK.

Specifying the Dimensions of a Window Style

Use this procedure to change the default dimensions of a window style.

- 1** Open a tool palette that has a window tool.
- 2** Right-click a window tool, and click Window Styles.
- 3** Select the style you want to edit.

4 Click the Dimensions tab.

5 Change dimension values:

If you want to...	Then...
change the frame width and depth	under Frame, enter values for Width and Depth.
set the frame width to the wall thickness	under Frame, select Auto-Adjust to Width of Wall.
change the sash dimensions	under Sash, enter values for Width and Depth.
change the window thickness	enter a value for Glass Thickness.

6 Click OK.

Specifying the Standard Sizes of a Window Style

Use this procedure to create the standard window sizes in a window style.

Standard sizes ensure consistency by allowing designers to select sizes from a predefined list specific to the window style. You can also enter custom sizes when you add or modify individual windows.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the window style you want to edit.
- 4 Click the Standard Sizes tab, and add, change, or remove window-size values:

If you want to...	Then...
create standard sizes	click Add. Under Standard Sizes, enter values for Description, Width and Height; if applicable, enter values for Rise and Bottom Sash.
change a size	select the size, and click Edit. Enter new values as needed.
delete a size	select a size, and click Remove.

Description can be used to identify standard window sizes in window schedules. For example, you can specify a manufacturer's size or model code for Description.

Rise applies to Arch, Gothic, and Peak Pentagon window shapes. Bottom Sash applies to Uneven Single Hung and Uneven Double Hung windows. For more information on window types and shapes, see [Specifying the Design Rules of a Window Style](#) on page 1331.

5 Click OK.

Creating a Custom Window Shape

Use this procedure to create a profile for a custom window shape. You can make custom shapes for windows and apply them to window styles.

The profile is made up of two concentric, closed polylines. The outer polyline, or ring, becomes the window shape, and the inner polyline creates a void for the inside shape of the window frame. You can create multiple voids by adding more inner polylines. The inner polyline must be entirely within the polyline representing the outer shape of the window frame. The polylines are proportional in size and shape to each other and also to the windows created from the window style.

You can draw these polylines anywhere in the drawing and use any convenient scale relative to your final window frame size. One method for sizing the polylines relative to the window is to draw them by snapping to an existing window, and then moving the completed polylines to the side.

Adding a profile-based window to a wall

- 1 Draw concentric, closed polylines representing the outer and inner lines of the window frame.
- 2 Select the outer polyline, right-click, and click Convert To ► Profile Definition.

- 3 Enter **a** (Add ring).
- 4 Select the inner polyline.
- 5 Specify the insertion point of the profile.
The insertion point is typically the lower-left corner.
- 6 Enter a name for the profile, and click OK.

To add the profile to a window style, see [Specifying the Design Rules of a Window Style](#) on page 1331.

Specifying the Design Rules of a Window Style

Use this procedure to specify the shape and the type of window for a window style.

Window shapes are named geometrical descriptions of a window. You can select predefined and custom window shapes, or create your own shape from profiles. For more information, see [Creating a Custom Window Shape](#) on page 1330.

The window type describes the method for opening the window. For example, you can use the Rectangular or Half Round predefined shapes for the Double Casement or Single Hopper window types. Or, you can use a custom Hinged-Single-Full Lite shape for a Single Casement with Muntins.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the window style you want to edit.
- 4 Click the Design Rules tab.
- 5 Select a window shape:

If you want to...	Then...
use a predefined window shape	under Shape, click Predefined, and select a shape.
use a custom window shape	under Shape, click Use Profile, and select a profile.

- 6 Select a window type.
- 7 Click OK.

Editing the Geometry of a Window Style

Use this procedure to edit the geometry of the profile used to define a window style. You can also add a profile to a window style that does not currently use a profile to define its shape.

- 1 Add a window that has the style you want to change.
- 2 Add or edit a profile:

If you want to...	Then...
add an existing profile to the style	select the window, right-click, and click Add Profile. Select the name of the profile, and click OK.
create a profile and add it to the style	select the window, right-click, and click Add Profile. Select Start from scratch for Profile Definition, enter a name for new profile, and click OK. A rectangular

If you want to...	Then...
edit the existing profile for the style	<p>profile is created for you to edit to define the required geometry.</p> <p>select the window, right-click, and click Edit Profile in Place.</p>

3 If prompted that the profile is not drawn to size, click Yes.

The area of the window defined by the profile is selected and hatched in the drawing.

NOTE After you perform an editing task from the shortcut menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the shortcut menu, select the profile, and right-click to display the shortcut menu.

4 Edit the profile:

If you want to...	Then...
change the shape of the perimeter of the profile or its ring	<p>select the profile, and use edge and vertex grips to adjust the shape.</p> <p>The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.</p> <p>Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.</p> <p>Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.</p>
add vertices to the profile	<p>select an Edge grip, and press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press <i>ENTER</i>.</p>
remove vertices from the profile	<p>select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.</p>
replace an existing ring of the profile with new geometry	<p>select the profile, right-click, and click Replace Ring. Select the ring to replace, and select the new geometry. Press <i>ENTER</i> to keep the geometry, or enter <i>n</i> (No) to erase it.</p>

5 Save or discard the changes:

If you want to...

Then...

restore the profile to its original shape

select the profile and click  .

save the changes to the current profile

select the profile, and click  . The window style uses the edited profile to define its geometry. Any other objects or styles that use this profile are also updated with the edited geometry.

save the changes to a new profile definition

select the profile, right-click, and click Save as New Profile. Enter a name for the new profile definition, and click OK. The window uses the new profile to define its geometry. Any windows of this style are updated with the new geometry. Other styles or objects that use the original profile are not affected.

About Window Display Components and Materials

A window object consists of a number of components whose display properties can be determined by a material assigned to each component.

When you assign materials to a window, you assign one material to each display component of the window. For example, you assign a wood material to the frame and a glass material to the window glass.

If you want to use the display properties of the window object or window style instead of using material display properties, you can turn off the material assignments in the display properties of the window or the window style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in Plan view. The Surface Hatch component of a material is used to hatch all object surfaces in 3D model views and elevations.

For a complete list of material components and their description, see [Material Components and Display Properties](#) on page 610.

The following table lists all window components that can be displayed using materials assigned to them, and identifies the material component of each window component.

Window Component	Material Component
Plan, Plan High Detail, Reflected	
Frame	LInework
Sash	LInework
Glass	Linework
Plan Low Detail	

Window Component	Material Component
Window	Linework
Model	
Frame	3D Body
Sash	3D Body
Glass	3D Body
Elevation	
Frame	2D Section/Elevation Linework
Sash	2D Section/Elevation Linework
Glass	2D Section/Elevation Linework

Assigning Materials to a Window Style

Use this procedure to assign materials to the individual components of a window style. When you assign materials to window components, the components use the display properties of the material. For more information, see [About Window Display Components and Materials](#) on page 1333.

You can specify the materials used to display the following components of a window style:

- Frame
- Sash
- Glass
- Muntin

NOTE If a material assignment does not determine the display properties of a window component, you can change the display properties of the window style as described in [Specifying the Display Properties of a Window Style](#) on page 1335.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which you want changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.

If the setting for By Material is not available, the display of this component cannot be determined by a material.

9 Click the Materials tab.

10 Click the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

11 Click OK.

Adding Classifications to a Window Style

Use this procedure to specify classifications for any classification definition applied to a window style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

1 Open a tool palette that has a window tool.

2 Right-click a window tool, and click Window Styles.

3 Select the style that you want to change.

4 Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to window styles.

5 For each classification definition, select the classification you want to apply to the current window style.

6 Click OK.

Specifying the Display Properties of a Window Style

In most cases, you want the appearance of windows that belong to the same style to be consistent throughout a drawing. To achieve this, you specify the display properties of the windows in each window style:

- The layer, color, and linetype of window components
- The hatching used with each component
- The cut plane height and the display of components relative to the cut plane
- Other specific window display information, such as window rise

Changing the Layer, Color, and Linetype of Window Components

Use this procedure to change the display properties of the window style:

- Visibility (display component is on or off)
- By material (material assigned to the display component determines its layer properties)

- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE If a material assignment determines the properties of components in the window style, you can change the properties of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Assigning Materials to a Window Style](#) on page 1334.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which you want changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Turning on Materials for a Window Style

Use this procedure to turn on material assignments for individual display representations in a window style.

For information on creating and assigning materials, see [About Window Display Components and Materials](#) on page 1333.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which you want changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for each component you want to be controlled by the material. The ByMaterial checkbox is unavailable for components that cannot be assigned a material.

When you select By Material for a display component, all other settings in the dialog are greyed out. The display properties are now taken from the material definition, so you can no longer set them directly in the display properties of the window style.
- 9 Click OK.

Using Custom Blocks to Create Window Components

You can add custom blocks for components, such as window hardware, to the display components or to replace the default display components. For example, you can replace a simple window frame with a custom window frame containing shutters in which you want the custom component to appear. You can have a different custom block for each display representation.

When you add a custom block, you can specify several rules for positioning and scaling the new component. Each custom block also appears in the display properties component list so that you can control its layer, color, and linetype. For more information on adding custom blocks, see [Adding Components to a Window Style](#) on page 1337.

If you create a custom block from mass elements, you can use the material assignments of the mass elements to determine the display properties of the custom block.

Be sure to set the properties of the objects used to create your custom blocks to ByBlock. Otherwise, you cannot control these objects through the display properties. For more information about ByBlock, see “Work with Layers” in AutoCAD Help.

Adding Components to a Window Style

Use this procedure to add or edit custom block components in the display representation of window styles.

- 1 Create a block for the component to add to the window style.
Create the block in the same plane as the window that you use to represent the style. For more information about custom blocks, see [Using Custom Blocks to Create Window Components](#) on page 1337.
- 2 Open a tool palette that has a window tool.
- 3 Right-click a window tool, and click Window Styles.
- 4 Select the style you want to edit.
- 5 Click the Display Properties tab.
- 6 Select the display representation in which you want changes to appear, and select Style Override.
- 7 If necessary, click  .
- 8 Click the Other tab.
- 9 Specify whether to add or edit a block component:

If you want to...	Then...
add a new block component	click Add, and then click Select Block.
edit an existing block component	select the component to edit, and click Edit.

- 10 Select the block to use, and click OK.
- 11 Specify whether you want to scale to fit the block component to the object by width, depth, and height, or to lock the XY ratio:

If you want to...	Then...
set the block scale to the width of the object	select Width.
set the block scale to the depth of the object	select Depth.

If you want to...	Then...
set the block scale to the height of the object	select Height.
scale the whole block equally, so that one direction is scaled to fit another of the scale criteria	select Lock to XY Ratio.
scale the block to its original size	clear all options under Scale to Fit.

12 Specify whether to mirror the block in the X,Y, or Z direction:

If you want to create a mirror of the block...	Then...
in the X direction	select Mirror X.
in the Y direction	select Mirror Y.
in the Z direction	select Mirror Z.

13 Specify the X, Y, and Z location of the insertion point.

14 Specify an insertion offset of the block in the X, Y, and Z directions.

15 Specify whether the component is for the window frame or window glass component:

If you want to add the block...	Then...
to the inside or outside of the frame	click Frame Component, and click either Outside or Inside.
to all window glass components or a single window glass component	click Window Component, and click either All or Single. If you select Single, enter the component number.

NOTE If you specified Depth for Scale to Fit, the depth is scaled to the glass thickness. You can scale to the window panel thickness instead by selecting Scale Depth to Panel Thickness.

16 Frame and Glass components are not available in some display representations. Click OK three times.

Turning Off Components in a Window Style

Use this procedure to turn off custom blocks in a window style.

You can turn off the display of component blocks without removing them from the style.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.

- 5 Select the display representation in which you want to turn off the display of the window component, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select Disable Custom Blocks.
- 9 Click OK.

Removing Components from a Window Style

Use this procedure to remove components from a window style.

Removing component blocks from a window style deletes them from the style.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which you want to remove the window component, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select the component to remove, and click Remove.
- 9 Click OK.

Specifying the Opening Percentage for a Window Style

Use this procedure to override the opening percentage in the display representation of a window style. For example, you can specify that a window is displayed closed in model and elevation representations, but open in plan representations.

NOTE This setting overrides other window opening percent settings. If the opening percent is specified here, the opening percent entered on the Properties palette when you add or modify windows is ignored.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which you want to override the opening percent, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Select Override Open Percent.
- 9 Enter a value for the opening percent.
- 10 Click OK.

Specifying the Display of Window Sills in a Window Style

Use this procedure to change the window sill dimensions in the Sill Plan display representation.

You must use a display representation for a window that has a sill. You can turn on the Sill Plan display representation in addition to the Plan display representation.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select Sill Plan for Display Representations, and select Style Override.

6 If necessary, click .

7 Click the Other tab.

Window Sill Dimensions

- 8 Under Sill Dimensions, enter the sill extension and depth dimensions.
Sill components A and B are for the swing or outside of the window. Sill components C and D are for the interior side.
- 9 If you want to use the cut plane of the wall for anchored windows, instead of using the cut plane of the window, select Respect Cut Plane of Container Object when Anchored.
- 10 Click the Layer/Color/Linetype tab.
- 11 Under Visible, click the icons to turn on visibility.
- 12 Click OK twice.

Defining a Window Style as Bounding for Associative Spaces

Use this procedure to define a window style that can bound associative spaces.

When a window style is set as bounding, by default all windows that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the window style in an individual window, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Window Styles.
- 3 Select a window style.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Window Style

Use this procedure to enter notes and attach reference files to a window style. You can also edit reference files attached to the style.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the window, enter the description under Description.
- 6 Click Notes.
- 7 To add or edit a note, click the Notes tab, and enter the note.
- 8 To attach, edit, or detach a reference file, click the Reference Docs tab:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Click OK.
detach a reference file	select the file name, click Delete, and click OK.

- 9 Click OK.

Creating Muntins in a Window Style

Window muntins are secondary framing members that hold multiple panes of glass in a window sash. AutoCAD Architecture provides an easy way to create muntins with different layout patterns.

Window muntins are available in several patterns that you can customize into many different styles:

- Rectangular
- Diamond
- Prairie 9 Lights
- Prairie 12 Lights
- Starburst
- Sunburst
- Gothic

Starburst and Sunburst patterns are a combined-rectangular pattern with a half-round or quarter-round spoked top and can be used for half- and quarter-round as well as rectangular muntins. Gothic is similar but has a gothic muntin pattern. The other patterns are primarily rectangular but fit into half-round window sash.

You can make custom shapes for window muntins by creating profiles from polylines and adding them to a new window style. For information about creating profiles and adding them to a window style, see [Creating a Custom Window Shape](#) on page 1330.

Window muntin components

Adding Rectangular Muntins to a Window Style

Use this procedure to add rectangular muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can apply the rectangular pattern to all window shapes and window types except Pass Through.

Specifying rectangular pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the window style contains multiple sash, specify whether you want muntins applied to the Top, All, or a Single sash component in the window:

If you want to attach muntins to...

Then...

the top sash only

under Window Pane, select Top. Top also applies to single sash.

If you want to attach muntins to...

Then...

all sash

under Window Pane, select Other, and select All.

an individual sash component

under Window Pane, select Other. Select Single, and specify the index number for window sash. Sash is indexed counterclockwise, starting from the lower left corner.

Specifying rectangular muntins for top sash

single pane treated as top pane

top pane in single-hung window

top pane in glider window

Specifying rectangular muntins for an individual sash component

single sash index 1

single sash index 2

11 Enter a value for the width of all muntins.

12 Enter a value for the depth of all muntins.

13 Clean up the muntin intersections:

If you want to convert...

Then...

the muntin intersections to corners

under Muntin, select Clean Up Joints.

all the muntins to one body with the joints cleaned up

under Muntin, select Convert to Body.

Specifying rectangular muntin cleanup joints

cleanup muntin joints on

cleanup muntin joints off

- 14 Under Lights, select Rectangular for Pattern.
- 15 Enter a value for Lights High to specify the number of light rows in the vertical direction.
- 16 Enter a value for Lights Wide to specify the number of light columns in the horizontal direction.
- 17 Click OK.
- 18 Add additional muntins:

If you want to add muntins to...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

- 19 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Adding Diamond Muntins to a Window Style

Use this procedure to add diamond muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can apply the diamond pattern to all window shapes and window types except Pass Through.

Specifying diamond pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the window style contains multiple sash, specify whether you want muntins applied to the Top, All, or a Single sash component in the window:

If you want to attach muntins to...	Then...
the top sash only	under Window Pane, select Top. Top also applies to single sash.
all sash	under Window Pane, select Other, and select All.
an individual sash component	under Window Pane, select Other. Select Single, and specify the index number for window sash. Sash is indexed counterclockwise, starting from the lower left corner.

- 14 Under Lights, select Diamond for Pattern.
- 15 Enter a value for Lights High to specify the number of light rows in the vertical direction.
- 16 Enter a value for Lights Wide to specify the number of light columns in the horizontal direction.
- 17 Click OK.
- 18 Add additional muntins:

If you want to add muntins to ...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

- 19 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Adding Prairie-9 Lights Muntins to a Window Style

Use this procedure to add prairie-9 lights muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can apply the prairie-9 lights pattern to all window shapes and window types except Pass Through.

Specifying prairie-9 lights pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the window style contains multiple sash, specify whether you want muntins applied to the Top, All, or a Single sash component in the window:

If you want to attach muntins to...

Then...

the top sash only

under Window Pane, select Top. Top also applies to single sash.

all sash

under Window Pane, select Other, and select All.

an individual sash component

under Window Pane, select Other. Select Single, and specify the index number for window sash. Sash is indexed counterclockwise, starting from the lower left corner.

- 14 Under Lights, select Prairie-9 Lights for Pattern.
- 15 Enter a value for Edge X Offset to specify the horizontal distance of the muntins from the edges of the pane.
- 16 Enter a value for Edge Y Offset to specify the vertical distance of the muntins from the edges of the pane.

Specifying prairie-9 lights pattern muntin edge X and Y offsets

- 17 Click OK.
- 18 Add additional muntins:

If you want to add muntins to...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

- 19 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Adding Prairie-12 Lights Muntins to a Window Style

Use this procedure to add prairie-12 lights muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can apply the prairie-12 lights pattern to all window shapes and window types except Pass Through.

Specifying prairie-12 lights pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 If the window style contains multiple sash, specify whether you want muntins applied to the Top, All, or a Single sash component in the window:

If you want to attach muntins to...	Then...
the top sash only	under Window Pane, select Top. Top also applies to single sash.
all sash	under Window Pane, select Other, and select All.
an individual sash component	under Window Pane, select Other. Select Single, and specify the index number for window sash. Sash is indexed counterclockwise, starting from the lower left corner.

- 14 Under Lights, select Prairie-12 Lights for Pattern.
- 15 Enter a value for Edge X Offset to specify the horizontal distance of the muntins from the edges of the pane.
- 16 Enter a value for Edge Y Offset to specify the vertical distance of the muntins from the edges of the pane.

Specifying prairie-12 lights pattern muntin edge X and Y offsets

- 17 Click OK.
- 18 Add additional muntins:

If you want to add muntins to...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

- 19 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Adding Starburst Muntins to a Window Style

Use this procedure to add starburst muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can add the starburst pattern only to the top window sash. You can apply the starburst pattern to window shapes with a round, half round, or quarter round top.

You can apply the starburst pattern to the following window types: awning, single hopper, single transom, vertical pivot, horizontal pivot, double hung, glider, single hung, single casement, and picture.

Specifying starburst pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 Under Window Pane, select Top.

NOTE The Starburst pattern is available only when Top is selected for Window Pane.

- 11 Enter a value for the width of all muntins.
- 12 Enter a value for the depth of all muntins.
- 13 Clean up the muntin intersections:

If you want to...	Then...
convert the muntin intersections to corners	under Muntin, select Clean Up Joints.
convert all the muntins to one body with the joints cleaned up	under Muntin, select Convert to Body.

Specifying starburst muntin cleanup joints

four spokes

18 Click OK.

19 Add additional muntins:

If you want to add muntins to...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

20 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Adding Sunburst Pattern Muntins to a Window Style

Use this procedure to add sunburst muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can add the sunburst pattern only to the top window sash. You can apply the sunburst pattern to window shapes with a round, half round, or quarter round top.

You can apply the sunburst pattern to the following window types: awning, single hopper, single transom, vertical pivot, horizontal pivot, double hung, glider, single hung, single casement, and picture.

Specifying sunburst pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.
- 10 Under Window Pane, select Top.

NOTE The Sunburst pattern is available only when Top is selected for Window Pane.

- 11 Enter a value for the width of all muntins.
- 12 Enter a value for the depth of all muntins.
- 13 Clean up the muntin intersections:

If you want to...	Then...
convert the muntin intersections to corners	under Muntin, select Clean Up Joints.
convert all the muntins to one body with the joints cleaned up	under Muntin, select Convert to Body.

Specifying sunburst muntin cleanup joints

cleanup muntin joints on

20 Click OK.

21 Add additional muntins:

If you want to add muntins to...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

22 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Adding Gothic Muntins to a Window Style

Use this procedure to add gothic muntins to a window style.

You add the muntins by editing the display properties of the window style for a display representation, such as Model or Elevation, where you want the muntins to appear. You can add muntins to display representations individually. You can also add muntins to a single display representation and automatically apply the muntins to all display representations of that window style. You add the muntins block to the window style in the display properties. Each muntins block becomes a display component of the window style.

You can add the gothic pattern only to the top window sash. You can apply the gothic pattern to the following window shapes: round, half round, gothic, peak pentagon, or arch.

You can apply the gothic pattern to the following window types: awning, single hopper, single transom, vertical pivot, horizontal pivot, double hung, glider, single hung, single casement, and picture.

Specifying gothic pattern muntins

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Muntins tab.
- 8 Click Add.
- 9 Enter a name for the muntins block.

10 Under Window Pane, select Top.

NOTE The Gothic pattern is available only when Top is selected for Window Pane.

11 Enter a value for the width of all muntins.

12 Enter a value for the depth of all muntins.

13 Clean up the muntin intersections:

If you want to...	Then...
convert the muntin intersections to corners	under Muntin, select Clean Up Joints.
convert all the muntins to one body with the joints cleaned up	under Muntin, select Convert to Body.

Specifying gothic muntin cleanup joints

cleanup muntin joints on

cleanup muntin joints off

14 Under Lights, select Gothic for Pattern.

15 Enter a value for Lights High to specify the number of light rows in the vertical direction.

16 Enter a value for Lights Wide to specify the number of panes in the horizontal direction.

Count the panes across the bottom row.

17 Click OK.

18 Add additional muntins:

If you want to add muntins to...	Then...
another window sash in the window style	repeat this procedure from step 8.
another display representation	click OK, and repeat this procedure from step 5.
all display representations of the selected window style	select Automatically Apply to Other Display Representations and Object Overrides.

19 Click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display](#)

[Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624

Editing a Window Muntins Block in a Window Style

Use this procedure to edit the muntins settings for a window style.

After you create a muntins block, you can change any of its settings by editing the display properties of the window style for each display representation, such as Model or Elevation. You can edit the muntins for display representations individually. You can also edit the muntins for a single display representation and automatically apply the changes to all display representations of that window style.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and click .
- 6 Click the Muntins tab.
- 7 Select the muntins block to edit.
- 8 Click Edit.
- 9 Edit any of the settings.

For more information on the settings, see the window muntins type in [Creating Muntins in a Window Style](#) on page 1341.

- 10 Select Automatically Apply to Other Display Representations and Object Overrides to apply the changes to all display representations of the selected window style.
Clear this setting to apply the changes to only the selected display representation.
- 11 When you finish editing the window muntins block in the window style, click OK three times.

After you add a muntins block to a window style, you can assign a material, such as wood, and specify display properties, such as color and linetype, for the muntins. For more information, see [About Window Display Components and Materials](#) on page 1333, [Specifying the Display Properties of a Window Style](#) on page 1335, and [Creating and Editing Material Definitions](#) on page 624 respectively.

Turning Off the Display of Muntins in a Window Style

Use this procedure to turn off the display of muntins in a window style. You can turn off the display of window muntins without removing them from the window.

- 1 Open a tool palette that has a window tool.
- 2 Right-click a window tool, and click Window Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want to turn off the display of window muntins, and click .
- 6 Click the Muntins tab.
- 7 Select Disable Muntins Blocks.

- 8** Select Automatically Apply to Other Display Representations and Object Overrides to apply the changes to all display representations of the selected window style.
Clear this setting to apply the changes to only the selected display representation.
- 9** Click OK twice.

Removing a Window Muntins Block from a Window Style

Use this procedure to remove muntins from a window style. When you remove existing muntins blocks from the window style, they are deleted.

To turn off muntins without deleting them, see [Turning Off the Display of Muntins in a Window Style](#) on page 1360.

- 1** Open a tool palette that has a window tool.
- 2** Right-click a window tool, and click Window Styles.
- 3** Select the style you want to edit.
- 4** Click the Display Props tab.
- 5** Select the display representation where you want to remove window muntins, and click  .
- 6** Click the Muntins tab.
- 7** Select the muntins block to remove.
- 8** Click Remove.
- 9** Repeat steps 7 and 8 to remove multiple muntins blocks.
- 10** Select Automatically Apply to Other Display Representations and Object Overrides to apply the changes to all display representations of the selected window style.
Clear this setting to apply the changes to only the selected display representation.
- 11** When you finish removing muntins blocks from the window style, click OK twice.

Openings

24

An opening is an AEC object that interacts with walls to represent an opening of any size at any elevation. You can also add openings as freestanding objects.

Openings

An opening is an AEC object that interacts with walls to represent an opening of any size at any elevation. You can also add openings as freestanding objects.

Opening Shapes

When you add an opening to a drawing, you can select from a number of predefined shapes, such as rectangular, half-round, oval, or arch. You can also create openings with custom shapes using profiles to define the geometry of the opening.

Examples of predefined shapes for openings

Anchoring Openings

After you place an opening in a wall, the opening is constrained to the object and cannot move outside it.

Openings can also be anchored to specific locations in walls, so that when the wall moves or changes size, the location of the opening in that object remains constant.

Opening Endcaps

Openings that are anchored in a wall can have endcap styles applied to them. The endcap shapes for wall openings are defined in the wall style and are a property of the wall. For information on setting an opening endcap style in a wall, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

Opening Dimensions

All openings have height and width. The rise dimension depends on the opening shape. Rise is the height from the top of the rectangular portion of an opening to the peak of the opening for gothic, arch, peak pentagon, and trapezoid shapes.

Vertical Alignment of Openings

Use the vertical alignment settings to control how to place an opening in the wall, the location of the working point vertically in the wall, and how the opening responds to modifications in height. Use the sill and head height settings to determine the working point on the opening. You can place the working point at the sill or at the head. For example, if you specify the vertical alignment as 0" and the opening height as 7'-0", the opening height is 7'-0". If you next specify the height of the opening as 6'-8", the sill remains at 0" and the opening height becomes 6'-8".

For the opening head working point, if you specify the vertical alignment as 7'-0" and the opening height as 7'-0", the opening height is 7'-0". If you specify the opening height as 6'-8", the head remains at 7'-0" and the sill becomes 4".

Using Opening Tools to Create Openings

Tools provided with AutoCAD Architecture let you quickly place openings by selecting an opening tool with a specific opening style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can also use opening tools to create new openings by applying tool properties to existing door/window assemblies, doors and windows.

Tool palette containing opening tool

The default tool palettes in the workspace contain a sample opening tool that you can use and customize as needed. In addition, the following catalogs provided with the software contain opening tools that you can add to your tool palettes:

- Stock Tool catalog

■ Sample Palette catalog

Custom palettes created by your CAD manager or other users may also contain opening tools with properties that are customized for your projects or office standards.

Creating an Opening

Use this procedure to add an opening that has the properties specified in the opening tool that you select. To specify settings when you add an opening, see [Creating an Opening with User-Specified Settings](#) on page 1365.

Adding an opening to a wall

- 1 Open the tool palette that you want to use, and select an opening tool.
If necessary, scroll to display the desired tool.
- 2 Select a wall in which to insert the opening, or press *ENTER* to add a freestanding opening.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Specify the insertion point of the opening.
If you are adding a freestanding opening, specify the rotation of the opening after you specify the insertion point.
- 4 Continue adding openings, and press *ENTER*.

Creating an Opening with User-Specified Settings

Use this procedure to create an opening with settings that you specify.

Adding an opening to a wall

- 1 Open the tool palette that you want to use, and select an opening tool.
If necessary, scroll to display the desired tool.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a shape for the opening.
To specify a custom shape, select Custom for Shape, and select the profile that provides the geometry of the shape for Profile.
- 4 Expand Dimensions.
- 5 Enter values for Width, Height, and Rise.
Rise is available only for arch, gothic, peak pentagon, and trapezoid shapes.

6 Expand Location.

7 If you are placing the opening in a wall, specify the opening position:

If you want to...

Then...

position the edge of the opening at a specific distance from the end of a wall segment

select Offset/Center for Position along wall, and enter a value for Automatic offset.

center the opening on a wall segment

select Offset/Center for Position along wall, and specify a point near the center of the wall segment.

position the opening anywhere along the wall

select Unconstrained for Position along wall.

8 Specify whether you want the opening to be aligned vertically by sill height or by head height:

If you want to...

Then...

align the opening by sill height

select Sill for Vertical alignment, and enter a value for Sill height.

align the opening by head height

select Head for Vertical alignment, and enter a value for Head height.

9 Specify the insertion point for an opening in a wall or for a freestanding opening:

If you want to...	Then...
place an opening in a wall	select the wall, and specify an insertion point along the wall.
place a freestanding opening	press <i>ENTER</i> , and specify an insertion point and rotation angle for the opening.

10 Continue to place openings, and press *ENTER*.

Creating an Opening from Doors, Door/Window Assemblies and Windows

Use this procedure to convert a door, door/window assembly, or window to an opening that has the properties of the opening tool you select. You can edit these properties after creating the opening.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click an opening tool, and click Apply Tool Properties to ► Door, Door/Window Assembly, Window.
- 3 Select the door, door/window assembly or window to convert, and press *ENTER*.
- 4 Edit the properties of the opening in the Properties palette, if needed.

Creating and Editing Custom Openings

In addition to using predefined shapes for openings, you can create openings with custom shapes. You create a profile from a closed polyline to define the two-dimensional (2D) geometry of the shape. The profile is then extruded when it is applied to an opening. You can edit the profile to change the shape of the opening. You can then save the changes to the current profile or to a new profile. You can apply the profiles you create to any openings.

Creating a Profile for a Custom Opening

Use this procedure to create a profile that provides the geometry for an opening with a custom shape.

You can create the profile as you add it to an opening. However, if the shape you need is elaborate and has curved segments, you may find it easier to create the profile from a polyline first. You can then add the profile to the opening.

- 1 Draw concentric, closed polylines representing the opening and any insets.
- 2 Select the polylines, right-click, and click Convert to ► Profile Definition.
- 3 Select the outermost polyline.
- 4 Enter **a** (Add ring).
- 5 Select an inner polyline.
- 6 Repeat steps 4 and 5 as needed to add more rings to the profile.
- 7 Specify the insertion point of the profile.

8 Enter n (New), enter a name for the profile, and click OK.

Creating an Opening with a Custom Shape

Use this procedure to create an opening with a custom shape and other settings that you specify.

Adding an opening with a custom shape

- 1 Open the tool palette that you want to use, and select an opening tool.
If necessary, scroll to display the desired tool.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Custom for Shape.
- 4 Select the profile that provides the geometry of the shape for Profile.
- 5 Expand Dimensions.
- 6 Enter values for Width and Height.
- 7 Expand Location.

8 If you are placing the opening in a wall, specify the opening position:

If you want to...	Then...
position the edge of the opening at a specific distance from the end of a wall segment	select Offset/Center for Position along wall, and enter a value for Automatic offset.
center the opening on a wall segment	select Offset/Center for Position along wall, and specify a point near the center of the wall segment.
position the opening anywhere along the wall	select Unconstrained for Position along wall.

9 Specify whether you want the opening to be aligned vertically by sill height or by head height:

If you want to...	Then...
align the opening by sill height	select Sill for Vertical alignment, and enter a value for Sill height.
align the opening by head height	select Head for Vertical alignment, and enter a value for Head height.

10 Specify the insertion point for an opening in a wall or for a freestanding opening:

If you want to...	Then...
place an opening in a wall	select the wall, and specify an insertion point along the wall.
place a freestanding opening	press <i>ENTER</i> , and specify an insertion point and a rotation angle for the opening.

11 Continue to place openings, and press *ENTER*.

Editing the Geometry of a Custom Opening

Use this procedure to edit the geometry of a profile that determines the shape of a custom opening. You can save the changes to the existing profile or to a new profile.

1 Select the opening that has the shape you want to change, right-click, and click Edit Profile In Place.

A temporary profile is created for you to edit the geometry of the custom opening.

A temporary profile for editing a custom opening

2 NOTE After you perform an editing task from the shortcut menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the shortcut menu, select the profile, and right-click to display the shortcut menu.

Edit the profile:

If you want to...

Then...

change the shape of the perimeter of the profile or its rings

select the profile, and use edge and vertex grips to adjust the shape.

The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added, as necessary.

Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc, as well.

Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.

add vertices to the profile

select an Edge grip, and press *CTRL* to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press *ENTER*.

remove vertices from the profile

select the Vertex grip for the vertex you want to remove, and press *CTRL* to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.

replace an existing ring of the profile with new geometry

select the profile, right-click, and click Replace Ring. Select the ring to replace, and select the new geometry. Press *ENTER* to keep the geometry, or enter *y* (Yes) to erase it.

add a ring to the profile

draw the linework in place on the temporary profile. Select the profile, right-click, and click Add Ring. Select the geometry to define the ring. Press *ENTER* to keep the geometry, or enter *y* (Yes) to erase it.

remove a ring from the profile

select the profile, right-click, and click Remove Ring. Select the ring to remove, and press *ENTER*. This option does not appear if the profile has only one ring.

Profile for custom opening after editing

3 Save or discard the changes:

If you want to...	Then...
restore the opening to its original shape	 click  .
save the changes to the current profile	 click  . The opening uses the edited profile to define its geometry. Any other objects or styles that use this profile are also updated with the edited geometry.
save the changes to a new profile	select the profile, right-click, and click Save as New Profile. Enter a name for the new profile, and click OK. The opening uses the new profile to define its geometry. Other styles or objects that use the original profile are not affected.

Creating an Opening Tool

Use this procedure to create an opening tool and add it to a tool palette. You may want to create your own opening tools if you are placing multiple openings that have the same properties.

For example, you are creating a restaurant floor plan that contains openings of various sizes. To work efficiently, you can create an opening tool for each size. You can then select the appropriate tool to place openings in the floor plan.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to...	Then...
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the tool catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Enter a description of the opening that you can create using this opening tool.

8 If you do not want to use the default layer key for openings, select a layer key.

9 If you want to override the default layer name for openings, select a layer override.

10 Select a shape for the opening.

To specify a custom shape, select Custom for Shape, and select the profile that provides the geometry of the shape for Profile.

11 Expand Dimensions.

12 Enter values for Width, Height, and Rise.

Rise is available only for arch, gothic, peak pentagon, and trapezoid shapes.

13 Expand Location.

14 If you are placing the opening in a wall, specify the opening position:

If you want to...	Then...
position the edge of the opening at a specific distance from the end of a wall segment	select Offset/Center for Position along wall, and enter a value for Automatic offset.
center the opening on a wall segment	select Offset/Center for Position along wall, and specify a point near the center of the wall segment.
position the opening anywhere along the wall	select Unconstrained for Position along wall.

15 Specify whether you want the opening to be aligned vertically by sill height or by head height:

If you want to...	Then...
align the opening by sill height	select Sill for Vertical alignment, and enter a value for Sill height.
align the opening by head height	select Head for Vertical alignment, and enter a value for Head height.

16 Click OK.

Editing Openings

After you create an opening, you can change the height, width, and rise. You can also change the endcap conditions applied to the opening. You can move the opening within the wall.

AutoCAD Architecture offers several methods for editing openings:

- Edit openings directly using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- Change settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- Select editing commands from the shortcut menu for a selected opening.

Using Grips to Edit Openings

Refer to the illustrations and steps in this topic to use opening grips to edit an opening.

Editing Opening Dimensions

- 1 Select the opening.
- 2 Select the grip for the dimension you want to change.

Opening dimension grips

- 3 Move the grip until the desired dimension value is displayed and click once, or enter a value.

Changing the Location of an Opening

- 1 Select the opening.

2 Move the Location grip to change the location of the opening.

Press *CTRL* to select the direction of movement: along the wall, within the wall, or vertically within the wall.

Opening location grip

Changing the Shape and Dimensions of an Opening

Use this procedure to change the shape and size of an opening.

1 Double-click the opening you want to change.

2 On the Properties palette, expand Basic, and expand General.

3 Select a shape.

To specify a custom shape, select Custom for Shape, and select the profile that provides the geometry of the shape for Profile.

4 Expand Dimensions.

5 Change the width, height, or rise for the opening.

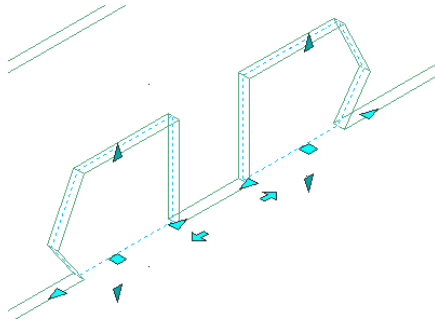

Flipping an Opening along the X or Y Axis

Use this procedure to reorient an opening along its *X* or *Y* axis.

TIP You can also flip an opening along its *X* axis using the Flip grip that is displayed when you select an opening.

1 To flip an opening along the *X* axis, select the openings you want to change, right-click, and click Wall Anchor ► Flip X.

Opening in original position, and flipped along its X axis

2 To flip an opening along the Y axis, select the openings, right-click, and click Wall Anchor ► Flip Y.

Opening in original position, and flipped along its Y axis

Changing Endcap Style for an Opening

Use this procedure to change the opening endcap style used at each side of an opening. An endcap is a user-definable condition for the edges of an opening. For more information about opening endcap styles, see [Working with Wall Endcaps and Opening Endcaps](#) on page 894.

- 1 Double-click the opening you want to change.
- 2 On the Properties palette, expand Basic, expand Location, and expand Endcaps.
- 3 Select an opening endcap style.

Applying Tool Properties to an Existing Opening

Use this procedure to apply the properties of an opening tool to one or more openings.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the desired tool.
- 2 Right-click an opening tool, and click Apply Tool Properties to Opening.
- 3 Select the openings, and press *ENTER*.
- 4 Edit the properties of the openings in the Properties palette, if necessary.

Repositioning an Opening

Use this procedure to change the location of an opening along the wall by offsetting the opening from a reference location.

This feature is useful when you want to position an opening at a specified distance from another object. For example, you may want to specify an exact distance between a series of openings along a wall.

Repositioning an opening by offsetting points

1 Select the opening you want to move, right-click, and click Reposition Along Wall.

A marker indicates the current location within the opening: left jamb, center of opening, or right jamb.

2 Specify how to measure the offset:

If you want to...	Then...
measure the offset from the center of the opening	select a point near the center of the opening.
measure the offset from the left or right jamb	select a point on the jamb of the opening from which you want to measure.

Selecting the center of the opening for measuring the offset

3 Select a point to measure to (the reference point).

You can select a point along the wall.

Specifying a reference point

4 Specify the distance between the points you selected:

If you want to...	Then...
move the opening to the reference point	enter 0 (zero).
move the opening a specified distance from the reference point	enter a value for the offset distance.
specify the distance as a measurement between two points, such as the distance between the centers of two openings that are correctly positioned	specify the two points measuring the distance.

Opening repositioned along the wall

Using Anchors to Change the Horizontal Position of an Opening

Use this procedure to change the horizontal position of openings along a wall to which the openings are anchored.

You can also change the horizontal position of the opening using the Location grip. For more information, see [Using Grips to Edit Openings](#) on page 1373.

Positioning an opening horizontally

- 1 Select the openings you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the X axis:

If you want to...	Then...
use the start of the wall as the reference point	under Position Along (X), select Start of wall for From.
use the midpoint of the wall as the reference point	under Position Along (X), select Midpoint of wall for From.
use the end of the wall as the reference point	under Position Along (X), select End of wall for From.

- 5 Enter the distance from the reference point at which to place the openings.
Use a negative value to measure from endpoint to start point.

- 6 Select the position of the openings to measure to:

If you want to measure...	Then...
to the start edge of the opening	select Start edge of object for To.
to the center of the opening	select Center of object for To.

If you want to measure...

Then...

to the end edge of the opening

select End edge of object for To.

7 Click OK.

Using Anchors to Change the Vertical Position of an Opening

Use this procedure to change the vertical position of openings in a wall to which the openings are anchored.

You can also change the vertical position of the opening using the Location grip. For more information, see [Using Grips to Edit Openings](#) on page 1373.

Changing the vertical position of an opening

z-axis wall parameters

z-axis opening parameters

- 1 Select the openings you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Select the reference point for the anchor along the Z axis:

If you want to...

Then...

use the bottom of the wall height as the reference point

under Position Along (Z), select Bottom of wall height for From.

use the center of the wall height as the reference point

under Position Along (Z), select Center of wall height for From.

use the top of the wall height as the reference point

under Position Along (Z), select Top of wall height for From.

- 5 Enter the distance from the reference point at which to place the openings.
Use a negative value to measure from endpoint to start point.

6 Select the position of the openings to measure to:

If you want to...	Then...
measure to the bottom of the openings in wall	select Sill of object for To.
measure to the center of the openings in walls	select Center of object for To.
measure to the top of the openings in walls	select Head of object for To.

7 Click OK.

Changing the Position of an Opening Within a Wall

Use this procedure to change the horizontal position of openings within a wall to which the openings are anchored.

You can also change the position of the opening within a wall using the Location grip. For more information, see [Using Grips to Edit Openings](#) on page 1373.

Changing the position of an opening within a wall

1 Select the openings you want to change, and double-click one of them.

2 On the Properties palette, expand Basic, and expand Location.

3 Click Anchor.

4 Select the reference point for the anchor along the Y axis:

If you want to...	Then...
use the left edge of the wall as your reference point	select Left edge of wall width for From.
use the center of the wall as your reference point	select Center of wall width for From.
use the right edge of the wall as your reference point	select Right edge of wall width for From.

5 Enter the distance from the reference point at which to place the openings.

Use a negative value to measure from endpoint to start point.

6 Select the position of the openings to measure to:

If you want to...	Then...
measure to the front of the opening	select Front of object for To.

If you want to...	Then...
measure to the center of the opening	select Center of object for To.
measure to the back of the opening	select Back of object for To.

7 Click OK.

Changing the Orientation of an Opening to a Wall

Use this procedure to change the vertical orientation of an opening in a wall to which the openings are anchored.

- 1 Select the openings you want to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Anchor.
- 4 Enter the *X* and *Z* rotation angles of the openings.
- 5 Indicate if you want to reverse the flip direction of the opening in the *X* and *Z* axes:

If you want to...	Then...
reverse the direction of the opening	select Flip X.
reverse the top and bottom of the opening	select Flip Z.
reverse the position of the opening in the side of the wall	select Flip Y.

6 Click OK.

Changing the Location of an Opening

Use this procedure to relocate a freestanding opening by changing the coordinate values of its insertion point. The opening also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the opening are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the opening by aligning its normal with another axis. You can also rotate the opening on its plane by changing the rotation angle.

- 1 Double-click the opening.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Additional information.
- 4 Specify a new location, orientation, or rotation angle:

If you want to...	Then...
relocate the opening	enter new coordinate values under Insertion Point.
locate the opening on the <i>XY</i> plane	make the normal of the opening parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .

If you want to...	Then...
locate the opening on the YZ plane	make the normal of the opening parallel to the X axis: under Normal, enter 1 for X and enter 0 for Y and Z.
locate the opening on the XZ plane	make the normal of the opening parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.
change the rotation of the opening	enter a new value for Rotation Angle.

5 Click OK.

Changing the Cut Plane Setting for an Opening

Use this procedure to specify whether a selected opening will use the cut plane of the containing object when anchored to that object in the current display representation. Note that cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the opening.
- 2 Click the Display tab.
- 3 Under the General category, for Display controlled by, select This object.

NOTE To apply your changes to all openings in the drawing, select Drawing default setting.

- 4 For Display representation, verify that the desired display representation is selected.
- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Use cut plane of containing object when anchored, select Yes or No.

Specifying the Display of Sills for an Opening

Use this procedure to change the sill dimensions for an opening in the Sill Plan display representation.

- 1 Double-click the opening.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all openings in the drawing, select Drawing default setting.

- 5 For Display representation, select Sill Plan.

6 If necessary, expand Object Display Properties ► Advanced, and click  Sill dimensions.

- 7 On the Sill Dimensions worksheet, enter the sill extension and depth dimensions.

Sill components A and B are for the outside of the opening. Sill components C and D are for the interior side.

- 8 Click OK.

9 In the Display component drop-down list, click the light bulb icons next to individual sill components to turn their visibility on or off as desired.

You can also access and modify sill dimensions and visibility settings through the opening's context menu, as follows:

- 1 Select the opening you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 Click the Other tab.

Opening sill dimensions

- 5 Under Sill Dimensions, enter the sill extension and depth dimensions.
- 6 On the Layer/Color/Linetype tab, under Visible, click the light bulb icons to turn on visibility for individual sill display components as necessary.
- 7 Click OK twice.

Specifying the Display of Custom Block Components of an Opening

Use this procedure to specify the display of custom block components for an individual opening. If you are going to use custom graphics for a new component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the opening.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all openings in the drawing, select Drawing default setting.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and for Custom block display, click  (The number in parentheses indicates the number of blocks currently attached to the opening.)
- 7 If you want to turn off the display of custom blocks for this opening without removing them, select Disable Custom Blocks.
- 8 Specify whether to add, edit, or remove a block component:

If you want to...	Then...
add a new block component	click Add, and then click Select Block, select the block, and click OK.

If you want to...	Then...
edit an existing block component	select the component to edit, and click Edit.
remove an existing block component	select the block, click Remove, and click OK.

9 Specify whether you want to scale to fit the block component to the object by width, depth, and height, or to lock the XY ratio:

If you want to...	Then...
set the block scale to the width of the object	select Width.
set the block scale to the depth of the object	select Depth.
set the block scale to the height of the object	select Height.
scale the whole block equally, so that one direction is scaled to fit another of the scale criteria	select Lock to XY Ratio.
scale the block to its original size	clear all options under Scale to Fit.

10 Specify whether to mirror the block in the X, Y, or Z direction:

If you want to create a mirror of the block...	Then...
in the X direction	select Mirror X.
in the Y direction	select Mirror Y.
in the Z direction	select Mirror Z.

11 Specify the X, Y, and Z locations of the insertion point.

12 Specify an insertion offset of the block in the X, Y, and Z directions.

13 Click OK twice.

Specifying the Display of Fill Type for an Opening

Use this procedure to specify the type of fill to display for an opening in display representations used in the Top view (plan view) of a drawing.

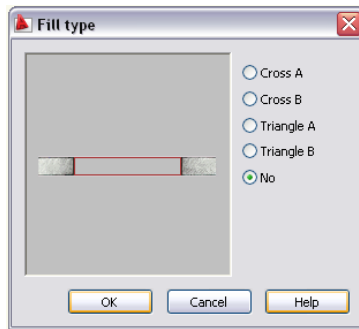

- 1 Double-click the opening.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 Under the General category, for Display controlled by, select This object.

NOTE To apply your changes to all openings in the drawing, select Drawing default setting.

- 5 For Display representation, verify that the desired display representation is selected.

- 6 If necessary, expand Object Display Properties ► Advanced, and click  Fill type.
- 7 On the Fill type worksheet, select the desired fill type.

Opening fill types

- 8 Click OK.

You can also access and modify frame display settings through the opening's context menu, as follows:

- 1 Select the opening you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 Click the Fill type tab.
- 5 Under Hatch Type, select the desired option.
- 6 Click OK twice.

Attaching Hyperlinks, Notes, and Files to an Opening

Use this procedure to enter notes and attach hyperlinks or reference files to an opening. You can also edit reference files attached to the style.

- 1 Double-click the opening to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
For more information, see "Add Hyperlinks to a Drawing" in AutoCAD help.
- 4 To add a note, click the setting for Notes, enter the note, and click OK.
- 5 Click the setting for Reference Docs.
- 6 Attach, edit, or detach a reference file:

If you want to...

Then...

attach a reference file

click , select a file, and click OPEN.

edit the description of a reference file

select the description of the file, and edit the description.

If you want to...	Then...
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

7 Click OK.

Changing the Display Properties of Openings

You use the display properties of openings to control their appearance in a drawing. In addition, you can create custom components for openings by adding custom blocks to any display representation where you want the components to appear.

Specifying the Display Properties of an Opening

Use this procedure to change the properties of the following display components of an individual opening:

- Visibility (display component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE Openings do not have material assignments.

1 Select the opening you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 Click the Layer/Color/Linetype tab.

5 Select the component to change, and select a different setting for the property.

6 Click OK twice.

Specifying the Hatching of an Opening

Use this procedure to specify the hatching of the components of an opening. Hatching is displayed only in display representations used in the Top view (plan view) of a drawing.

1 Select the opening you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

2 Click the Display Properties tab.

3 Select the display representation in which to display the changes.

4 Specify whether changes apply to all openings, or only to the selected opening:

If you want to...

Then...

apply the hatching to all openings in the drawing

verify that Object Override is cleared, and click 

apply the hatching only to the selected opening

select Object Override. If it is already selected, click

The display representation in bold is the current one.

5 Click the Layer/Color/Linetype tab.

6 Verify that the Hatch display component is turned on.

7 Click the Hatching tab.

8 Click the setting for Pattern.

9 Select the hatching:

If you want to...

Then...

select a hatching pattern that is available in the software

select Predefined for Type, and then select a pattern.

select a custom pattern

select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.

select single hatching

select User-Defined for Type, and clear Double Hatch.

select double hatching

select User-Defined for Type, and select Double Hatch.

select solid fill

select Solid Fill for Type.

10 Click OK.

11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

12 Click Angle, and enter the angle for the selected pattern.

13 Click Orientation, and specify how the hatching is oriented:

If you want to...

Then...

orient the hatching to the object regardless of the object rotation

select Object.

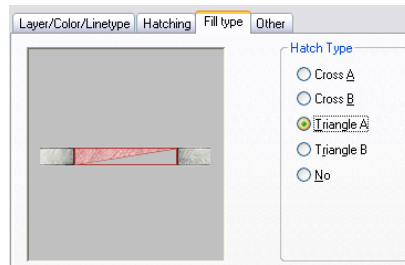

orient the hatching to the World Coordinate System

select Global.

14 Click the Fill type tab.

15 Select a graphic representation to use for hatching the opening.

Specifying hatching graphics for openings

16 Click OK twice.

Using Custom Blocks to Create Opening Components

You can add custom blocks for components, such as hardware, to the display components or to replace the default display components. You can have a different custom block for each display representation.

You can specify several rules for positioning and scaling the new component. Each custom block also appears in the display properties component list so that you can control its layer, color, and linetype.

If you create a custom block from mass elements, you can use the material assignments of the mass elements to determine the display properties of the custom block.

Be sure to set the properties of the objects used to create your custom blocks to ByBlock. Otherwise, you cannot control these objects through the display properties. For more information, see “Control the Color and Linetype Properties in Blocks” in AutoCAD help

Adding Components to an Opening

Use this procedure to add or edit custom block components in the display representation of openings.

1 Create a block for the component to add to the opening.

Create the block in the same plane as the opening.

2 Select the opening you want to change, right-click, and click Edit Object Display.

3 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

4 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

5 Click the Other tab.

6 Specify whether to add or edit a block component:

If you want to...	Then...
add a new block component	click Add.
edit an existing block component	select the component to edit, and click Edit. Proceed to step 10.

7 Click Select Block.

8 Select the block to use, and click OK.

9 Specify whether you want to scale to fit the block component to the object by width, depth, and height, or to lock the XY ratio:

If you want to...	Then...
set the block scale to the width of the object	select Width.
set the block scale to the depth of the object	select Depth.
set the block scale to the height of the object	select Height.
scale the whole block equally, so that one direction is scaled to fit another of the scale criteria	select Lock XY Ratio.
scale the block to its original size	clear all options under Scale to Fit.

10 Specify whether to mirror the block in the X, Y, or Z direction:

If you want to...	Then...
create a mirror of the block in the X direction	select Mirror X.
create a mirror of the block in the Y direction	select Mirror Y.
create a mirror of the block in the Z direction	select Mirror Z.

11 Specify the X, Y, and Z location of the insertion point.

12 Specify an insertion offset of the block in the X, Y, and Z directions.

13 Click OK three times.

Turning Off Custom Components in an Opening

Use this procedure to turn off custom blocks in an opening.

You can turn off the display of component blocks without removing them from the opening.

1 Select the opening you want to change, right-click, and click Edit Object Display.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 Click the Other tab.

5 Select Disable Custom Blocks.

6 Click OK twice.

Removing Custom Components from an Opening

Use this procedure to remove components from an opening.

Removing custom blocks deletes them from the opening.

1 Select the opening you want to change, right-click, and click Edit Object Display.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 Click the Other tab.

5 Select the component to remove, and click Remove.

6 Click OK twice.

Stairs

25

Stairs are AEC objects that use flights of treads and risers to accommodate vertical circulation. Stairs also interact with railing objects. You can control the style of the stair, the shape of the landing, the type of treads, and the height and width of the stair run.

Stairs

Stairs are AEC objects that use flights of treads and risers to accommodate vertical circulation. Stairs also interact with railing objects. You can control the style of the stair, the shape of the landing, the type of treads, and the height and width of the stair run.

Stair Shapes

While strictly rectangular stairs are predominant in modern buildings, in some cases the edges of a flight are not parallel, or they might be curved. Landings can also be non rectangular. Stairs allow the use of nearly arbitrary profiles for the edges of flights and landings. In addition, railings and stringers can be anchored to stairs and can follow the edges of flights and landings. You can create custom stairs from linework or profiles to model different conditions as well.

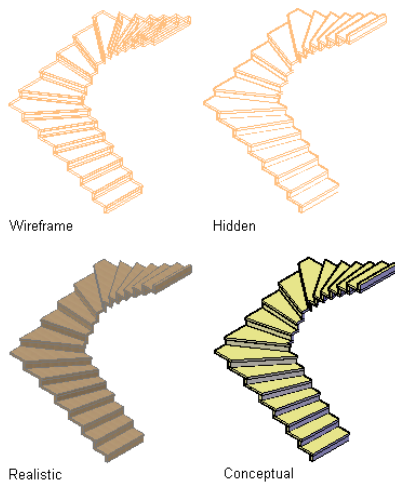

Landings and Turns

Stairs are created at a specified overall height that requires a total length based on the tread length. Within that length, you can place landings or turns. When you begin to create a stairway, a rectangular box is displayed that represents the width and length of the stair as if it were a straight stairway. As you select consecutive points, depending upon the shape of the stair, landings and turns are created.

Materials in Stairs

In AutoCAD Architecture, you can assign materials to a stair. These materials are displayed in the Realistic visual style, or when rendered. Materials have specific settings for the physical components of a stair, such as risers, nosing, and treads.

Viewing a stair in different visual styles

AutoCAD Architecture provides a number of predefined materials for common design purposes, which contain settings for stair components. You can use predefined materials, or modify them for your designs. You can also create your own materials. Object styles provided with the software have appropriate materials already assigned to them. For more information, see [Stair Materials and Display Components](#) on page 1517.

Solution Tips for Stairs

When AutoCAD Architecture detects a problem with the way a stair object is drawn, it displays a solution tip icon on the stair in the drawing.

Stair with solution tip icon

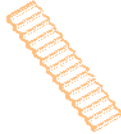

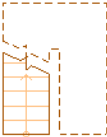

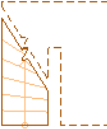

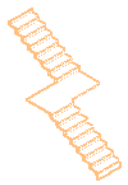

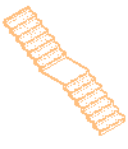

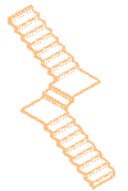

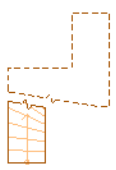

Move the cursor over the icon to display a message that describes the problem and provides one or more possible solutions. Where more detailed instructions are required, you can press *F1* to access the relevant topic in Help.

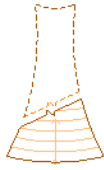

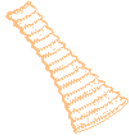

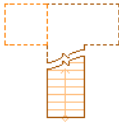

Stair with solution tip

A number of the solution tips for stair objects regard an invalid configuration for a particular type of stair. The F1 links for these tips bring you to this topic and the following table, which shows and describes the different types of stairs you can draw in AutoCAD Architecture. Follow the associated links to specific instructions for drawing each type of stair.

Stair 2D View	Stair 3D View	Stair Shape	Turn Type	How to Draw
		Straight	None	Specify flight start and endpoints. For more information, see Creating a Straight Stair with User-Specified Settings on page 1397.
		U-shaped	1/2 landing	Specify flight start and endpoints. For more information, see Creating a U-Shaped Stair with User-Specified Settings on page 1406.
		U-shaped	1/2 turn	Specify flight start and endpoints. For more information, see Creating a U-Shaped Stair with User-Specified Settings on page 1406.

Stair 2D View	Stair 3D View	Stair Shape	Turn Type	How to Draw
		Multi-landing	1/2 landing	Specify first flight start and endpoints; specify next flight start and endpoints. For more information, see Creating a Multi-Landing Stair with User-Specified Settings on page 1399.
		Multi-landing (straight)	1/2 landing	Specify first flight start and endpoints; specify next flight start and endpoints. For more information, see Creating a Multi-Landing Stair with User-Specified Settings on page 1399.
		Multi-landing	1/2 turn	Specify first flight start and endpoints; specify next flight start and endpoints - draw in one direction only. For more information, see Creating a Multi-Landing Stair with User-Specified Settings on page 1399.
		Multi-landing	1/4 landing	Specify first flight start and endpoints; specify next flight endpoint; specify next flight endpoint. For more information, see Creating a Multi-Landing Stair with User-Specified Settings on page 1399.
		Multi-landing	1/4 turn	Specify first flight start and endpoints; specify next flight endpoint; specify next flight endpoint. For more information, see Creating a Multi-Landing Stair with User-Specified Settings on page 1399.
		Spiral	None	Specify center of spiral stair; specify start point. For more information, see Creating a Spiral Stair with User-Specified Settings on page 1410.

Stair 2D View	Stair 3D View	Stair Shape	Turn Type	How to Draw
		Custom stair (from line-work)	None	Draw custom stair linework; select left and right sides; select stair path; select left, right, and center stringer paths; select first tread at current level; select remaining treads. For more information, see Creating a Custom Stair from Linework on page 1415.
		Custom stair (from tread profile)	None	Draw custom tread profile; array tread profile; select stair path; select left, right, and center stringer paths; select first tread profile at current level; select remaining tread profiles. For more information, see Creating a Custom Stair from Tread Profiles on page 1418.
		Anchor Stair to Landing	None	Draw multi-landing stair; draw straight stair; select multi-landing stair; anchor straight stair to multi-landing stair landing. For more information, see Anchoring a Stair to a Landing on page 1460.

Specifying AEC Options for Stairs

Use this procedure to specify parameters and options for stairs that are not specified in the stair styles or display properties. These options are on the AEC Object Settings tab of the Options dialog box:

- Presentation format
- Node Osnaps
- Flight height measurement
- Calculator limits

- 1 Click Format menu ► Options.
- 2 Click the AEC Object Settings tab.
- 3 Specify the stair defaults:

If you want to...	Then...
display the stair with no cut lines or path	select Presentation Format (No Cut Lines or Path).
use Node Osnap to select the corners of the stairs and landings	select Flight and Landing Corners for Node Osnap.
specify the stair height distance above the start of the stair and below the end of the stair as the position for the Node Osnap	select Vertical Alignment for Node Osnap.

If you want to...	Then...
include top and bottom offsets in the stair height measurement	select Finished Floor to Floor for Measure Stair Height.
ignore top and bottom offsets in the stair height measurement	select Rough Floor to Floor for Measure Stair Height.
display the stair with a solution tip icon when an edit causes it to violate the calculation limits set in the Calculation Rules tab of the Stair Style dialog box	select Strict for Calculator Limits.
display the stair normally when an edit causes it to violate the calculation limits set in the Calculation Rules tab of the Stair Style dialog box	select Relaxed for Calculator Limits.

NOTE The Calculator Limits setting is stored with the drawing. Some earlier versions of the software have the Calculator limits set to Relaxed by default. Any new drawing has it set to Strict by default.

4 Click OK.

Using Stair Tools to Create Stairs

Tools provided with AutoCAD Architecture let you quickly place stairs using a stair tool with a specific stair style and other predefined properties. You can use the default settings of the tool, or you can change the properties that are not controlled by the style.

The following catalogs provided with the software contain stair tools that you can add to your tool palettes:

- Stock Tool catalog
- AutoCAD Architecture Sample Palette catalog
- Design Tool catalog

Custom palettes created by your CAD manager or other users may also contain stair tools with stair styles and properties that are customized for your projects or office standards.

Creating a Stair

Use this procedure to add a new stair that has the properties specified in the stair tool that you select. To specify settings when you add a stair, see [Creating a Straight Stair with User-Specified Settings](#) on page 1397.

- 1 Open the tool palette that you want to use, and select a stair tool.
If necessary, scroll to display the tool that you want to use.
- 2 Specify the insertion point of the stair.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Specify the direction point of the stair.
The stair is created at the length necessary to accommodate the values specified.
- 4 Continue adding stairs, and press *ENTER*.

Creating a Straight Stair with User-Specified Settings

Use this procedure to add a straight stair with settings that you specify.

Creating a straight stair

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

1 Open the tool palette that you want to use, and select a stair tool.

If necessary, scroll to display the tool that you want to use.

2 On the Properties palette, expand Basic, and expand General.

3 Select a style.

4 In Shape, select Straight.

5 Specify the vertical orientation of the stair:

If you want to...

Then...

draw the stair from this floor to the floor above

select Up for Vertical Orientation.

draw the stair from this floor to the floor below

select Down for Vertical Orientation.

6 Expand Dimensions.

7 Specify stair dimensions:

If you want to...

Then...

specify the width of the stair

enter a value for Width.

specify the height of the stair

enter a value for Height.

If you want to...**Then...**

specify the justification of the stair

enter a value for Justify. The Justify value controls the insertion point when you place the stair (left, center, or right) at the beginning of the stair run.

end the stair run with a riser

select Riser for Terminate with.

NOTE Stairs that end with a riser will have an overall height that is one tread thickness less than the floor-to-floor height specified.

end the stair run with a tread

select Tread for Terminate with.

end the stair run with a landing

select Landing for Terminate with.

specify the overall linear length of the stair

select Calculation rules, and then enter a value for Straight Length.

- When Straight Length is set to  (automatic), the value is calculated based on the tread size and riser count.
 - When Straight Length is  (user-defined), the stair length is equal to the dimension entered, and the other three values are adjusted within the code limits.
 - When Riser Count is user-defined, the tread depth is increased or decreased to accommodate the stair.
-

If you want to...**Then...**

specify the total number of stair risers

select Calculation rules, and then enter a value for Riser Count.

- When Riser Count is set to  (automatic), the number of risers is based on the overall length and overall height of the stair and the code limits specified on the Design Rules tab. The Straight Length value of the stair is adjusted automatically.
- When Riser Count is  (user-defined), you can specify a value that is used to calculate the tread depth and riser height. If these values fall outside the stair limits, an error message is displayed.

specify the height of each riser in the stair flight

select Calculation rules, set all fields to  (automatic), click the icon to Riser to change it to  and enter a value for Riser.

NOTE If a value is set to user-defined on the Calculation rules worksheet, it can be modified directly in the Properties palette.

NOTE If  is displayed next to a field in the Calculation Rules dialog box, that field can't be changed until another field is changed from  (user-defined) to  (automatic).

8 In the drawing area, specify the insertion point of the stair.

You can move or hide the Properties palette to expose more of the drawing area.

9 Specify the endpoint of the stair.

10 Continue adding stairs, and press *ENTER*.

Creating a Multi-Landing Stair with User-Specified Settings

Use this procedure to create a multi-landing stair. You can use multi-landing stair shapes to define both straight and angled stair runs. You can insert quarter-landings, half-landings, and turns.

This type of stair is constrained by the design rules on the stair and the floor-to-floor height. For more information about stair design rules, see [Specifying the Design Rules of a Stair Style](#) on page 1509.

If you are drawing the risers or flights of a stair, lines for each tread are shown. If you are drawing a flat landing, no tread lines are shown. If you are drawing a turn-type landing, angled tread lines are shown through the turn. These temporary lines do not necessarily represent the actual locations of tread lines in the final stair. In addition, the number of risers currently added to the stair is displayed (to the left of the stair), as a fraction of the total number of risers required for the stair; for example, "10/18."

NOTE To create a straight stair with user-specified landings, use the multi-landing shape with half-landings. Select all the points in a straight line to define the flight start points and flight endpoints.

Creating a multi-landing stair with 1/4 landings

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

- 1 Open the tool palette that you want to use, and select a stair tool.
If necessary, scroll to display the tool that you want to use.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a style.
- 4 In Shape, select Multi-landing.
- 5 Specify the turn type:

If you want to...

Then...

create a flat landing with a user-defined length where the stair run turns

select 1/2 landing for Turn type.

create stairs with a user-defined length where the stair run turns with treads through the turn

select 1/2 turn for Turn type.

NOTE These stairs must have at least three segments and each corner must turn in the same direction.

If you want to...**Then...**

create a flat landing where the stair turns, with the length of the landing equal to the width of the stair

select 1/4 landing for Turn type.

NOTE These stairs typically have two or more flights joined by square landings.

create stairs having treads along the entire length, with one or more turns in any direction

select 1/4 turn for Turn type.

NOTE These stairs may have two or more segments, and corners may turn in either direction.

6 Specify the vertical orientation of the stair:**If you want to...****Then...**

draw the stair from this floor to the floor above

select Up for Vertical Orientation.

draw the stair from this floor to the floor below

select Down for Vertical Orientation.

7 Expand Dimensions.**8 Specify stair dimensions:****If you want to...****Then...**

specify the width of the stair

enter a value for Width.

specify the height of the stair

enter a value for Height.

specify the justification of the stair

enter a value for Justify. The Justify value controls the insertion point when you place the stair (left, center, or right) at the beginning of the stair run.

end the stair run with a riser

select Riser for Terminate with.

NOTE Stairs that end with a riser will have an overall height that is one tread thickness less than the floor-to-floor height specified.

If you want to...**Then...**

end the stair run with a tread

select Tread for Terminate with.

end the stair run with a landing

select Landing for Terminate with.

specify the overall linear length of the stair

select Calculation rules, and then enter a value for Straight Length.

- When Straight Length is set to  (automatic), the value is calculated based on the tread size and riser count.
- When Straight Length is  (user-defined), the stair length is equal to the dimension entered, and the other three values are adjusted within the code limits.
- When Riser Count is user-defined, the tread depth is increased or decreased to accommodate the stair.

specify the total number of stair risers

select Calculation rules, and then enter a value for Riser Count.

- When Riser Count is set to  (automatic), the number of risers is based on the overall length and overall height of the stair and the code limits specified on the Design Rules tab. The Straight Length value of the stair is adjusted automatically.
 - When Riser Count is  (user-defined), you can specify a value that is used to calculate the tread depth and riser height. If these values fall outside the stair limits, an error message is displayed.
-

If you want to...	Then...
specify the height of each riser in the stair flight	select Calculation rules, set all fields to  (automatic), click the icon to Riser to change it to  , and enter a value for Riser.
specify the tread depth for each tread in the stair flight	select Calculation rules, set all fields to  (automatic), click the icon next to Tread to change it to  , and enter a value for Tread. You can also specify the Riser count when you set the tread depth.

NOTE If a value is set to user-defined on the Calculation rules worksheet, it can be modified directly in the Properties palette.

NOTE If  is displayed next to a field in the Calculation Rules dialog box, that field can't be changed until another field is changed from  (user-defined) to  (automatic).

- 9 Expand Advanced.
- 10 Specify the Floor Settings:

If you want to...	Then...
change the thickness of the floor finish material at the top of the stair	enter a value for Top offset.
change the depth of the structure at the top of the stair	enter a value for Top depth.
change the thickness of the floor finish material at the bottom of the stair	enter a value for Bottom offset.
change the depth of the structure at the bottom of the stair	enter a value for Bottom depth.

- 11 Set the minimum or maximum height or number of risers in a stair flight.
- 12 In the drawing area, specify the insertion point of the stair.
You can move or hide the Properties palette to expose more of the drawing area.
- 13 Specify the point of the first turn or landing for the stair.
- 14 Continue specifying points for the stair.

NOTE If you specified Landing for Terminate with, the last point for the stair beyond the final riser defines the end of the landing.

Specifying terminal landing length for multi-landing stair

15 Continue adding stairs, and press *ENTER*.

Creating an L-Shaped Stair with 45-Degree Tread

Use this procedure to add an L-shaped stair with a 45-degree turn in the winder.

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Architectural Objects, and expand Stair Winder Styles.

3 Right-click, select New, and enter **Single Point – 2 Tread** as the style name.

4 On the Settings tab, confirm that Use Riser Line is not selected.

5 Specify Single Point for Winder Type.

6 Select Adjust Winder Turn and enter **2** for Number of Treads in Turn.

7 Click OK.

8 Open the tool palette that you want to use, and select a stair tool.

If necessary, scroll to display the tool that you want to use.

9 On the Properties palette, expand Basic, and expand General.

10 In Shape, select Multi-landing.

11 In Turn type, select 1/4 turn.

12 Right-click, click Flight length, and enter **t** for Tread length.

Creating an L-shaped stair with a 45 degree tread

NOTE If the stair style has Extend Landings to Prevent Risers and Treads Sitting under Landings turned on, the flight will not be pivoted exactly around the end of the stair.

13 In Winder Style, select Single Point – 2 Tread.

14 Draw a stair with one 90-degree turn, and press *ENTER*.

15 Select the stair, enter **winderturnadjust** at the command line, and press *ENTER*.

NOTE The winderturnadjust command changes the number of treads in a turn zone for a stair using a Single Point winder style. The default number of treads is specified in the Settings tab of the Stair Winder Styles. You can change the amount of treads on the command line while running the winderturnadjust command.

When you change the number of treads in the turn zone, the construction line changes location across the stair because the tread length must remain constant along the stair. Changing the winder treads changes the width, so the line moves. The construction line can be edited with grips. If you move the construction line, the winder treads are affected.

Creating a U-Shaped Stair with User-Specified Settings

Use this procedure to add a U-shaped stair with settings that you specify. U-shaped stairs have two equal-length runs joined by a half-landing. The justification setting controls where the points that define the stair fall within its width.

When drawing the stair, the flights are shown with lines for each tread. Flat landings have no tread lines, while turn-type landings show tread lines through the entire turn. For turn-type stairs, these temporary lines do not necessarily represent the actual locations of tread lines in the final stair.

Creating a U-shaped stair

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

- 1 Open the tool palette that you want to use, and select a stair tool.
If necessary, scroll to display the tool that you want to use.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a style.
- 4 In Shape, select U-shaped.
- 5 Specify the turn type:

If you want to...	Then...
create a flat landing where the stair run turns back in the opposite direction	select 1/2 landing for Turn type.
create stairs where the stair run turns back in the opposite direction with treads throughout the run	select 1/2 turn for Turn type.

- 6 Specify the horizontal orientation of the stair:

If you want to...	Then...
draw the U-shaped stair so that the right is the outer edge of the stair and left is the inner edge	select Counterclockwise for Horizontal Orientation.

If you want to...

Then...

draw the U-shaped stair so that the left is the outer edge of the stair and right is the inner edge

select Clockwise for Horizontal Orientation.

Specifying the horizontal direction for U-shaped stairs

7 Specify the vertical orientation of the stair:

If you want to...

Then...

draw the stair from this floor to the floor above

select Up for Vertical Orientation.

draw the stair from this floor to the floor below

select Down for Vertical Orientation.

8 Expand Dimensions.

9 Specify stair dimensions:

If you want to...

Then...

specify the width of the stair

enter a value for Width.

specify the floor-to-floor height of the stair

enter a value for Height.

specify the justification of the stair

enter a value for Justify. The Justify value you select controls the insertion point when you place the stair (left, center, or right) at the beginning of the stair run.

If you want to...**Then...**

end the stair run with a riser

select Riser for Terminate with.

NOTE Stairs that end with a riser will have an overall height that is one tread thickness less than the floor-to-floor height specified.

end the stair run with a tread

select Tread for Terminate with.

end the stair run with a landing

select Landing for Terminate with.

specify the overall linear length of the stair

select Calculation rules, and then enter a value for Straight Length.

- When Straight Length is set to  (automatic), the value is calculated based on the tread size and riser count.
 - When Straight Length is  (user-defined), the stair length is equal to the dimension entered, and the other three values are adjusted within the code limits.
 - When Riser Count is user-defined, the tread depth is increased or decreased to accommodate the stair.
-

If you want to...**Then...**

specify the total number of stair risers

select Calculation rules, and then enter a value for Riser Count.

- When Riser Count is set to  (automatic), the number of risers is based on the overall length and overall height of the stair and the code limits specified on the Design Rules tab. The Straight Length value of the stair is adjusted automatically.
- When Riser Count is  (user-defined), you can specify a value that is used to calculate the tread depth and riser height. If these values fall outside the stair limits, an error message is displayed.

specify the height of each riser in the stair flight

select Calculation rules, set all fields to  (automatic), click the icon to Riser to change it to , and enter a value for Riser.

specify the tread depth for each tread in the stair flight

select Calculation rules, set all fields to  (automatic), click the icon next to Tread to change it to , and enter a value for Tread. You can also specify the Riser count when you set the tread depth.

NOTE If a value is set to user-defined on the Calculation rules worksheet, it can be modified directly in the Properties palette.

NOTE If  is displayed next to a field in the Calculation Rules dialog box, that field can't be changed until another field is changed from  (user-defined) to  (automatic).

10 Expand Advanced.

11 Specify the Constraints:

If you want to...**Then...**

place the treads and risers with the minimum landing extension

select Free for Alignment.

align the tread of the up flight to the tread of the down flight

select Tread to tread for Alignment.

align the tread of the up flight to the riser of the down flight

select Tread to riser for Alignment.

align the riser of the up flight to the riser of the down flight

select Riser to riser for Alignment.

12 Specify a value for Alignment offset.

When you select Tread to tread, Tread to riser, or Riser to riser, you can specify an offset value. A positive offset value means that the down-flight tread location is closer to landing than the up-flight tread location.

Specifying tread to riser alignment offsets

13 Specify a value for the Extend alignment.

14 Specify a value for Uneven tread to determine which flight will be longer if the total number of treads is uneven. Select Upper flight to place the Uneven tread on the upper flight. Select Lower flight to place the uneven tread on the lower flight.

15 Specify floor settings:

If you want to...	Then...
change the thickness of the floor finish material at the top of the stair	enter a value for Top offset.
change the depth of the structure at the top of the stair	enter a value for Top depth.
change the thickness of the floor finish material at the bottom of the stair	enter a value for Bottom offset.
change the depth of the structure at the bottom of the stair	enter a value for Bottom depth.

16 Set the minimum or maximum height or number of risers in a stair flight.

17 In the drawing area, specify the insertion point of the stair.

You can move or hide the Properties palette to expose more of the drawing area.

18 Specify the endpoint of the stair.

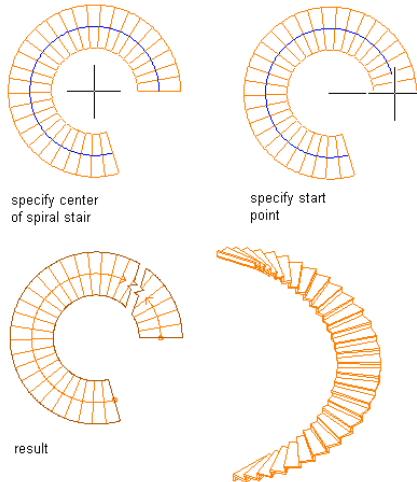

19 Continue adding stairs, and press *ENTER*.

Creating a Spiral Stair with User-Specified Settings

Use this procedure to create a circular sweeping and spiral stair. A spiral stair revolves about a common center point from bottom to top.

You can specify a radius directly or on the screen only when the arc constraint is free. Otherwise, the radius is determined from the specified tread length and arc constraint. In that case, you need to adjust the tread length to achieve the desired radius.

Creating a spiral stair

To create a spiral stair with the specified tread depth (T) that occurs at a specified distance from the inner edge, first construct the stair with a width equal to twice the required distance (A). Next, use Customized Edges to offset the outer edge to the desired total width B . The offset distance is equal to $B - 2A$.

Creating a spiral stair with a specified tread depth at a specified distance

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

1 Open the tool palette that you want to use, and select a stair tool.

If necessary, scroll to display the tool that you want to use.

2 On the Properties palette, expand Basic, and expand General.

3 Select a style.

4 In Shape, select Spiral.

5 Specify the horizontal orientation of the stair:

If you want to...

Then...

draw the spiral stair in a counterclockwise direction

select Counterclockwise for Horizontal Orientation.

draw the spiral stair in a clockwise direction

select Clockwise for Horizontal Orientation.

Specifying the horizontal orientation for a spiral stair

counterclockwise

clockwise

6 Specify the vertical orientation of the stair:

If you want to...

Then...

draw the stair from this floor to the floor above

select Up for Vertical Orientation.

draw the stair from this floor to the floor below

select Down for Vertical Orientation.

NOTE If Terminate with is set to Landing, the vertical orientation is up and cannot be changed.

7 Expand Dimensions.

8 Specify stair dimensions:

If you want to...

Then...

specify the width of the stair

enter a value for Width.

specify the floor-to-floor height of the stair

enter a value for Height.

specify the justification of the stair

enter a value for Justify. The Justify value you select controls the insertion point when you place the stair (left, center, or right) at the beginning of the stair run.

end the stair run with a riser

select Riser for Terminate with.

NOTE Stairs that end with a riser will have an overall height that is one tread thickness less than the floor-to-floor height specified.

If you want to...**Then...**

NOTE If the vertical orientation is set to Down, Terminate with is set to Riser and cannot be changed.

end the stair run with a tread

select Tread for Terminate with.

end the stair run with a landing

select Landing for Terminate with.

specify the exact radius for the spiral stair

select No for Specify On Screen and enter a value for Radius.

define the radius for the stair dynamically

select Yes for Specify On Screen.

specify the overall linear length of the stair

select Calculation rules, and then enter a value for Straight Length.

- When Straight Length is set to  (automatic), the value is calculated based on the tread size and riser count.
- When Straight Length is  (user-defined), the stair length is equal to the dimension entered, and the other three values are adjusted within the code limits.
- When Riser Count is user-defined, the tread depth is increased or decreased to accommodate the stair.

specify the total number of stair risers

select Calculation rules, and then enter a value for Riser Count.

- When Riser Count is set to  (automatic), the number of risers is based on the overall length and overall height of the stair and the code limits

If you want to...	Then...
	<p>specified on the Design Rules tab. The Straight Length value of the stair is adjusted automatically.</p> <ul style="list-style-type: none"> When Riser Count is  (user-defined), you can specify a value that is used to calculate the tread depth and riser height. If these values fall outside the stair limits, an error message is displayed.

specify the height of each riser in the stair flight	<p>select Calculation rules, set all fields to  (automatic), click the icon to Riser to change it to , and enter a value for Riser.</p>
--	---

specify the tread depth for each tread in the stair flight	<p>select Calculation rules, set all fields to  (automatic), click the icon next to Tread to change it to , and enter a value for Tread. You can also specify the Riser count when you set the tread depth.</p>
--	---

NOTE If a value is set to user-defined on the Calculation rules worksheet, it can be modified directly in the Properties palette.

NOTE If  is displayed next to a field in the Calculation Rules dialog box, that field can't be changed until another field is changed from  (user-defined) to  (automatic).

9 Select the type of arc constraint to use when creating the spiral stair:

If you want to...	Then...
create a spiral stair run with no constraints	select Free for Arc constraint.
create a spiral stair with a specific number of degrees for the stair flight	select Total Degrees for Arc constraint, and enter a value for Arc angle. This includes the terminal landing or tread.
create a spiral stair with a specific degree for each tread in the stair	select Degrees per Tread for Arc constraint, and enter a value for Arc angle.

10 Expand Advanced.

11 Specify the Floor Settings:

If you want to...	Then...
change the thickness of the floor finish material at the top of the stair	enter a value for Top offset.

If you want to...	Then...
change the depth of the structure at the top of the stair	enter a value for Top depth.
change the thickness of the floor finish material at the bottom of the stair	enter a value for Bottom offset.

- 12 Set the minimum or maximum height or amount of risers in a stair flight.
- 13 Specify the center point for the spiral stair.
- 14 Specify the location of the stair.
- 15 Continue adding stairs, and press *ENTER*.

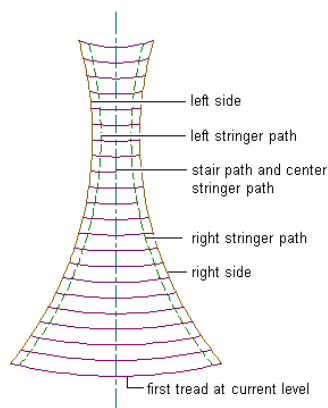

Creating a Custom Stair from Linework

Use this procedure to create a custom stair from linework. You can model irregularly shaped stairs and treads, and specify multiple flights at varying angles with a custom stair. You can select or create linework defining stair edges and tread edges. Create a custom stair to model complex existing stair conditions for analysis and explore non-code compliant conditions, or generate stair types that are not possible to create using regular AutoCAD Architecture stair commands.

The stairs outline component of a custom stair is delineated by the left and right stair sides, the nosing of the first tread, and the front of the last tread or landing.

Stair stringers can be selected as linework, or they can be automatically generated by AutoCAD Architecture. After you create a custom stair, you can replace stringer paths. You can add or modify stringers by editing the stair style. The stair style applied to the custom stair must have stringers defined in that particular stair style. If the stair style does include stringers, the left and right stringer path lines are converted to appropriate stringer geometry. The current stair properties govern the appearance of stair components in various representations.

Create the linework for your custom stair using lines, light-weight polylines, or arc segments. All tread lines must intersect with the sides of the stair. Graphics representing the stringer paths must be continuous throughout the path of the stair.

Linework for custom stairs can represent the following components:

- left and right stair sides (required)
- stair path (optional)

- left, right, and center stair stringers (optional)
- first tread at current level (required)
- remaining treads (required)

NOTE A custom stair must have a minimum of 2 treads. At least 2 lines must be selected for remaining treads when creating a custom stair.

Creating a Custom Stair from Linework

- 1 Open the tool palette that contains the stair tool that you want to use, and select the tool. You may have to scroll to display the desired tool.

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

- 2 Verify that your current drawing includes a stair style with defined stringers.
- 3 Right-click the stair tool and click Apply Tool Properties to ► Linework.
- 4 Select the linework that represents the left and right sides of the custom stair. Only lines, light-weight polylines, or arc segments that intersect all treads can be selected for the stair sides.
- 5 Select the linework that represents the stair path, or press *ENTER* to have it generated automatically.

Only single or multi-segment light-weight polylines or arc segments that intersect all treads can be selected for the stair path.

6 Select the linework that represents the left, right, and center stair stringers, or press *ENTER* to have the left, right, and center stair stringers generated automatically.

7 Select the linework that represents the first tread at the current level.

Only lines, light-weight polylines, or arc segments that intersect the stair sides can be selected for the stair treads.

8 Select the remaining treads.

9 In the Convert to Stair dialog, verify or change the parameter values for Style, Height, Vertical Orientation, and Terminate with. Specify a style with defined stringers. Specify whether to erase the layout geometry, then click OK.

NOTE The Standard stair style does not have defined stringers.

IMPORTANT You cannot convert a custom stair to a ramp stair style.

The custom stair from linework is generated.

Once you create a custom stair, you can convert any part of it to a landing. See [Modifying Custom Stairs](#) on page 1420 to do this.

Creating a Custom Stair from Tread Profiles

Use this procedure to create a custom stair from tread profiles. Use defined profiles generated from closed polylines for custom stair treads. All tread profiles in each stair run must either intersect or overlap.

The stairs outline component of a custom stair is delineated by the left and right stair sides, the nosing of the first tread, and the front of the last tread or landing.

Stair stringers can be selected as linework or they can be automatically generated by AutoCAD Architecture. After you create a custom stair, you can replace stringer paths. You can add or modify stringers by editing the stair style. The current stair properties govern the appearance of stair components in various representations.

Linework and profiles for custom stairs can represent the following components:

- stair path (required)
- left and right stair stringers (optional)
- first tread profile at current level (required)
- remaining treads (required)

Creating a Custom Stair from Tread Profiles

- 1 Open the tool palette that contains the stair tool that you want to use, and select the tool.
You may have to scroll to display the desired tool.

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

- 2 Right-click the stair tool and click Apply Tool Properties to ► Linework.

- 3 Enter **T** for Treadprofile.

- 4 Select the linework that represents the stair path.

Only single or multi-segment light-weight polylines or arc segments that intersect all treads can be selected for the stair path.

- 5 Select the linework that represents the left, right, and center stair stringers, or press *ENTER* to have the left, right, and center stair stringers generated automatically.

- 6 Select the linework that represents the first tread profile at the current level.

Only defined profiles can be selected for stair treads.

- 7 Select the remaining treads.

IMPORTANT You cannot convert a custom stair to a ramp stair style.

- 8 In the Convert to Stair dialog, verify or change the parameter values for Style, Height, Vertical Orientation, and Terminate with. Specify whether to erase the layout geometry, then click OK.

IMPORTANT You cannot convert a custom stair to a ramp stair style.

The custom stair from tread profiles is generated.

Once you create a custom stair, you can convert any part of it to a landing. See [Modifying Custom Stairs](#) on page 1420 to do this.

Modifying Custom Stairs

Use these procedures to perform the following modifications for custom stairs:

- Edit the faces of treads and risers
- Match treads and risers to source components
- Convert a tread to a landing and back again
- Replace an existing stringer path with a new stringer path by selecting linework

Edit a Custom Stair Tread

- 1 Use this procedure to convert the edge of a custom stair tread to an arc.

Select the custom stair that you want to change, right-click and click **Modify Custom Stair** ► **Edit Tread/Riser**.

2

A grip appears at the midpoint of each tread and riser.

- 3 Select the bottom Edit Tread grip.

You can select either edge or vertex grips to modify the face of the tread. The following grips are displayed for editing the face of a custom stair tread:

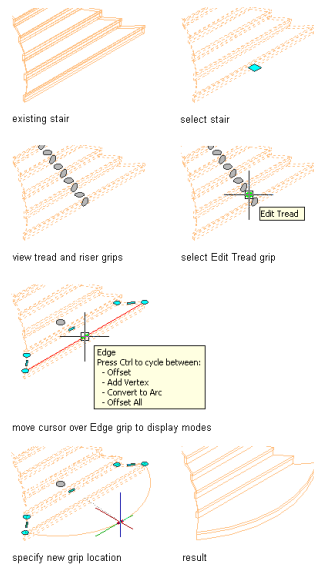

4 Move the cursor over the front Edge grip.

A tooltip with the following options is displayed:

- Offset
- Add Vertex
- Convert to Arc
- Offset All

5 Select the Edge grip, and press *CTRL* twice to cycle to the Convert to Arc option.

6 Specify a new location for the Edge grip.

Match Tread/Riser

1 Use this procedure to modify a custom stair tread by matching an existing tread on another custom stair.

Create 2 custom stairs: one with a source tread to match, and one as the destination custom stair.

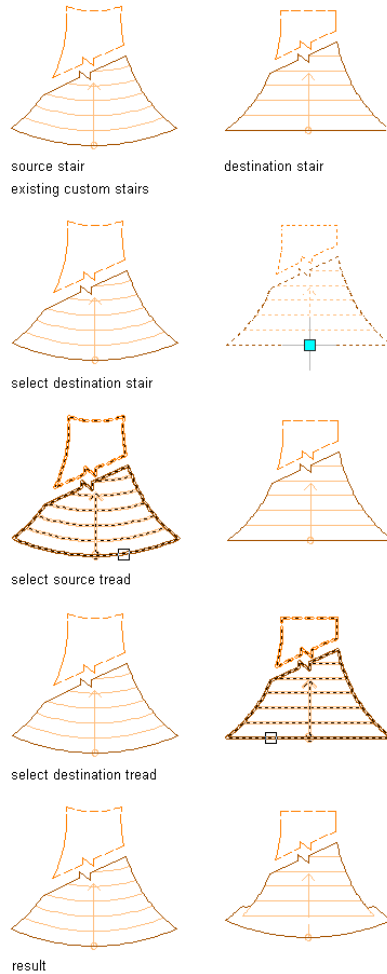

2 Select the custom stair that you want to change, right-click, and click Modify Custom Stair ► Match Tread/Riser.

3 Specify tread to match.

You have the option of matching a tread, a riser, or both.

4 Select the tread to match on the source custom stair.

5 Select the tread on the destination custom stair to replace.

Toggle Tread/Landing

1 Use this procedure to convert a custom stair tread to a landing, or convert a custom stair landing to a tread.

Select the custom stair that you want to change, right-click, and click **Modify Custom Stair** ► **Toggle Tread/Riser**.

2 Select the tread to convert to a landing.

When you use a stair style that has defined stringers, you can see that the stringer is parallel to the landing and sloping for the duration of the tread.

NOTE This feature does not override the Terminate with option. If Terminate with Landing is specified, you cannot use this feature to convert the landing to a tread.

Replace Stringer Path

1 Use this procedure to replace an existing custom stair stringer path with a new stringer path by selecting linework. The linework must occur within the stair to be valid for selection as a replacement stringer path, and must follow the entire length of the stair.

Select the custom stair that you want to change, right-click, and click **Modify Custom Stair** ► **Replace Stringer Path**.

2 Specify the left, right, or center stringer path (depending on the custom stair configuration) to replace.

3 Select the linework to represent the new stringer path.

Creating a Ramp

Use this procedure to create a ramp using stairs. The Ramp-Concrete style (in the Stair Styles drawing) includes the correct settings for creating a ramp.

TIP For a listing of the location of all styles and support drawings, see [Styles and Support Files](#) on page 117.

The ramp stringer type should be used for creating ramps. The stringer facets display component provides the landing lines for ramps, and an End with tread setting makes the connection to the next level work correctly, instead of having one riser height between the ramp and the surface it should meet.

TIP To ensure that the Properties palette is displayed before you select a tool, right-click in the drawing area, and click Properties.

1 Import the ramp style from the Stair Styles drawing.

For information about copying styles into your drawing, see [Copying Styles Between Drawings](#) on page 598.

2 Open the tool palette that you want to use, and select a stair tool.

If necessary, scroll to display the tool that you want to use.

3 On the Properties palette, expand Basic, and expand General.

4 Select the Ramp-Concrete style.

5 Specify the location of the stair.

6 Continue adding stairs, and press *ENTER*.

Creating a U-shaped concrete ramp

Creating a Stair Tool

Use this procedure to create a stair tool and add it to a tool palette. You may want to create your own stair tools if you are placing multiple stairs of a specific style and they all have the same property.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...

Then...

create a tool from a stair in the drawing

select the stair, and drag it to the tool palette.

create a tool from a stair style in the Style Manager

on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.

copy a tool in the current tool palette

right-click the tool, and click Copy. Right-click, and click Paste.

copy a tool from another tool palette

open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

copy a tool from a tool catalog

open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

- 4 Enter a name for the tool.
- 5 Click the setting for Description, enter a description of the tool, and click OK.
- 6 Expand Basic, and expand General.
- 7 Click the setting for Description, enter a description of the stair created from this tool, and click OK.
- 8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.
- 9 Select a stair style.

NOTE If a multi-landing or u-shaped stair is selected, the turn type can be set. If the turn type is 1/2 or 1/4 turn, the winder style can be set.

- 10 Select the drawing file containing the style used for this stair.
- 11 Click OK.

Editing Stairs

You can edit stairs by changing the style of the stair, the width and height of the stair, the size of the tread, and the justification. You can also change constraints, components, landing extensions, and location, in addition to the style and dimensions.

AutoCAD Architecture offers several methods for editing stairs:

- You can directly edit stairs using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- You can change stair settings on the Properties palette.
- You can use editing commands from the context menu for a selected stair.

Using Grips to Edit Stairs

When you use grips to edit stairs, the stairway continues to be constrained by the design limits and length specified when the stair was created, if Automatic Length is set to No. This is the case for all stairs in earlier-version drawings. If you move beyond those limits, a solution tip icon is displayed.

Stair with solution tip icon

You can use grips to create multi-landing stairs that have skewed landings and angled stair runs. Changing the configuration of a landing may result in changes to the stair run.

You can increase or decrease the overall width of the stair run for U-shaped stairs.

The radius and start point can be changed for spiral stairs. You can use grips to increase or decrease the overall width of the stair run for spiral stairs. If you change the width of the stair after grip-editing a side, the changes are lost.

NOTE You cannot use any of the plan representation grips to alter the floor-to-floor height. Select the stair in a view direction other than TOP to use a grip to change the floor-to-floor height.

Each stair shape has different grips associated with it.

Using Grips to Edit Straight Stairs

Refer to the illustrations and steps in this topic to use straight stair grips to edit stairs.

Editing Stair Dimensions

- 1 Select the straight stair.
- 2 Select the grip for the dimension you want to change.

In order to edit the flight width and flight taper, click the Edit Edges grip to access the edges edit mode. When you have finished editing the stair edges, click the Exit Edit Edges grip to return to the default stair edit mode.

Straight stair Flight Taper, Flight Width, and Exit Edit Edges grips

Straight stair Flight Start and End, Location, and Lengthen Stair grips

NOTE The Lengthen Stair grips move a straight stair unless it ends with a landing.

3 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

Changing the Location or Position of a Straight Stair

- 1 Select the straight stair.
- 2 Select the appropriate grip to change the location of the stair, its start point, construction line, graphics path, or endpoint.

Straight stair Flight Start and End, Lengthen Stair, and Location grips

Straight stair Construction Line Location, Graphics Path Location, and Edit Edges grips

3 Move the stair to the desired location, and click once; or enter a value, and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the stair along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the stair is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the stair is constrained to the *Y* dimension direction.

4 Right-click, and click Deselect All to turn off grips.

Changing the Height of a Straight Stair

1 Select the straight stair.

2 Move the Height grip to change the height of the stair.

NOTE This grip displays only in 3D views of the stair. Height cannot be edited in Plan view.

Straight stair Height grip

Using Grips to Edit Multi-Landing Stairs

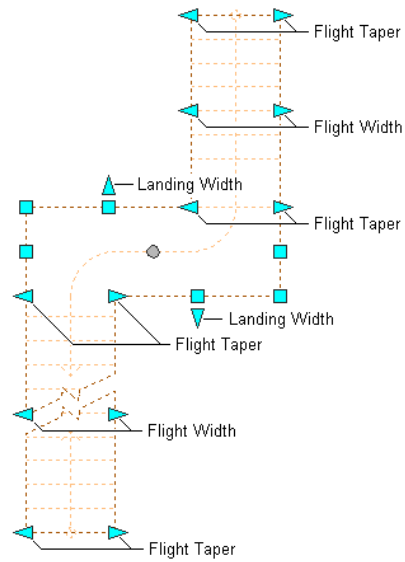

Refer to the illustrations and steps in this topic to use multi-landing stair grips to edit stairs.

Editing Multi-Landing Stair Dimensions

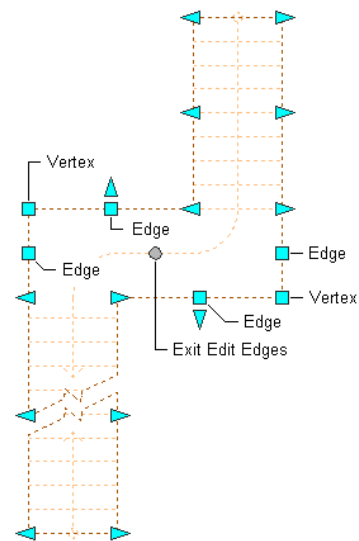

- 1 Select the multi-landing stair.
- 2 Select the grip for the dimension you want to change.

In order to edit the flight width and flight taper, click the Edit Edges grip to access the edges edit mode. When you have finished editing the stair edges, click the Exit Edit Edges grip to return to the default stair edit mode.

Multi-landing stair Flight Taper and Flight Width, and Landing Width grips

Multi-landing stair landing Edge and Vertex, and Exit Edit Edges grips

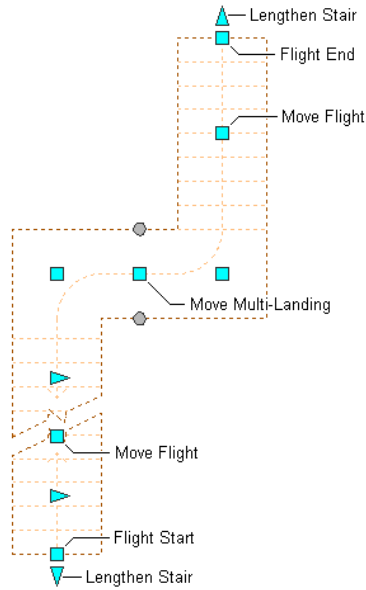

3 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

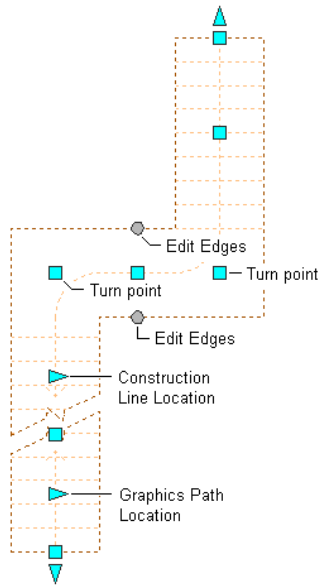

Changing the Location or Position of a Multi-Landing Stair

- 1 Select the multi-landing stair.
- 2 Select the appropriate grip to change the location of the stair, its start point, construction line, graphics path, or endpoint.

Multi-landing stair Flight Start and End, Move Flight, Move Multi-Landing, and Lengthen Stair grips

Multi-landing stair Landing Turn Point, Construction Line Location, Graphics Path Location, and Edit Edges grips

3 Move the stair to the desired location, and click once; or enter a value, and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the stair along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the stair is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the stair is constrained to the *Y* dimension direction.

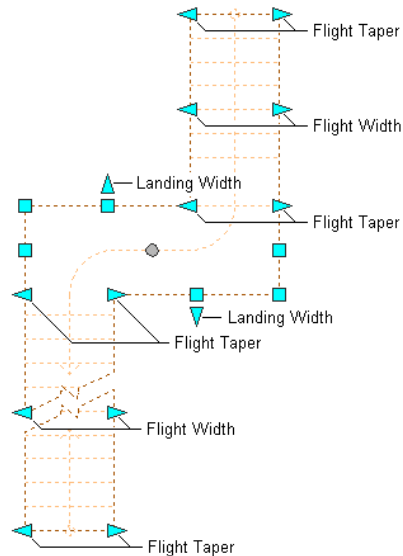

4 Right-click, and click Deselect All to turn off grips.

Changing the Shape of Landings for Multi-Landing Stair

- 1 Select the multi-landing stair.
- 2 Select the Edit Edges grip.

In order to edit the landing width, landing edges, and landing vertices, click the Edit Edges grip to access the edges edit mode. When you have finished editing the landing edges, click the Exit Edit Edges grip to return to the default stair edit mode.

Multi-landing stair Flight Taper and Flight Width, and Landing Width grips

Multi-landing stair Landing Edge and Vertex, and Exit Edit Edges grips

- 3 Move the appropriate grip to change the shape of the landing of the stair.

NOTE Once a landing edge has been customized by moving any of the vertex or edge grips, the landing width grips are no longer displayed.

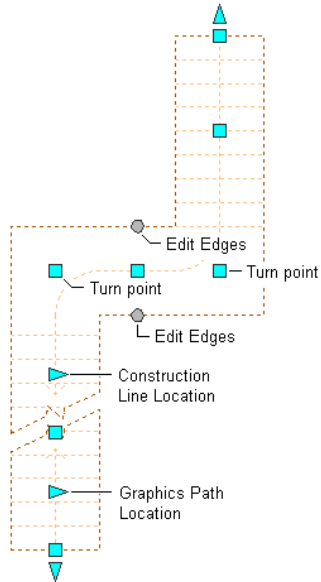

Changing the Location of a Landing for a Multi-Landing Stair

- 1 Select the multi-landing stair.
- 2 Move the appropriate grip to change the location of the landing by changing the location of the turn point for each side of the landing, or by moving the entire landing.

Changing the Construction Line or Graphics Path of a Multi-Landing Stair

- 1 Select the multi-landing stair.
- 2 Move the Construction Line or Graphics Path grip.

Multi-landing stair landing Turn Point, Construction Line Location, Graphics Path Location, and Edit Edges grips

NOTE Only one of the Construction Line or Graphics Path can be displayed at a time. This is controlled on the Other tab of the current plan display representation. For information about this setting, see [Specifying the Display of Other Characteristics of a Stair](#) on page 1503.

Changing the Height of a Multi-Landing Stair

- 1 Select the multi-landing stair.
- 2 Move the Height grip to change the height of the stair.

NOTE This grip displays only in 3D views of the stair.

Multi-landing stair Height grip

Using Grips to Edit U-Shaped Stairs

Refer to the illustrations and steps in this topic to use U-shaped stair grips to edit stairs.

Editing U-Shaped Stair Dimensions

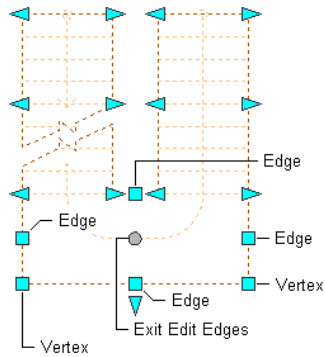

- 1 Select the U-shaped stair.
- 2 Select the Edit Edges grip.

In order to edit the flight width and flight taper, click the Edit Edges grip to access the edges edit mode. When you have finished editing the stair edges, click the Exit Edit Edges grip to return to the default stair edit mode.

U-shaped stair Flight Taper, Flight Width, and Landing Width grips

U-shaped stair Landing Vertex and Edge, and Exit Edit Edges grips

3 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

Changing the Location or Position of a U-Shaped Stair

- 1 Select the U-shaped stair.
- 2 Select the appropriate grip to change the location of the stair, its start point, construction line, graphics path, or endpoint.

U-shaped stair Flight Start and End, Flip, and Location grips

U-shaped stair Graphics Path Location, Construction Line Location, and Edit Edges grips

3 Move the stair to the desired location, and click once; or enter a value, and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the stair along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the stair is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the stair is constrained to the *Y* dimension direction.

4 Right-click, and click Deselect All to turn off grips.

Changing the Shape of Landings for a U-Shaped Stair

1 Select the U-shaped stair.

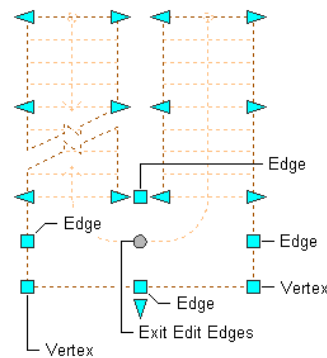

2 Select the Edit Edges grip.

In order to edit the landing width, landing edges, and landing vertices, click the Edit Edges grip to access the edges edit mode. When you have finished editing the landing edges, click the Exit Edit Edges grip to return to the default stair edit mode.

U-shaped stair Flight Taper, Flight Width, and Landing Width grips

U-shaped stair Landing Vertex and Edge, and Exit Edit Edges grips

3 Move the appropriate grip to change the shape of the landing of the stair.

Changing the Construction Line or Graphics Path of a U-Shaped Stair

1 Select the U-shaped stair.

2 Move the Construction Line or Graphics Path grip.

U-shaped stair Graphics Path Location, Construction Line Location, and Edit Edges grips

NOTE Only one of the Construction Line or Graphics Path can be displayed at a time.

- 3 Move the appropriate Flip grip to flip the stair landing from one side of the flight start grip to the other, or to switch the two flights.

Changing the Height of a U-Shaped Stair

- 1 Select the U-shaped stair.
- 2 Move the Height grip to change the height of the stair.

NOTE This grip displays only in 3D views of the stair.

U-shaped stair Height grip

Using Grips to Edit Spiral Stairs

Refer to the illustrations and steps in this topic to use spiral stair grips to edit stairs.

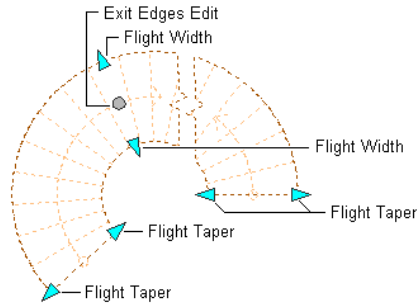

Editing Spiral Stair Dimensions

- 1 Select the spiral stair.
- 2 Select the Edit Edges grip.

In order to edit the flight width and flight taper, click the Edit Edges grip to access the edges edit mode. When you have finished editing the stair edges, click the Exit Edit Edges grip to return to the default stair edit mode.

- 3 Select the grip for the dimension you want to change.

Spiral stair Flight Taper and Width, and Exit Edges Edit grips

- 4 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

Changing the Location or Position of a Spiral Stair

- 1 Select the spiral stair.
- 2 Select the appropriate grip to change the location of the stair, its start point, construction line, graphics path, or endpoint. You can also flip the stair around the start point.

Spiral stair Radius, Flip, Rotate Flight, and Location grips

Spiral stair Graphics Path Location and Edit Edges grips

- 3 Move the stair to the desired location, and click once; or enter a value, and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the stair along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the stair is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the stair is constrained to the *Y* dimension direction.

4 Right-click, and click Deselect All to turn off grips.

Changing the Height of a Spiral Stair

- 1 Select the spiral stair.
- 2 Move the Height grip to change the height of the stair.

NOTE This grip displays only in 3D views of the stair.

Spiral stair Height grip

Changing the Width of a Flight

Use this procedure to change width of a stair flight. You can also change the stair width on the Properties palette.

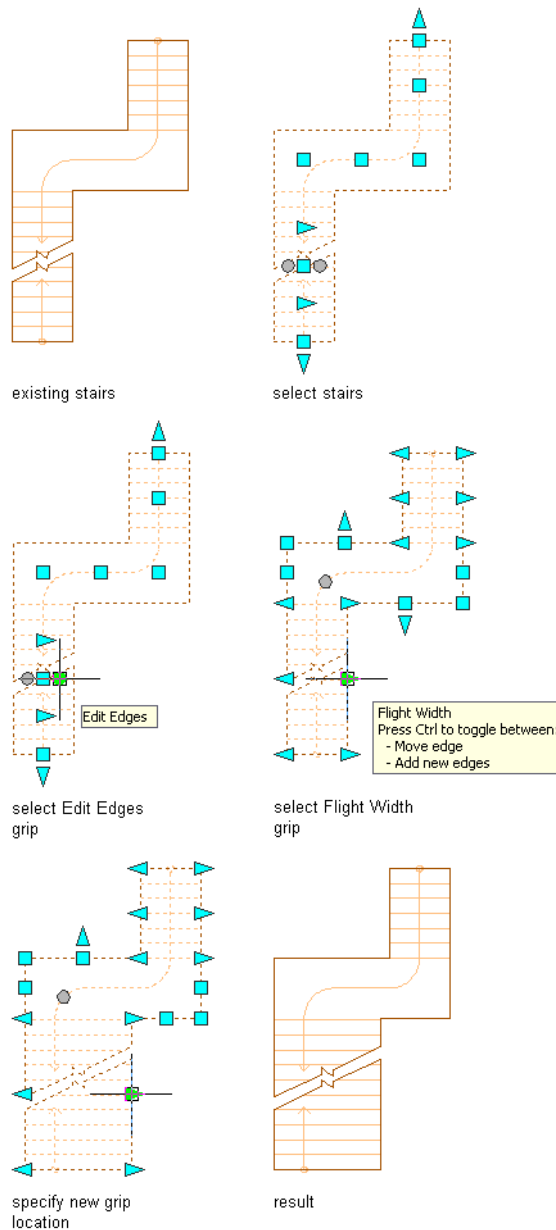

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

NOTE If you change the width of the stair after grip-editing a side, the grip changes are lost.

- 1 Select the stair.
- 2 Select a Flight Width grip, move the grip until the width value you want is displayed, and click once.
After selecting a grip, you can also enter a precise value to increase or decrease the width of the stair.

The entire edge of the flight moves to the selected location. The flight entry width also changes to fit the new stair width.

Using grips to change stair flight width

Changing the Shape of a Flight

Use this procedure to change the top and bottom width of a single flight on U-shaped, multi-landing, or spiral-shape stairs. Each side of a flight can be tapered independently using grip points.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

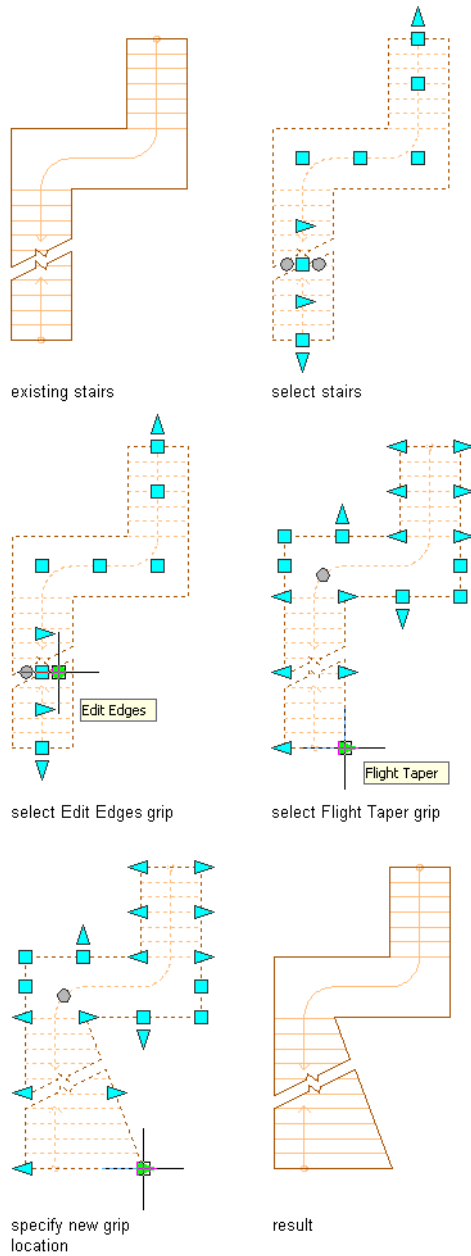

NOTE If you change the width of the stair after grip editing a side, the grip changes are lost.

1 Select the stair to modify.

2 Select the Flight Taper grip on the stair flight, and move the grip away from stair path to new location.

The flight changes to the new shape.

Using grips to change stair flight taper

Changing the Shape of a Landing

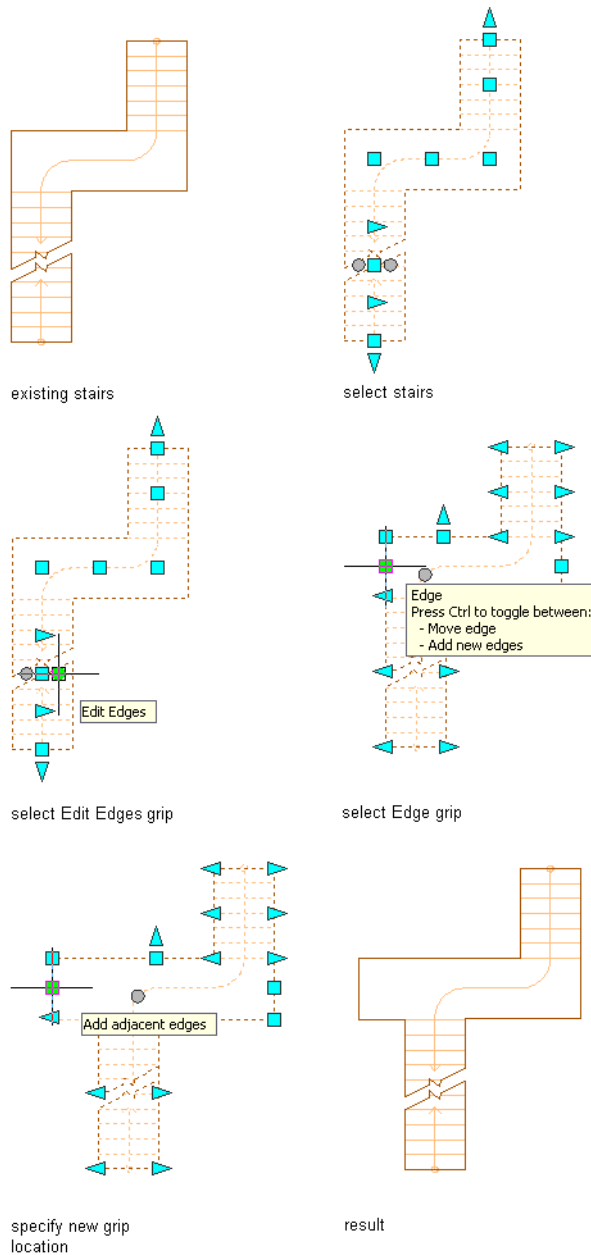

Use this procedure to change the angles and positions of landing edges on U-shaped and multi-landing stairs. Each edge of a landing can be tapered or moved independently using grip points.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

NOTE If you change the width of the stair after grip-editing a side, the grip changes are lost.

- 1 Select the stair to modify.
- 2 Select a Vertex grip on the landing, and move the grip away from the stair path to a new location.
The landing changes to the new shape. If the vertex grip is shared between a landing and flight, the flight moves with the landing.
- 3 Select an Edge grip on the landing, and move the grip perpendicular to the stair path to the new location.
The entire edge of the landing moves to the selected location.

Using grips to change a stair landing width by adding an edge

- 4 Select an Edge grip on the side of a landing, press *CTRL*, then move the grip away from the stair path.
An adjacent edge of the landing is created.

Changing the Side of a Stair

You can determine the shape of one edge of a stair run that includes flights and landings for straight, U-shaped, multi-landing, or spiral stairs.

The size of the landing must be adjusted to prevent overlapping treads when the inner edge of a stair is projected to a profile that lies outside the original stair. The initial size of the landing is determined by projecting the diagonal of the original landing to the profile.

Using grips to change a stair landing width

Pushing one tread into the landing with its grip forces the landing to lengthen in the other direction. Pulling one tread away from the landing does not affect the other end of the landing. The stair is lengthened at its top to accommodate the larger landing. You can modify the length with the top and bottom grips, at the end of the stair walking path.

About Projecting the Side of a Stair

You can project the edge of a stair to most AEC objects, such as walls or mass elements, but excluding multi-view blocks.

Projecting a stair edge to an object

NOTE When projecting an edge of a stair that has an inner corner, it is clear how to project the outer edge of the stair to the selected object, but projection of the inner corner is ambiguous. Rather than attempting to guess the correct solution, these cases are not projected, and a dialog box is displayed with an explanation that edges of stairs with interior corners can be projected only to objects that extend beyond both ends of the stair.

The stair length is extended at its original width when the object (or polyline) does not extend far enough for the stair to project completely.

Projecting the Side of a Stair

Use this procedure to project the side of a stair to an existing polyline, wall, other AEC object, or solid. Objects to project to must extend the full length of the stair for an interior corner to project properly.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

Projecting stair edges to curved polyline segments

Projecting stair edges to straight polyline segments

NOTE If you change the width of the stair after projecting a side, the changes to the projected edge are lost.

- 1 Select a stair, right-click, and click Customize Edge ► Project.
- 2 Select the edge of a stair to change.
- 3 Select a polyline, object or profile to project to, and press *ENTER*.

Projecting stair edges to a profile

Treads are extended using the line of the current front and back edge.

NOTE If edges intersect, which can happen with only spiral and winding shapes, a solution tip icon displays.

Offsetting the Side of a Stair

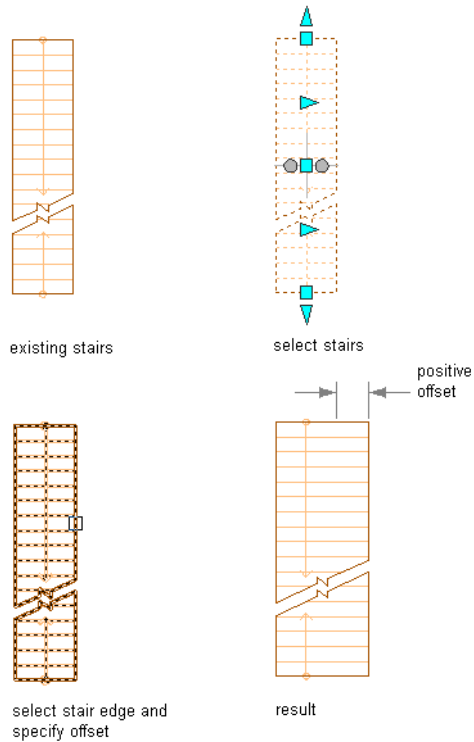

Use this procedure to offset the side of a stair flight by a specified value.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

NOTE If you change the width of the stair after offsetting a side, the offset changes are lost.

- 1 Select a stair, right-click, and click Customize Edge ► Offset.
 - 2 Select the edge of a stair to be offset.
 - 3 Enter the distance to offset, where positive is out and negative is in, and press *ENTER*.
- Treads are extended using the line of the current front and back edge.

Offsetting the edge of a stair

NOTE If edges intersect, which can happen with only spiral and winding shapes, a solution tip icon displays.

Generating a Polyline from the Edge of a Stair

Use this procedure to generate a polyline from the edge of a stair. The polyline is generated at the stair bottom elevation.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

You can keep some sample polylines in the drawing, and use the final choice to project to. That way, you can project the stair edge, edit the stair, and then generate the polyline, change the stair again, generate another polyline, change the stair again, and, finally, project to the best version you created.

Generating a polyline from a stair edge

- 1 Select a stair, right-click, and click Customize Edge ► Generate Polyline.
- 2 Select the edge of a stair.
- 3 Press *ENTER*.

A polyline is created at the stair bottom elevation along the length of the stair run.

Removing Changes from the Side of a Stair

Use this procedure to return the selected edge of the stair to its default profile. If the stair is back to its original condition, the width is restored to the original value, rather than *VARIES*. This change affects the treads, risers, and stringers.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

Removing changes made to the side of a stair

- 1 Select a stair, right-click, and click **Customize Edge** ► **Remove Customization**.
- 2 Select the edge of a stair.
- 3 Press **ENTER**.

Changing the Height of a Stair

Use this procedure to change the height of a stair. You can also change the stair height on the Properties palette.

For more information about stair grips, see [Using Grips to Edit Stairs](#) on page 1426.

Changing the height of a stair using grips

- 1 Select the stair in an isometric view.
- 2 Select the Height grip, move the grip until the value you want is displayed, and click once.
After selecting a grip, you can also enter a precise value to increase or decrease the height of the stair.

NOTE If you edit the height of a stair with landings, so that a landing would be below the new height, the landing is not displayed. If you edit the height again, and move it to a location above the previous landing, the landing is no longer there. To retain the stair path, which includes the landing, use the AecStairFit command to set Automatic Landings to No.

Changing the Justification of a Stair

Use this procedure to change the justification of an individual stair. The stair remains in the same location, but changes in the width keep the new justification point constant.

For example, a stair with right justification changes the left edge when the width is changed.

- 1 Select the stair you want to change, and double-click it.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select Left, Center, or Right for Justify.

This does not change the location of the stair, but changing this value specifies the point from which changes to the width are calculated from now on.

Changing the Style of a Stair

Use this procedure to select a different stair style for one or more stairs.

- 1 Select the stairs to change, and double-click one of them.
- 2 Expand Basic, and expand General.
- 3 Select a different style.

Changing the Horizontal Direction of a Spiral or U-Shaped Stair

Use this procedure to change the orientation of a spiral stair.

- 1 Select a spiral or U-shaped stair.
- 2 Specify the horizontal orientation of the stair:

If you want to...

Then...

draw the spiral or U-shaped stair in a counterclockwise direction

select Counterclockwise for Horizontal Orientation.

draw the spiral or U-shaped stair in a clockwise direction

select Clockwise for Horizontal Orientation.

NOTE This is equivalent to selecting the Flip grip that mirrors the stair around its start point.

Changing the Constraints of a Spiral Stair

Use this procedure to control what constrains the spiral stair by specifying the total degrees or the number of degrees per tread to use. These fields are available only when you select a spiral-shaped stair to modify.

- 1 Select a spiral stair.
- 2 Specify the arc constraint:

If you want to...

Then...

display the spiral stair with no constraint

select Free for Arc Constraint.

specify the total degrees for the stair flight

select Total Degrees for Arc Constraint, and enter a value for Arc Angle.

specify the specific degree for each tread in the stair

select Degrees per Tread for Arc Constraint, and enter a value for Arc Angle.

- 3 Specify the Radius of the stair.

The radius is measured from the center point of the spiral stair to the selected justification point.

4 Click OK.

Changing the Outside Edge of a Spiral Stair

Use this procedure to change the outside edge of a spiral stair. You can change the edge in two ways:

- When you use the Flight Width grip point, you uniformly change the width of the stair along the entire arc. The endpoints of the outer edges of the stair move. This changes the size of the stair.
- When you click the Flight Width grip point and press *CTRL*, you maintain the center of the stair and the outside grip points. This changes the shape of the stair.

1 Select a spiral stair.

2 Change a spiral stair:

If you want to...	Then...
uniformly change the width of a spiral stair along the entire arc	click the Flight Width grip of the spiral stair.
maintain the center and outside grip points while changing the shape of a spiral stair	click the Flight Width grip of the spiral stair and press <i>CTRL</i> .

3 Move the grip to change the size or shape of the stair.

Using grips to change the flight width of a spiral stair run

existing stairs

select stairs

select Edit Edges grip

select Flight Width grip

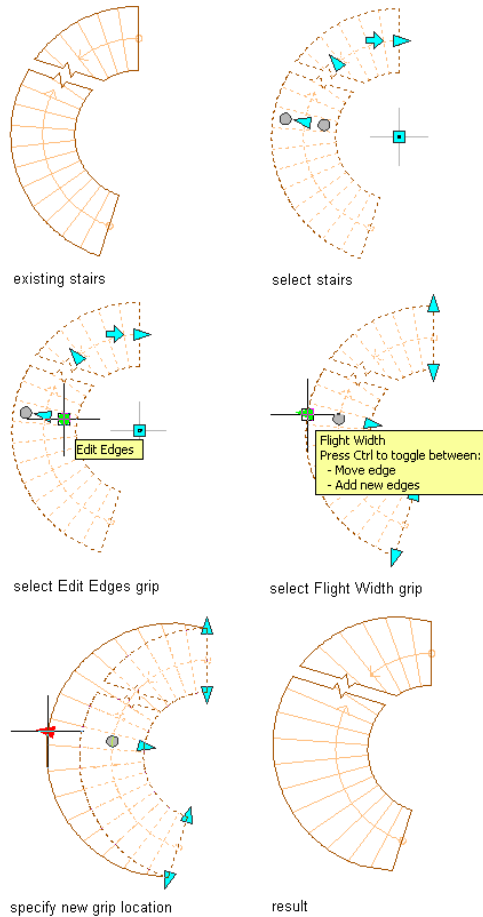

specify new grip location

result

Using grips to change the shape of a spiral stair run by adding an edge

Changing the Dimensions of a Stair

Use this procedure to control the various dimensions associated with calculating the stair.

Some of the interacting dimensions can be user-defined and some are automatic, depending upon the combination of fields that are selected. Only logical combinations are available when the rule-based calculator is in effect. When the rule-based calculator is not in effect, either tread or straight length can be user-defined and either riser count or riser height can be user-defined.

- 1 Select the stair.
- 2 On the Properties palette, expand Basic, and expand Dimensions.
- 3 Change any of the dimensions of the stair:

If you want to...

specify the width of the stair run

Then...

enter a value for Width.

NOTE If you change the width of the stair after grip-editing or otherwise customizing an edge, the changes are lost.

If you want to...**Then...**

specify the floor-to-floor height for the stair

enter a value for Height.

specify the justification of the stair

select Left, Center, or Right for Justify. This does not change the location of the stair, but changing this value determines the point from which the width is calculated if it is subsequently changed.

4 Select Calculation rules:

If you want to...**Then...**

specify the overall linear length of the stair

enter a value for Straight Length.

- When Straight Length is set to  (automatic), the value is calculated based on the tread size and riser count.
- When Straight Length is  (user-defined), the stair length is equal to the dimension entered, and the other three values are adjusted within the code limits. If these values fall outside the stair limits, an error message is displayed.
- When Riser Count is user-defined, the tread depth is increased or decreased to accommodate the stair.

specify the total number of stair risers

enter a value for Riser Count.

- When Riser Count is set to  (automatic), the number of risers is based on the overall length and overall height of the stair and the code limits specified on the Design Rules tab. The Straight Length value of the stair is adjusted automatically.
 - When Riser Count is  (user-defined), you can specify a value that is used to calculate the tread depth and riser height. If these values fall outside the stair limits, an error message is displayed.
-

If you want to...**Then...**

specify the height of each riser in the stair flight

set all fields to  (automatic), click the icon to Riser to change it to , and enter a value for Riser height.

specify the tread depth for each tread in the stair flight

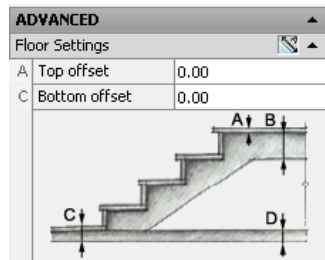

set all fields to  (automatic), click the icon next to Tread to change it to , and enter a value for Tread depth. You can also specify the Riser count when you set the tread depth.

NOTE If  is displayed next to a field in the Calculation Rules dialog box, that field can't be changed until another field is changed from  (user-defined) to  (automatic).

Changing the Floor Settings of a Stair

Use this procedure to control how the stair interacts with the floor at the beginning and end of the stair run.

- 1 Select a stair.
- 2 On the Properties palette, expand Advanced, and expand Floor Settings.

- 3 Change settings for how the stair meets the top and bottom floors:

If you want to...**Then...**

specify the thickness of the floor finish material at the top floor of the stair

enter a value for Top Offset.

specify the depth of the structure at the top floor

enter a value for Top Depth.

specify the thickness of the floor finish material at the bottom floor of the stair

enter a value for Bottom Offset.

specify the depth of the structure at the bottom floor

enter a value for Bottom Depth.

NOTE The Top and Bottom Depth settings currently have no effect on the stair or stringers. In addition, the Top offset has no visible effect on the stair. Bottom offset extends or truncates any attached stringers. Both offset values affect the rough floor-to-floor height, if it is displayed.

Adjusting Stair Length Automatically

Use this procedure to adjust stair length automatically with the StairFit setting.

With the StairFit setting enabled, a stair adjusts its length to accommodate a height change. With the StairFit setting disabled, a stair does not adjust its length to accommodate a height change. Also, a solution tip icon displays if the stair path is not long enough to accommodate the new height.

All newly created stairs have the StairFit setting enabled. All stairs created in versions earlier than Autodesk Architectural Desktop 2004 have the StairFit setting disabled.

- 1 Draw a stair run.
- 2 On the Command Line, enter **StairFit**.
- 3 Select the stair run.
- 4 Enter **Y** to enable the StairFit setting or **N** to disable the StairFit setting.

NOTE You can also access the StairFit setting by clicking Design menu ► Stairs ► Automatic Length.

- 5 Select the stair run again, right-click, and click Properties.
- 6 Specify a new stair height.

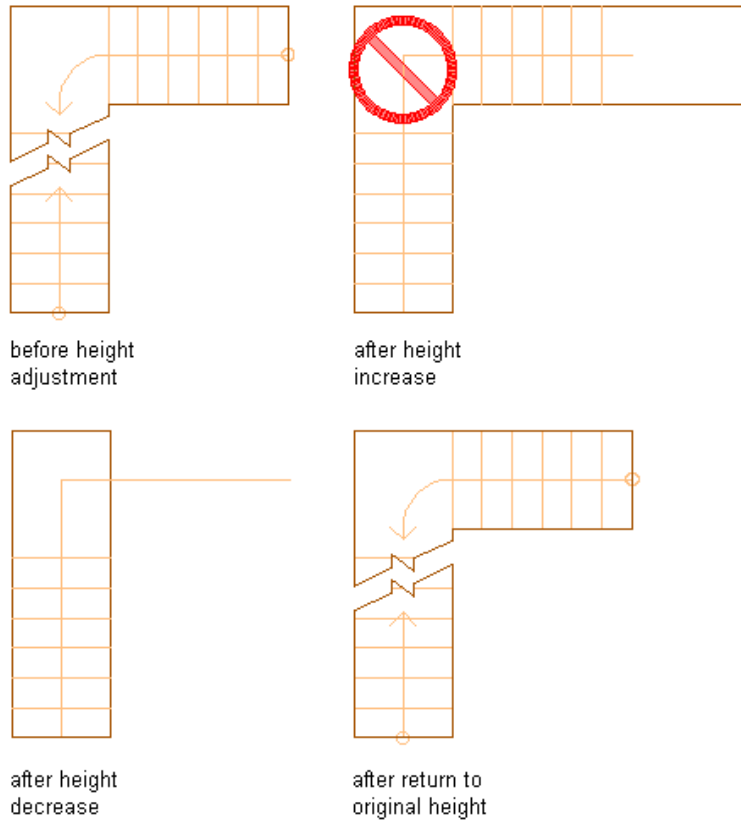

The following illustration shows an example of a straight stair run with the StairFit option enabled before and after height changes.

Stair run height change with StairFit option enabled

The following illustration shows an example of a straight stair run with the StairFit option disabled before and after height changes.

Stair run height change with StairFit option disabled

Changing the Length Limits of a Flight

Use this procedure to change the limits for the flight of a stair. A flight can have no limits, or limits that are constrained by a minimum number of risers, minimum height, maximum number of risers, or maximum height.

Use these settings to create automatic landings in a stair flight. For example, if a stair flight has 18 treads and you set the maximum treads to 15, the stair will have two flights with one landing in the middle, keeping under the 15 maximum risers on either side of the landing.

Specifying flight height limits for a stair run

- 1 Select a stair.
- 2 On the Properties palette, expand Advanced, and expand Flight Height.

Flight Height with Risers Limit type

Flight Height	
Minimum limit type	Risers
Minimum risers	3
Maximum limit type	Risers
Maximum risers	15

- 3 Specify the constraints for flight length:

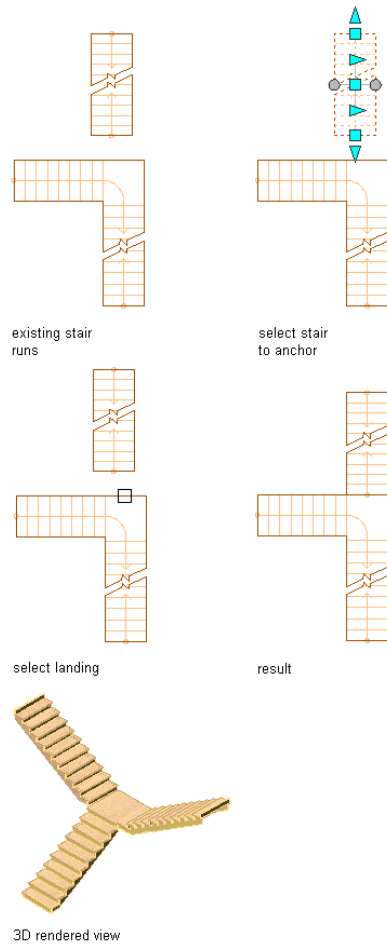

If you want to...	Then...
specify no limits on the flight	select None for Minimum Limit type and None for Maximum Limit type.
specify a minimum number of risers per flight	select Risers for Minimum Limit type, and enter a value for Minimum risers.
specify a minimum height for the flight	select Height for Minimum Limit type, and enter a value for Minimum height.
specify a maximum number of risers per flight	select Risers for Maximum Limit type, and enter a value for Maximum risers.
specify a maximum height for the flight	select Height for Maximum Limit type, and enter a value for Maximum height.

Anchoring a Stair to a Landing

Use this procedure to anchor a stair or other AEC object to an existing landing.

- 1 Draw a stair with a landing and draw a second stair to attach to the landing. For more information about creating stairs, see [Using Stair Tools to Create Stairs](#) on page 1396.
- 2 Select the stair with a landing, right-click, and click Stair Landing Anchor ► Anchor to landing.
- 3 Select the stair or other AEC object to anchor to the landing.
- 4 Select a location on the landing to anchor the center of the start of the stair run. The flight will be perpendicular to the landing edge.
Select the insertion point of the AEC object that you are attaching to the landing. The object will be oriented parallel to the edge of the landing.

Anchoring a stair run to a landing

NOTE Stairs created with a vertical orientation of Up go up from the landing, while stairs created with a vertical orientation of Down go down from the landing.

The renumber riser numbering feature is helpful in this situation. See [Specifying the Riser Numbering Display for Individual Stairs](#) on page 1505.

Releasing Anchored Stairs

Use this procedure to release stairs anchored to landings.

- Select the stair to anchor to the landing, right-click, and click Stair Landing Anchor ► Release.

NOTE The stair remains in the same location, but is no longer anchored to the landing.

Editing Winders

Three different winder types give you different levels of control for 1/2 turn and 1/4 turn stairs: Balanced, Single Point, and Manual.

The Balanced winder style has the total turn distributed evenly throughout the stair run.

The Single Point winder styles allow you to align tread edges or riser faces with the winder turn center, and add or remove individual treads from the winder turn. You can also assign a default number of treads to a winder turn, resulting in the specified number of treads appearing in the stair turn zone.

Manual winder styles can be based on any winder style, by assigning either a Manual - Tread or Manual - Riser condition to a stair run. Both manual styles allow you to straighten individual treads or risers in the stair run and to move the tread endpoints on either side of individual treads so you can angle tread edges or riser faces to suit your stair design.

For information about creating new winder styles, see [Creating a Stair Winder Style](#) on page 1523.

Winder style examples

Lengthening a Flight to Align a Tread Edge with a Winder Turn Center

Use this procedure to lengthen a flight to align a Single Point winder style tread edge with a winder turn center.

The winders within the turn zone are set to an angle converging on the Turn Center grip.

- 1 Select a 1/2 turn or 1/4 turn stair.
- 2 If the Winder Style is balanced, select the circular Edit Turns trigger grip. The Select Winder styles dialog box is displayed.

NOTE Only the winder styles present in the drawing are displayed.

Select Stair Winder Style dialog box

3 Select a Single Point style from the list, and click OK.

NOTE To select the style from the Properties palette, expand Basic, expand General, and select Single Point for Winder Style.

4 Select the Edit Turns trigger grip.

Note the initial flight length of the existing stairs.

5 Select the Lengthen Flight to Align Tread grip.

The flight is lengthened as the tread edge is now aligned with the turn center.

Lengthening a Flight to Align a Tread Edge with Turn Center

NOTE To have the converging point on the edge of the stair, you must clear the Use Riser Lines setting. See [Specifying the Stair Winder Style Settings](#) on page 1523 for more information about this setting.

Aligning a Tread Edge with a Winder Turn Center

Use this procedure to align a Single Point winder style tread edge with a winder turn center.

The winders within the turn zone are set to an angle converging on the Turn Center grip.

- 1 Select a 1/2 turn or 1/4 turn stair.

2 If the Winder Style is balanced, select the circular Edit Turns trigger grip. The Select Winder styles dialog box is displayed.

NOTE Only the winder styles present in the drawing are displayed.

Select Stair Winder Style dialog box

3 Select a Single Point style from the list, and click OK.

NOTE To select the style from the Properties palette, expand Basic, expand General, and select Single Point for Winder Style.

4 Select the Edit Turns trigger grip.

5 Select the Align with Turn Center grip.

The tread edge is now aligned with the turn center, and the grip is no longer displayed.

Aligning a tread edge with turn center

NOTE To have the converging point on the edge of the stair, you must clear the Use Riser Lines setting. For more information about this setting, see [Specifying the Stair Winder Style Settings](#) on page 1523.

Removing a Tread from a Winder Turn

Use this procedure to remove a tread from a winder turn.

The winders within the turn zone are set to an angle converging on the Turn Center grip.

- 1 Select a 1/2 turn or 1/4 turn stair.
- 2 If the Winder Style is balanced, select the circular Edit Turns trigger grip. The Select Winder styles dialog box is displayed.

NOTE Only the winder styles present in the drawing are displayed.

Select Stair Winder Style dialog box

3 Select a Single Point style from the list, and click OK.

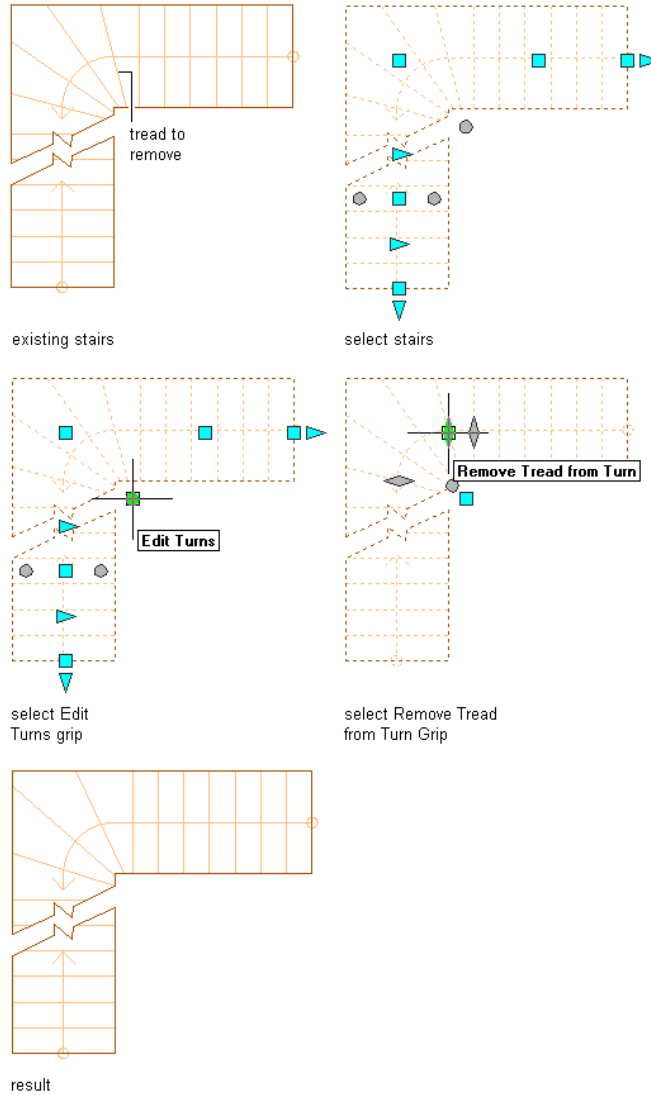

NOTE To select the style from the Properties palette, expand Basic, expand General, and select Single Point for Winder Style.

4 Select the Edit Turns trigger grip.

5 Select the Remove Tread from Turn grip.

The selected tread is removed from the winder turn. If you continue to remove treads, the stair will eventually display a solution tip icon. Use the Undo command to restore the previous tread configuration.

Removing a Tread from a Winder Turn

NOTE To have the converging point on the edge of the stair, you must clear the Use Riser Lines setting. For more information about this setting, see [Specifying the Stair Winder Style Settings](#) on page 1523.

Adding a Tread to a Winder Turn

Use this procedure to add a tread to a winder turn.

The winders within the turn zone are set to an angle converging on the Turn Center grip.

- 1 Select a 1/2 turn or 1/4 turn stair.
- 2 If the Winder Style is balanced, select the circular Edit Turns trigger grip. The Select Winder styles dialog box is displayed.

NOTE Only the winder styles present in the drawing are displayed.

Select Stair Winder Style dialog box

3 Select a Single Point style from the list, and click OK.

NOTE To select the style from the Properties palette, expand Basic, expand General, and select Single Point for Winder Style.

4 Select the Edit Turns trigger grip.

5 Select the Add Tread to Turn grip.

A tread is added to the winder turn. If you continue to add treads, the stair will eventually display a solution tip icon. Use the Undo command to restore the previous tread configuration.

Adding a tread to a winder turn

NOTE To have the converging point on the edge of the stair, you must clear the Use Riser Lines setting. For more information about this setting, see [Specifying the Stair Winder Style Settings](#) on page 1523.

Straightening Treads with the Manual Winder Style

Use this procedure to straighten individual treads on stairs assigned either the Manual - Tread or Manual - Riser Balanced winder style.

The Straighten Tread grip is located at the intersection of the tread edge or riser face and the stair construction line, based on the Use Riser Line setting in the Stair Winder Style dialog box. For more information, see [Specifying the Stair Winder Style Settings](#) on page 1523.

- 1 Select a 1/2 turn or 1/4 turn stair.
- 2 If the Winder Style is balanced, select the circular Edit Turns trigger grip. The Select Winder styles dialog box is displayed.

Select Winder Style dialog box

3 Select either Manual - Tread or Manual - Riser from the list, and click OK.

NOTE To select the style from the Properties palette, expand Basic, expand General, and select Manual for Winder Style.

4 Select the Edit Turns trigger grip.

5 Select the Straighten Tread grip on the tread edge or riser face that you want to straighten.
The selected tread is straightened.

Straightening a tread with a manual riser style

NOTE Because the tread depth must be the same for each tread, the tread edge line will pivot around the construction line.

Moving Tread Ends with the Manual Winder Style

Use this procedure to move the ends of individual treads on stairs assigned either the Manual - Tread or Manual - Riser Balanced winder style. Each tread edge or riser face pivots on a point established by the intersection of the tread edge and the stair's construction line. Drag the Tread Edge grip to a new location to specify a new angle for the tread edge.

The Tread End grips are located at each end of the tread edge or riser face, based on the Use Riser Line setting in the Stair Winder Style dialog box. For more information, see [Specifying the Stair Winder Style Settings](#) on page 1523.

- 1 Select a 1/2 turn or 1/4 turn stair.

2 If the Winder Style is balanced, select the circular Edit Turns trigger grip. The Select Winder styles dialog box is displayed.

Select Winder Style dialog box

3 Select either Manual - Tread or Manual - Riser from the list, and click OK.

NOTE To select the style from the Properties palette, expand Basic, expand General, and select Manual for Winder Style.

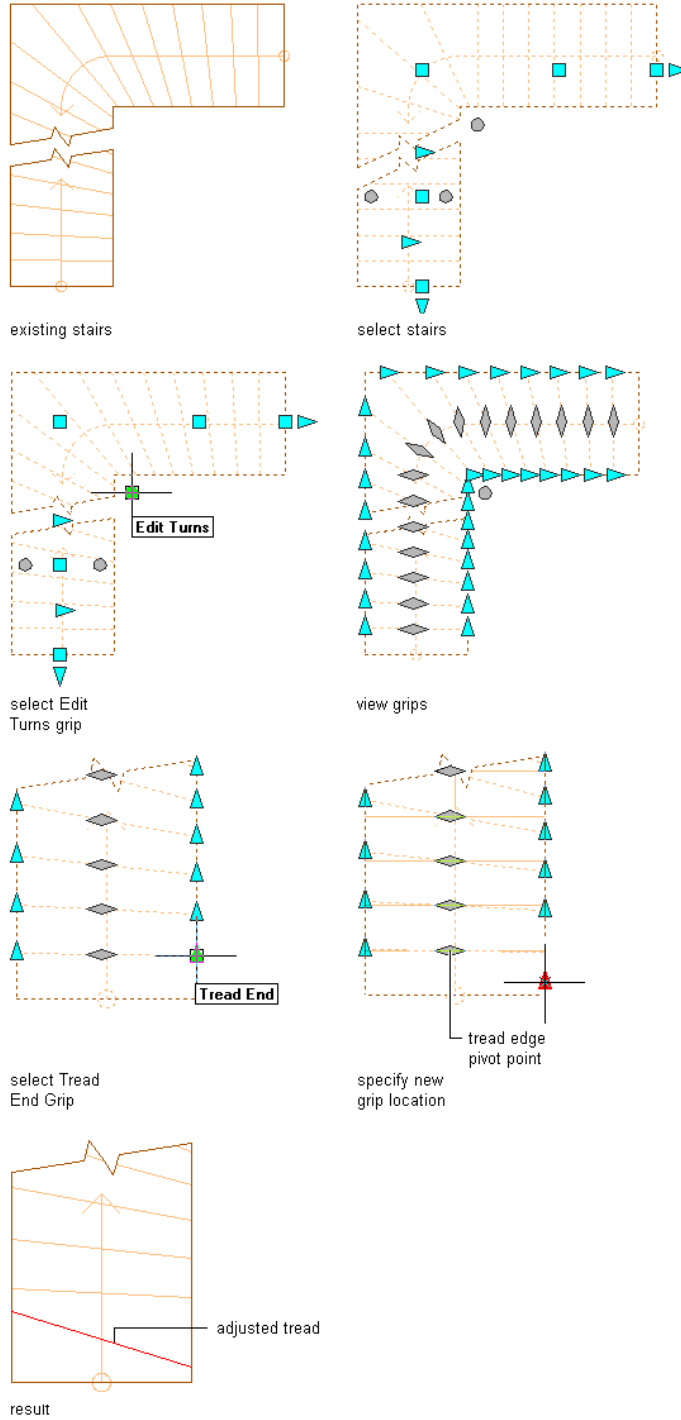

4 Select the Edit Turns trigger grip.

5 Select the Tread End grip on the tread edge or riser face that you want to move.

6 Specify a new location for the Tread End grip.

The selected tread is angled as specified.

Moving a tread edge with a manual riser style

NOTE Because the tread depth must be the same for each tread, the tread edge line will pivot around the construction line.

Working with Stair Body Modifiers

Body modifiers use the three-dimensional (3D) geometry of an object, such as a mass element or a mass group, to add to or subtract from a stair component (tread, riser, or stringer depending on the stair style). Body Modifiers only work on a single instance of a tread, riser, or stringer at a time.

After you create a body modifier from an object, you can delete the original object. However, if you have created a complex object, such as a mass group comprising many mass elements, you may want to retain the object in the drawing until you are sure you have the results you want for the stair.

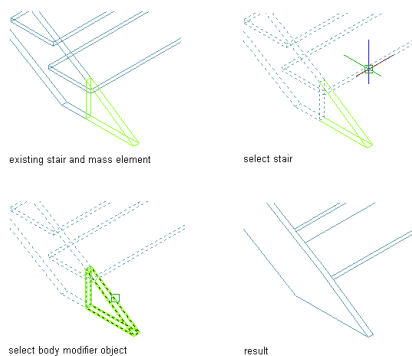

Adding a Body Modifier to a Stair Component

Use this procedure to create a body modifier and add it to a stair.

You can create a three-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

The following illustration shows you how to use a mass element as a body modifier to add to a stair stringer component.

Adding a body modifier to a stair component

- 1 Place the object in the location where you want to add the body modifier to the stair.
- 2 Select the stair you want to change with the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to add to the stair component.
- 4 In the Add Body Modifier dialog box, select Stringer for Stair Component and Additive for Operation.

- 5 Enter a description for the body modifier.
- 6 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.

7 Click OK.

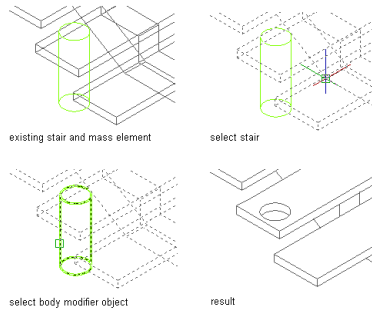

Subtracting a Body Modifier from a Stair Component

Use this procedure to create a body modifier and subtract it from a stair component.

You can create a three-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

The following illustration shows you how to use a mass element as a body modifier to subtract from a stair tread component.

Subtracting a body modifier from a stair component

- 1 Place the object in the location where you want to subtract the body modifier from the stair.
- 2 Select the stair you want to change with the body modifier, right-click, and click **Body Modifiers** ► **Add**.
- 3 Select the object to subtract from the stair.
- 4 In the Add Body Modifier dialog box, select **Tread** for Stair Component and **Subtractive** for Operation.

- 5 Enter a description for the body modifier.
- 6 Select **Erase Selected Object(s)** if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 7 Click OK.

Replacing a Stair Component with a Body Modifier

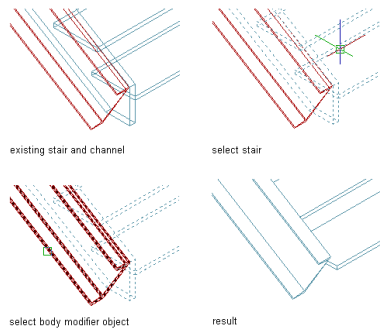

Use this procedure to create a body modifier to replace a stair component.

You can create a three-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies.

You must place the object in the location you want in the drawing before defining the object as a body modifier.

The following illustration shows you how to use a channel as a body modifier to replace a stair stringer component.

Replacing a stair component with a body modifier

- 1 Place the object in the location where you want to replace the stair component with the body modifier.
- 2 Select the stair you want to change with the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to replace the stair component.
- 4 In the Add Body Modifier dialog box, select Stringer for Stair Component and Replace for Operation.

- 5 Enter a description for the body modifier.
- 6 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 7 Click OK.

Editing the Geometry of a Body Modifier

Use this procedure to edit the shape of a body modifier that is attached to a stair. You can edit the body using grips to edit faces, using Boolean commands to add or remove other objects from the body modifier, and other editing commands to change its shape.

- 1 Select the stair that has the body modifier you want to change, right-click, and click Body Modifiers ► Edit in Place.

A temporary mass element is created for you to edit the geometry of the body modifier. If the stair contains multiple body modifiers, a mass element is created for each body modifier. If

object was not originally a mass element (for example, if you used a slab as a body modifier), the object becomes a temporary Free Form mass element with faces that you can edit.

2 NOTE After you perform an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select a profile, and right-click to redisplay the menu.

Edit the body modifier:

If you want to ...

Then ...

change the shape of a body modifier that is a Free Form mass element

select the body modifier. Select a Face grip to activate edge grips for the face. Move the grips to the desired locations. Continue editing other faces in the same manner.

change the shape of a body modifier that is a conventional mass element

select the body modifier. Select grips and move them to change the shape of the body modifier. The grips that are available depend on the type of mass element used as a body modifier and the current view direction.

add an object to a body modifier

place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Union. Select the object, and press *ENTER*. Enter *y* (Yes) to keep the object in the drawing, or press *ENTER* to erase it.

subtract an object from a body modifier

place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Subtract. Select the object, and press *ENTER*. Enter *y* (Yes) to keep the object in the drawing, or press *ENTER* to erase it.

create a body modifier that is the intersection of the original body modifier with another object

place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Intersect. Select the object, and press *ENTER*. Enter *y* (Yes) to keep the object in the drawing, or press *ENTER* to erase it.

trim a body modifier

select the body modifier, right-click, and click Trim. Specify the points that define the trim plane, and select the side of the body modifier to be trimmed. The trimmed body modifier is converted to a Free Form mass element.

divide the face of a body modifier into two faces

select the body modifier, right-click, and click Split Face. Specify the points that define the edge created by splitting the faces.

join two faces that are on the same plane into a single face

select the body modifier, right-click, and click Join Faces. Select the edge that separates the coplanar faces.

If you want to ...	Then ...
remove a body modifier	select the object that forms the body modifier, and press <i>DELETE</i> .

3 Save or discard the changes:

If you want to ...	Then ...
restore the body modifier to its original shape	select the body modifier, and click  .
save the changes to the body modifier	select the body modifier, and click  . The body modifier uses the edited mass element to define its geometry.

Managing Body Modifiers

Use this procedure to edit or remove three-dimensional (3D) body modifiers from a stair. You can change the component the body modifier is added to and select a different operation. You can also enter or edit the descriptions of body modifiers.

NOTE To remove a body modifier from a stair and restore the modifier as a mass element that you can edit or apply to other stairs, see [Restoring a Body Modifier to a Mass Element](#) on page 1480.

- 1 Double-click the stair you want to change.
- 2 Expand Advanced, and expand Worksheets.
- 3 Click the setting for Body modifiers.
- 4 Select a body modifier, and change its settings:

If you want to ...	Then ...
apply the body modifier to a different stair component	select a different component for Component.
change the operation used to apply the body modifier to the stair	select a different operation for Operation: <ul style="list-style-type: none"> ■ Select Additive to add the body modifier to the stair component. ■ Select Subtract to subtract the shape of the body modifier from the stair component. ■ Select Replace to replace the stair component with the body modifier.
delete the body modifier from the stair component	select the body modifier, and click  .
enter a description of the body modifier	click Description, enter text, and press <i>ENTER</i> .

5 Click OK.

Restoring a Body Modifier to a Mass Element

Use this procedure to remove a body modifier from a stair and add it to the drawing as a mass element. Restoring a body modifier to a mass element enables you to modify the shape as a mass element and then add it to the stair again as a body modifier. You can also restore the body modifier to a mass element while leaving the body modifier still applied to the stair. This is useful if you want to create other stairs with the same shape.

If the object used to create the body modifier was a conventional mass element, it is restored to that mass element. For example, a Gable mass element is restored as a Gable mass element. However, if the body modifier was created from another object, such as a slab, or was edited using Boolean operations or face editing commands, the body modifier is restored as a Free Form mass element.

1 Select the stair you want to change, right-click, and click Body Modifiers ► Restore.

2 **NOTE** This procedure restores all body modifiers attached to a stair.

Create mass elements from the body modifiers:

If you want to ...

Then ...

create mass elements from the body modifiers while keeping the body modifiers attached to the stair

press *ENTER*.

remove *all* body modifiers from the stair, and create mass elements from their shapes

enter *y* (Yes), and press *ENTER*.

Stair Interference Conditions

You can control the height and width of a stair's interference condition with walls, slabs, spaces, curtain walls, and door and window assemblies. When you add an interference condition between a stair and one of the valid objects, a box is cut out around the stair, based on the specified headroom height and side clearance.

Creating an Interference Condition in a Wall

Use this procedure to create a stair interference area in a wall. When you add an interference condition between a stair and a wall, an opening is created in the wall around the stair, based on the stair's specified headroom height and left and right side clearances for straight and multi-landing stairs or inside and outside clearances for spiral and U-shaped stairs.

Specifying the left and right side clearances for a wall interference condition

1 Create a stair that intersects with a wall. For information about creating stairs, see [Using Stair Tools to Create Stairs](#) on page 1396.

2 On the Properties palette, expand Advanced, and expand Interference.

Interference	
Headroom height	84.00
Left clearance	0.00
Right clearance	0.00

3 Set the size of the interference condition:

If you want to...

Then...

specify the height above the treads for the interference condition

enter a value for Headroom height.

specify the left and right side clearances for the interference condition for straight and multi-landing stairs

enter values for Left and Right Clearance.

specify the inside and outside clearances for the interference condition for spiral and U-shaped stairs

enter values for Inside and Outside Clearance.

4 Click in the drawing, not on the stair, to remove the selection.

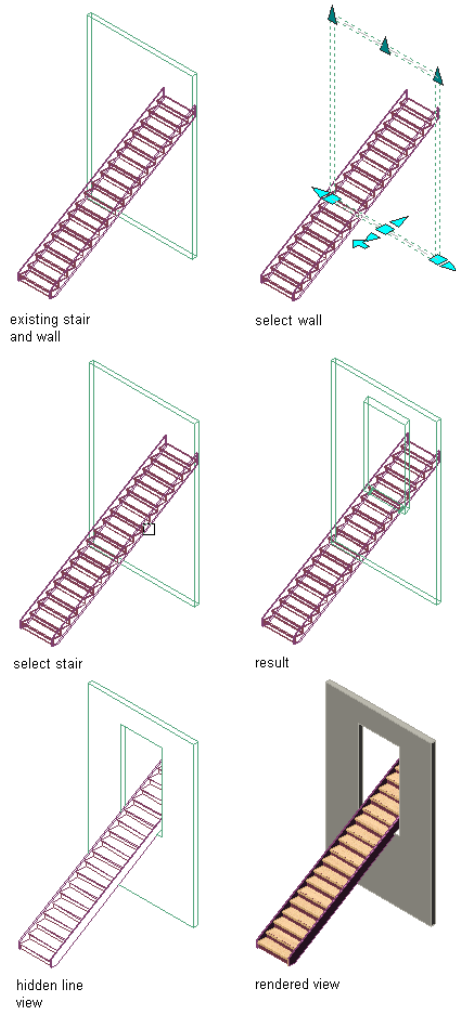

5 Select the wall to intersect, right-click, and click Interference Condition ► Add.

6 Select the stair.

7 Select the shrinkwrap effect, and press *ENTER*. For more information about shrinkwrapping, see [Working with Interference Conditions](#) on page 872.

NOTE Changing the Interference values of the stair changes the size of the intersection with the wall.

Creating a wall and stair interference condition

Removing a Stair Interference Condition from a Wall

Use this procedure to remove a stair interference from a wall.

- 1 Click in the drawing.
- 2 Select the wall from which to remove the interference, right-click, and click Interference Condition ► Remove.
- 3 Select the stair, and press *ENTER*.

Creating an Interference Condition in a Slab

Use this procedure to create a stair interference area in a slab. When you add an interference condition between a stair and a slab, a box is cut out around the stair based on the specified headroom height and left and right side clearances for straight and multi-landing stairs or inside and outside clearances for spiral and U-shaped stairs.

Specifying the left and right side clearances for a slab interference condition

Specifying the inside and outside clearances for a slab interference condition

1 Create a stair that intersects with a slab. For information about creating stairs, see [Using Stair Tools to Create Stairs](#) on page 1396.

2 On the Properties palette, expand Advanced, and expand Interference.

Interference	
Headroom height	84.00
Left clearance	0.00
Right clearance	0.00

3 Set the size of the interference condition:

If you want to...

Then...

specify the height above the treads for the interference condition

enter a value for Headroom height.

specify the left and right side clearances for the interference condition for straight and multi-landing stairs

enter values for Left and Right Clearance.

specify the inside and outside clearances for the interference condition for spiral and U-shaped stairs

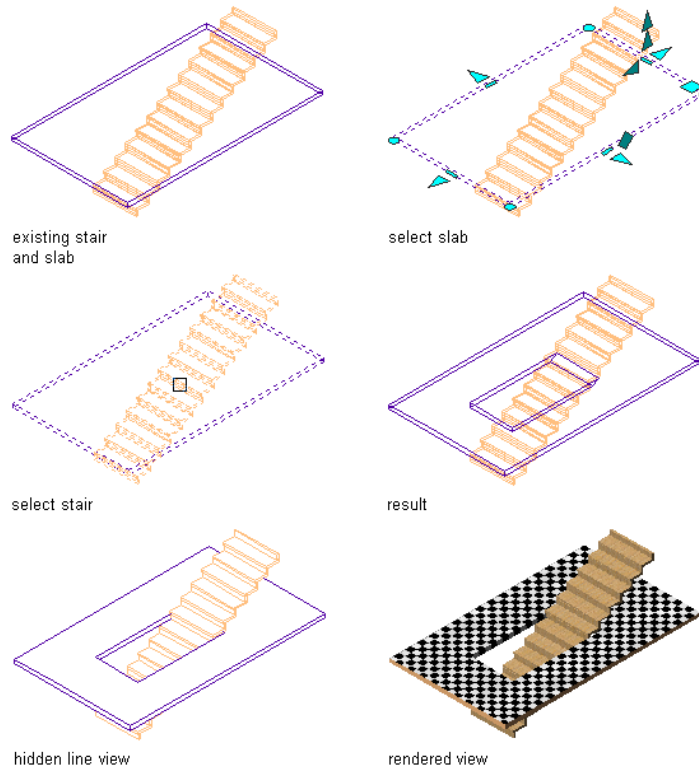

enter values for Inside and Outside Clearance.

4 Click in the drawing, not on the stair, to remove the selection.

5 Select the slab to intersect, right-click, and click Interference ► Add.

6 Select the stair, and press *ENTER*.

Creating a slab and stair interference condition

NOTE Changing the Interference values of the stair changes the size of the intersection with the slab.

Removing a Stair Interference Condition from a Slab

Use this procedure to remove a stair interference from a slab.

- 1 Select the slab from which to remove the interference, right-click, and click Interference ► Remove.

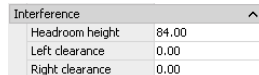

2 Select the stair, and press *ENTER*.

Creating an Interference Condition in a Space

Use this procedure to create a stair interference area in a space. When you add an interference condition between a stair and a space, a box is cut out around the stair based on the specified headroom height and side clearance.

1 Create a stair that intersects with a space. For information about creating stairs, see [Using Stair Tools to Create Stairs](#) on page 1396.

2 On the Properties palette, expand Advanced, and expand Interference.

Interference	
Headroom height	84.00
Left clearance	0.00
Right clearance	0.00

3 Set the size of the interference condition:

If you want to...	Then...
-------------------	---------

specify the height above the treads for the interference condition

enter a value for Headroom height.

specify the left and right side clearances for the interference condition for straight and multi-landing stairs

enter values for Left and Right Clearance.

specify the inside and outside clearances for the interference condition for spiral and U-shaped stairs

enter values for Inside and Outside Clearance.

4 Click in the drawing, not on the stair, to remove the selection.

5 Select the space to intersect, right-click, and click Interference Condition.

6 Enter **a** (Add), select the space, and press *ENTER*.

7 Select the stair, and press *ENTER* twice.

NOTE Changing the Interference values of the stair changes the size of the intersection with the space.

Removing a Stair Interference Condition from a Space

Use this procedure to remove a stair interference from a space.

1 Select the space from which to remove the interference, right-click, and click Interference Condition.

2 Enter **r** (Remove), select the space, and press *ENTER*.

3 Select the stair, and press *ENTER* twice.

Creating an Interference Condition in a Curtain Wall

Use this procedure to create a stair interference area in a curtain wall. When you add an interference condition between a stair and a curtain wall, a box is cut out around the stair based on the specified headroom height

and left and right side clearances for straight and multi-landing stairs or inside and outside clearances for spiral and U-shaped stairs. You have the option of cutting the infills, frames and mullions of the curtain wall.

Specifying the left and right side clearances for a curtain wall interference condition

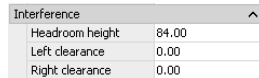

Specifying the inside and outside clearances for a curtain wall interference condition

- 1 Create a stair that intersects with a curtain wall. For information about creating stairs, see [Using Stair Tools to Create Stairs](#) on page 1396.

2 On the Properties palette, expand Advanced, and expand Interference.

Interference	
Headroom height	84.00
Left clearance	0.00
Right clearance	0.00

3 Set the size of the interference condition:

If you want to...

Then...

specify the height above the treads for the interference condition

enter a value for Headroom height.

specify the left and right side clearances for the interference condition for straight and multi-landing stairs

enter values for Left and Right Clearance.

specify the inside and outside clearances for the interference condition for spiral and U-shaped stairs

enter values for Inside and Outside Clearance.

4 Click in the drawing, not on the stair, to remove the selection.

5 Select the curtain wall to intersect, right-click, and click Interference Condition ► Add.

6 Select the stair.

7 Specify whether to apply the interference condition to the infill, frames or mullions of the curtain wall.

Removing a Stair Interference Condition from a Curtain Wall

Use this procedure to remove a stair interference from a curtain wall.

1 Click in the drawing, not on the stair, to remove the selection.

2 Select the curtain wall from which to remove the interference, right-click, and click Interference Condition ► Remove.

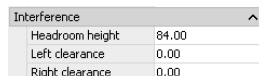

3 Select the stair, and press *ENTER*.

Creating an Interference Condition in a Door/Window Assembly

Use this procedure to create a stair interference area in a door/window assembly. When you add an interference condition between a stair and a door/window assembly, a box is cut out around the stair based on the specified headroom height and side clearance. You have the option of cutting the infills, frames, and mullions of the door/window assembly.

1 Create a stair that intersects with a door/window assembly. For information about creating stairs, see [Using Stair Tools to Create Stairs](#) on page 1396.

2 On the Properties palette, expand Advanced, and expand Interference.

Interference	
Headroom height	84.00
Left clearance	0.00
Right clearance	0.00

3 Set the size of the interference condition:

If you want to...	Then...
specify the height above the treads for the interference condition	enter a value for Headroom height.
specify the left and right side clearances for the interference condition for straight and multi-landing stairs	enter values for Left and Right Clearance.
specify the inside and outside clearances for the interference condition for spiral and U-shaped stairs	enter values for Inside and Outside Clearance.

4 Click in the drawing, not on the stair, to remove the selection.

5 Select the door/window assembly to intersect, right-click, and click Interference Condition ► Add.

6 Select the stair.

7 Specify whether to apply the interference condition to the infill, frames, or mullions of the door/window assembly.

Removing a Stair Interference Condition from a Door/Window Assembly

Use this procedure to remove a stair interference from a door/window assembly.

1 Click in the drawing, not on the stair, to remove the selection.

2 Select the door/window assembly from which to remove the interference, right-click, and click Interference Condition ► Remove.

3 Select the stair, and press *ENTER*.

Changing the Interference Size of a Stair

Use this procedure to control the size of the stair interference area.

Specifying headroom height and side clearance for a stair and a space object

- 1 Select the stair.
- 2 On the Properties palette, expand Advanced, and expand Interference.

Interference	
Headroom height	84.00
Left clearance	0.00
Right clearance	0.00

- 3 Set the size of the interference condition:

If you want to...

Then...

specify the height above the treads for the interference condition

enter a value for Headroom height.

specify the left and right side clearances for the interference condition for straight and multi-landing stairs

enter values for Left and Right Clearance.

specify the inside and outside clearances for the interference condition for spiral and U-shaped stairs

enter values for Inside and Outside Clearance.

Changing the Alignment of a U-Shaped Stair

Use this procedure to change the alignment and the alignment offset of a U-shaped stair. These fields are available only when you select a U-shaped stair.

- 1 Select a U-shaped stair.
- 2 On the Properties palette, expand Advanced, and expand Constraints.
- 3 Specify the alignment of a U-shaped stair:

If you want to...

Then...

place the treads and risers where necessary to complete the stair

select Free for Alignment.

If you want to...	Then...
align the tread of the up flight to the tread of the down flight	select Tread to Tread for Alignment.
align the tread of the up flight to the riser of the down flight	select Tread to Riser for Alignment.
align the riser of the up flight to the riser of the down flight	select Riser to Riser for Alignment.

4 Specify a value for Alignment offset.

When you select Tread to Tread, Tread to Riser, or Riser to Riser, you can specify an offset value. A positive offset value means that the down flight tread location is closer to the landing than the up flight tread location.

Specifying tread to riser alignment offsets

5 Specify a value for Extend alignment.

6 Specify a value for Uneven tread. This value specifies which flight will be longer if the total number of treads is uneven. Select Upper flight to place the Uneven tread on the upper flight. Select Lower flight to place the uneven tread on the lower flight.

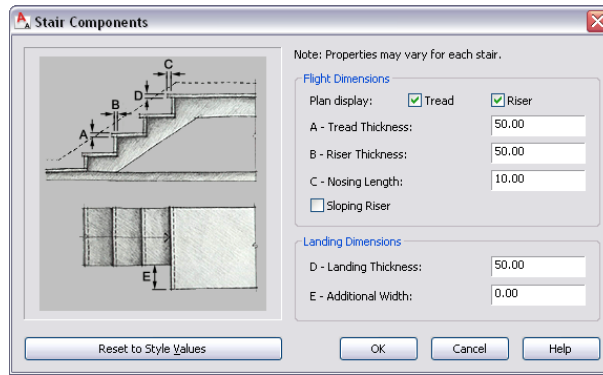

Changing the Components of a Flight

Use this procedure to change the tread, riser thickness, and nosing length for each stair. You can also turn on or off the display of the tread and riser.

NOTE If component settings are unavailable, they are controlled by the stair style, and you cannot change them for individual stairs.

1 Select the stair.

2 On the Properties palette, expand Advanced, expand Worksheets, and click Components.

3 Under Flight Dimensions, select or clear the display of treads and risers.

When the tread or riser display is off, the corresponding thickness becomes unavailable.

4 Specify the flight dimensions:

If you want to...

Then...

specify the thickness of each tread

select Tread, and enter a value for Tread Thickness.

specify the thickness of the riser

select Riser, and enter a value for Riser Thickness.

specify the length of the edge of a stair tread that projects over the riser

enter a value for Nosing Length.

specify sloping risers

select Sloping Riser.

5 Click OK.

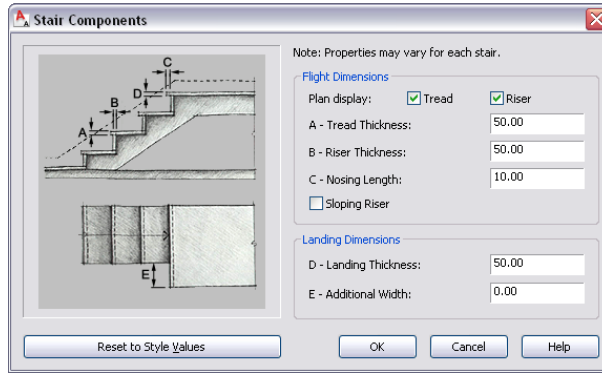

Changing the Components of a Landing

Use this procedure to change the landing thickness and specify additional width for stair landings.

NOTE If component settings are unavailable, they are controlled by the stair style, and you cannot change them for individual stairs.

1 Select the stair.

2 On the Properties palette, expand Advanced, expand Worksheets, and click Components.

3 Enter a value for Landing Thickness.

4 Enter a value for Additional Width.

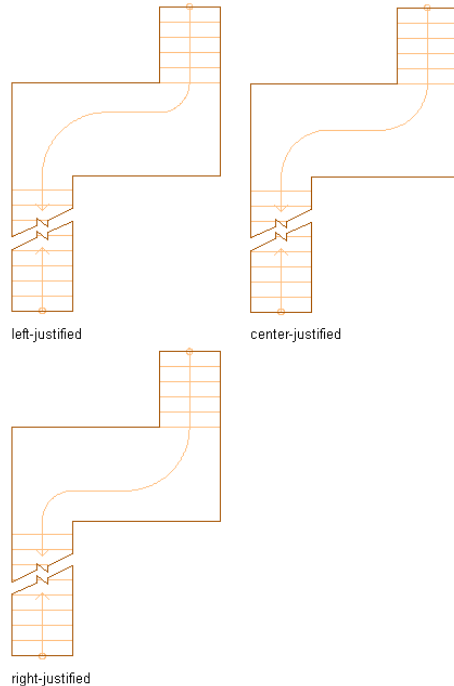

NOTE The setting for additional landing width affects only true landings of Multi-landing and U-shaped stairs. The automatic landings introduced by flight height limits and terminating landings are not affected by this setting.

The type of landing and the justification of the stair determine where the additional width is added to the landing.

Adding width to a quarter landing based on stair justification

Adding width to a half landing based on stair justification

5 Click OK.

About the Dimensions of Landing Components

Landing components are specified as part of the style, but apply only to multi-landing and U-shaped stairs. Stringer dimensions are specified for the flight and landing in a single table. The flight stringer type (slab, housed, or saddled) controls what is available for the landing (total depth *only* for housed and ramp, waist depth for all types). If the flight has no stringers, the landing has none.

All landings of a single stair initially use the same dimensions. You can then customize each one separately by grip-stretching or projection. Horizontal positions and the widths of stringers are identical between flights and landings.

Landing extension values apply only to U-shaped and multi-landing stairs with flat landings. Landing-specific dimensions are ignored for turn landings. The default values for styles in the Stair Styles drawing are specified in accordance with the most common situation for stairs.

If the option to resolve the meeting of flight and landing stringers is off, the flight stringer terminates at the landing.

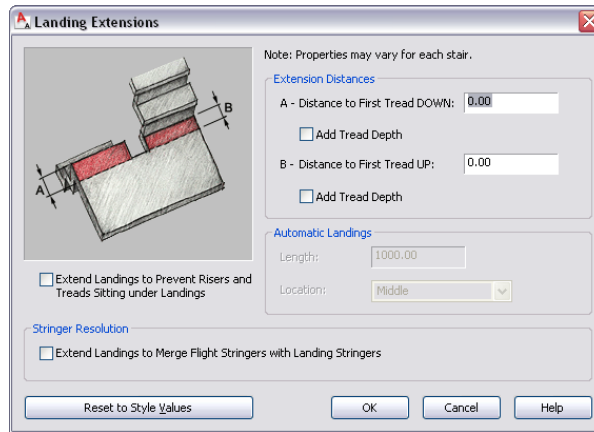

Changing the Extension of a Landing

Use this procedure to change the distances between landings and treads and the stringer resolution for stairs. You can differentiate the size of landing components from those used for the stair flights.

NOTE If settings for landing extensions are unavailable, they are controlled by the stair style, and you cannot change them for individual stairs.

1 Select the stair.

2 On the Properties palette, expand Advanced, expand Worksheets, and click Landing extensions.

3 Specify the extension distances:

If you want to...

Then...

add to the distance to the first tread on the down side of the landing

enter a value for Distance to First Tread DOWN. To extend the landing down by a single tread, select Add Tread Depth.

add to the distance to the first tread on the up side of the landing

enter a value for Distance to First Tread UP. To extend the landing up by a single tread, select Add Tread Depth.

For more information about landing extensions and stringer resolution, see [About the Dimensions of Landing Components](#) on page 1493.

4 Under Stringer Resolution, select Extend Landings to Merge Flight Stringers with Landing Stringers to automatically merge the flight stringers with the landing stringers.

This provides additional landing extension, if necessary, to make the flight stringers meet the landing stringers without any discontinuity.

NOTE Automatic landing settings are always controlled by the stair style.

5 Click OK.

Stairs created in earlier versions of the software have the setting for Extend Landings to Prevent Risers and Treads Sitting Under Landings turned on. This setting should be turned off to achieve flush or rectangular landings, but it will change the position of the top or bottom of the stair, which may require adjusting other building objects.

Specifying Stair Component Display by Cut Plane Elevation

Use this procedure to specify the display of stair components in plan view depending on their occurrence above or below the cut plane elevation. You can specify the above cut plane, up, and down component properties for each type of stair component.

Cut Plane Elevation Display Properties

1 Take a look at the display properties for these kinds of stair components.

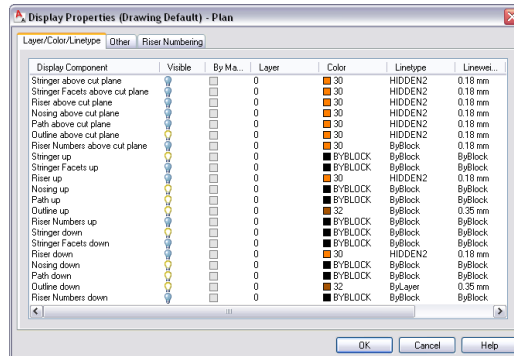

Select the stair.

2 Right-click, and click Edit Object Display.

3 In the Object Display dialog, click the Display Properties tab.

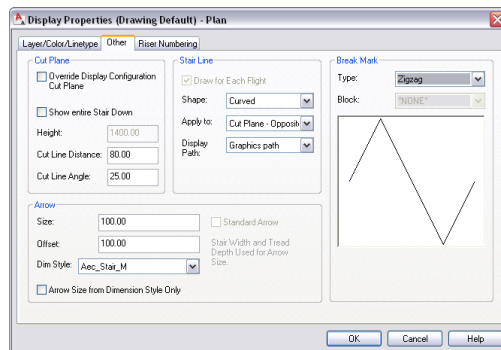

4 Verify that Plan is the default Display Representation, and then click Edit Display Properties.

5 Click the Layer/Color/Linetype tab.

There are components to support the representation of stair components above the cut plane elevation so that the down stair components are only used to display the stair components that occur below the current level.

6 Click the Other tab.

For stairs created in versions of Autodesk Architectural Desktop earlier than 2004, the Override Display Configuration Cut Plane option is selected by default. In the current version, this option is cleared by default, and the display of stair components is handled automatically by specific display configurations for each level.

When the Override Display Configuration Cut Plane option is selected, the cut height elevation is measured from the bottom of each stair run. The up display components and the above cut plane display components above the current level are displayed, and the down display components are not.

Specifying cut plane elevation with display configuration override

When the Override Display Configuration Cut Plane option is cleared, the cut height elevation is measured from the current level. The up display components above the current level are displayed, as are the down display components below the current level.

Specifying cut plane elevation without display configuration override

Specifying Stair Display at Different Levels

1 The following procedure provides an example of how to specify the display of stair components at different levels in a stair tower.

Create a U-shaped stair, 5'-0" (1520 mm) wide and 12'-0" (3650 mm) high to represent the lobby stairs.

2 Create a second U-shaped stair, 3'-8" (1120 mm) wide and 10'-0" (3050 mm) high, and locate it 12'-0" (1520 mm) above the lobby stairs.

3 Create a third U-shaped stair, 3'-8" (1120 mm) wide and 10'-0" (3050 mm) high, and locate it 10'-0" (3050 mm) above the second set of stairs.

The following illustration shows how the stair tower should appear with added floor slabs in a 3D view:

3D view of stair tower

4 Save this stair tower configuration as the base stair drawing file.

5 Create 4 new host drawing files as follows:

- First Floor
- Second Floor
- Third Floor
- Roof Level

The following illustration shows how the levels should appear in an elevation view:

Elevation view of stair tower

- 6 Open the First Floor drawing, and attach the base stair as an Xref at an elevation of 0'-0" (0 mm).
- 7 Verify that the Medium Detail display configuration is current.
- 8 View the first floor lobby stairs in plan.

Stair display components at first floor

- 9 The up display components above the first floor are displayed, as are the above cut plane display components, in outline with a dashed linetype.
- 10 Open the Second Floor drawing, and attach the base stair as an Xref at an elevation of -12'-0" (-3650 mm).
- 11 Verify that the Medium Detail Intermediate Level display configuration is current.
- 12 View the second floor stairs in plan.

Stair display components at second floor

- 13 The up display components above the second floor are displayed, as are the down display components below the second floor.
- 14 Open the Third Floor drawing, and attach the base stair as an Xref at an elevation of -22'-0" (-6700 mm).

15 Verify that the Medium Detail Intermediate Level display configuration is current.

16 View the third floor stairs in plan.

Stair display components at third floor

17 The up display components above the third floor are displayed, as are the down display components below the third floor.

18 Open the Roof Level drawing, and attach the base stair as an Xref at an elevation of -32'-0" (-9750 mm).

19 Verify that the Medium Detail Top Level display configuration is current.

20 View the roof level stairs in plan.

Stair display components at roof level

21 Only the down display components below the roof level are displayed.

Changing the Display of an Overlapping Stair

Use this procedure to create an overlapping stair and set the display properties to view the overlapped section correctly.

To set the stair display, the Plan Overlapping display representation needs to be turned on and specific components need to be set. For the overlapping stairs, in addition to the usual up and down groups, four other groups of display components available in Plan Overlapping.

Display representation group	Definition
"components" up (above overlap)	Stair components below the cut height that are above the overlap section
"components" down (above overlap)	Stair components above the cut height that are above the overlap section
"components" up (below overlap)	Stair components below the cut height that are below the overlap section

Display representation group	Definition
"components" down (below overlap)	Stair components above the cut height that are below the overlap section

- 1 Open the tool palette that you want to use, and select a stair tool.
If necessary, scroll to display the tool that you want to use.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a style.
- 4 In Shape, select Multi-landing.
- 5 Specify the 1/2 landing for Turn Type.
- 6 Draw a multi-landing stair that overlaps itself.

Viewing an overlapping stair condition

- 7 Click Format menu ► Display Manager.
- 8 Expand Sets, select the current (bold) display set.
- 9 Click the Display Representation Control tab. Scroll to the Stair object.
- 10 Turn on Plan Overlapping in addition to the current display representation, and click OK.
- 11 For this example, we will display all components of the stair above the overlap section outlined in red. Select the stair, right-click, and click Edit Object Display.
- 12 Click the Display Properties tab.
- 13 Click Object Override for Plan, Plan Low Detail, or Plan High Detail (whichever is displayed in the current display set). Select all the components, turn off visibility, and click OK.
- 14 Click Object Override for Plan Overlapping. Select the desired components and turn on visibility. For this example, turn on visibility for Riser up, Nosing up, Path up, Outline up, Riser down, Nosing down, Path down, Outline down, Riser down (above overlap), Nosing down (above overlap), Path down (above overlap), Outline down (above overlap), Riser down (below overlap), Nosing down (below overlap), Path down (below overlap), and Outline down (below overlap).
- 15 Select Riser down (above overlap), Nosing down (above overlap), Path down (above overlap), and Outline down (above overlap). Select any of the colors from the selected components; then select red in the Select Color dialog box, and click OK twice.

NOTE If the stair style includes stringers, they should be added to the set of components.

- 16 Click OK twice.

Applying Tool Properties to an Existing Stair

Use this procedure to apply the properties of a stair tool to one or more existing stairs. The properties include the stair style and any other settings specified in the tool you select.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a stair tool, and click Apply Tool Properties to Stair.
- 3 Select the stairs, and press *ENTER*.
- 4 Edit the properties of the stairs in the Properties palette, if necessary.

NOTE Some tool properties cannot be applied to existing stairs. For example, stair shape and turn type do not change. In addition, some properties may be incompatible with existing stairs. For example, a stair that has a vertical orientation of Down cannot terminate with a landing.

Changing the Location of a Stair

Use this procedure to relocate a stair by changing the coordinate values of its insertion point. The stair also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the stair are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the stair by aligning its normal with another axis. You can also rotate the stair on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD help.

- 1 Double-click the stair you want to change.
- 2 In the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the stair:

If you want to...	Then...
relocate the stair	enter new coordinate values under Insertion Point.
locate the stair on the <i>XY</i> plane	make the normal of the stair parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the stair on the <i>YZ</i> plane	make the normal of the stair parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> , and enter 0 for <i>Y</i> and <i>Z</i> .
locate the stair on the <i>XZ</i> plane	make the normal of the stair parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the stair	enter a new value for Rotation Angle.

- 5 Click OK.

Specifying the Materials of a Stair

Use this procedure to select a different material for components of an individual stair.

To change the materials assigned to all stairs of the same stair style, see [Assigning Materials to a Stair Style](#) on page 1517.

NOTE If a material assignment does not determine the display properties of a stair component, you can change the properties of the display component as described in [Specifying the Display Properties of a Stair Style](#) on page 1518.

- 1 Select the stair you want to change, right-click, and click Edit Object Display.
- 2 To verify that the material assignment determines the display properties of the component, click the Display Properties tab, select the display representation where you want the changes to appear, and click .

NOTE Only the Model display representation supports properties By Material.

- 3 Click the Layer/Color/Linetype tab, verify that By Material is selected for the component, and click OK.
- 4 Click the Materials tab.
- 5 Select the component you want to change, select Object Override, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

- 6 Click OK.

Changing the Display Properties of Individual Stairs

In most cases, you want the appearance of stairs that belong to the same style to be consistent throughout a drawing. However, in certain instances, you may need to override a display property for an individual stair to achieve a specific result. All the display properties that you can specify in stair styles are available for individual stairs. You can override the following specifications:

- Whether the display properties of stair components are determined by material assignments
- The layer, color, and linetype of the display components of the stair
- The cut plane height and the display of components relative to the cut plane
- Other specific stair display information, such as riser numbering

When you change the display properties of an individual stair, the changes apply only to that stair. Other stairs of the same style are not affected. To change the display properties of all stairs of a specific stair style, see [Stair Styles](#) on page 1507.

Specifying the Layer, Color, and Linetype of a Stair

Use this procedure to change the following display properties of the components of an individual stair:

- Visibility (component is on or off)
- By Material (a material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

To change these display properties for all stairs of the same stair style, see [Specifying the Display Properties of a Stair Style](#) on page 1518.

NOTE If a material assignment determines the properties of a stair display component, you can change the properties of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Materials of a Stair](#) on page 1501.

1 Select the stair you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

2 Click the Display Properties tab.

3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click .

5 Click the Layer/Color/Linetype tab.

6 Select the component to change, and select a different setting for the property.

7 Click OK twice.

Specifying the Cut Plane Display of a Stair

Use this procedure to specify the properties of one or more cut planes for an individual stair. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

1 Double-click the stair you want to change.

2 On the Properties palette, click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all stairs in the drawing, select Drawing default setting. To apply changes to all stairs of this style, select Stair Style:<style name>. For more information on styles, see [Stair Styles](#) on page 1507.

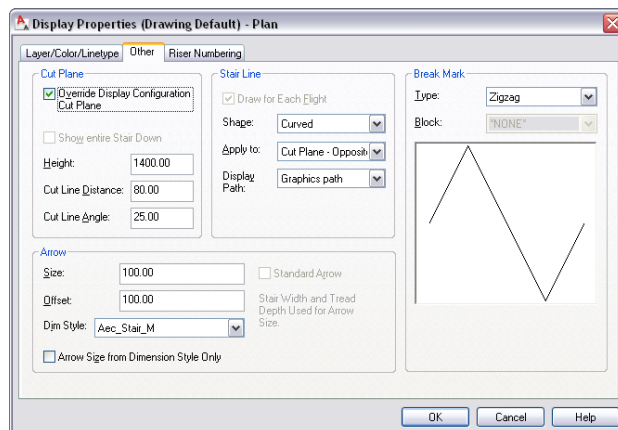

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object.
- 8 For Cut line distance, enter a value to specify the distance between the 2 cut lines.
- 9 For Cut line angle, enter a value to specify the angle between the stair cut lines.
- 10 If you selected No for Override cut plane, for Show entire stair down, specify whether you want to display the stair's down display components (Stringer down, Riser down, Nosing down, and so on; for more information, see [Specifying Stair Component Display by Cut Plane Elevation](#) on page 1494).

You can also access and modify these same cut plane settings through the stair's context menu, as follows:

- 1 Select the stair you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 4 If necessary, click  .
- 5 Click the Other tab.

- 6 In the Cut Plane panel, change the settings as needed.
- 7 Click OK twice.

Specifying the Display of Other Characteristics of a Stair

Use this procedure to specify other display properties for an individual stair, such as how to display the arrow in the path, which Display Path to show, and what type of break mark to use in the stair display. These display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the stair you want to change.

- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all stairs in the drawing, select Drawing default setting. To apply changes to all stairs of this style, select Stair Style:<style name>. For more information on styles, see [Stair Styles](#) on page 1507.

- 5 If necessary, expand Object Display Properties ► Advanced, and click  Additional properties.
- 6 Specify the additional display properties for the stair:

If you want to...	Then...
change the display size of the arrow and break mark	enter a value for Size.
change the offset location of the arrow display	enter a value for Offset.
change the dimension style used for the arrow display	select a style for Dim Style.
	<p>NOTE If a dimension style other than Standard is used for the arrow, and you want the arrow size to be controlled by the dimension style, select Arrow Size from Dimension Style Only. This is the default for all previous version drawings. If you do not select this option, the size of the arrow is multiplied by the arrow size setting.</p>
change the shape of the stair line	select a shape for Shape. Curved adds an arc when the stair line changes. Straight displays an angle when the stair line changes.
display the arrow at the end of each cut plane pointing in the same direction throughout the length of the stair	select Cut Plane - Parallel for Apply to and make sure that Draw for Each Flight is not selected.
display the arrow at the end of each cut plane and at the end of each flight pointing in the same direction	select Cut Plane - Parallel for Apply to and make sure that Draw for Each Flight is selected.
display the arrow at the end of the entire stair	select Entire Stair for Apply to and make sure that Draw for Each Flight is not selected.
display the arrow on each side of the cut plane	select Cut Plane - Opposite for Apply to.
change which stair line is displayed	select a path for Display Path.
change the type of break mark that is displayed at the cut plane	under Break Mark, select a mark for Type.
specify a custom break mark to display at the cut plane	select Custom Shape for Type, and then select a block for Block.

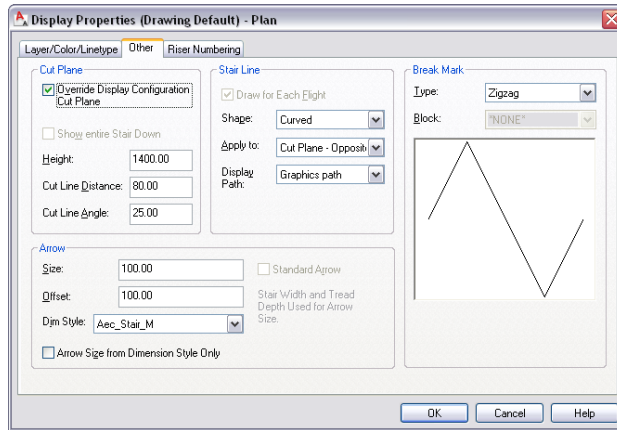

7 Click OK.

You can also access and modify these same settings through the stair's context menu, as follows:

- 1 Select the stair you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

- 4 If necessary, click  .
- 5 Click the Other tab.

6 Specify the additional display properties as needed.

7 Click OK twice.

Specifying the Riser Numbering Display for Individual Stairs

Use this procedure to define and display riser numbers for individual stairs.

- 1 Double-click the stair you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all stairs in the drawing, select Drawing default setting. To apply changes to all stairs of this style, select Stair Style:<style name>. For more information on styles, see [Stair Styles](#) on page 1507.

- 5 If necessary, expand Object Display Properties ► Advanced, and click  Riser numbering.
- 6 Specify the riser numbering display properties for the stair:

If you want to...

Then...

change the text style of the riser numbers

select a style for Text Style, or click  to edit the text style.

If you want to...	Then...
change the alignment of the riser numbers	select an alignment for Text Alignment.
change the orientation of the riser numbers	select an orientation for Text Orientation.
change the text height of the riser numbers	enter a value for Text Height.
change the location to which the numbers are justified	select Left, Center or Right for Justify to.
change the location of the numbers along the length of the stair flight	enter a value for X Offset. This is relative to the selected position of the riser.
change the location of the numbers to the left or right	enter a value for Y Offset. This is relative to the selected position of the riser.
set the first number for the riser numbering	enter a value for First Riser Number.
number the last riser in the stair	select Number Final Riser.

7 Click OK.

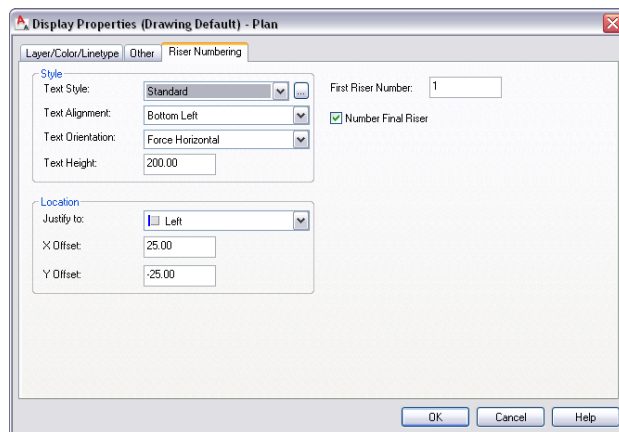

You can also access and modify these same cut plane settings through the stair's context menu, as follows:

- 1 Select the stair you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click  .

5 Click the Riser Numbering tab.

6 Specify riser numbering settings as needed.

7 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Stair

Use this procedure to attach hyperlinks, notes, or files to a stair. You can also edit hyperlinks and notes, and edit or detach reference files from a stair.

- 1 Select the stair to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
For more information about adding hyperlinks, see “Add Hyperlinks to a Drawing” in AutoCAD help.
- 4 Click OK.
- 5 To add a note, click the setting for Notes, and enter the note.
- 6 Click OK.
- 7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click, select a file, click Open and click OK.
edit the description of a reference file	click the document’s Description field. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application. NOTE If the referenced file is an AutoCAD drawing, you must click OK in the Reference Docs dialog before the drawing is displayed.
detach a reference file	select the file name, and click  .

- 8 Click OK.

Stair Styles

A stair style is a group of properties assigned to a stair that determines the appearance and other characteristics of the stair.

You can use a stair style to control properties for all stairs that use that style, rather than changing properties for each stair in the drawing. Various styles exist in the templates for common stair configurations, such as steel-pan, ramp - concrete, and wood-housed. Within the stair style, you can specify the dimensions, landing extensions, components, and display properties of the stair.

Stair Components and Design Rules

In a stair style, you specify these properties of stair components:

- risers and treads

- stringers
- landings
- landing extensions

Design rules determine the code limits for maximum, optimum, and minimum slopes for the stair style.

Display Components of Stairs

Display components determine the graphical characteristics, such as color and linetype, of stair components. Other display properties you can change for a stair style include cut plane, stair line, arrow properties, and the break mark.

Using Materials in Stair Styles

You can use materials to control how stairs of each style are displayed in a drawing. You assign materials to the stair components in the style. The components are then displayed using the display properties of the assigned materials.

Creating Tools from Stair Styles

You can create a stair tool from any stair style. You can drag the style from the Style Manager onto a tool palette. You can then specify default settings for any stair created from the tool. For more information, see [Creating a Stair Tool](#) on page 1425.

Managing Stair Styles

To create, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture for working with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Creating a Stair Style

Use this procedure to create a stair style. You can create a style that uses default style properties by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Architectural Objects, and expand Stair Styles.

- 3 Create a stair style:

If you want to...	Then...
create a style with default properties	right-click Stair Styles, and click New.
create a style from an existing style	right-click the stair style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new stair style.

5 Edit the new stair style:

If you want to...	Then...
specify design rules for the style	see Specifying the Design Rules of a Stair Style on page 1509.
specify the stringer properties for the style	see Specifying the Stringers of a Stair Style on page 1510.
specify the thicknesses and widths of treads, risers, and landings for the style	see Specifying the Components of a Stair Style on page 1514.
specify the landing extension properties of the style	see Specifying the Landing Extension of a Stair Style on page 1515.
specify display properties, such as layer, color, and linetype, for the components of the style	see Specifying the Layer/Color/Linetype of a Stair Style on page 1518.
specify cut plane properties, arrow properties, and other display properties of the style	see Specifying the Display of Other Characteristics of a Stair Style on page 1519.
add notes and files to the style	see Adding Notes and Files to a Stair Style on page 1522.

6 When you finish specifying the properties of the stair style, click OK.

7 If you want to assign the style to a stair tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Stair Tool](#) on page 1425.

8 Click OK.

Specifying the Design Rules of a Stair Style

Use this procedure to specify the minimum, maximum, and optimal code limits for the riser height and tread depth, and to specify the stair calculator rules.

Specifying stair design rules

1 Open a tool palette that has a stair tool.

2 Right-click a stair tool, and click Stair Styles.

3 Select the stair style you want to change.

4 Click the Design Rules tab.

	Riser Height	Tread Depth
A - Maximum Slope	7.00	11.00
B - Optimum Slope	7.00	11.00
C - Minimum Slope	4.00	24.00

Calculator Rule

Use Rule Based Calculator

Minimum Limit: 24.00 <= (2 * Riser Height + 1 * Tread Depth) <= Maximum Limit: 25.00

Design Rules cannot be applied to a Custom Stair

5 Specify the default Riser Height and Tread Depth for Minimum Slope, Optimum Slope, and Maximum Slope.

NOTE Use values that represent the actual dimensions of the tread and riser components you want to create, and not just the ratios of these dimensions.

Subject to the constraints of the calculator rules and the fact that the tread heights must be an even divisor of the floor-to-floor height, the software gets as close as possible to the selected optimal tread length and riser height.

6 To change the default stair calculator, select Use Rule Based Calculator.

The fields in the Calculator Rule section become available for editing.

7 When you finish changing the properties of the stair style, click OK.

Specifying the Stringers of a Stair Style

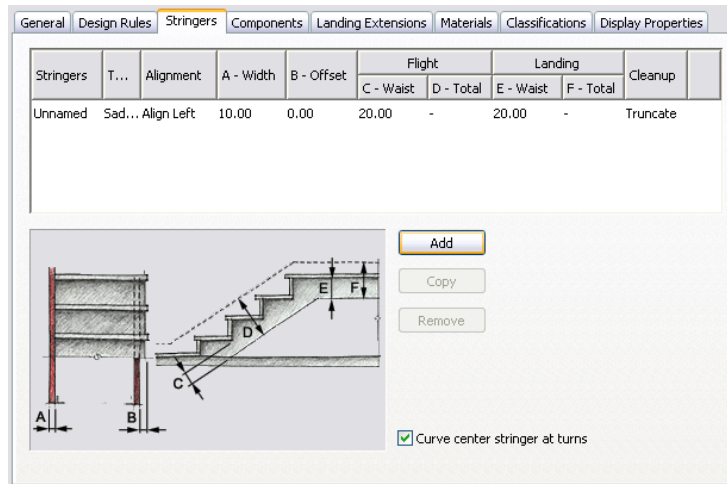

Use this procedure to include stringers with the stair style. A stair style can have one or more stringers. You can specify the properties of each stringer. If the style uses stringers, you can specify the depth of the waist at flights and landings, as well as have center stringers with mitered or curved corners at landing turns. For Ramp or Housed stringers, you can also specify the total depth at flights and landings.

1 Open a tool palette that has a stair tool.

2 Right-click a stair tool, and click Stair Styles.

3 Select the stair style you want to change.

4 Click the Stringers tab.

If the style does not use stringers, proceed to step 6.

5 Add or remove stringers:

If you want to...	Then...
add a stringer to the stair style	click Add.
add an identical stringer to the list	select the stringer you want to duplicate, and click Copy.
delete a stringer from the list	select the stringer, and click Remove.

6 Specify the properties of each stringer:

If you want to...	Then...
specify the name of a stringer	select the current name, and enter a new name.
specify the type of stringer	click the current Type, and select Saddled or Housed.
specify the alignment of a stringer	click the current alignment, and select Align Left, Align Right, Center, or Full Width.
specify the width of a stringer	enter a value for Width.
specify the offset of a stringer	enter a value for Offset.
specify the flight waist	under Flight, enter a value for Waist.
specify the flight total	under Flight, enter a value for Total.
specify the landing waist	under Landing, enter a value for Waist.
specify the landing total	under Landing, enter a value for Total.

If you want to...

Then...

stop the stringer at a landing

select Truncate for Cleanup.

allow the stringer to continue under a landing

select Cleanup for Cleanup.

specify mitered corners for a center stringer at a turn or landing

clear Curve center stringer at turns

7 Click Slab for Type to edit the slab settings:

If you want to...

Then...

specify the thickness of the slab at flights

under Flight, enter a value for Waist.

specify the thickness of the slab at landings

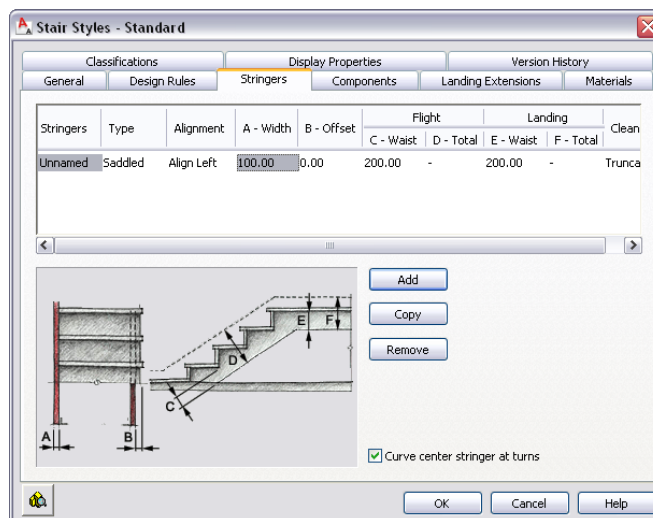

under Landings, enter a value for Waist.

8 When you finish changing the properties of the stair style, click OK.

Specifying Mitered Corners for Center Stringers

Use this procedure to specify mitered corners for center stringers at landings and turns. You can specify this option when working with multi-landing, u-shaped, and custom stairs. You cannot specify this option when working with straight or spiral stairs.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style you want to change.
- 4 Click the Stringers tab.
- 5 Clear Curve center stringers at turns.

6 Click OK.

Curved and mitered center stringers at landing turns

center stringer curved
at landing turns

center stringer mitered
at landing turns

With the Curve center stringers at turns option cleared, the center stringer is mitered to match the angle of the landing turn. In most cases, this will be a right angle, but any other angle is also possible.

Mitered center stringers at angled landing turns

mitered center stringer at
right-angled landing turn

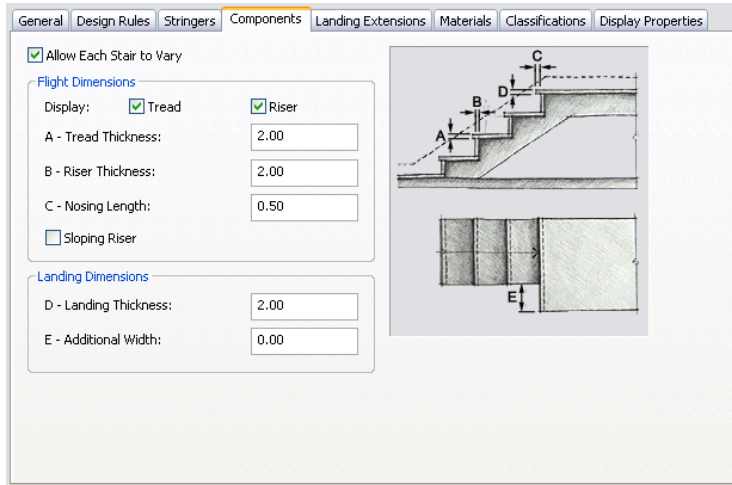

mitered center stringer at
non-right-angled landing turn

Specifying the Components of a Stair Style

Use this procedure to specify the display of treads and risers and edit the thicknesses and widths of treads, risers, and landings. Also, you can specify whether these properties of the style are allowed to vary with individual stairs.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style you want to change.
- 4 Click the Components tab.

- 5 Specify whether stairs of this style can vary:

If you want to...

Then...

specify flight dimensions, such as tread thickness, riser thickness, and nosing length, when you add or modify stairs

select Allow Each Stair to Vary.

require that all stairs of this style use the flight dimension settings of the style

clear Allow Each Stair to Vary.

NOTE If Allow Each Stair to Vary is checked, changes on this tab do not affect existing stairs. To make these stairs match the style settings, select the stair, display its properties, display the Components worksheet, and click Reset to Style Values.

- 6 Turn the display of treads and risers on or off.

If tread is off, the tread thickness and landing thickness become unavailable.

- 7 Specify the flight dimensions:

If you want to...

Then...

specify the thickness of treads

enter a value for Tread Thickness.

specify the thickness of risers

enter a value for Riser Thickness.

If you want to...	Then...
specify the length of the edge of a stair tread that projects over the riser	enter a value for Nosing Length.
specify sloping risers	select Sloping Riser.

8 Specify the landing dimensions:

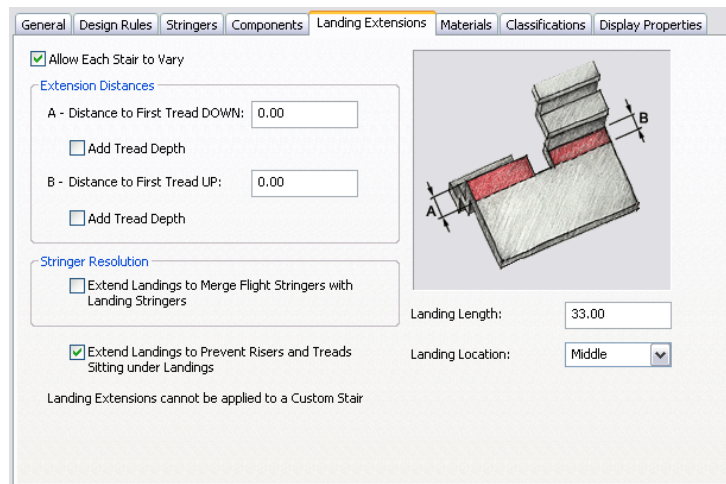

If you want to...	Then...
specify the thickness of landings	enter a value for Landing Thickness.
specify additional width for landings	enter a value for Additional Width.

9 When you finish changing the properties of the stair style, click OK.

Specifying the Landing Extension of a Stair Style

Use this procedure to change the distances between landings and treads and the stringer resolution of stairs. You can differentiate the size of landing components from those used for the stair flights.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style you want to change.
- 4 Click the Landing Extensions tab.

5 Specify whether stairs of this style can vary:

If you want to...	Then...
specify stringer resolution and extension dimensions, such as distance to first tread up and distance to first tread down, when you add or modify stairs	select Allow Each Stair to Vary.

If you want to...	Then...
require that all stairs of this style use the extension dimension settings of the style	clear Allow Each Stair to Vary.

6 Specify extension distances:

If you want to...	Then...
increase the distance to the first tread on the down side of the landing	enter a value for Distance to First Tread DOWN. To extend the landing down by a single tread, select Add Tread Depth.
increase the distance to the first tread on the up side of the landing	enter a value for Distance to First Tread UP. To extend the landing up by a single tread, select Add Tread Depth.

7 Select Extend Landings to Merge Flight Stringers with Landing Stringers.

This option extends the landing to merge the flight stringers with the landing stringers.

8 Select Extend Landings to Prevent Risers and Treads Sitting Under Landings.

This option is on by default for all stairs from earlier-release drawings. Clear it to allow the creation of flush rectangular landings.

9 When landings are placed automatically, their length and location are specified in Landing Length and Landing Location.

If you want to...	Then...
set the size of automatic landings	enter a value for Landing Length.
set the placement of automatic landings	select Top, Middle, or Bottom for Landing Location.

10 When you finish changing the properties of the stair style, click OK.

Assigning Materials to Components in a Stair Style

A stair consists of a number of components whose display properties can be determined by the materials assigned to each component. You assign one material to each physical component of the stair; for example, you assign a wood or metal material to treads, concrete to a concrete component, and so on. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the stair style instead of material display properties, you can turn off the material assignments in the display properties of the stair style.

Material definitions consist of display components that correspond to component types of objects. For example, the 3D body component of a material is used for all linework in model views.

Stair Materials and Display Components

The following table identifies the material component that corresponds to each stair component.

Stair Component	Material Component
Model	
Stringer	3D Body
Tread	3D Body
Landing	3D Body
Riser	3D Body

Assigning Materials to a Stair Style

Use this procedure to assign materials to the individual components of a stair style. When By Material is selected for a component, the component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the stair. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, a riser is a physical component that can be assigned a material while the graphics path is a symbol that cannot be assigned a material.

NOTE If a material assignment does not determine the display properties of a stair component, you can change the display properties of the stair style as described in [Specifying the Display Properties of a Stair Style](#) on page 1518.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

NOTE Only the Model display representation uses materials.

- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

11 Click OK.

Specifying the Display Properties of a Stair Style

In most cases, you can assign materials to stair components so that the appearance of stairs that belong to the same style is consistent throughout a drawing and with other stairs and objects that use the same materials.

If a component cannot be assigned a material, or if you do not want to use materials but still want consistency among stairs of the same style, you can specify the following display properties of the stair components in the stair style:

- The layer, color, and linetype of stair components
- The cut plane height and the display of components relative to the cut plane
- Other specific stair display information, such as riser numbering

Specifying the Layer/Color/Linetype of a Stair Style

Use this procedure to specify how the various components of the stair are displayed in a particular view. You can change the following display properties of the components of a stair style:

- Visibility (on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale
- Plot style (if the drawing uses style-based rather than color-based plotting)

Plan views of stairs include stringers, risers, nosing, path symbols, and stair outlines. You can specify the visibility of these components for above and below the cut plane of the stair. Isometric (model) views of stairs include stringers, treads, and risers.

To change these display properties for an individual stair, see [Changing the Display Properties of Individual Stairs](#) on page 1501.

NOTE If a material assignment determines the display properties of components in the stair style, you can change the properties of the display component by clearing *By Material*. You can also override the material assignment with a different material. For more information, see [Assigning Materials to a Stair Style](#) on page 1517.

1 Open a tool palette that has a stair tool.

- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Specifying the Display of Other Characteristics of a Stair Style

Use this procedure to specify settings for the cut plane and related symbols.

Plan views of stairs includes stringers, risers, nosing, path symbols, and stair outlines. You can specify the visibility of these components for above and below the cut plane of the stair.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Click Override Display Configuration Cut Plane to change the elevation of the Display Configuration cut plane for the stair.

NOTE When the Display Configuration Cut Plane is used, stairs display only from the current floor elevation up to the cut height, and from the current floor elevation down to the appropriate cut height of the level below.

- 9 Enter a value for Elevation.
- 10 Enter a value for Distance to change the space between the two cut plane lines.
- 11 Enter a value for Angle to change the angle of the stair cut lines.
- 12 Specify the display of the cut plane:

If you want to...	Then...
specify the height of the cut plane measured from the beginning of the stair	enter a value for Elevation. The space for the cut plane is centered on the closest tread.
specify the width of the cut plane	enter a value for Distance.
specify the angle of the cut plane	enter a value for Angle.

13 Specify the display of the arrow and the stair line:

If you want to...	Then...
change the display size of the arrow	enter a value for Size.
change the offset location of the arrow display	enter a value for Offset.
change the dimension style used for the arrow display	select a style for Dim Style. NOTE If a dimension style other than Standard is used for the arrow, and you want the arrow size to be controlled by the dimension style, select Arrow Size from Dimension Style Only. This is the default for all previous version drawings. If you do not select this option, the size of the arrow is multiplied by the arrow size setting.
change the shape of the stair line	select a shape for Shape. Curved adds an arc when the stair line changes. Straight displays an angle when the stair line changes.
display the arrow at the end of each cut plane pointing in the same direction throughout the length of the stair	select Cut Plane - Parallel for Apply to and make sure that Draw for Each Flight is not selected.
display the arrow at the end of each cut plane and at the end of each flight pointing in the same direction	select Cut Plane - Parallel for Apply to and make sure that Draw for Each Flight is selected.
display the arrow at the end of the entire stair	select Entire Stair for Apply to and make sure that Draw for Each Flight is not selected.
display the arrow at the end of each flight pointing in the same direction	select Entire Stair for Apply to and make sure that Draw for Each Flight is selected.
display the arrow on each side of the cut plane	select Cut Plane - Opposite for Apply to.
change which stair line is displayed	select a path for Display Path.
change the type of break mark that is displayed at the cut plane	under Break Mark, select a mark for Type.
specify a custom break mark to display at the cut plane	select Custom Shape for Type, and then select a block for Block.

14 Specify the display of the break mark:

If you want to...	Then...
change the style of the break mark	select an option for Type. The available options are None, Curved, Zigzag, and Custom Shape.

If you want to...	Then...
specify a custom shape for the break mark	select Custom Shape for Type, and select the desired name for Block.

15 Click OK.

Specifying the Riser Numbering Display of a Stair Style

Use this procedure to define the display of riser numbers for a stair style.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

6 If necessary, click .

7 Click the Riser Numbering tab.

8 Select the riser numbering display properties for the stair style:

If you want to...	Then...
change the text style of the riser numbers	select a style for Text Style, or click  to edit the text style.
change the alignment of the riser numbers	select an alignment for Text Alignment.
change the orientation of the riser numbers	select an orientation for Text Orientation.
change the text height of the riser numbers	enter a value for Text Height.
change the location to which the numbers are justified	select Left, Center or Right for Justify to.
change the location of the numbers along the length of the stair flight	enter a value for X Offset. This is relative to the selected position of the riser.
change the location of the numbers to the left or right	enter a value for Y Offset. This is relative to the selected position of the riser.
set the first number for the riser numbering	enter a value for First Riser Number.
number the last riser in the stair	select Number Final Riser.

9 Click OK twice.

Specifying Classifications for a Stair Style

Use this procedure to specify classifications for any classification definition applied to a stair style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the style that you want to change.
- 4 Click the Classifications tab.
By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to stair styles.
- 5 For each classification definition, select the classification you want to apply to the current stair style.
- 6 Click OK.

Adding Notes and Files to a Stair Style

Use this procedure to enter notes and attach reference files to a stair style. You can also edit notes and edit or detach reference files attached to the style.

- 1 Open a tool palette that has a stair tool.
- 2 Right-click a stair tool, and click Stair Styles.
- 3 Select the stair style that you want to change.
- 4 Click the General tab.
- 5 To add a description to the stair style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Text Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 9 Click OK.

Stair Winder Styles

A stair winder style is a group of properties assigned to a stair winder that determines the type of winder used in stairs that contain 1/4 turn or 1/2 turns.

To create, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture for working with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Creating a Stair Winder Style

Use this procedure to create a stair winder style. You can create a style that uses default style properties by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Architectural Objects, and expand Stair Winder Styles.

- 3 Create a stair winder style:

If you want to...	Then...
create a style with default properties	right-click Stair Winder Styles, and click New.
create a style from an existing style	right-click the stair winder style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new stair winder style.

- 5 Edit the new stair winder style. For more information, see [Specifying the Stair Winder Style Settings](#) on page 1523.

- 6 When you finish specifying the properties of the stair winder style, click OK twice.

Specifying the Stair Winder Style Settings

Use this procedure to determine which type of winder is defined for the selected winder style.

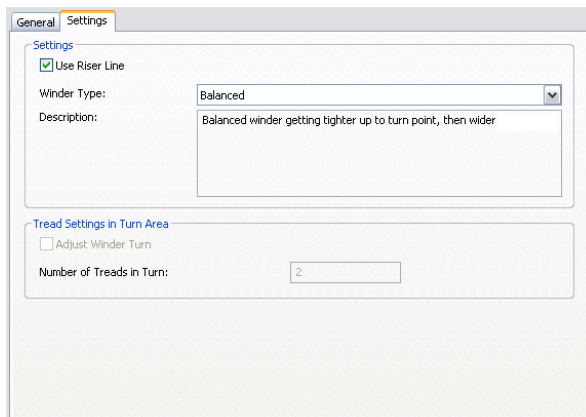

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

- 2 Expand Architectural Objects, and expand Stair Winder Styles.

- 3 Select a Stair Winder Style.

- 4 Click the Settings tab.

5 Specify the stair winder settings:

If you want to...	Then...
use the riser lines to adjust the winders	select Use Riser Line.
use the tread lines to adjust the winders	clear Use Riser Line.
have the treads turn continuously along the length of the stair	select Balanced for Winder Type. NOTE This is the type used by all earlier-release version stairs with 1/2 or 1/4 turns.
adjust each winder separately	select Manual for Winder Type.
adjust winders based on a single point and a turn zone	select Single Point for Winder Type.
set a number of winders to use when Single Point is selected for Winder Type	select Adjust Winder Turn and enter a value for Number of Treads in Turn.

NOTE When using the single point type, it is important to clear Use Riser Line if the turn point will be on the edge or corner of the stair. Otherwise, the treads will overlap and the stair will be defective, causing a solution tip icon to display in the drawing.

6 When you finish specifying the properties of the stair winder style, click OK.

Adding Notes and Files to a Stair Winder Style

Use this procedure to enter notes and attach reference files to a stair winder style. You can also edit notes and edit or detach reference files attached to the style.

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Architectural Objects, and expand Stair Winder Styles.

3 Select a Stair Winder Style.

4 Click the General tab.

5 To add a description to the stair style, enter it for Description.

6 Click Notes.

7 To add a note, click the Text Notes tab, and enter the note.

8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.

If you want to...	Then...
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

9 Click OK.

Stair Tower Generator

The Stair Tower Generator creates vertically stacked stairs based on a single stair and selected levels in the building. Optionally, slabs and railings can be included in the stair tower.

Creating a Stair Tower

You create a stair tower from one stair, which is replicated on selected levels in the building. You can create a stair tower with all stair shapes except spiral. The floor-to-floor height and starting elevation of each stair are adjusted to match these values for each selected level. The x,y coordinates for each stair start point are fixed.

NOTE The stair must be in a construct with multiple levels for the stair tower to be created. For more information, see [Constructs](#) on page 287.

- 1 Create a stair within a construct.
- 2 Select the stair, right-click, then click Stair Tower Generate.
- 3 Select any slabs or railings to be added to the stair tower.

NOTE If you select a slab to include in the stair tower, the slab should be at the top of the selected stair.

- 4 In the Select Levels dialog box, select the levels on which the stair tower generates the stairs.
You can include anchored railings by clicking Include Anchored Railings, even if they have not been selected in step 3.
- 5 If the stair you created was U-shaped, you can select Keep Landing Location while Adjusting U-Shaped Stair to maintain the landing position instead of the start point of the stair when it is edited.
- 6 Click OK.

The stair tower is created by adding stairs to the selected levels.

Generating a Stair Tower From an Existing U-Shaped Stair Run

existing stairs
and railings

select stairs

select railings
and slabs

result

NOTE If the stair height is different than the floor to floor height, the height of the stair is changed to match the floor height.

Modifying a Stair Tower

Once a stair tower has been created, you can modify each stair individually. You can also change one stair and propagate that change throughout the stair tower.

- 1 Select a stair in the tower.
- 2 Modify the stair.

For more information about modifying stairs, see [Editing Stairs](#) on page 1426.

- 3 Select the edited stair, right-click, and then click Stair Tower Generate.
- 4 Select any slabs or railings to be added to the stair tower.

NOTE If you select a slab to include in the stair tower, the slab should be at the top of the selected stair.

5 In the Select Levels dialog box, select the levels on which to change the existing stairs.

You can include anchored railings by selecting Include Anchored Railings.

6 If the stair you created was U-shaped, you can select Keep Landing Location while Adjusting U-Shaped Stair to maintain the landing position instead of the start point of the stair when it is edited.

7 Click OK.

Each selected stair is changed to match the modified stair.

Railings

26

Railings are objects that interact with stairs and other objects. You can add railings to existing stairs, or you can create freestanding railings.

Railings

Railings are objects that interact with stairs and other objects. You can add railings to existing stairs, or you can create freestanding railings.

Railing Components

Railings can have guardrails, handrails, posts, balusters, and one or more bottom rails. Additionally, you can add custom blocks to railings.

Railing components

Railing Shapes

You can attach railings to one or both sides of a stair, and you can wrap them around a landing. You can also attach railings to any other type of AEC object, like a massing element. You can create a custom railing by converting a polyline. Therefore, railings can have a variety of shapes and can be anchored to a straight stair, a multi-landing stair, a U-shaped stair, or a spiral stair.

Custom Railings

You can create custom railings by specifying custom blocks and profiles to be used for individual railing components. You can assign profiles to railing components by style so that you can reuse the custom portion to create detailed railings.

Railing Styles and Their Properties

You can use a railing style to control properties for all railings that use that style, rather than changing properties for each railing in the drawing. Various styles exist in the templates for common railing configurations, such as guardrail pipe, handrail grip, and handrail round. Within the railing style, you can specify the rail locations and height, post locations and intervals, components and profiles, extensions, material assignments, and display properties of the railing.

Materials in Railings

In AutoCAD Architecture, you can assign materials to a railing. These materials are displayed in wireframe and working shade views, or when rendered. Materials have specific settings for the physical components of a railing, such as the various types of rails and posts, and the baluster. You could, for example, create a wooden railing with a stainless steel handrail and bottomrail.

Railing in 2D wireframe model and rendered views

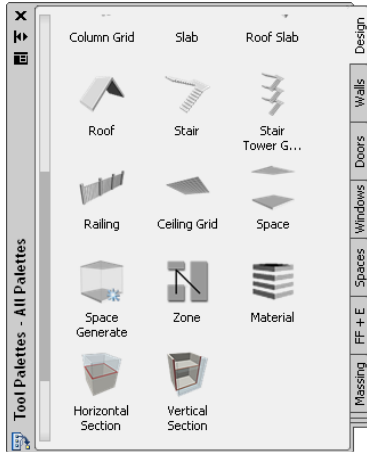

AutoCAD Architecture provides a number of predefined materials for common design purposes, which contain settings for railings. You can use these predefined materials “as is”, or modify them to your special designs. You can also create your own materials from scratch.

For more information, see [Specifying the Materials of a Railing Style](#) on page 1570.

Using Railing Tools to Create Railings

Tools provided with AutoCAD Architecture let you quickly place railings using a railing tool with specific predefined properties. You can use the default settings of the tool, or you can change the properties. You can also use railing tools to convert linework to railings and to apply the settings of a railing tool to existing railings.

Tool palettes containing railing tools

The default tool palettes in the workspace contain sample railing tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain railing tools that you can add to your tool palettes:

- Stock Tool catalog
- AutoCAD Architecture Sample Palette catalog

Custom palettes created by your CAD manager or other users may also contain railing tools with railing styles and properties that are customized for your projects or office standards.

Creating a Railing

Use this procedure to add a new railing that has the properties specified in the railing tool that you select. To specify settings when you add a railing, see [Creating an Attached Railing with User-Specified Settings](#) on page 1531 and [Creating a Freestanding Railing with User-Specified Settings](#) on page 1534.

- 1 Open the tool palette that you want to use, and select a railing tool.
If necessary, scroll to display the tool that you want to use.
- 2 Specify the start point of the railing.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Specify the endpoint of the railing.
- 4 Continue adding railings, and press *ENTER*.

Creating an Attached Railing with User-Specified Settings

Use this procedure to create a railing that is attached to a stair and that has the settings that you specify.

Creating a railing attached to a stair

1 Open the tool palette that you want to use, and select a railing tool.

If necessary, scroll to display the tool that you want to use.

2 On the Properties palette, expand Basic, and expand General.

3 Select a style.

4 Expand Dimensions.

5 Click the setting for Rail Locations.

NOTE If the settings in the Rail Locations worksheet are read-only, the rail locations have been set in the style, and cannot be overridden here. For more information, see [Specifying the Upper Rails of a Railing Style](#) on page 1564 and [Specifying the Bottom Rails of a Railing Style](#) on page 1565.

6 Specify the parameters for the guardrail or the handrail:

If you want to...

Then...

specify the height of the guardrail or the handrail

enter a value for Horizontal Height.

specify the height of guardrail or the handrail while it is on a stair flight

enter a value for Sloping Height.

specify the distance that the guardrail or the handrail is offset from the posts

enter a value for Offset from Post.

specify the side of the post for the offset, based on the direction the stair (or railing) was drawn

select Center, Left, Right, or Auto for Side for Offset. Side for Offset is available only when there is an offset value.

Auto is useful only for railings attached to the edges of stairs. A positive value is toward the center of the stair, while a negative value is toward the outside edge. Side for Offset for handrails also has a selection of Both, so you can specify a handrail on both sides of the railing.

If you select Auto, and the railing is not attached to or is along the center of a stair, the offset is to the right.

7 Specify the settings for bottom rails:

If you want to...

Then...

specify the height of the lowest rail when it is horizontal

enter a value for Horizontal.

If you want to...	Then...
specify the height of the lowest rail when it is on a stair flight	enter a value for Sloping.
specify the distance that the bottomrail is offset from the posts	enter a value for Offset from Post.
specify the side of the post for the offset, based on the direction the stair (or railing) was drawn	select Center, Left, Right, or Auto for Side for Offset. (Side for Offset is available only when there is an offset value.)
designate more than one bottom rail	enter a value for Number of Rails. When you designate multiple bottom rails, you can enter a value for Spacing of Rails.

8 If you want to revert to the rail settings defined in the style, click Reset To Style Values.

9 Click OK to return to the Properties palette.

10 Click the setting for Post Locations.

NOTE If the settings in the Post Locations worksheet are read-only, the post locations have been set in the style, and cannot be overridden here. For more information, see [Specifying Posts of a Railing Style](#) on page 1566.

11 Specify the post locations:

If you want to...	Then...
include fixed posts at the beginning and end of the railing	select Fixed Posts.
specify the distance above or below the top rail for all posts	enter a value for Extension of ALL Posts from Top Railing.
specify the height of all posts from the floor	enter a value for Extension of ALL Posts from Floor Level.
include fixed posts at the corners of the railing	select Fixed Posts at Railing Corners.
include dynamic posts with the railing	select Dynamic Posts. You can then enter a value for Maximum Center to Center Spacing.
include balusters with the railing	select Balusters.
specify the height of all balusters from the floor	enter a value for Extension of Balusters from Floor Level.
specify the maximum distance between the balusters	enter the appropriate value for Maximum Center to Center Spacing.

If you want to...**Then...**

override the number of balusters on each stair tread

select Stair Tread Length Override. You can then enter a value for Number per Tread. (This applies only to railings that are attached to stairs.)

12 If you want to revert to the post settings defined in the style, click Reset To Style Values.

13 Click OK to return to the Properties palette.

14 Expand Location.

15 For Attached to, select Stair or Stair Flight.

16 To offset the railing in or out from the side of the stair, enter an offset value.

Positive values are in toward the center of the stair and negative values are out from the center of the stair. If the railing is center justified, a positive value is to the right and a negative value is to the left.

17 To attach the railing automatically to the full length of the stair or the stair flight, select Yes for Automatic Placement.

NOTE This option is available only if you have selected to attach the railing to a whole stair. If you are attaching the railing to a stair flight, it is always attached to the full length of the stair flight.

18 Select the stair or stair flight in the drawing to which you want to attach the new railing.

19 Select a side of a stair or a stair flight to place the railing.

20 If you have selected no automatic placement for the stair, define the contour of the desired railing by selecting points in the drawing. Then press *ENTER*.

Creating a Freestanding Railing with User-Specified Settings

Use this procedure to create a freestanding railing in the drawing.

Creating a freestanding railing

1 Open the tool palette that you want to use, and select a railing tool.

If necessary, scroll to display the tool that you want to use.

2 On the Properties palette, expand Basic, and expand General.

- 3 Select a style.
- 4 Expand Dimensions.
- 5 Click the setting for Rail Locations.

NOTE If the settings in the Rail Locations worksheet are read-only, the rail locations have been set in the style, and cannot be overridden here. For more information, see [Specifying the Upper Rails of a Railing Style](#) on page 1564 and [Specifying the Bottom Rails of a Railing Style](#) on page 1565.

6 Specify the parameters for the guardrail or the handrail:

If you want to...	Then...
specify the height of the guardrail or the handrail	enter a value for Horizontal Height.
specify the height of the guardrail or the handrail while it is on a stair flight	enter a value for Sloping Height.
specify the distance that the guardrail or the handrail is offset from the posts	enter a value for Offset from Post.
specify the side of the post for the offset, based on the direction the stair (or railing) was drawn	select Center, Left, Right, or Auto for Side for Offset. (Side for Offset is available only when there is an offset value.)

Auto is useful only for railings attached to the edges of stairs. A positive value is toward the center of the stair, while a negative value is toward the outside edge. Side for Offset for handrails also has a selection of Both, so you can specify a handrail on both sides of the railing.

If you select Auto, and the railing is not attached to or is along the center of a stair, the offset is to the right.

7 Specify the settings for bottom rails:

If you want to...	Then...
specify the height of the lowest rail when it is horizontal	enter a value for Horizontal.
specify the height of the lowest rail when it is on a stair flight	enter a value for Sloping.
specify the distance that the bottomrail is offset from the posts	enter a value for Offset from Post.
specify the side of the post for the offset, based on the direction the stair (or railing) was drawn	select Center, Left, Right, or Auto for Side for Offset. (Side for Offset is available only when there is an offset value.)
designate more than one bottom rail	enter a value for Number of Rails. When you designate multiple bottom rails, you can enter a value for Spacing of Rails.

- 8 If you want to revert to the rail settings defined in the style, click Reset To Style Values.
- 9 Click OK to return to the Properties palette.

10 Click the setting for Post locations.

NOTE If the settings in the Post Locations worksheet are read-only, the post locations have been set in the style, and cannot be overridden here. For more information, see [Specifying Posts of a Railing Style](#) on page 1566.

11 Specify the post locations:

If you want to...	Then...
include fixed posts at the beginning and end of the railing	select Fixed Posts.
specify the distance above or below the top rail for all posts	enter a value for Extension of ALL Posts from Top Railing.
specify the height of all posts from the floor	enter a value for Extension of ALL Posts from Floor Level.
include fixed posts at the corners of the railing	select Fixed Posts at Railing Corners.
include dynamic posts with the railing	select Dynamic Posts. You can then enter a value for Maximum Center to Center Spacing.
include balusters with the railing	select Balusters.
specify the height of all balusters from the floor	enter a value for Extension of Balusters from Floor Level.
specify the maximum distance between the balusters	enter the appropriate value for Maximum Center to Center Spacing.
override the number of balusters on each stair tread	select Stair Tread Length Override. You can then enter a value for Number per Tread. (This applies only to railings that are attached to stairs.)

12 If you want to revert to the post settings defined in the style, click Reset To Style Values.

13 Click OK to return to the Properties palette.

14 Expand Location.

15 For Attached to, select NONE.

16 Specify the start point of the railing.

17 Specify further points for the railing.

18 Press *ENTER*.

Creating a Railing from a Polyline

Use this procedure to convert a polyline to a railing that has the properties of the railing tool you select. You can edit these properties after creating the railing.

Converting a polyline to a railing

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a railing tool, and click Apply Tool Properties ► Polyline.
- 3 Select the polyline to convert, and press *ENTER*.
- 4 When prompted to erase the original geometry, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the railing in the Properties palette, if needed.

Creating a Railing Tool

Use this procedure to create a railing tool and add it to a tool palette. You may want to create your own railing tools if you are placing multiple railings of a specific style that all have the same properties.

- 1 Open the tool palette on which you want to add a tool.
- 2 Create the tool:

If you want to...	Then...
create a tool from a railing in the drawing	select the railing, and drag it to the tool palette.
create a tool from a railing style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Re-open the tool palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

- 3 Right-click the new tool, and click Properties.

- 4 Enter a name for the tool.
- 5 Click the setting for Description, enter a description of the tool, and click OK.
- 6 Expand Basic, and expand General.
- 7 Click the setting for Description, enter a description of the railing created from this tool, and click OK.
- 8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.
- 9 Select a railing style.
- 10 Select the drawing file containing the style used for this railing.
- 11 Select whether railings created from this tool should be attached to a stair, a stair flight, or be freestanding.
- 12 Click OK.

Editing Railings

You can edit railings by changing the style of the railing, the inclusion and location of various rails and posts, and the insertion point. You can also specify the height and offset of guardrails and handrails, and the extension and spacing of posts.

Methods of Editing Railings

AutoCAD Architecture offers several methods for editing railings:

- You can directly edit railings using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- You can change railing settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- You can use editing commands from the shortcut menu for a selected railing.

Using Grips to Edit Railings

Use these procedures to edit railings using grips.

Editing Railing Dimensions

- 1 Select the railing.
- 2 Select the grip for the dimension you want to change.

Viewing railing Start, End, Location, and Reverse Direction grips

3 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

Viewing railing Fixed Post Position and Lengthen grips

Changing the Location or Position of a Railing

- 1 Select the railing.
- 2 Move the appropriate grip to change the location of the railing, its start point, or its endpoint.

Reversing the direction of the Railing

- 1 Select the railing.
- 2 Click the direction grip (arrow grip).

Adding a Post to a Railing

Use this procedure to add a post to a railing. The post is placed at a selected point on the railing.

Adding a post to a railing

- 1 Select a railing.
- 2 Right-click, and click Post Placement ► Add.
- 3 Select a location for a new post.
- 4 Press *ENTER*.

Removing a Post from a Railing

Use this procedure to remove posts you have added to railings. You can only remove fixed posts. You cannot remove dynamic posts. The manually added post closest to the selected point is removed from the railing. If two posts are equidistant from the selected point, the post closer to the starting point of the railing is removed. If the current first fixed post is removed, then the next post becomes the first fixed post. Likewise, if the current last fixed post is removed, then the next post from the last becomes the last fixed post. If all but one post is removed from a railing, then the sole remaining post becomes the first fixed post.

- 1 Select a railing.
- 2 Right-click, and click Post Placement ► Remove.

Redistributing Posts on a Railing

Use this procedure to reposition dynamic posts to account for posts that have been added or removed. You cannot redistribute displayed posts to account for hidden posts.

You may also want to redistribute posts after dragging the endpoints (start and end offset) of a railing attached to a stair. If posts are lost after trimming a railing, use the Redistribute Posts command to restore the posts.

If you have created a railing that is so short that only one post can be created, grip-editing and dragging the railing does not create another post. You must use the Redistribute Posts command to add another post to the end of the railing.

- 1 Select an existing railing.
- 2 Right-click, and click Redistribute Posts.

Hiding Posts

Use this procedure to hide posts in a railing. It is useful to hide posts in plan view so that the railing is visible as a solid component. These posts are not deleted; they are merely hidden from view. You can only hide fixed posts. You cannot hide dynamic posts. If the current first or last fixed post is hidden, then it remains the first or last fixed post regardless of its visibility.

- 1 Select a railing.
- 2 Right-click, and click Post Placement ► Hide.

Showing Hidden Posts

Use this procedure to show hidden posts.

- 1 Select a railing.
- 2 Right-click, and click Post Placement ► Show.

Reversing the Direction of the Railing

Use this procedure to reverse the direction of the railing to change the location of railing components. The direction in which the railing is drawn affects the behavior of the railing and its components.

NOTE You can also reverse the direction of a railing by clicking its direction grip (arrow grip).

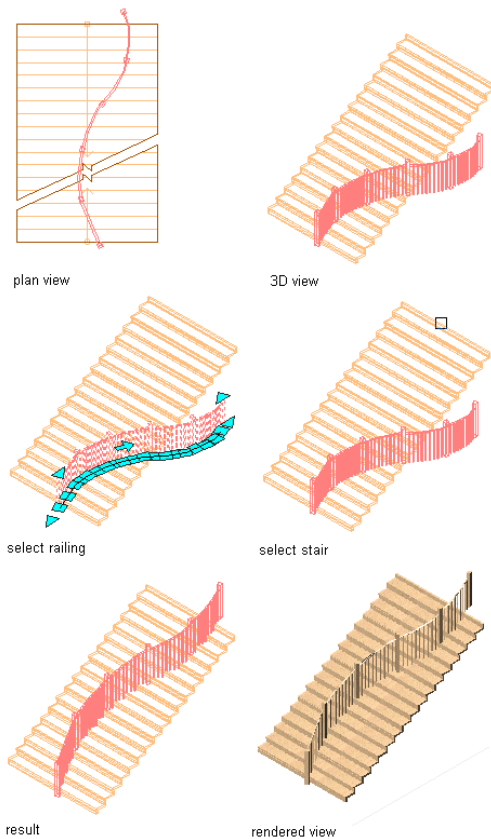

- 1 Select a railing.
- 2 Right-click, and click Reverse.

Anchoring an Existing Railing to a Stair

Use this procedure to anchor an existing railing to a stair. Once attached, the railing stays where it is located in the drawing, but it moves when the attached stair is moved. This allows you to create free-form paths for a railing along a stair. For example, you might want to create a curved railing in the middle of a straight stair.

Railings attached to stairs respect the stair cut plane. The height of the railing follows the slope of the stair, no matter where the posts are placed on the treads.

Attaching a railing to a stair

Railings that are attached to a stair or to a stair flight when created are anchored to the stair, at either side of the stairs or at the centerline.

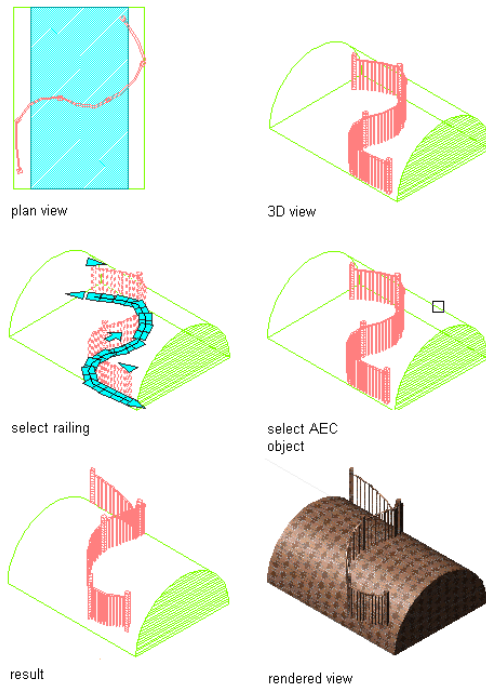

- 1 Select a railing.
- 2 Right-click, and click Railing Anchor ► Anchor To Stair.
- 3 Select a stair object, and press *ENTER*.

Anchoring an Existing Railing to an Object

Use this procedure to anchor an existing railing to an AEC object other than a stair. Once attached, the railing stays where it is located in the drawing, but it moves when the attached object is moved. This allows you to create free-form paths for a railing along a stair or other object.

Railings attached to objects other than stairs follow the height of the centerline of each post.

Attaching a railing to an AEC object

- 1 Select a railing.
- 2 Right-click, and click Railing Anchor ► Anchor To Object.
- 3 Select an AEC object other than a stair, and press *ENTER*.
- 4 If you want to clean up the railing posts with the surface of the object to which it is attached, enter *y* (Yes) on the command line.
- 5 Define the contour of the railing:

If you want to...	Then...
adapt only the posts to the surface of the attached object, and have straight segments between the posts	select At Post Locations Only for Calculate Height.
adapt the whole railing to the surface of the attached object,	select Follow Surface for Calculate Height.

Releasing an Anchored Railing

Use this procedure to release an anchored railing from a stair. After the railing is released, it is independent of the stair. The railing and the stair can then be moved separately.

NOTE When a railing that is anchored to a stair is released, any changes to the railing (such as grip-editing or changing properties) may cause the railing to lose its slope. Be sure to correct the appearance of the railing before releasing it from the stair.

- 1 Select a railing.
- 2 Right-click, and click Railing Anchor ► Release.
The railing is no longer anchored to the stair.

Specifying the Display of Custom Block Components of a Railing

Use this procedure to specify the display of custom block components for an individual railing in any of the display representations used for model views. If you are going to use custom graphics for a new component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the railing.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all railings in the drawing, select Drawing default setting. To apply changes to all railings of this style, select Railing Style:<style name>. For more information on styles, see [Railing Styles](#) on page 1562.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and for Custom block display, click

(the number in parentheses indicates the number of blocks currently attached to the railing).

- 7 If you want to turn off the display of custom blocks for this railing without removing them, select Disable Custom Blocks.
- 8 Specify whether to add, edit, or remove a block component:

If you want to...	Then...
add a new block component	click Add, and then click Select Block, select the block, and click OK.
edit an existing block component	select the component to edit, and click Edit.
remove an existing block component	select the block, click Remove, and click OK.

- 9 Specify the scale of the custom block:

If you want to...	Then...
use the block at its drawn size	clear all options under Scale to Fit.
scale the custom block to the width of the object to which it is attached	select Width.
scale the custom block to the depth of the object to which it is attached	select Depth.
scale the custom block to the height of the object to which it is attached	select Height.
lock the XY shape of the object	select Lock Ratio. If the object is scaled in one direction to fit another criterion for Scale to Fit, the whole custom block is scaled equally.

If you want to...	Then...
add the selected block to the railings between the selected components	select Between Comp. Baluster, Main Post, and Dynamic Posts are the only valid component selections.

10 Specify the Mirror In direction, if necessary:

If you want to...	Then...
create a mirror of the component in the X direction, along the length of the railing	select Mirror X.
create a mirror of the component in the Y direction, across the width of the railing	select Mirror Y.
create a mirror of the component in the Z direction	select Mirror Z.

11 Specify the location of the insertion point in relation to the object:

If you want to...	Then...
specify the location of the X insertion point	select Left, Center, or Right for X.
specify the location of the Y insertion point	select Front, Center, or Back for Y.
specify the location of the Z insertion point	select Bottom, Middle, or Top for Z.

Specify the post orientation relative to the up and down directions on a stair run in plan view as shown in the following illustration:

Specify the post orientation relative to the up and down directions on a stair run in elevation view as shown in the following illustration:

12 Specify the insertion offset for the component in the X, Y, and Z directions.

13 Specify the type of railing component that the block represents:

If you want to...	Then...
represent balusters with the block	select Baluster for Component.

If you want to...	Then...
represent main posts with the block	select Main Post for Component.
represent dynamic posts with the block	select Dynamic Post for Component.
replace the current baluster, main post, or dynamic post with the block	select Replace.
represent a guardrail with the block	select Guardrail for Component.
represent a handrail with the block	select Handrail for Component.
represent a bottom rail with the block	select Bottomrail for Component.

The two groups of components are mutually exclusive, so selecting an object from one column makes the other unavailable. You can select more than one object in each column to apply the block to each selected component. For example, you can use the same block for the main posts and dynamic posts.

14 Specify where the block is applied to the components:

If you want to...	Then...
apply the block to all instances of the selected components	select All for Attach to.
apply the block to the first instance of the selected component, based on the direction the railing was drawn	select First for Attach to.
apply the block to the last instance of the selected component, based on the direction the railing was drawn	select Last for Attach to.
apply the block to a selected number of components	select Selection for Attach to. The components are numbered in the order the railing was drawn, beginning with 1.

15 Click OK.

You can also specify custom block display properties through the railing's context menu, as follows:

- 1 Right-click the railing, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

- 4 If necessary, click  .
- 5 Click the Other tab.
- 6 Add, edit, or remove custom blocks as explained in the previous procedure.

Specifying Cleanup Settings for a Railing

Use this procedure to specify the cleanup settings for a railing in display representations used for model views.

- 1 Double-click the railing.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all railings in the drawing, select Drawing default setting. To apply changes to all railings of this style, select Railing Style:<style name>. For more information on styles, see [Railing Styles](#) on page 1562.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and click  Cleanup properties.
- 7 Specify whether you want to disable the cleanup of rails at post.
- 8 Specify whether you want to disable the cleanup of balusters at rails.
- 9 Click OK.

You can also access and modify the same cleanup settings through the railing's context menu, as follows:

- 1 Select the railing you want to change, right-click, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the desired display representation, and select Object Override.
The display representation in bold is the current display representation.

- 4 If necessary, click  .
- 5 Click the Other tab.
- 6 Adjust the settings as desired, and click OK twice.

Adding a Custom Profile to a Railing Component

Use this procedure to add a custom profile to a railing component.

Guardrails, handrails, bottom rails, and fixed and dynamic posts can be defined by a custom profile. You can add a profile to a railing component either in the railing style, as described in [Specifying the Components of a Railing Style](#) on page 1568 or directly on screen. When you add a custom profile on screen, the new profile is automatically saved back to the railing style. You can also add, remove, or edit custom profiles from the Properties palette, as described in [Specifying the Display of a Custom Profile Component of a Railing](#) on page 1550.

- 1 Create the necessary profile definition, as described in [Creating a Profile for a Custom Railing Component](#) on page 1569.
- 2 Select the railing to which you want to add a custom profile, right-click, and click Add Profile.
- 3 Select the railing component to which you want to add a profile.
You can select guardrails, handrails, bottom rails, fixed posts, and dynamic posts.

NOTE If you have difficulty selecting the correct component, switch to another view that makes the selection easier. For example, to select a bottom rail, switch to a Model view.

Adding a custom profile to a railing post

4 Select the profile for the railing component.

5 Either save the custom profile to the railing style immediately, or proceed with editing the profile:

If you want to...	Then...
save the new profile to the railing style	click OK.
edit the new profile	click Continue Editing, and then click OK. For information on editing a custom profile, see Editing a Custom Profile of a Railing Component on page 1548.

Editing a Custom Profile of a Railing Component

Use this procedure to edit a custom profile of a railing component.

1 Select the railing with a custom profile you want to edit.

2 Right-click, and click Edit Profile In Place.

This command is available only if you have profile-based components in the railing.

3 Select the component you want to edit.

NOTE If you have difficulty selecting the correct component, switch to another view that makes the selection easier. For example, to select a bottom rail, switch to a Model view.

You have begun an in-place editing session, depicted by the magenta-colored grips and light blue hatch of the temporary in-place editing profile, as well as the faded color of other objects in the drawing. Note that while you are editing in-place, you have limited access to other commands in the drawing. Before working on other objects, you should first end the in-place editing session.

4 Edit the profile:

If you want to...	Then...
use grips to edit the profile	<p>move the edge or vertex grips as needed.</p> <p>The Edge grip has three edit modes: Offset, Add Vertex, and Convert to Arc. The default mode is Offset, which offsets the selected edge in a direction that is perpendicular to the midpoint of the edge. Depending on the shape of the profile and the edge you choose to modify, neighboring lines are extended or trimmed, and new lines are added as necessary.</p> <p>Use the Add Vertex edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is an arc as well.</p> <p>Convert to Arc changes the selected edge to an arc and stretches the midpoint of the edge. The edge grip for an arc also has a Stretch mode, so that you can stretch the midpoint of the edge after it has been converted to an arc.</p>
add a vertex to the profile	<p>select an Edge grip, and press <i>CTRL</i> to switch to the Add Vertex edit mode. Move the edge to the desired location, and click; or enter a value, and press <i>ENTER</i>.</p>
remove a vertex from the profile	<p>select the Vertex grip for the vertex you want to remove, and press <i>CTRL</i> to switch to the Remove edit mode. Move the cursor off the selected vertex, and click.</p>
add a ring to a profile	<p>select the profile, right-click, and click Add Ring. Then select a closed polyline, spline, ellipse, or circle for an additional ring. Specify if you want to erase the source linework, and press <i>ENTER</i>.</p>
remove a ring from a profile	<p>select the profile, right-click, and click Remove Ring. Then select the ring you want to remove.</p> <p>NOTE You cannot remove the last ring from a profile.</p>
replace a ring on a profile	<p>select the profile, right-click, and click Replace Ring. Then select a closed polyline, spline, ellipse, or circle for the replaced ring. Specify if you want to erase the source linework, and press <i>ENTER</i>.</p>

5 Save the changes to the profile:

If you want to...	Then...
change the existing profile definition to reflect the new shape	<p>select the profile, and click  .</p>

If you want to...	Then...
create a new profile definition with the shape you have created	select the profile, right-click, and click Save As New Profile. Then enter a name for the new profile, and click OK. The in-place edit session closes and the new profile definition is available in the Style Manager.
discard all changes on the profile and revert to the previous shape	select the profile, and click  .

Specifying the Display of a Custom Profile Component of a Railing

Use this procedure to add, remove, or edit a custom profile component for an individual railing in any of the display representations used for plan views. If you are adding a new profile, you must first create the necessary profile definition, as described in [Creating a Profile for a Custom Railing Component](#) on page 1569.

- 1 Double-click the railing.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all railings in the drawing, select Drawing default setting. To apply changes to all railings of this style, select Railing Style:<style name>. For more information on styles, see [Railing Styles](#) on page 1562.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and for Custom profile display, click  (the number in parentheses indicates the number of profiles currently attached to the railing).
- 7 If you want to turn off the display of custom profiles for this railing without removing them, select Disable Custom Profiles.
- 8 Specify whether to add, edit, or remove a profile component:

If you want to...	Then...
add a new profile component	click Add, and then click Select Profile, select the profile, and click OK.
edit an existing profile component	select the component to edit, and click Edit.
remove an existing profile component	select the component, click Remove, and click OK.

- 9 Specify the scale of the custom profile:

If you want to...	Then...
use the profile at its drawn size	clear all options under Scale to Fit.

If you want to...	Then...
scale the custom profile to the width of the object to which it is attached	select Width.
scale the custom profile to the depth of the object to which it is attached	select Depth.
scale the custom profile to the height of the object to which it is attached	select Height.
lock the <i>XY</i> shape of the object	select Lock Ratio. If the object is scaled in one direction to fit another criterion for Scale to Fit, the entire custom profile is scaled equally.
add the selected profile to the railings between the selected components	select Between Comp. (Baluster, Main Post, and Dynamic Posts are the only valid component selections.)

10 Specify the Mirror In direction, if necessary:

If you want to...	Then...
create a mirror of the component in the <i>X</i> direction, along the length of the railing	select Mirror X.
create a mirror of the component in the <i>Y</i> direction, across the width of the railing	select Mirror Y.

11 Specify the angle to rotate the component in the *Z* direction, if necessary.

12 Specify the location of the insertion point in relation to the object:

If you want to...	Then...
specify the location of the <i>X</i> insertion point	select Left, Center, or Right for X.
specify the location of the <i>Y</i> insertion point	select Front, Center, or Back for Y.

Specify the post orientation relative to the up and down directions on a stair run in plan view as shown in the following illustration:

Specify the post orientation relative to the up and down directions on a stair run in elevation view as shown in the following illustration:

13 Specify the insertion offset for the component in the *X* and *Y* directions.

14 Specify the type of railing component that the profile represents:

If you want to...	Then...
represent balusters with the selected profile	select Baluster for Component.
represent main posts with the selected profile	select Main Post for Component.
represent dynamic posts with the selected profile	select Dynamic Post for Component.
replace the current baluster, main post, or dynamic post with the selected profile	select Replace.
add a guardrail to the selected profile	select Guardrail for Component.
add a handrail to the selected profile	select Handrail for Component.
add a bottom rail to the selected profile	select Bottomrail for Component.

The two groups of components are mutually exclusive, so selecting an object from one column makes the other unavailable. You can select more than one object in each column, and apply the profile to each selected component. For example, you can use the same profile for the main posts and dynamic posts.

15 Specify where the profile is applied to the components:

If you want to...	Then...
apply the profile to all instances of the selected components	select All for Attach to.
apply the profile to the first instance of the selected component, based on the direction the railing was drawn	select First for Attach to.
apply the profile to the last instance of the selected component, based on the direction the railing was drawn	select Last for Attach to.
apply the profile to a selected number of components	select Selection for Attach to. The components are numbered in the order the railing was drawn.

16 Click OK.

You can also specify custom profile display properties through the railing's context menu, as follows:

- 1 Right-click the railing, and click Edit Object Display.
- 2 Click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.

4 If necessary, click .

5 Click the Other tab.

6 Add, edit, or remove custom profiles as explained in the previous procedure.

Changing the Style of a Railing

Use this procedure to change the style associated with existing railings.

- 1 Select the railings for which you want to change the style, and double-click one of them.
- 2 Expand Basic, and expand General.
- 3 Select a different style.
- 4 Click OK twice.

Changing the Upper Rails

Use this procedure to change the following settings for an individual railing:

- guardrails
- handrails
- height
- sloping height
- offset from posts
- side for offset

NOTE If these settings are unavailable, they are controlled by the railing style. You cannot modify them for individual railings.

- 1 Double-click the railing for which you want to change the upper rails.
- 2 Expand Basic, and expand Dimensions.
- 3 Click the setting for Rail Locations.
- 4 Select whether to include guardrails or handrails.

NOTE A railing must have a guardrail or a handrail. Both cannot be turned off.

5 Specify the parameters for the guardrail or the handrail:

If you want to...	Then...
specify the height of the guardrail or the handrail	enter a value for Horizontal Height.
specify the height of guardrail or the handrail while it is on a stair flight	enter a value for Sloping Height.
specify the distance that the guardrail or the handrail is offset from the posts	enter a value for Offset from Post.
specify the side of the post for the offset, based on the direction the stair (or railing) was drawn	select Center, Left, Right, or Auto for Side for Offset. (Side for Offset is available only when there is an offset value.)

Auto is useful only for railings attached to the edges of stairs. A positive value is toward the center of the stair, while a negative value is toward the outside edge. Side for Offset for handrails also has a selection of Both, so you can specify a handrail on both sides of the railing.

If you select Auto, and the railing is not attached to or is along the center of a stair, the offset is to the right.

6 If you want to undo your changes and revert to the values set in the railing style, click Reset to Style Values.

7 Click OK.

Changing the Bottom Rails

Use this procedure to change the following settings for the bottom rails of an individual railing:

- whether to use bottom rails
- number of bottom rails
- distance between rails
- height of lowest rail

NOTE If these settings are unavailable, they are controlled by the railing style. You cannot modify them for individual railings.

1 Double-click the railing for which you want to change the bottom rails.

2 Expand Basic, and expand Dimensions.

3 Click the setting for Rail Locations.

4 Select Bottomrail to add bottom rails to the railing.

5 Specify the settings for bottom rails:

If you want to...	Then...
specify the height of the lowest rail when it is horizontal	enter a value for Horizontal.

If you want to...	Then...
specify the height of the lowest rail when it is on a stair flight	enter a value for Sloping.
specify the distance that the bottomrail is offset from the posts	enter a value for Offset from Post.
specify the side of the post for the offset, based on the direction the stair (or railing) was drawn	select Center, Left, Right, or Auto for Side for Offset. (Side for Offset is available only when there is an offset value.)
designate more than one bottom rail	enter a value for Number of Rails. When you designate multiple bottom rails, you can enter a value for Spacing of Rails.

6 If you want to undo your changes and revert to the values set in the railing style, click Reset to Style Values.

7 Click OK.

Changing the Posts

Use this procedure to change the following settings for the posts of an individual railing:

- type of posts
- number of posts that extend above the railing
- maximum center-to-center spacing between posts
- maximum center-to-center spacing between balusters
- number of balusters per tread for railings that are attached to stairs

NOTE If these settings are unavailable, they are controlled by the railing style. You cannot modify them for individual railings.

1 Double-click the railing for which you want to change the post locations.

2 Expand Basic, and expand Dimensions.

3 Click the setting for Post locations.

4 Specify the post locations:

If you want to...	Then...
include fixed posts at the beginning and end of the railing	select Fixed Posts.
specify the distance above or below the top rail for all posts	enter a value for Extension of ALL Posts from Top Railing.
specify the height of all posts from the floor	enter a value for Extension of ALL Posts from Floor Level.

If you want to...	Then...
include fixed posts at the corners of the railing	select Fixed Posts at Railing Corners.
include dynamic posts with the railing	select Dynamic Posts. You can then enter a value for Maximum Center to Center Spacing.
include balusters with the railing	select Balusters.
specify the height of all balusters from the floor	enter a value for Extension of Balusters from Floor Level.
specify the maximum distance between the balusters	enter the appropriate value for Maximum Center to Center Spacing.
override the number of balusters on each stair tread	select Stair Tread Length Override. You can then enter a value for Number per Tread. (This applies only to railings that are attached to stairs.)

5 If you want to undo your changes and revert to the values set in the railing style, click Reset to Style Values.

6 Click OK.

Changing the Railing Extensions at Floor Levels

Use this procedure to control the length of the handrail and guardrail extensions at the top and bottom of stair flights. If a bottom rail exists, it extends as far as the railing above it.

NOTE If these settings are unavailable, they are controlled by the railing style. You cannot modify them for individual railings.

1 Double-click the railing for which you want to change the extensions.

2 Expand Basic, and expand Dimensions.

3 Click the setting for Railing Extensions.

4 Specify the railing extension properties:

If you want to...	Then...
use values in this dialog box to specify extensions	clear Use Stair Landing Extension.
specify the length of the handrail and guardrail at the top of an entire stair	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.
specify the length of the handrail and guardrail at the bottom of an entire stair	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.

5 If you want to undo your changes and revert to the values set in the railing style, click Reset to Style Values.

6 Click OK.

Changing the Railing Extensions at Landings

Use this procedure to control the length of the handrail and guardrail extensions at landings. If a bottom rail exists, it extends as far as the railing above it.

NOTE If these settings are unavailable, they are controlled by the railing style. You cannot modify them for individual railings.

1 Double-click the railing for which you want to change the extensions.

2 Expand Basic, and expand Dimensions.

3 Click the setting for Railing Extensions.

4 Specify the railing extension properties:

If you want to...	Then...
use values in this dialog box to specify extensions	clear Use Stair Landing Extension under At Landings.
specify the length of the handrail and guardrail at the top of a flight	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.
specify the length of the handrail and guardrail at the bottom of a flight	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.

5 If you want to undo your changes and revert to the values set in the railing style, click Reset to Style Values.

6 Click OK.

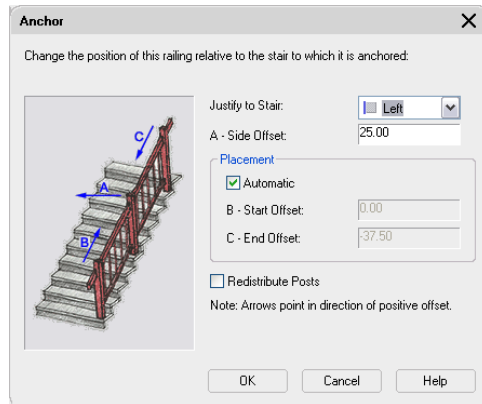

Changing the Anchor Properties of a Railing

Use this procedure to change the justification of a railing and the side, start, and end offsets. These properties apply only to railings attached to stairs.

1 Double-click the railing for which you want to change the anchor properties.

2 Expand Basic, and expand Location.

3 Click Anchor.

4 Change the justification of the railing.

5 Change the side offset from the stair:

- A value of zero places the start and end fixed posts exactly at the ends of the stair.
- Positive values move the start/end onto the stair.
- Negative values extend the railing beyond the stair bounds.

NOTE If Automatic is selected, the start and end offset options are not available.

6 Change the start offset from the top of the stair.

7 Change the ending offset at the bottom of the stair.

8 Click Redistribute Posts to change the existing posts.

NOTE If you edit a railing using grips so that the railing does not end on a post, you can use Redistribute Posts to move a post to the end of the edited railing.

9 Click OK.

Specifying Perpendicular Railing Orientation

Use this procedure to specify perpendicular or vertical railing orientation relative to a stair flight. By default, railings have a vertical orientation when you create them.

Specifying perpendicular railings

1 Select the railing.

2 On the Properties palette, under Dimensions, select Yes for Perpendicular Posts. Under Location, select Yes for Automatic Cleanup.

Once a perpendicular railing orientation has been specified, you can use grips to change first and last posts to a vertical orientation.

Specifying perpendicular railings

1 Select the perpendicular railing.

2 Select the Make Vertical grip.

The Make vertical grip changes to a Make perpendicular grip once you have specified a vertical orientation for the railing post. Select the Make perpendicular grip to return the post to a perpendicular orientation.

Viewing post orientation grips

When a stair has a landing, you also have the option of specifying the orientation of landing posts.

Specifying landing post orientation

- 1 Select the railing.
- 2 On the Properties palette, under Dimensions, select Yes for Perpendicular Posts, then select Yes for Maintain Sloping Posts at Landings. Under Location, select Yes for Automatic Cleanup.

Changing the Location of a Railing

Use this procedure to relocate a railing by changing the coordinate values of its insertion point. The railing also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the railing are parallel to the XY plane, its normal is parallel to the Z axis. You can change the orientation of the railing by aligning its normal with another axis. You can also rotate the railing on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD help.

NOTE You can change the location of freestanding railings only. The location of a railing attached to a stair is defined by the stair.

- 1 Select the railings you want to relocate, and double-click one of them.
- 2 Expand Basic, and expand Location.
- 3 Enter a value for Rotation.
- 4 Enter a value for Elevation.
- 5 Click Additional Information for further location properties:

If you want to...

Then...

relocate the railing

enter new coordinate values under Insertion Point.

If you want to...	Then...
locate the railing on the XY plane	make the normal of the railing parallel to the Z axis: under Normal, enter 1 for Z, and enter 0 for X and Y.
locate the railing on the YZ plane	make the normal of the railing parallel to the X axis: under Normal, enter 1 for X, and enter 0 for Y and Z.
locate the railing on the XZ plane	make the normal of the railing parallel to the Y axis: enter 1 for Y, and enter 0 for X and Z.
change the rotation of the railing	enter a new value for Rotation Angle.

6 Click OK.

Applying Tool Properties to an Existing Railing

Use this procedure to apply the properties of a railing tool to one or more existing railings. The properties include the railing style and any other settings specified in the tool you select.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a railing tool, and click Apply Tool Properties to ► Railing.
- 3 Select the railings, and press *ENTER*.
- 4 Edit the properties of the railing in the Properties palette, if necessary.

Attaching Hyperlinks, Notes, and Files to a Railing

Use this procedure to attach hyperlinks, text notes, and files to a railing.

- 1 Double-click the railing to which you want to attach information.
- 2 Click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
For more information about adding hyperlinks, see “Add Hyperlinks to a Drawing” in AutoCAD help.
- 4 Click the setting for Notes, and add a note. Then click OK.
- 5 Click the setting for Reference Documents.
- 6 Attach or detach reference files:

If you want to ...	Then ...
attach a reference file	click  , select a file, and click Open.
edit the description of a reference file	enter text under Description.

If you want to ...	Then ...
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

7 Click OK.

Railing Styles

A railing style is a group of properties assigned to a railing that determines the appearance and other characteristics of the railing.

Railing Components

In a railing style, you specify the following properties of railing components:

- guardrails
- handrails
- bottom rails
- first fixed post
- last fixed post
- interior fixed posts
- dynamic posts
- balusters

You can specify the height of rails and posts, the spacing between posts, the spacing between rails, and the width and depth of components. You can specify the display of different first and last posts, as well as different interior fixed posts. You can also create custom railing components by assigning custom profiles to replace standard railing components.

Custom Railing Components and Special Conditions

To create custom extruded components (railings, posts, or balusters) in a railing style, you define a profile and select it to replace a component on the Components tab. The resulting component is displayed appropriately in all views and does not have to be added to the display properties.

You can create a custom block to represent a complex design for a component that cannot be created from a profile, such as an elaborate wrought iron design in place of balusters, or an unusually shaped component. That block is used to represent the component in model views. You can create a profile to represent the custom component in plan views.

You can also use the custom blocks and profiles features of the display properties to represent additional railing components other than posts, rails, and balusters. In such cases, the component is added to the component rather than replacing it. For example, you can create a custom block for Model views and a profile for Plan views of a curved-railing return piece that ends by attaching to a wall. You can then add the block or profile to the rail components.

Using Materials in Railing Styles

You can use materials to control how railings of each style are displayed in a drawing. You assign materials to the railing components in the style. The components are then displayed using the display properties of the assigned materials.

AutoCAD Architecture provides a number of predefined materials for common design purposes. You can use these materials “as is,” or modify them for your project requirements. You can also define new materials. For more information about materials and how to define them, see [Materials](#) on page 601.

Creating Tools from Railing Styles

You can create a railing tool from any railing style. You can drag the style from the Style Manager onto a tool palette. You can then specify default settings for any railing created from the tool. For more information, see [Creating a Railing Tool](#) on page 1537.

Managing Railing Styles

To create, copy, or purge styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture, for working with styles from multiple drawings and templates. For more information about using the Style Manager, see [Getting Started with the Style Manager](#) on page 590.

Creating a Railing Style

Use this procedure to create a railing style. You can create a style using default style properties or by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Railing Styles.
- 3 Create a railing style:

If you want to...	Then...
create a style with default properties	right-click Railing Styles, and click New.
create a style from an existing style	right-click the railing style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new railing style, and press *ENTER*.

- 5 Edit the new railing style:

If you want to...	Then...
specify default dimensions and offsets for upper rails of the style	see Specifying the Upper Rails of a Railing Style on page 1564.
specify default dimensions and offsets for bottom rails of the style	see Specifying the Bottom Rails of a Railing Style on page 1565.
specify the location and interval of posts and balusters for the style	see Specifying Posts of a Railing Style on page 1566.

If you want to...	Then...
specify the structural components of the style	see Specifying the Components of a Railing Style on page 1568.
specify railing extensions at floor levels and at landings	see Specifying the Railing Extensions of a Railing Style on page 1569.
assign materials to the components of the railing style	see Assigning Materials to a Railing Style on page 1571.
add classifications to a railing style	see Specifying Classifications for a Railing Style on page 1573.
specify display components of the style	see Specifying the Display Components of a Railing Style on page 1572.
add notes and files to the style	see Attaching Notes and Files to a Railing Style on page 1573.

6 If you want to assign the style to a railing tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Railing Tool](#) on page 1537.

7 Click OK.

Specifying the Upper Rails of a Railing Style

Use this procedure to change the following settings for guardrails and handrails in a railing style:

- sloping height
- offset from posts
- side for offsets

- 1** Open a tool palette that has a railing tool.
- 2** Right-click a railing tool, and click Railing Styles.
- 3** Select the style you want to edit.
- 4** Click the Rail Locations tab.

5 Specify whether upper rail properties of this railing style can be overridden for individual railing objects:

If you want to...	Then...
specify guardrail and handrail properties, such as horizontal height, sloping height, and offset distance, when you add or modify railings	select Allow Each Railing to Vary.
require that all railings of this style use the upper rail settings of the style	clear Allow Each Railing to Vary.

NOTE Changes to guardrails and handrails do not affect existing railings of this style unless Allow Each Railing to Vary is clear.

6 Select whether to include guardrails and handrails.

A railing must have a guardrail or handrail. Both cannot be turned off.

7 Specify the following parameters for the guardrail or the handrail:

If you want to...	Then...
specify the height for the guardrail or the handrail	enter a value for Horizontal Height.
specify the height for the guardrail or the handrail while it is on a stair flight	enter a value for Sloping Height.
specify the distance that the guardrail or the handrail is offset from the posts	enter a value for Offset from Post.
specify the side of the post for the offset, based on the direction the stair (or railing) was drawn	select Center, Left, Right, or Auto for Side for Offset. (Side for Offset is available only when there is an offset value.)

Auto is useful only for railings attached to the edges of stairs. A positive value is toward the center of the stair, while a negative value is toward the outside edge. Side for Offset for handrails also has a selection of Both, so you can specify a handrail on both sides of the railing.

If you select Auto, and the railing is not attached to a stair or is along the center of a stair, the offset is to the right.

8 Click OK.

Specifying the Bottom Rails of a Railing Style

Use this procedure to change the following settings for bottom rails in a railing style:

- number of bottom rails
- distance between rails
- height of lowest rail

1 Open a tool palette that has a railing tool.

2 Right-click a railing tool, and click Railing Styles.

3 Select the style you want to edit.

4 Click the Rail Locations tab.

5 Specify whether bottom rail properties of this railing style can be overridden for individual railing objects:

If you want to...	Then...
specify bottom rail properties, such as horizontal height, sloping height, and number of rails, when you add or modify railings	select Allow Each Railing to Vary.
require that all railings of this style use the bottom rail settings of the style	clear Allow Each Railing to Vary.

6 Select Bottomrail to add bottom rails to the railing.

NOTE Changes to bottom rails do not affect existing railings of this style unless Allow Each Railing to Vary is clear.

7 Specify the parameters for bottom rails:

If you want to...	Then...
specify the height of the lowest rail when it is horizontal	enter a value for Horizontal.
specify the height of the lowest rail when it is on a stair flight	enter a value for Sloping.
designate more than one bottom rail	enter a value for Number of Rails. When you designate multiple bottom rails, you can enter a value for Spacing of Rails.

8 Click OK.

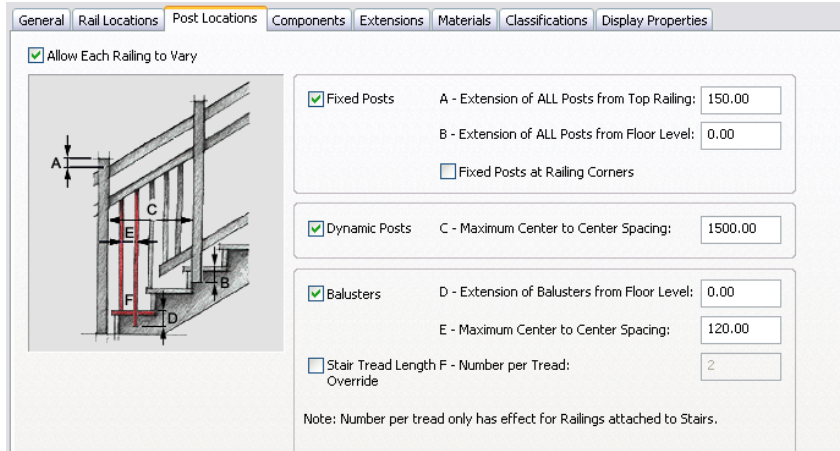

Specifying Posts of a Railing Style

Use this procedure to change the following settings for posts in a railing style:

- type of posts (first fixed, last fixed, fixed, dynamic, and balusters)
- distance the posts extend above railings
- maximum spacing between posts and balusters
- number of balusters for each tread for railings that are attached to stairs

First fixed posts and last fixed posts are attached at the beginning and end of each railing, respectively. Additional fixed posts and dynamic posts are added to the railing between the first and last fixed posts. Balusters are closely spaced supports for a railing. You can specify the spacing between dynamic posts and between balusters.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.
- 4 Click the Post Locations tab.

5 Specify whether the post properties of this railing style can be overridden for individual railing objects:

If you want to...

Then...

specify post properties, such as fixed posts, dynamic posts, and balusters, when you add or modify railings

select Allow Each Railing to Vary.

require all railings of this style to use the post settings of the style

clear Allow Each Railing to Vary.

NOTE Changes to posts do not affect existing railings of this style unless Allow Each Railing to Vary is clear.

6 Specify the post locations:

If you want to...

Then...

include fixed posts at the beginning and end of the railing

select Fixed Posts.

specify the distance above or below the top rail for all posts

enter a value for Extension of ALL Posts from Top Railing.

specify the height of all posts from the floor

enter a value for Extension of ALL Posts from Floor Level.

include fixed posts at the corners of the railing

select Fixed Posts at Railing Corners.

If you want to...	Then...
include dynamic posts with the railing	select Dynamic Posts. You can then enter a value for Maximum Center to Center Spacing.
include balusters with the railing	select Balusters. You can then enter a value for Maximum Center to Center Spacing.
override the number of balusters on each stair tread	select Stair Tread Length Override. You can then enter a value for Number per Tread. This applies only to railings that are attached to stairs.

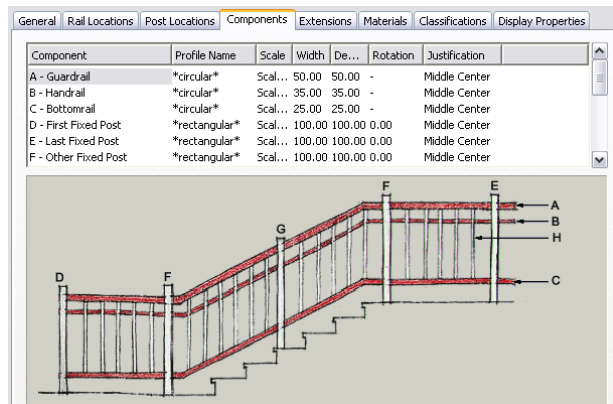

7 Click OK.

Specifying the Components of a Railing Style

Use this procedure to specify the shape of the railing components, and the width, depth, and rotation of each component for each railing style.

You can use profiles to create railing components with custom shapes. The custom profile replaces a component on the Components tab of the Railing Styles dialog box. For more information, see [Creating a Profile for a Custom Railing Component](#) on page 1569.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.
- 4 Click the Components tab.

- 5 Select the component to change.
- 6 Select the profile you want to use for the selected component.
The default profiles are circular and rectangular. Any profiles in the current drawing are also displayed.
- 7 Click Width, and enter a width for the selected component.
- 8 Click Depth, and enter a depth for the selected component.
Depth is not available for the default circular profile.
- 9 Click Rotation, and enter a rotation for the selected component.

Rotation is not available for rail components, or when the default circular profile is used for posts.

10 Click OK.

Creating a Profile for a Custom Railing Component

Use this procedure to create a profile from a closed polyline. You can then use the profile to define a custom railing component. The custom shape is extruded from the profile along the length of the component.

The height and the width of the polyline you use to create the profile define the height and the width of the railing component. You can change the scale and dimensions of the profile as you add it.

- 1 Draw a closed polyline of the height and the depth needed for the resulting railing component.
- 2 Click Format menu ► Style Manager.
- 3 Expand Multi-Purpose Objects, and expand Profiles.
- 4 Right-click, and click New.
- 5 Enter a name for the profile.
- 6 Right-click the new profile, and click Set From.
- 7 Select the profile in the drawing area.
- 8 When prompted to add another ring, press *ENTER*.
- 9 Press *ENTER* to accept Centroid as the insertion point of the profile.
- 10 Click OK.

You can now use the profile to replace a railing component. For more information, see [Adding Custom Railing Blocks and Profiles to a Railing Style](#) on page 1574.

Specifying the Railing Extensions of a Railing Style

Use this procedure to control the length of the handrail and guardrail extensions at the top and bottom of stair flights. If a bottom rail exists, it extends as far as the railing above it. If railing extensions are not allowed to vary, the endpoint cannot be grip-edited.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.
- 4 Click the Extensions tab.

Allow Each Railing to Vary

These values apply only to railings that are attached to stairs.

At Floor Levels
For railings attached to entire stairs or to individual stair flights.

Use Stair Landing Extension

	Handrail	Guardrail
A - Top of Entire Stair	300.00 <input type="checkbox"/> + T	0.00 <input type="checkbox"/> + T
B - Bottom of Entire Stair	300.00 <input checked="" type="checkbox"/> + T	0.00 <input type="checkbox"/> + T

At Landings
For Railings attached to individual stair flights.

Use Stair Landing Extension

	Handrail	Guardrail
C - Top of Flight	300.00 <input type="checkbox"/> + T	0.00 <input type="checkbox"/> + T
D - Bottom of Flight	300.00 <input checked="" type="checkbox"/> + T	0.00 <input type="checkbox"/> + T

5 Specify whether railing extensions of this railing style can be overridden for individual railing objects:

If you want to...	Then...
specify railing extension properties, such as handrails and guardrails at the top and bottom of entire stairs, when you add or modify railings	select Allow Each Railing to Vary.
require that all railings of this style use the extension settings of the style	clear Allow Each Railing to Vary.

NOTE Changes to railing extensions do not affect existing railings of this style unless Allow Each Railing to Vary is clear.

6 Specify the properties of railing extensions:

If you want to...	Then...
use values in this dialog box to specify extensions	clear Use Stair Landing Extension under At Floor Levels.
specify the length of the handrail and guardrail at the top of an entire stair	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.
specify the length of the handrail and guardrail at the bottom of an entire stair	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.
use values in this dialog box to specify extensions	clear Use Stair Landing Extension under At Landings.
specify the length of the handrail and guardrail at the top of a flight	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.
specify the length of the handrail and guardrail at the bottom of a flight	enter values for Handrail and Guardrail. Select + T next to the value to add the tread length to the extension value.

7 Click OK.

Specifying the Materials of a Railing Style

A railing consists of a number of components whose display properties can be determined by the materials assigned to each component. You assign one material to each physical component of the railing. For example, you assign a wood material to the balusters of a railing and a stainless steel material to the handrail and bottomrail. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the railing style, instead of using material display properties, you can turn off the material assignments in the display properties of the railing style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in three dimensional (3D) model views and in elevations.

Railing Materials and Display Components

The following table identifies the material component that corresponds to each railing component.

Railing Component	Material Component
Plan, Plan Screened, Plan High Detail	
Posts	Linework
Guardrail	Linework
Handrail	Linework
Bottomrail	Linework
Plan Low Detail	
Posts	Linework
Guardrail	Linework
Handrail	Linework
Model, Model ByBlock, Model Monochrome	
Baluster	3D Body
Posts	3D Body
Guardrail	3D Body
Handrail	3D Body
Bottomrail	3D Body

Assigning Materials to a Railing Style

Use this procedure to assign materials to the individual components of a railing style. The component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the railing. Custom components and components that are only symbolic graphics do not use materials for their display properties.

NOTE If a material assignment does not determine the display properties of a railing component, you can change the display properties of the railing style as described in [Specifying the Display Components of a Railing Style](#) on page 1572.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

- 11 Click OK.

Specifying the Display Components of a Railing Style

Use this procedure to change the following properties of the display components of a railing style:

- Visibility (display component is on or off)
- By Material (material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE If a material assignment determines the display properties of components in the railing style, you can change the properties of the display component by clearing By Material. You can also override the material assignment with a different material. For more information, see [Specifying the Materials of a Railing Style](#) on page 1570.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.

- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Specifying Classifications for a Railing Style

Use this procedure to specify classifications for any classification definition applied to a railing style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style that you want to change.
- 4 Click the Classifications tab.
By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to area styles.
- 5 For each classification definition, select the classification you want to apply to the current railing style.
- 6 Click OK.

Attaching Notes and Files to a Railing Style

Use this procedure to enter notes and attach reference files to a railing style. You can also edit notes and edit or detach reference files from a railing style.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the railing style, enter the description under Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Click OK when you finish editing.

If you want to...

Then...

detach a reference file

select the file name, click Delete, and click OK.

9 Click OK.

Adding Custom Railing Blocks and Profiles to a Railing Style

You can specify custom blocks and profiles to add to or replace individual railing components. You can add to or replace posts, dynamic posts, and balusters can be added to or replaced, and you can add to (but not replace) other railing components.

When you add a custom block and profile, you can specify several rules for positioning and scaling the new component. Each custom block or profile is also added to the display properties so that you can control its layer, color, and linetype. Be sure that the objects used to create the custom blocks are created with their properties designated as ByBlock. Otherwise, they cannot be controlled through the display properties. For more information about ByBlock, see “Control the Color and Linetype Properties in Blocks” in AutoCAD help.

After you create custom blocks and profiles, you can attach them to railing styles. Using custom blocks and profiles, railing styles can provide a much richer and more flexible set of railing graphics.

Adding a Custom Block to a Railing Style

Use this procedure to add a custom block to a railing style. The block can replace a railing component, such as a baluster, or be added to a component. You attach the block in display representations, such as Model, that show the railing in three dimensions.

Assigning a custom block as a baluster component to a railing

You can use a block to replace a component on the Components tab of the Railing Styles dialog box, or you can use a block to represent additional railing components in the display of railings. You add a block to the display components of a style; a component that you replace on the Components tab is already a part of the display properties.

1 Create a block to represent the component to add to the railing.

Create the block in the same plane as the railing to which you will attach it. Be sure that the objects used to create the custom blocks are created with their properties designated as ByBlock. Otherwise, they cannot be controlled through the display properties.

- 2 Open a tool palette that has a railing tool.
- 3 Right-click a railing tool, and click Railing Styles.
- 4 Select the style you want to edit.
- 5 Click the Display Properties tab.
- 6 Select the display representation where you want the changes to appear, and select Style Override.

NOTE You can add a custom block to a railing only in Model-based display representations.

- 7 If necessary, click .
- 8 Click the Other tab.
- 9 Click Add.
- 10 In the Custom Block dialog box, click Select Block.
- 11 Select the block to use, and click OK.
- 12 Specify the scale of the custom block:

If you want to...	Then...
use the block at its drawn size	clear all options under Scale to Fit.
scale the custom block to the width of the object to which it is attached	select Width.
scale the custom block to the depth of the object to which it is attached	select Depth.
scale the custom block to the height of the object to which it is attached	select Height.
lock the <i>XY</i> shape of the object	select Lock Ratio. If the object is scaled in one direction to fit another criterion for Scale to Fit, the whole custom block is scaled equally.
add the selected block to the railings between the selected components	select Between Comp. Baluster, Main Post, and Dynamic Posts are the only valid component selections.

- 13 Specify the Mirror In direction, if necessary:

If you want to...	Then...
create a mirror of the component in the <i>X</i> direction, along the length of the railing	select Mirror X.
create a mirror of the component in the <i>Y</i> direction, across the width of the railing	select Mirror Y.
create a mirror of the component in the <i>Z</i> direction	select Mirror Z.

14 Specify the location of the insertion point in relation to the object:

If you want to...	Then...
specify the location of the X insertion point	select Left, Center, or Right for X.
specify the location of the Y insertion point	select Front, Center, or Back for Y.
specify the location of the Z insertion point	select Bottom, Middle, or Top for Z.

Specify the post orientation relative to the up and down directions on a stair run in plan view as shown in the following illustration:

Specify the post orientation relative to the up and down directions on a stair run in elevation view as shown in the following illustration:

15 Specify the insertion offset for the component in the X, Y, and Z directions.

16 Specify the type of railing component that the block represents:

If you want to...	Then...
represent balusters with the block	select Baluster for Component.
represent main posts with the block	select Main Post for Component.
represent dynamic posts with the block	select Dynamic Post for Component.
replace the current baluster, main post, or dynamic post with the block	select Replace.
represent a guardrail with the block	select Guardrail for Component.
represent a handrail with the block	select Handrail for Component.
represent a bottom rail with the block	select Bottomrail for Component.

The two groups of components are mutually exclusive, so selecting an object from one column makes the other unavailable. You can select more than one object in each column to apply the

block to each selected component. For example, you can use the same block for the main posts and dynamic posts.

17 Specify where the block is applied to the components:

If you want to...	Then...
apply the block to all instances of the selected components	select All for Attach to.
apply the block to the first instance of the selected component, based on the direction the railing was drawn	select First for Attach to.
apply the block to the last instance of the selected component, based on the direction the railing was drawn	select Last for Attach to.
apply the block to a selected number of components	select Selection for Attach to. The components are numbered in the order the railing was drawn, beginning with 1.

18 Click OK twice.

After adding the block to the style, you can specify the layer, color, and linetype of the block. For more information, see [Specifying the Display Components of a Railing Style](#) on page 1572.

Adding a Custom Profile to a Railing Style

Use this procedure to add a custom profile to a railing style in the Plan display representation. You can replace one or more railing components with a custom profile, or you can assign different custom profiles to different railing components.

You can use a profile to replace a component on the Components tab of the Railing Styles dialog box, or you can use a profile to represent additional railing components in the display of railings. You add a profile to the display properties of a style; a component that you replace on the Components tab is already a part of the display properties.

For more information about creating profiles for railing components, see [Creating a Profile for a Custom Railing Component](#) on page 1569.

Assigning a profile to a baluster in a railing

- 1 Create a profile to represent the component to add to the railing. Create the profile in the *XY* plane.
- 2 Open a tool palette that has a railing tool.
- 3 Right-click a railing tool, and click Railing Styles.
- 4 Select the style you want to edit.
- 5 Click the Display Properties tab.
- 6 Select the display representation where you want the changes to appear, and select Style Override.

NOTE You can add a custom profile to a railing only in Plan-based display representations.

- 7 If necessary, click .
- 8 Click the Other tab.
- 9 Click Add.
- 10 In the Custom Profile dialog box, click Select Profile.
- 11 Select the profile, and click OK.
- 12 Specify the scale of the custom profile:

If you want to...	Then...
use the profile at its drawn size	clear all options under Scale to Fit.
scale the custom profile to the width of the object to which it is attached	select Width.
scale the custom profile to the depth of the object to which it is attached	select Depth.
scale the custom profile to the height of the object to which it is attached	select Height.
lock the <i>XY</i> shape of the object	select Lock Ratio. If the object is scaled in one direction to fit another criterion for Scale to Fit, the entire custom profile is scaled equally.

If you want to...**Then...**

add the selected profile to the railings between the selected components

select Between Comp. Baluster, Main Post, and Dynamic Posts are the only valid component selections.

13 Specify the Mirror In direction, if necessary:

If you want to...**Then...**

create a mirror of the component in the *X* direction, along the length of the railing

select Mirror X.

create a mirror of the component in the *Y* direction, across the width of the railing

select Mirror Y.

14 Specify the angle to rotate the component in the *Z* direction, if necessary.**15 Specify the location of the insertion point in relation to the object:**

If you want to...**Then...**

specify the location of the *X* insertion point

select Left, Center, or Right for *X*.

specify the location of the *Y* insertion point

select Front, Center, or Back for *Y*.

Specify the post orientation relative to the up and down directions on a stair run in plan view as shown in the following illustration:

Specify the post orientation relative to the up and down directions on a stair run in elevation view as shown in the following illustration:

**16 Specify the insertion offset for the component in the *X* and *Y* directions.****17 Specify the type of railing component that the profile represents:**

If you want to...**Then...**

represent balusters with the selected profile

select Baluster for Component.

represent main posts with the selected profile

select Main Post for Component.

If you want to...	Then...
represent dynamic posts with the selected profile	select Dynamic Post for Component.
replace the current baluster, main post, or dynamic post with the selected profile	select Replace.
add a guardrail to the selected profile	select Guardrail for Component.
add a handrail to the selected profile	select Handrail for Component.
add a bottom rail to the selected profile	select Bottomrail for Component.

The two groups of components are mutually exclusive, so selecting an object from one column makes the other unavailable. You can select more than one object in each column, and apply the profile to each selected component. For example, you can use the same profile for the main posts and dynamic posts.

18 Specify where the profile is applied to the components:

If you want to...	Then...
apply the profile to all instances of the selected components	select All for Attach to.
apply the profile to the first instance of the selected component, based on the direction the railing was drawn	select First for Attach to.
apply the profile to the last instance of the selected component, based on the direction the railing was drawn	select Last for Attach to.
apply the profile to a selected number of components	select Selection for Attach to. The components are numbered in the order the railing was drawn.

19 Click OK twice.

Turning Off a Custom Block or Custom Profile in a Railing Style

Use this procedure to turn off the display of all custom blocks or profiles without actually removing them from the railing style.

You can selectively turn off the visibility of individual display blocks on the Layer/Color/Linetype tab. This is one way to switch between alternate blocks. For more information, see [Specifying the Display Components of a Railing Style](#) on page 1572.

- 1 Open a tool palette that has a railing tool.
- 2 Right-click a railing tool, and click Railing Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.

5 Select the display representation where you want the changes to appear, and select Style Override.

NOTE Custom blocks are added and turned off in Model-based display representations; Custom profiles are added and turned off in Plan-based display representations.

6 If necessary, click  .

7 Click the Other tab.

8 Disable the custom component:

If you want to...	Then...
turn off a custom block	click Disable Custom Blocks.
turn off a custom profile	click Disable Custom Profile

9 Click OK.

Removing a Custom Block from a Railing Style

Use this procedure to delete custom components from a railing style.

1 Open a tool palette that has a railing tool.

2 Right-click a railing tool, and click Railing Styles.

3 Select the style you want to edit.

4 Click the Display Properties tab.

5 Select the display representation where you want the changes to appear, and select Style Override.

NOTE Custom blocks are added and removed in Model-based display representations; Custom profiles are added and removed in Plan-based display representations.

6 If necessary, click  .

7 Click the Other tab.

8 Select the component to remove, and click Remove.

9 Click OK.

Roofs

27

Roofs are AEC objects that model an entire roof surface. You can create roofs independently of other objects, or you can select a polyline shape and place a roof on that shape. You can also select closed walls and place a roof on the walls, change the slope of a roof, and edit its edges and faces.

Roofs

Roofs are AEC objects that you can use to model an entire multiple-face roof surface. You can create roofs independently of other objects, or you can place a roof on a shape defined by a polyline or by a closed set of walls. After creating the roof, you can change its overall dimensions and slope, or edit its edges and faces individually. For more flexibility in customizing a roof, you can convert it to a collection of individual roof slabs.

Roof Slabs

A roof slab models a single face of a roof. Roof slab objects also differ from roof objects in that each roof slab is a separate entity with no direct connection to other entities. When you use multiple roof slabs to model an entire roof surface, you have more flexibility in editing the roof, but the combined topology (3D geometry) of the roof is not calculated automatically. For this reason, it is recommended that when you design complex roofs, you start with a roof object. Then, when the design is substantially complete, but you need more flexibility for customizing edges and other details, you can convert the roof to individual roof slabs. For information on creating and editing roof slabs, see [Slabs and Roof Slabs](#) on page 1599.

While roof slabs do not dynamically interact with each other, they do allow significant control over the roof geometry. For example, you can trim roof slabs individually, extend them, and miter them with other roof slabs. You can also cut holes in roof slabs, add or subtract mass elements, and apply detailed fascia and soffit profiles to any edge at any angle and orientation. Because roof slabs are style-based, you can apply design changes globally.

Materials in Roofs

You can assign materials to a roof. Materials are displayed in wireframe and working shade views, or when rendered. Materials have specific settings for the physical components of a roof, such as slab. For more information see [Material Components and Display Properties](#) on page 610.

Viewing roofs in 2D wireframe and rendered views

2D wireframe

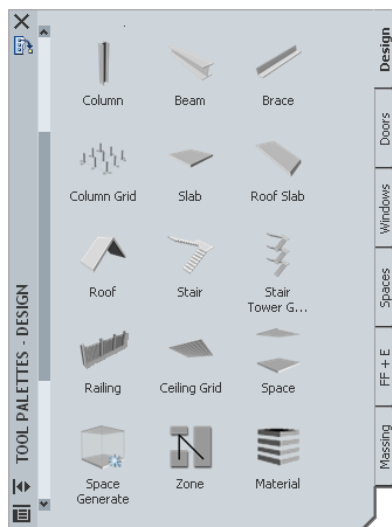

rendered

AutoCAD Architecture provides predefined materials for common design purposes. These materials contain settings for roof components. You can use the predefined materials as they are, or modify them for your designs. You can also create your own materials. Object styles provided with the software have appropriate materials already assigned to them. For more information, see [Slab/Roof Slab Materials and Display Components](#) on page 1660 and [Material Components and Display Properties](#) on page 610.

Using RoofTools to Create Roofs

Tools provided with AutoCAD Architecture let you quickly place roofs by selecting a roof tool with a specific roof style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can create roofs with single or double slopes and gable roofs. You can also use roof tools to create new roofs by applying tool properties to existing polylines and walls.

Tool palette containing roof tool

The default tool palettes in the workspace contain sample roof tools that you can use and customize as necessary. In addition, the following catalogs provided with the software contain roof tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog

Custom palettes created by your CAD manager or other users may also contain roof tools with properties customized for your projects or office standards.

Creating a Slope Roof

Use this procedure to add a slope roof that has the properties specified in the roof tool that you select. You can create a single slope or a double slope roof object. To specify settings when you add a roof, see [Creating a Slope Roof with User-Specified Settings](#) on page 1586.

NOTE To add additional slopes to a roof face, right-click a roof object and click Edit Edges/Faces.

Creating a single slope roof

Creating a double slope roof

- 1 Open the tool palette that contains the roof tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, select Single slope or Double slope for Shape.

TIP After specifying the desired setting, you can move or hide the Properties palette to expose more of the drawing area.

- 3 In the drawing area, specify points for the corners of the roof.
- 4 When you are finished specifying points, press *ENTER*.

Creating a Gable Roof

Use this procedure to add a gable roof that has the properties specified in the roof tool that you select. You can create a single sloped roof and set each edge to gable as needed. You can specify a slope for the gable ends to create a hip. To specify settings when you add a roof, see [Creating a Gable Roof with User-Specified Settings](#) on page 1587.

Viewing a gable roof end

NOTE You can create a gable on an existing roof by gripping any ridge line point and stretching it past the roof edge.

1 Open the tool palette that contains the roof tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)

2 On the Properties palette, select Single slope for Shape.

3 In the drawing area, specify the first point for the first roof edge.

4 Specify the second point to complete the first sloped roof edge.

5 On the Properties palette, select Gable for Shape.

6 In the drawing area, specify the next point to create a gable roof edge.

7 Select Single slope for Shape.

8 Specify the next point to create a sloped roof edge.

9 Select Gable slope for Shape.

10 Specify additional points as needed to define the roof, and press *ENTER*.

To create a clipped gable roof, you first need to convert the gabled roof to roof slabs. For more information, see [Creating a Roof Slab from a Roof](#) on page 1608 and [Creating a Clipped Gable Roof](#) on page 1650.

Creating Dormers

To add a dormer to a roof, you must first convert the roof to roof slabs, and then create additional roof slabs, walls, and all other parts of the dormer. For more information, see [Creating a Roof Slab from a Roof](#) on page 1608 and [Creating a Dormer in a Roof Slab](#) on page 1651.

Creating a Slope Roof with User-Specified Settings

Use this procedure to add a slope roof with settings that you specify. You can create a single slope or a double slope roof object.

Creating a single slope roof

Creating a double slope roof

1 Open the tool palette that contains the roof tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)

2 On the Properties palette, expand Basic, and expand Next Edge.

3 Select Single slope or Double slope for Shape.

4 Enter a value for Overhang.

5 Expand Lower Slope, and enter values for Plate Height, Rise, and Slope.

Plate height is the height of the bottom surface of the roof at its lowest edge (where the overhang begins). This is usually the height of the top plate of the wall that the roof sits on.

6 For a double slope roof, expand Upper Slope, and enter values for Upper Height, Rise, and Slope.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

7 In the drawing area, specify points for the corners of the roof.

8 When you are finished specifying points, press *ENTER*.

Creating a Gable Roof with User-Specified Settings

Use this procedure to add a gable roof with settings that you specify. You create a single sloped roof and set each edge to gable as needed. You can specify a slope for the gable ends to create a hip.

TIP You can create a gable on an existing roof by dragging a ridge line grip to the roof edge or beyond, as shown.

Viewing a gable roof end

- 1 Open the tool palette that contains the roof tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand Next Edge.
- 3 Select Single slope for Shape.

TIP You can move or hide the Properties palette to expose more of the drawing area.

- 4 In the drawing area, specify the first point for the first roof edge.
- 5 Specify the second point to complete the first sloped roof edge.
- 6 On the Properties palette, select Gable for Shape.
- 7 In the drawing area, specify the next point to create a gable roof edge.
- 8 Select Single slope for Shape.
- 9 Specify the next point to create a sloped roof edge.
- 10 Select Gable slope for Shape.
- 11 Specify additional points as needed to define the roof, and press *ENTER*.

Creating a Roof from Walls

Use this procedure to create a roof that is based on a selected closed set of walls and has the properties of the roof tool you select. You can edit these properties after creating the roof. The roof takes its plate height from the top of each wall segment.

NOTE If your walls are not properly cleaned up, the roof conversion is unpredictable. For more information, see [Cleanup Group Definitions](#) on page 843.

Creating a roof from walls

- 1 Open the tool palette that contains the roof tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click a roof tool, and click Apply Tool Properties to ► Linework and Walls.
- 3 Select the walls to convert, and press *ENTER*.

NOTE If the walls you select are not closed, a roof is added to the top of each wall segment.

- 4 When prompted to erase the original geometry, press *ENTER* to keep the wall, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the roof on the Properties palette, if needed.

Creating a Roof from Polylines

Use this procedure to create a roof that is based on a two-dimensional (2D) polyline and has the properties of the roof tool you select. You can edit these properties after creating the roof.

Creating a roof from a polyline

- 1 Draw a closed 2D polyline in the shape of the intended roof, in the location where you want to place the roof.
- 2 Open the tool palette that contains the roof tool you want to use.
(You may have to scroll to display the desired tool.)
- 3 Right-click a roof tool, and click Apply Tool Properties to ► Linework and Walls.
- 4 Select the polyline to convert, and press *ENTER*.

- 5 When prompted to erase the original geometry, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.
- 6 Edit the properties of the roof on the Properties palette, if needed.

Creating a Roof Tool

Use this procedure to create a roof tool and add it to a tool palette. You may want to create your own roof tools if you are placing multiple roofs that have the same properties.

For example, you are creating an office building that has a multi-peaked roof. Although the entire roof is single sloped, each peak has a different slope. To work efficiently, you can create a roof tool for each slope, and select the appropriate tool to place the roofs with the correct slope on each area of the building.

1 Open the tool palette on which to create a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a roof in the drawing	select the object, and drag it to the tool palette.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 Expand Basic, and expand General.

7 Click the setting for Description, enter a description of the roof created from this tool, and click OK.

8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.

9 Specify roof settings:

If you want to...	Then...
change the thickness value	expand Dimensions, and enter a value for Thickness.
change the type of edge	expand Dimensions, and select a new setting for Edge cut.
change the roof shape	expand Next Edge, and select a new setting for Shape.

If you want to...	Then...
add or remove the overhang, or change the overhang value	expand Next Edge, and enter a value for Overhang.
change the plate height	expand Lower Slope, and enter a value for Plate Height.
change the upper height for a double slope roof	expand Upper Slope, and enter a value for Upper Height.
change the rise or slope angle for each slope	expand Lower Slope, or Upper Slope for a double slope roof, and enter a value for Rise or Slope.

10 Click OK.

Editing Roofs

After placing roofs, you can edit any characteristics of the roof that you specified when you drew the roof. You can change the basic geometry of a roof, apply a different roof shape, and change the roof edge or overhang conditions.

AutoCAD Architecture offers several methods for editing roofs:

- Edit roofs directly using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- Change roof settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- Select editing commands from the context menu for a selected roof.

Using Grips to Edit Roofs

Refer to the illustrations and steps in this topic to use roof grips to edit roofs.

Editing Roof Dimensions

- 1 Select the roof.
- 2 Select the grip for the dimension you want to change.

Roof grips

3 Move the grip until the dimension value you want is displayed, and click once, or enter a value.

Applying Tool Properties to an Existing Roof

Use this procedure to apply the properties of a roof tool to one or more existing roofs. The properties include any settings specified in the tool you select.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a roof tool, and click Apply Tool Properties to ► Roof.
- 3 Select the roof, and press *ENTER*.
- 4 When prompted to erase the original geometry, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the roof on the Properties palette, if necessary.

Changing the Dimensions of a Roof

Use this procedure to change the dimensions of a roof, including the plate height, the upper height for a double slope (gambrel) roof, the slope, and the depth of the overhang. You can also change the thickness of the roof slabs and the type of roof edge.

NOTE You can create a gable end on a roof by gripping any ridge line point and stretching it past the roof edge.

- 1 Select the roof.
- 2 On the Properties palette, specify roof settings:

If you want to...

Then...

change the thickness value

under Dimensions, enter a value for Thickness.

change the type of edge

under Dimensions, select a new setting for Edge cut.

change the number of slopes

under Dimensions, select a new setting for Shape.

add or remove the overhang, or change the overhang value

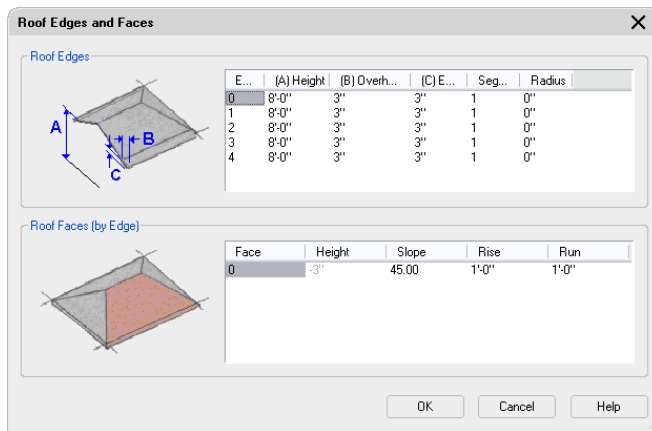

under Dimensions, enter a value for Overhang.

If you want to...	Then...
change the plate height	under Lower Slope, enter a value for Plate Height.
change the upper height for a double slope roof	under Upper Slope, enter a value for Upper Height.
change the rise or slope angle for each slope	under Lower Slope, or Upper Slope for a double slope roof, enter a value for Rise or Slope.

Changing the Edges and Faces of a Roof

Use this procedure to edit the edges and faces of a roof. You can edit:

- the height and overhang of individual edges
- the number of segments and the radius for curved segments
- the height and slope of individual roof faces

1 Select the roof you want to change, right-click, and click Edit Edges/Faces.

2 Select roof edges that you want to change and press *ENTER*.

As you select edges, they are numbered consecutively, beginning with zero, for display in the dialog box.

3 Specify new values for each roof edge:

If you want to...	Then...
change the height of a roof edge	select Height for the roof edge, and enter the height value.
change the overhang of a roof edge	select Overhang for the roof edge, and enter the overhang value.
change the number of segments in a curved roof for a roof edge	select Segments for the roof edge, and enter the number of segments.

If you want to...	Then...
change the radius of the curved roof edge	select Radius for the roof edge, and enter the radius.
4 Specify new dimensions for the roof faces of the selected edges:	
If you want to...	Then...
change the height of a roof face	select Height for the roof face, and enter the height value.
change the slope of a roof face	select Slope for the roof face, and enter the slope value.
add a face to the selected edge	click the blank space under the last number in the Face column, and enter values for Height and Slope.
remove a roof face	select the Face column number, and press <i>DELETE</i> .

5 Click OK.

Converting a Roof to Roof Slabs

Use this procedure to convert a roof to one or more roof slabs, each modeling a separate face of the roof. Roof slab objects differ from roof objects in that each roof slab is a separate entity, defined by its perimeter, edge conditions, and style. This gives you more flexibility in controlling to geometry of the roof and its edges. Also, because roof slabs are style based, you can apply design changes globally.

For more information about working with roof slabs, see [Slabs and Roof Slabs](#) on page 1599.

1 Select the roof you want to convert, right-click and click Convert to Roof Slabs.

The Convert to Roof Slabs worksheet displays the roof slab styles that exist in your current drawing.

Convert to Roof Slabs worksheet

2 Select a roof slab style.

3 Select Erase Layout Geometry to erase the roof and click OK.

4 Select individual roof slabs and edit them as needed.

Specifying the Material of a Roof

Use this procedure to select a different material for the components of an individual roof.

NOTE If a material assignment does not determine the display properties of the roof component, you can change the properties of the display component as described in [Specifying the Display Properties of a Roof](#) on page 1595.

- 1 Select the roof you want to change, right-click, and click Edit Object Display.
- 2 To verify that the material assignment determines the display properties of the component, click the Display Properties tab, select the display representation in which to display the changes, and click  .
- 3 Click the Layer/Color/Linetype tab, verify that By Material is selected for the component, and click OK.
- 4 Click the Materials tab.
- 5 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new one and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make apply to all objects that are assigned the material.

- 6 Click OK.

Specifying the Display Properties of a Roof

Use this procedure to change the following properties of the display components of an individual roof:

- Visibility (display component is on or off)
- By material (material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE If a material assignment determines the properties of a roof display component, you can change the properties of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Material of a Roof](#) on page 1594.

- 1 Select the roof you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

- 2 Click the Display Properties tab.
- 3 Select the display representation in which to display the changes, and select Object Override. The display representation in bold is the current one.

- 4 If necessary, click .
- 5 Click the Layer/Color/Linetype tab.
- 6 Select the component to change, and select a different setting for the property.
- 7 Click OK twice.

Specifying the Hatching of a Roof

Use this procedure to specify the hatching of the components of an individual roof. Hatching is displayed only in the section display representation.

NOTE If a material assignment determines the hatching properties of a roof display component, you can change the hatching of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Material of a Roof](#) on page 1594.

- 1 Select the roof you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

- 2 Click the Display Properties tab.
- 3 Select the Section display representation, and select Style Override.

- 4 If necessary, click .
- 5 Click the Hatching tab.
- 6 Select the display component, and click the setting for Pattern.
- 7 Select the hatching for the display component:

If you want to...	Then...
specify a hatching pattern that is available in the software	select Predefined for Type, and select a pattern.
specify a custom pattern	select Custom for Type, and enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder that contains the custom pattern file.
specify single hatching	select User-Defined for Type, and clear Double Hatch.
specify double hatching	select User-Defined for Type, and select Double Hatch.
specify solid fill	select Solid Fill for Type.

- 8 Click OK.
- 9 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.
- 10 Click Angle, and enter the angle for the selected pattern.

11 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the roof slab, regardless of the roof slab rotation	select Object.
orient the hatching to the world coordinate system	select Global.

12 Click X Offset and Y Offset, and enter offset values.

13 Click OK twice.

Changing the Location of a Roof

Use this procedure to relocate a roof by changing the coordinate values of its insertion point. The roof also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the roof are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the roof by aligning its normal with another axis. You can also rotate the roof on its plane by changing the rotation angle.

For information about the WCS and UCS, see “Use Coordinates and Coordinate Systems” in AutoCAD help.

- 1 Select the roof you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the roof:

If you want to...	Then...
relocate the roof	enter new coordinate values under Insertion Point.
locate the roof on the <i>XY</i> plane	make the normal of the roof parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the roof on the <i>YZ</i> plane	make the normal of the roof parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the roof on the <i>XZ</i> plane	make the normal of the roof parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the roof	enter a new value for Rotation Angle.

5 Click OK.

Attaching Hyperlinks, Notes, or Files to a Roof

Use this procedure to attach hyperlinks, notes, or files to a roof. You can also edit hyperlinks and notes, and edit or detach reference files from a roof.

- 1 Select the roof to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

4 Click OK.

5 To add a note, click the setting for Notes, and enter the note.

6 Click OK.

7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

8 Click OK twice.

Slabs and Roof Slabs

28

In AutoCAD Architecture, a slab object is a three-dimensional (3D) body that is bounded by a planar polygon (perimeter) of any shape, and has multiple edges. A slab is defined by its perimeter, edge conditions, and style. You can use slabs to draw floors and other building model components that require a flat surface and edge conditions.

Roof slabs are similar to slabs in most respects, but are based on distinct roof slab styles. When modeling a roof, you can convert individual faces of the roof into roof slabs, which give you more flexibility in modeling details of the roof's geometry.

Overview of Slabs and Roof Slabs

Slabs and roof slabs are AutoCAD Architecture objects that you use to model floors, roof faces, and other flat surfaces where edge conditions need to be specified. The slab or roof slab object is a three-dimensional (3D) body bounded by a planar polygon (perimeter) of any shape, and has multiple edges. The object is defined by its perimeter, edge conditions, and style. Though they share many of the same properties, slabs and roof slabs represent separate style categories and tool types. For instance, you cannot apply the properties of a slab tool to an existing roof slab object.

Roof Slabs

A roof slab models a single face of a roof. Roof slab objects also differ from roof objects in that each roof slab is a separate entity with no direct connection to other entities. When you use multiple roof slabs to model an entire roof surface, you have more flexibility in editing the roof, but the combined topology (3D geometry) of the roof is not calculated automatically. For this reason, it is recommended that when you design complex roofs, you start with a roof object. Then, when the design is substantially complete, but you need more flexibility for customizing edges and other details, you can convert the roof to individual roof slabs.

While roof slabs do not dynamically interact with each other, they do allow significant control over the roof geometry. For example, you can trim roof slabs individually, extend them, and miter them with other roof slabs. You can also cut holes in roof slabs, add or subtract mass elements, and apply detailed fascia and soffit profiles to any edge at any angle and orientation. Like slabs, roof slabs are style-based, so you can apply design changes globally.

Methods of Creating Slabs/Roof Slabs

Using slab and roof slab tools, you can create slabs and roof slabs independently, or you can create them from existing objects, such as walls and polylines. Slabs and roof slabs created from other objects do not maintain a link to the original object.

Pitched roofs are usually designed by specifying a plate line and a slope angle. Roof slabs are designed so that you can use the same approach in laying them out. To add a roof slab, you simply specify two points and an angle.

If you have a traditionally designed roof created from a two-dimensional (2D) plan showing ridge, hip, and valley lines, you can trace over that plan with roof slabs, specifying the desired height and slope. From these values and the specified points, the software creates the correct three-dimensional (3D) model.

Slab/Roof Slab Bodies

The body of a slab or roof slab is an extrusion perpendicular to the plane of the perimeter and is defined by the following geometry:

- The perimeter of a slab/roof slab is a planar polygon defined by the X,Y,Z coordinates of its vertices.
- A slab/roof slab has 3 or more vertices, with the ability to add or remove vertices. Each pair of vertices defines an edge.
- The thickness of a slab/roof slab extrusion is specified either in the object style (when it has a fixed thickness) or for the individual object.
- The position of the slab/roof slab bottom, relative to its perimeter plane, is controlled by the thickness offset value in the style.
- The baseline of a slab/roof slab is defined by the first two points you select when defining the vertices.
- The slab/roof slab insertion point, by default, is the first point on the baseline. You can offset the baseline either horizontally or vertically from the insertion point to allow for precise alignment with walls or structural elements.
- A slab/roof slab has a slope (pitch), which you can specify either as an angle or as a rise-to-run ratio. If you change the slope, the slab/roof slab rotates around the slope pivot point.
- The pivot point is initially the first vertex of the baseline, but you can move it to any other point, either on or off the slab/roof slab. A small pyramid-shaped marker represents the pivot point.
- An imaginary line passing through a slab/roof slab at the perimeter line (in section) is called the slopline. The slopline aligns the slab/roof slab with the wall base height. The slopline is the position of the slab/roof slab baseline relative to its bottom face. The value you enter for the thickness offset in the slab/roof slab style determines the distance between the slab/roof slab baseline and the bottom face of the slab/roof slab.

Geometry of a roof slab

Slab/Roof Slab Edges

The following parameters define a slab or roof slab edge:

- edge cut orientation (plumb or square)
- angle (relative to the orientation)
- edge style (fascia and soffit)
- overhang (defines the point at which the fascia begins)

You apply a fascia and soffit to slab or roof slab edges with styles that define edge conditions

- The fascia is defined by a profile, with its insertion point located at the top of the slab/roof slab edge. The local Y axis of the profile polyline aligns with the slab/roof slab edge angle.
- The soffit is also defined by a profile, with its insertion point positioned at the X and Y offsets from the fascia insertion point.

Roof slab with fascia and soffit components

Edge Control

You can customize each slab or roof slab edge individually, applying styles and making other adjustments as required by your design. A slab/roof slab edge style defines the fascia and soffit design from profiles that you create for these components. You can specify whether the style uses a fascia, a soffit, both, or neither. You also specify how the fascia and soffit are positioned relative to the slab/roof slab.

Slab and Roof Slab Styles

Slabs and roof slabs have their own distinct style categories in which individual styles specify the default properties for specific types of slabs/roof slabs. These properties include dimensions, edge styles for the fascia and soffit, and entity properties for layer, color, and linetype. Slab and roof slab styles allow you to use a different edge style for each edge.

Materials in Slabs and Roof Slabs

You can assign materials to a slab or roof slab. For example, a floor slab can be assigned a material representing tiles with concrete edges. These materials are displayed in wireframe or rendered views. Materials have specific settings for individual components of slabs/roof slabs, such as the body, fascia and soffit.

Slab appearance in different views

2D wireframe

rendered

AutoCAD Architecture provides predefined materials for common design purposes. These materials contain settings for slabs/roof slabs that you can use as provided or modify for special designs. You can also create materials from scratch. If you create a material to use only for slabs, name it accordingly; for example, Slab—Ceramic Tile or Slab Edge—Concrete. This will help in organizing your material definitions. For more information, see [Specifying the Materials of a Slab or Roof Slab Style](#) on page 1659.

Editing Tools

In addition to the control provided by slab/roof slab styles and edge styles, AutoCAD Architecture includes a variety of tools that let you edit slabs and roof slabs to fit unique conditions. For example, you can add holes to slabs for structures such as chimneys and vent pipes. You can also use roof slabs to create dormers. For a description of the tools available, see [Editing Slabs and Roof Slabs](#) on page 1613.

Using Tools to Create Slabs and Roof Slabs

Tools provided with AutoCAD Architecture let you quickly place slabs or roof slabs by selecting a tool with a specific slab/roof slab style and other predefined properties. You can use the tool with all of its default settings, or you can change any properties that are not controlled by the style. You can also use slab/roof slab tools to create new slabs/roof slabs by applying tool properties to existing linework, walls, and spaces.

The Design tool palette contains sample slab and roof slab tools that you can use and customize as needed. Custom palettes created by your CAD manager or other users may also contain slab/roof slab tools with styles and properties that are customized for your projects or office standards.

Tool palette containing slab and roof slab tools

Slab and roof slab tools are also included in the Stock Tool catalog supplied with the Content Browser. For information about using the Content Browser, see [Understanding the Content Browser](#) on page 121.

Creating a Slab or a Roof Slab

Use this procedure to add a new slab or roof slab that has the properties specified in the slab/roof slab tool you select. To specify your own settings when you add a slab or roof slab, see [Creating a Slab/Roof Slab with User-Specified Settings](#) on page 1604.

You add the slab/roof slab by specifying points to define its perimeter as follows:

- The first point determines the insertion point of the slab/roof slab and the start of the baseline. This point also locates the default pivot point of the slab/roof slab.
- The second point determines the endpoint of the baseline.
- Subsequent points establish the vertices of the perimeter.

1 Open the Design tool palette, and select the Slab tool or the Roof Slab tool.
(You may have to scroll to display the desired tool.)

2 Specify the start point of the slab/roof slab.

3 Specify a second point to define the first edge (baseline) of the slab.

4 Specify further points to finish defining the perimeter:

If you want to...

Then...

close the perimeter by drawing two edges that meet at a right angle

specify a point in the direction in which the perimeter is to close; then enter *o* (for Ortho). The edge is extended until it meets another edge perpendicular to the first edge.

close the perimeter by adding an edge from the previous point to the start point of the baseline

enter *c* (for Close).

5 Press *ENTER*.

Drawing a slab

Creating a Slab/Roof Slab with User-Specified Settings

Use this procedure to create a slab or roof slab with settings that you specify.

- 1 Open the Design palette, and select the Slab tool or the Roof Slab tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a slab/roof slab style.
- 4 Specify a value for Bound Spaces:

If you want to...**Then...**

allow the slab/roof slab to be used as a bounding object for associative spaces

select Yes.

prevent the slab/roof slab from being used as a bounding object for associative spaces

select No.

use the bounding settings from the slab or roof slab style

select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

- 5 Select Projected or Direct for Mode.

If you select Projected, the X,Y coordinates of the first point you specify are projected to a Z value of the current base height. This establishes the insertion point. The second point establishes the baseline. All subsequent points are projected onto a plane established by the baseline and the specified slope angle. This mode is provided for architects who wish to lay out a slab/roof slab by tracing over a plan drawing.

If you select Direct, the points you specify become the vertices of the slab perimeter.

- 6 Expand Dimensions.

7 Enter a value for Thickness.

8 Enter a value for the vertical offset distance from the insertion point for Vertical Offset.

9 Enter a value for the horizontal offset distance from the insertion point for Horizontal Offset.

10 Select the justification:

If you want to align the ...	Then...
top of the slab/roof slab with the first specified point	select Top.
center of the slab/roof slab with the first specified point	select Center.
bottom of the slab/roof slab with the first specified point	select Bottom.
sloped line of the slab/roof slab with the first specified point	select Sloped.

NOTE This justification is used only for inserting a slab/roof slab and is not retained as a parameter of the inserted object. Justification is intended primarily for Direct mode.

The sloped line is the position of the slab/roof slab baseline relative to its bottom face. The thickness offset in the style determines the distance between the baseline and the bottom face.

11 Enter a value for the height of the slab/roof slab insertion point for Base Height.

This is available only when you select Projected mode.

12 Select a direction, or define how the slab/roof slab is drawn relative to the baseline.

13 Enter a value for the depth of the overhang for Overhang.

14 Select a style for Perimeter edge.

15 If you selected the Projected mode, expand Slope, and enter values for Rise, Run, or Angle to define the slope of the slab/roof slab.

16 Specify the start point of the slab/roof slab.

The start point is the insertion point and the start of the baseline. The start point also determines the location of the default pivot point for the slab/roof slab.

17 Specify a second point to define the first edge (baseline).

18 Specify further points to establish the vertices of the slab/roof slab perimeter:

If you want to...	Then...
close the perimeter by drawing two edges that meet at a right angle	specify a point in the direction in which the perimeter is to close; then enter Ortho . The edge is extended until it meets another edge perpendicular to the first edge.
close the perimeter by adding an edge from the previous point to the start point of the baseline	enter Close .

19 Continue to place slabs/roof slabs, and press *ENTER* when finished.

Creating a Slab or Roof Slab from Walls

Use this procedure to create a rectangular slab or roof slab from one or more walls. This is useful when you want a specific alignment between the slab/roof slab baseline and the wall baseline. When you create a slab/roof slab from a single wall, the base height of the wall defines the baseline edge of the slab/roof slab. When you create a slab/roof slab from multiple walls, the top of the first selected wall defines the baseline edge of the slab/roof slab.

You can create a flat slab/roof slab that follows the outline of multiple walls by specifying a zero slope. If you select multiple walls and a non-zero slope, multiple slabs/roof slabs are created.

If the closed polyline intersects one of the selected walls, the slab/roof slab is invalid and you must select the walls again.

TIP This procedure is useful to place roof slabs on top of existing walls. The Convert to Roof Slabs command, accessed by right-clicking an existing roof object, is useful when you want a specific alignment between the slab baseline and the wall baseline.

Creating a roof slab from a wall

NOTE When selecting multiple walls, if your walls are not properly “cleaned up,” the slab/roof slab conversion is unpredictable. For more information, see [Cleanup Group Definitions](#) on page 843.

- 1 Open the tool palette that contains the slab or roof slab tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click the tool, and click Apply Tool Properties to ► Linework and Walls (or Linework, Walls and Roof, in the case of roof slab tools).
- 3 Select one or more walls, and press *ENTER*.
- 4 Enter *y* (Yes) to erase the walls, or *n* (No) to keep the walls in the drawing.
- 5 Specify a justification method:

If you want to align the ...	Then...
top of the slab/roof slab with the first specified point	select Top.

If you want to align the ...	Then...
center of the slab/roof slab with the first specified point	select Center.
bottom of the slab/roof slab with the first specified point	select Bottom.
slopline of the slab/roof slab with the first specified point	select Slopeline.

NOTE This justification is used only for inserting a slab/roof slab and is not retained as a parameter of the inserted object.

The slopline is the position of the slab/roof slab baseline relative to its bottom face. The thickness offset in the style determines the distance between the baseline and the bottom face.

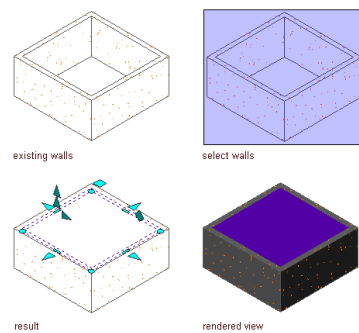

6 Specify the justification for edge alignment:

If you want to align the baseline edge of the slab/roof slab to the...	Then...
left side of the wall, based on the direction the wall was drawn	enter l (Left).
center of the wall	enter c (Center).
right side of the wall, based on the direction the wall was drawn	enter r (Right).
baseline of the wall	enter b (Baseline).

7 To specify the slope direction, enter **l** (Left) or **r** (Right).

This is based on the direction the wall was drawn.

Creating a slab based on walls

8 Edit the properties of the slab/roof slab in the Properties palette, if needed.

Creating a Roof Slab from a Roof

Use this procedure to convert the faces of an existing roof object to individual roof slabs that have the properties of the roof slab tool you select. You can then edit the roof slabs and their edges individually.

You can also convert a roof to roof slabs through its context menu. For more information, see [Converting a Roof to Roof Slabs](#) on page 1594.

TIP When you convert a roof to roof slabs, the roof slabs will have the same overhang as the roof.

- 1 Open the tool palette that contains the roof slab tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click the tool, and click Apply Tool Properties to ► Linework, Walls and Roof.
- 3 Select the roof to convert, and press *ENTER*.
- 4 When prompted to erase the original geometry, press *ENTER* to keep the existing roof, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the roof slabs on the Properties palette, if needed.

Creating a Slab or Roof Slab from a Polyline

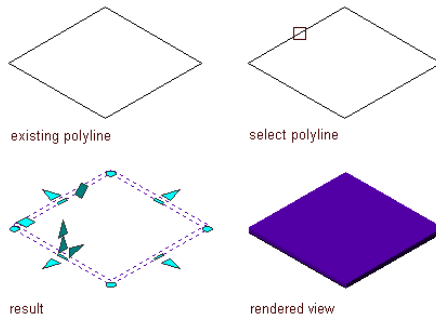

Use this procedure to convert a closed polyline to a single slab or roof slab that has the properties of the tool you select. You can edit these properties after the object is created. The first line drawn in the polyline becomes the baseline edge of the slab/roof slab.

Creating slabs or roof slabs from polylines is useful when you need to create a complex shape or one with curved edges. The smoothness (tessellation) of curved edges is controlled by 2 AEC display resolution settings called Facet Deviation and Facet Maximum. Beginning with Autodesk Architectural Desktop 2007, you can adjust these settings after the slab/roof slab is created. Also, the individual segments or facets making up a curved edge are no longer treated as separate edges; each arc on the perimeter of a slab/roof slab is treated as a single edge. For more information, see [Specifying the Display Resolution of Objects with Facets](#) on page 169.

- 1 Draw a closed polyline of the desired shape in the location where you want to place the slab/roof slab.
- 2 Open the tool palette that contains the slab or roof slab tool you want to use.
(You may have to scroll to display the desired tool.)
- 3 Right-click the tool, and click Apply Tool Properties to ► Linework and Walls (or Linework, Walls and Roof, in the case of roof slab tools).
- 4 Select a closed polyline, and press *ENTER*.
- 5 Enter *y* (Yes) to erase the polyline, or *n* (No) to keep the polyline in the drawing.
- 6 Specify a mode:

If you enter **d** (Direct), the polyline vertices become the vertices of the slab/roof slab perimeter. Any slope value specified in the tool properties is ignored.

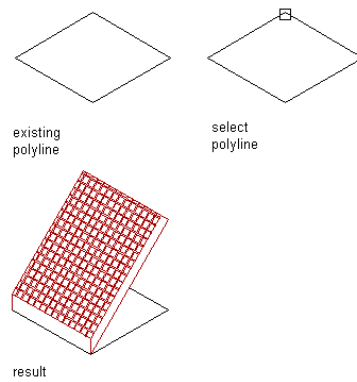

Converting a polyline to a slab using the direct mode

Converting a polyline to a roof slab using direct mode

Converting a polyline to a roof slab using direct mode and adding a slope angle

If you enter **p** (Projected), you are prompted for the base height of the slab/roof slab. The X, Y coordinates of the first polyline vertex are projected to a Z value of the base height. This establishes the insertion point.

Converting a polyline to a slab using the projected mode

7 If you specified Projected mode, enter a value for Base Height.

8 Specify a justification method:

If you want to align the slab/roof slab...

Then...

top with the polyline (or base height, when using projected mode)

enter **t** (Top).

center with the polyline (or base height, when using projected mode)

enter **c** (Center).

bottom with the polyline (or base height, when using projected mode)

enter **b** (Bottom).

sloped with the polyline (or base height, when using projected mode)

enter **s** (Sloped).

NOTE This justification is used only for inserting a slab/roof slab and is not retained as a parameter of the inserted object.

9 Edit the properties of the slab/roof slab in the Properties palette, if needed. For example, you can add a slope angle.

Creating a Slab from a Space

Use this procedure to convert a space to a slab that has the properties of the slab tool you select. You can edit these properties after creating the slab. If there is an interference condition on any of the selected spaces, you can specify whether you want these applied as holes in the new slab.

NOTE This procedure is currently available for slab tools only.

- 1 Open the tool palette that contains the tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click the tool, and click Apply Tool Properties to ► Space.
- 3 Select one or more spaces, and press *ENTER* to open the Convert Space to Slab worksheet.

- 4 If you want to create a slab from the ceiling of the space, select Convert Ceiling to Slab.
- 5 If you want to create a slab from the floor of the space, select Convert Floor to Slab.
- 6 If you want interference conditions on any of the spaces you selected to be ignored, clear Apply Interferences to Slab.
- 7 Select Erase Layout Geometry to erase the space.
- 8 Click OK.
- 9 Edit the properties of the new slab in the Properties palette, if needed.

Creating a Slab or Roof Slab Tool

Use this procedure to create a slab tool or a roof slab tool and add it to a tool palette. You may want to create your own tools if you are placing multiple slabs/roof slabs of specific styles that have the same properties.

For example, you are creating an office building that has a complex roof system. Although all sections of pitched roof use the same roof slab and edge style, each roof slab has a different slope. To work efficiently, you can create a roof slab tool for each slope, and select the appropriate tool to place the roof slabs with the correct slope for each section of the roof.

You can use any of the following methods to create a slab/roof slab tool:

- Drag a slab/roof slab that has the properties you want to a tool palette.
- Drag a slab/roof slab style from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Copy an existing slab/roof slab tool, and then customize the properties of the new tool.
- Drag a slab/roof slab tool from a tool catalog in the Content Browser, and then customize the properties of the tool.

1 Open the tool palette on which you want to create a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a slab/roof slab in the drawing	select the slab/roof, and drag it to the tool palette. TIP Drag the slab/roof slab by a point on its perimeter, not by one of its grips.
create a tool from a slab/roof slab style in the Style Manager	click Format menu ► Style Manager, locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool on the current palette	right-click the tool, click Copy, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tool's tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Enter a description of the tool.

8 If you do not want to use the default layer key, select a layer key.

9 If you want to override the default layer names, select a layer override.

10 Select a slab/roof slab style.

11 For Style location, select the drawing file containing the style to be used for this tool, or select Browse and use a standard file selection dialog box to select the file.

12 Specify a value for Bound Spaces:

If you want to...	Then...
allow the slab/roof slab to be used as a bounding object for associative spaces	select Yes.
prevent the slab/roof slab from being used as a bounding object for associative spaces	select No.
use the bounding settings from the slab or roof slab style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

13 Select Projected or Direct for Mode.

14 Expand Dimensions.

15 Enter a value for Thickness.

16 Enter a value for the vertical offset distance from the insertion point for Vertical Offset.

17 Enter a value for the horizontal offset distance from the insertion point for Horizontal Offset.

18 Select the justification:

If you want to align the ...	Then...
top of the slab/roof slab with the first specified point	select Top.
center of the slab/roof slab with the first specified point	select Center.
bottom of the slab/roof slab with the first specified point	select Bottom.
sloped line of the slab/roof slab with the first specified point	select Sloped.

NOTE This justification is used only when inserting the slab and is not retained as a parameter of the slab. Justification is intended primarily for Direct mode.

The sloped line is the position of the slab/roof slab baseline relative to its bottom face. The thickness offset in the style determines the distance between the baseline and the bottom face.

19 Select a direction, or define how the slab/roof slab is drawn relative to the baseline.

20 Enter a value for the depth of the overhang for Overhang.

21 Select a style for Perimeter edge.

22 For Edge style location, select the drawing file containing the edge style used for slabs created with this tool, or select Browse and use a standard file selection dialog box to select the file.

23 Click OK.

Editing Slabs and Roof Slabs

After placing a slab or roof slab object, you can change its style, location, size, shape, slope, edge styles, and other characteristics. You can miter its edges and trim or extend it using another object as a reference. You can also modify slabs and roof slabs using other objects as interference conditions or body modifiers.

Depending on the type of editing you want to perform, various methods may be available:

- After selecting a slab or roof slab, you can click any non-grip point along the perimeter and drag the entire object to a new location. You can also move the object by clicking a grip, pressing the Space bar, and then moving the object to the new location and clicking again.
- You can drag the grips that are displayed on a selected slab/roof slab to reorient it, resize it, or change other physical characteristics.
- For grip edits where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of dragging a grip. (This feature is activated by default; you can toggle it on and off by clicking DYN on the application status bar. For more information, see [Dynamic Dimensions](#) on page 101.)
- You can apply the properties of a slab tool to an existing slab or the properties of a roof slab tool to an existing roof slab.

- You can change settings on the object's Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- You can use editing commands from the object's context menu.

Using Grips to Edit Slabs/Roof Slabs

Various types of editing grips are displayed for a selected slab or roof slab object. You can drag these grips as needed to reposition or resize the object, or you can enter precise distance or angle values using the Dynamic Input feature. When you select a grip that has multiple functions, you can cycle among them by pressing *Ctrl*.

The types of editing grips available for a selected slab or roof slab depend on the view direction. As shown in the following illustrations, Edge, Edge Overhang, Vertex, and Pivot Point grips are displayed in both plan and three-dimensional (3D) isometric views. Angle, Vertical Offset, Horizontal Offset, and Thickness grips are available only in 3D isometric views.

Slab Vertex and Edge grips

Slab Edge Overhang and Pivot Point grips

Slab Angle, Thickness, Horizontal Offset, and Vertical Offset grips

Roof Slab Vertex and Edge grips

Roof Slab Edge Overhang and Pivot Point grips

Roof Slab Angle, Thickness, Horizontal Offset, and Vertical Offset grips

Using Slab/Roof Slab Edge Grips

Edge grips let you change the size, shape, or slope of a selected slab or roof slab by moving one edge at a time. When you move the cursor over an Edge grip, a tooltip lists the available edit modes (see mode descriptions following the procedure below). After you click the Edge grip, you can cycle through the modes by pressing *Ctrl*.

Use the following general procedure to select an Edge grip mode and edit an edge of a slab/roof slab:

- 1 Select the slab/roof slab you want to edit.
Edge grips are displayed.
- 2 Move the cursor over the Edge grip on the edge you want to edit.
The list of available edit modes is displayed. (Modes differ for straight and curved edges; see descriptions below.)
- 3 Click the Edge grip, and move the cursor slightly in the direction that you want to move the edge. If you want to use the default edit mode, proceed to the next step; otherwise, press *Ctrl* to cycle through the edit modes to the one you want.
- 4 Either enter values as needed to specify a distance or position, or move the cursor until the preview is in the desired position, and then click to complete the edit and deselect the grip.
- 5 Press *Esc*, or right-click, and click Deselect All to deselect the slab and turn off all grips.
Normal grip editing maintains the slope angle of the slab/roof slab regardless of the Z value of the specified point.

NOTE The pivot point is unaffected by editing the slab/roof slab edges with grips.

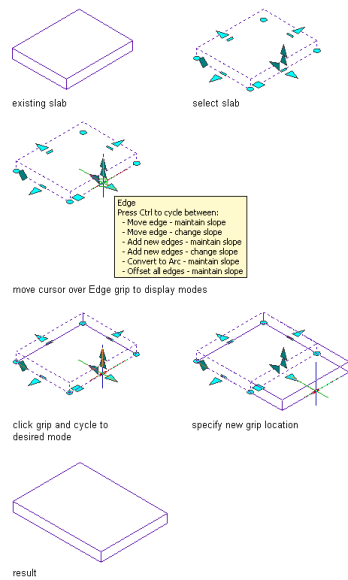

Edit Modes for Straight Edges

Edge grips for straight slab or roof slab edges have the following 6 edit modes:

- Move edge - maintain slope
- Move edge - change slope
- Add new edges - maintain slope
- Add new edges - change slope
- Convert to arc - maintain slope
- Offset all edges - maintain slope

Move edge - maintain slope

As you move the edge, adjacent edges stretch or shorten accordingly with no change to the slope. This is the default mode for straight edges.

Move edge - change slope

As you move the edge, adjacent edges stretch or shorten according to the direction of the move, and the slope changes as necessary to maintain the elevation of the edge being moved.

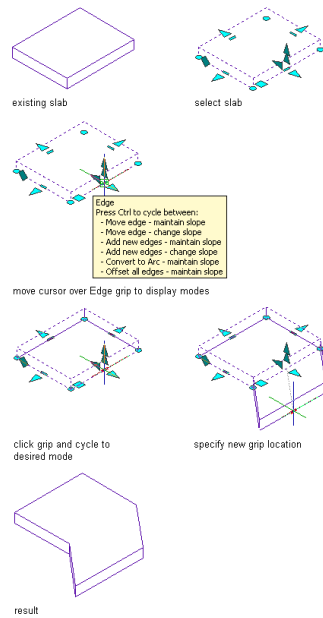

Side view

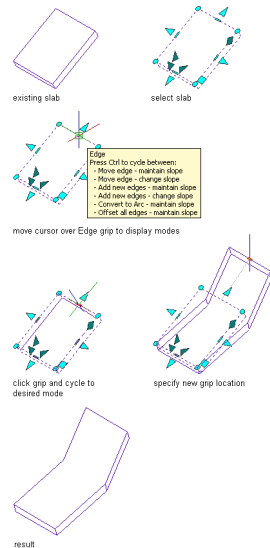

Add new edges - maintain slope

As you move the edge outward, rather than adjacent edges being stretched, new edges are added, each with its own Edge and Edge Overhang grips. There is no change to the slope.

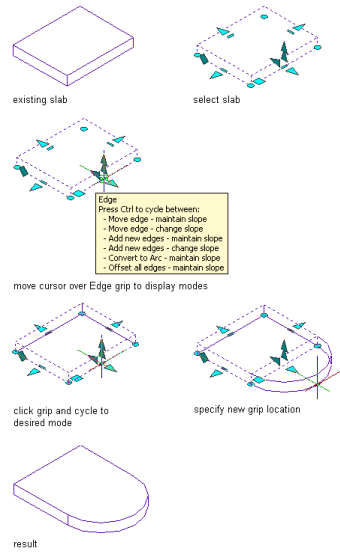

Add new edges - change slope

As you move the edge outward, rather than adjacent edges being stretched, new edges are added, each with its own Edge and Edge Overhang grips. The slope changes as necessary to maintain the elevation of the edge being moved.

Convert to arc - maintain slope

Converts the edge to an arc, which you can move inward or outward in the current plane to specify the arc direction and degree. Adjacent edges are not affected.

Offset all edges - maintain slope

All outside perimeter edges move inward or outward in the current plane the same distance as you move the selected Edge grip. The degree of arc is maintained. If holes have been added to the slab/roof slab, their edges are unaffected.

Edge Grip Edit Modes for Curved Edges

For curved edges (whether originally created as such, or converted from a straight edge using the Convert to arc mode listed above), the Edge grip has 5 modes, none of which change the slope:

- Stretch edge - maintain slope
- Move edge - maintain slope
- Add new edges - maintain slope
- Convert to line - maintain slope
- Offset all edges - maintain slope

Stretch edge - maintain slope

Move the Edge grip inward or outward in the current plane to reposition the midpoint of the arc. Adjacent edges are not affected. This is the default mode for curved edges.

Move edge - maintain slope

As you move the edge Grip inward or outward in the current plane, adjacent edges stretch or shorten according to the direction of the move. The distance between the endpoints of the arc changes, but the degree of arc is maintained.

Add new edges - maintain slope

As you move the edge Grip outward in its current plane, rather than adjacent edges being stretched or reoriented, new edges are added, each with its own Edge and Edge Overhang grips. The degree of arc and the distance between the arc endpoints are both maintained.

Covert to line - maintain slope

When you click, the curved edge is converted to a straight line between the endpoints of the arc. Adjacent edges are not affected.

Offset all edges - maintain slope

All outside perimeter edges move inward or outward in the current plane the same distance as you move the selected Edge grip. The degree of arc is maintained. If holes have been added to the slab/roof slab, their edges are unaffected.

Using Slab/Roof Slab Edge Overhang Grips

Use this procedure to change the overhang of a slab or roof slab edge. (You can also change the overhang using the worksheet available from the object's Properties palette or its context menu. For more information, see [Changing the Edges of a Slab/Roof Slab](#) on page 1633.)

- 1 Select the slab or roof slab.
- 2 Select an Edge Overhang grip.
- 3 Enter a value to specify the desired overhang distance, or move the grip until the desired value is displayed.

Changing the edge overhang of a slab using the Edge Overhang grip

Using Slab/Roof Slab Vertex Grips

Use this procedure to change the size or shape of a slab or roof slab by moving one or more of its vertices.

- 1 Select the slab or roof slab.

- 2 Select the Vertex grip for the vertex you want to move (or press *Shift* while selecting multiple Vertex grips).
- 3 Move the vertex to the desired location, and click. Adjacent edges stretch or shorten accordingly. If you have Shift-selected multiple Vertex grips, drag one of them to the desired location, and click; any other selected Vertex grip also moves, maintaining its position relative to the grip you drag.
- 4 Changing the perimeter of a slab by moving a Vertex grip

Using Slab/Roof Slab Thickness Grips

Use this procedure to change the thickness of a slab or roof slab in a 3D isometric view. (To change the thickness of multiple objects at once, regardless of the type of view, see [Changing the Thickness of a Slab/Roof Slab](#) on page 1629.)

- 1 Select the slab/roof slab.
- 2 Select the Thickness grip.
- 3 Enter a value to specify the desired thickness, or move the cursor until the desired value is displayed, and then click.

Changing the thickness of a slab using the Thickness grip

Using Slab/Roof Slab Offset Grips

Use this procedure to change the vertical and horizontal offsets of a slab or roof slab object in a 3D isometric view. (To change the horizontal or vertical offsets of multiple objects at once, regardless of the type of view, see [Changing the Offsets of a Slab/Roof Slab](#) on page 1630.)

The offsets are the vertical and horizontal distances from the insertion point of the slab.

- 1 Select the slab.
- 2 Select the Vertical Offset or Horizontal Offset grip.
- 3 Enter a value to specify the desired offset distance, or move the cursor until the desired value is displayed, and then click.

Changing the horizontal offset of a slab using the Horizontal Offset grip

existing slab

select slab

select Horizontal Offset grip

verify initial grip location

specify new grip location

result

Changing the vertical offset of a slab using the Vertical Offset grip

Using Slab/Roof Slab Angle Grips

Use this procedure to change the slope of a slab or roof slab in a 3D isometric view. (You can also use the Properties palette to adjust the slope and control the automatic alignment of the fascia. For more information, see [Changing Slab/Roof Slab Slope Settings](#) on page 1630).

- 1 Select the slab.
- 2 Select the Angle grip. If Dynamic Input is turned on, the associated Slope, Rise, and Run values are displayed in the drawing area.

IMPORTANT The Angle grip is available only when you select a slab/roof slab in a 3D isometric view.

Using the Angle grip to edit slab slope

existing slab

select slab

move cursor over Angle grip

verify initial grip location

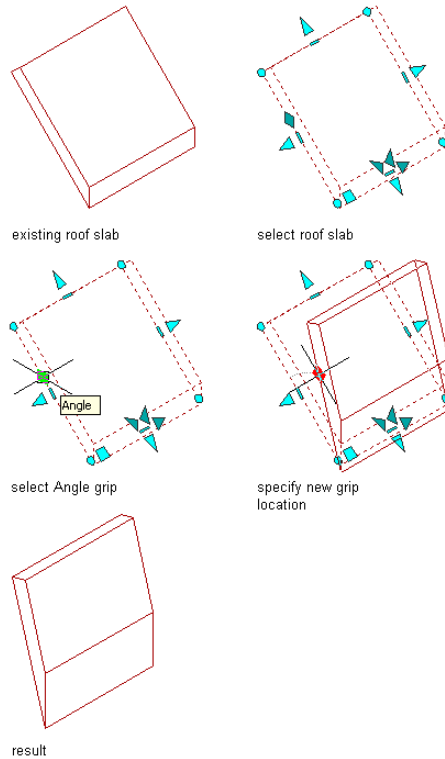

specify new grip location

result

Using the Angle grip to edit roof slab slope

3 Adjust the slope:

If you want to...

Then...

adjust the slope manually

either enter a value, or move the grip until the desired angle is displayed, and then click.

adjust the slope by changing the rise of the slab

press **TAB** until the rise value is highlighted, and then either enter a value, or move the grip until the desired rise is displayed, and then click.

4 Click once.

Using Slab/Roof Slab Pivot Point Grips

Use this procedure to change the pivot point of a slab or roof slab. (You can also use the Properties palette to change the *X*, *Y*, and *Z* values of the pivot point.)

By default, the pivot point is the first vertex of the baseline. However, you can move the pivot point to any other point, either on or off the slab/roof slab.

NOTE If a Hold fascia elevation constraint was set for the object, the pivot point is ignored. For information about setting this option, see [Changing Slab/Roof Slab Slope Settings](#) on page 1630.

1 Select the slab or roof slab.

2 Select the Pivot Point grip.

- 3 Move the cursor until the pivot point is in the desired location, and then click.

Applying Tool Properties to an Existing Slab/Roof Slab

Use this procedure to modify one or more slabs or roof slabs by applying the properties of a slab or roof slab tool. The properties include the style and any other settings specified in the tool you select.

- 1 Open the tool palette that contains the slab or roof slab tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click the tool, and click Apply Tool Properties to ► Slab or Apply Tool Properties to ► Roof Slab.
- 3 Select the slabs or roof slabs to be modified, and press *ENTER*.
- 4 Edit the properties of the modified slabs/roof slabs in the Properties palette, if necessary.

Changing the Properties of Slabs or Roof Slabs

Many of the slab/roof slab properties that you can edit using grips can also be edited on the Properties palette. In cases where multiple selected objects have the same value for a property, you can change the value for all the objects with a single entry on the Properties palette. The Properties palette also provides access to the Slab Edges and Roof Slab Edges worksheets, and enables you to attach hyperlinks, notes, or files to slabs/roof slabs.

Changing the Style of Slabs/Roof Slabs

Use this procedure to change the style for one or more slabs or for one or more roof slabs in a drawing. Note that the procedure cannot be applied to slabs and roof slabs simultaneously.

- 1 Select one or more slabs/roof slabs, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand General.
If the selected objects are of different styles, the value of the Style property is *VARIES*.
- 3 For Style, select a new style from the drop-down list.
The selected style is assigned to all selected objects.

Changing the Thickness of a Slab/Roof Slab

Use this procedure to change the thickness of a slab/roof slab for which the Base Thickness (BT) variable is used to define the Thickness value in the object style. If the style specifies a fixed thickness for the slab/roof slab (or for any component of a multi-component slab/roof slab), then the Thickness value on the Properties palette is read-only and can only be changed by editing the style or applying a different style. For more information on using the BT variable, see [Specifying the Thickness and Offset of a Slab/Roof Slab Component](#) on page 1657.

- 1 Select the slab/roof slab you want to change.
- 2 On the Properties palette, expand Basic, and expand Dimensions.
- 3 Click the Thickness value, and enter a new value.

Changing the Offsets of a Slab/Roof Slab

Use this procedure to change the vertical or horizontal offset of a slab or roof slab. The offsets are the vertical and horizontal distances from the insertion point of the slab/roof slab.

- 1 Double-click the slab/roof slab you want to change.
- 2 On the Properties palette, expand Basic, and expand Dimensions.
- 3 Click the Vertical offset or Horizontal offset value, and enter a new value.

Changing Slab/Roof Slab Edges

Use this procedure to access the Slab Edges or Roof Slab Edges worksheet from the Properties palette.

- 1 Double-click the slab/roof slab whose edge(s) you want to change.
- 2 On the Properties palette, expand Basic, and expand Dimensions.
- 3 Click  next to Edges.

The Slab Edges and Roof Slab Edges worksheets are identical in function to the Edit Slab Edges and Edit Roof Slab Edges worksheets accessed from the slab/roof slab context menu. For more information on using these worksheets, see [Changing the Edges of a Slab/Roof Slab](#) on page 1633

Changing Slab/Roof Slab Slope Settings

Use this procedure to change the slope settings of a slab or roof slab, and to specify whether the fascia is to be aligned when the slope is changed.

You can also control the adjustment of the overhang or baseline height of the slab. This constraint applies only to the baseline edge, and it works only when the baseline is horizontal.

- 1 Double-click the slab you want to change.
- 2 On the Properties palette, expand Dimensions, and expand Slope.
- 3 Enter a value for Rise, Run, or Angle to define the slope.
- 4 Select a setting for Hold fascia elevation:

If you want to...	Then...
force the fascia to align with other slab/roof slab fascias, regardless of style, by adjusting the overhang	select By adjusting overhang.
force the fascia to align with other slab/roof slab fascias, regardless of style, by adjusting the baseline height	select By adjusting baseline height.
ignore fascia alignment	select No.

Changing the Location of a Slab/Roof Slab

Use this procedure to relocate a slab or roof slab by changing the coordinate values of its insertion point. The slab/roof slab object also has an orientation with respect to the WCS or the current UCS. For example,

if the top and bottom of the object are parallel to the *XY* plane, the object's normal is parallel to the *Z* axis. You can change the orientation of the object by aligning its normal with another axis. You can also rotate the object on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see "Use Coordinates and Coordinate Systems" in AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic referenced in AutoCAD Architecture Help is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

1 Double-click the slab or roof slab you want to move.

2 Expand Basic, and expand Location.

3 Click Additional Information.

4 Specify the location of the slab/roof slab:

If you want to...	Then...
relocate the slab/roof slab	enter new coordinate values under Insertion Point.
locate the slab/roof slab on the <i>XY</i> plane	make the normal of the slab/roof slab parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the slab/roof slab on the <i>YZ</i> plane	make the normal of the slab/roof slab parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the slab/roof slab on the <i>XZ</i> plane	make the normal of the slab/roof slab parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the slab/roof slab	enter a new value for Rotation Angle.

5 Click OK.

Specifying the Cut Plane Display of a Slab or Roof Slab

Use this procedure to specify the properties of one or more cut planes for an individual slab or roof slab. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

1 Double-click the slab or roof slab you want to change.

2 On the Properties palette, click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all slabs/roof slabs in the drawing, select Drawing default setting. To apply changes to all slabs/roof slabs of this style, select Slab/Roof Slab Style:<style name>. For more information on styles, see [Slab and Roof Slab Styles](#) on page 1652.

5 If necessary, expand Object Display Properties ► Cut Plane.

- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object. Or, click , and specify 2 points in the drawing area to define the new height.)

You can also access and modify these same cut plane settings through the slab's or roof slab's context menu, as follows:

- 1 Select the slab/roof slab you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.
- 5 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Slab/Roof Slab

Use this procedure to attach hyperlinks, enter notes, or attach reference files to a slab or roof slab. You can also edit existing notes and edit or detach currently attached reference files.

- 1 Double-click the slab or roof slab to which to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
- 4 To add or edit a note, click  next to Notes, enter text, and click OK.
- 5 To attach, detach, or edit a reference, click  next to Reference documents, and then do any of the following:

If you want to...	Then...
attach a reference file	click  , select a file, and click Open.
edit the description of a reference file	enter text under Description.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

- 6 Click OK.

Using Slab and Roof Slab Context Menu Tools

In addition to grip-editing slabs and roof slabs, or changing values on their Properties palettes, you can edit these objects using the tools available on their context menus. These tools let you trim, extend, and cut an

object, edit its edges, add and edit interference conditions and body modifiers, and edit the object display properties.

Changing the Edges of a Slab/Roof Slab

Use this procedure to edit one or more edges of a slab or roof slab. For each selected edge, you can change the overhang, style, cut (square or plumb), and angle. A viewer box shows you which edge(s) of the slab you are editing.

- 1 Select the slab or roof slab to be modified, right-click, and click Edit Slab Edges or Edit Roof Slab Edges.
- 2 Select the edges to be modified, and press *ENTER*.
- 3 In the Edit Slab Edges/Roof Slab Edges worksheet, in the list of edges, select the edge to edit. To modify multiple edges using the same values, press and hold *CTRL* while selecting each edge.

NOTE Beginning with Autodesk Architectural Desktop 2007, the individual segments or facets making up a curved edge are no longer listed as separate edges on this worksheet. Each arc on the perimeter of a slab/roof slab is treated as a single edge.

The selected edges are highlighted in the viewer in the right pane of the worksheet.

- 4 Enter a value for Overhang.
- 5 Select a slab edge style.
- 6 Select Square or Plumb for Edge Cut.
- 7 Enter a value for Angle.
To reset the angle to the slab/roof slab style defaults, right-click the edge number, and click Reset to Style Defaults. This option is available only if an edge style has been assigned, and the value for Angle is different than the default.
- 8 If desired, select additional edges from the list and edit them as described above.
- 9 When edits are completed for all edges, click OK.

Trimming a Slab/Roof Slab

Use this procedure to trim a slab or roof slab using a polyline, wall, roof slab, or slab to define the trim plane. The trimming object itself does not need to intersect the slab/roof slab, as long as it projects an intersection in the current user coordinate system (UCS). However, the trim plane must intersect the slab/roof slab perimeter line; you cannot trim only the overhang.

Any fascia or soffit profile that intersects the trim plane is trimmed at the same angle as the slab/roof slab.

If the trimming object is a wall or a slab, the trim plane is at the closest surface. The new edge at the trim plane has its edge angle defined by the trim plane.

Trimming a slab to a wall

existing slab and wall

select slab

select trimming object

specify side to trim

result

Trimming a roof slab to a wall

existing roof slab and wall segments

select roof slab

select trimming object

specify side to be trimmed

result

- 1 Select the slab/roof slab to be trimmed, right-click, and click Trim.
- 2 Select a wall, a polyline, or another slab or roof slab for the trimming object.
- 3 Select the side of the slab/roof slab to be trimmed.

Extending a Slab/Roof Slab

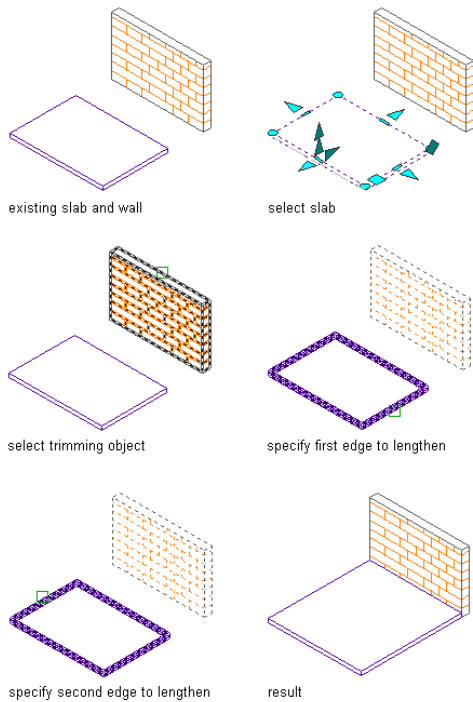

Use this procedure to extend a slab or roof slab to a plane defined by another slab, roof slab, or wall. This target object itself does not have to intersect with the extended slab/roof slab, as long as it projects an intersection in the current user coordinate system (UCS).

Because multiple edges may need to move in an extend operation, you are prompted to select the adjacent edges to lengthen, rather than the specific edges to move. These selected edges retain their current vector (angle) and are stretched until they intersect the plane of the target object.

If multiple edges exist between the selected edges, they are joined to form a single edge. The new edge is set to the angle of the target surface.

Any fascia or soffit profile on the adjacent edges is extended to the target surface and trimmed to its angle.

Extending a slab to a wall

Extending a roof slab to a wall

- 1 Select the slab or roof slab to be extended, right-click, and click Extend.
- 2 Select the target wall, slab, or roof slab to which the slab/roof slab is to be extended.
- 3 Select the slab/roof slab to be extended.
- 4 Select the first edge to lengthen.
- 5 Select the second edge to lengthen.

NOTE You cannot use curved walls as objects to lengthen a slab or roof slab to.

Mitering Slabs/Roof Slabs by Intersection

Use this procedure to miter 2 intersecting slabs or roof slabs. Both slabs or roof slabs are trimmed along the intersection of their perimeter lines. Vertices are added or removed as required. The new edges of the slabs or roof slabs are set to angles required for a true miter cut. If the slab thicknesses of the two edges are different, the angles are different.

If you want to miter slabs or roof slabs that do not intersect, you can miter them by edges. For more information, see [Mitering Roof Slabs Using Edges](#) on page 1637

Mitering roof slabs by intersection

- 1 Select one of the two slabs or roof slabs you want to miter, right-click, and click Miter.
- 2 Enter **i** (Intersection) to miter at the intersection of the two slabs or roof slabs.
- 3 Select the first roof slab at the side of that slab to keep.
The opposite side is trimmed.
- 4 Select the second roof slab at the side of that slab to keep.
The opposite side is trimmed.

Mitering Roof Slabs Using Edges

Use this procedure to miter two roof slabs that do not intersect. You can select particular edges to miter. You can miter edges of overlapping roof slabs without trimming the entire slab. To accomplish this, however, you may need to insert additional vertices. Only one edge of each roof slab is mitered.

If you need to miter multiple edges of a roof slab, stretch them to overlap the other roof slab and then miter them at their intersection. For more information, see [Mitering Slabs/Roof Slabs by Intersection](#) on page 1636.

Mitering roof slabs by edge

- 1 Select one of the two roof slabs you want to miter, right-click, and click Miter.
- 2 Enter **e** (Edges) to miter selected edges of the roof slabs.
- 3 Select one edge on the first roof slab.
- 4 Select one edge on the second roof slab.

Cutting a Slab/Roof Slab

Use this procedure to cut a slab or roof slab into two or more slabs/roof slabs. You can use any 3D object or polyline to define the cutting geometry. If you use a 3D body, such as a wall, slab, mass element, or closed polyline, the slab/roof slab is cut along the intersection lines of the surfaces.

The slab/roof slab is cut only when the 3D body or closed polyline intersects its perimeter line. If you use an open polyline, the slab/roof slab is cut along the projection to its surface.

In either case, when the intersection line crosses the slab/roof slab multiple times, multiple slabs/roof slabs are created. If the intersection line has multiple edges, multiple edges are added to the new objects.

The smoothness (tessellation) of curved edges is controlled by 2 AEC display resolution settings called Facet Deviation and Facet Maximum. Beginning with Autodesk Architectural Desktop 2007, you can adjust these settings after the slab/roof slab is created. Also, the individual segments or facets making up a curved edge are no longer treated as separate edges; each arc on the perimeter of a slab/roof slab is treated as a single edge. For more information, see [Specifying the Display Resolution of Objects with Facets](#) on page 169.

- 1 Draw an object or polyline for defining the cutting geometry.
- 2 Select the slab or roof slab to be cut, right-click, and click Cut.
- 3 Select the objects or polylines that represent the cutting geometry, and press *ENTER*.
- 4 Enter **n** (No) to keep the geometry, or enter **y** (Yes) to erase the geometry.

Adding a Vertex to a Slab/Roof Slab

Use this procedure to add a vertex to a slab or roof slab edge. Adding a vertex creates two edges from one edge.

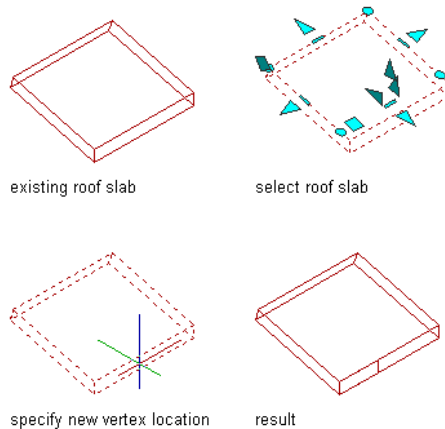

1 Select a slab or roof slab, right-click, and click Add Vertex.

2 Specify a point for the new vertex.

To place a new vertex at a precise intersection point, use Intersection or Apparent Intersection object snaps.

The new vertex is added to the nearest edge, perpendicular to the specified point. If there is no point perpendicular to the slab/roof slab, no vertex is added.

Adding a vertex to a roof slab

3 To see the new vertex, select the slab/roof slab.

A new Vertex grip is displayed at the point you specified, and new grips are displayed for the edge that has been added.

Deleting a Vertex from a Slab/Roof Slab

Use this procedure to delete a vertex from a slab or roof slab. After the vertex is deleted, the 2 adjacent vertices connect in a straight line.

1 Select the slab or roof slab, right-click, and click Remove Vertex.

2 Select the vertex to remove.

Adding a Hole to a Slab/Roof Slab

Use this procedure to add a hole to a slab or roof slab. The hole adds new vertices and edges, which you can edit as you do other slab/roof slab vertices and edges.

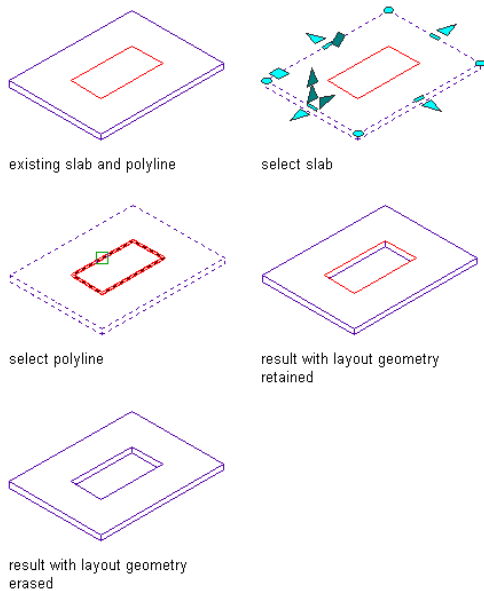

You can use polylines or three-dimensional (3D) objects, such as walls and mass elements, to create the hole.

- Holes generated by a closed polyline are projected from the polyline to the slab/roof slab, using the current user coordinate system (UCS).
- 3D objects must intersect the slab/roof slab without any projection.

If the objects contain an interior void, you are prompted to use the inside or outside surface to create the hole. For example, if you create a chimney using four wall objects, you can cut the hole at the inside or outside of the chimney. The new hole faces are aligned with the surfaces of the cutting bodies, and are not necessarily parallel to each other.

The smoothness (tessellation) of curved edges is controlled by 2 AEC display resolution settings called Facet Deviation and Facet Maximum. Beginning with Autodesk Architectural Desktop 2007, you can adjust these settings after the slab/roof slab is created. Also, the individual segments or facets making up a curved edge are no longer treated as separate edges; each arc on the perimeter of a slab/roof slab is treated as a single edge. For more information, see [Specifying the Display Resolution of Objects with Facets](#) on page 169.

Adding a hole to a slab

Adding a hole to a roof slab

- 1 Draw a closed polyline in the shape and location for the hole, or add an object in the location for the hole.
- 2 Select the slab or roof slab, right-click, and click Hole ► Add.
- 3 Select the closed polyline or the connected objects that define the hole, and press *ENTER*.
- 4 Enter *n* (No) to keep the geometry, or enter *y* (Yes) to erase the geometry.
- 5 If you select 3D objects, you are prompted to create the hole at the inside or outside surface of the cutting objects. Press *ENTER* to use the outside of the object to define the hole, or enter *i* (Inside) to use the inside or void of the object to define the hole. This prompt is displayed even if the bodies do not contain an inner void, in which case the Inside option does not create a hole.

NOTE If you create a hole that is outside or which overlaps the slab/roof slab baseline or perimeter line at an overhang, the body of the slab/roof slab is cut, but the fascia and soffit remain. In this case, it is better to create a hole by cutting the slab/roof slab. For more information, see [Cutting a Slab/Roof Slab](#) on page 1638.

Removing a Hole from a Slab/Roof Slab

Use this procedure to remove a hole from a slab or roof slab.

Removing a hole from a slab

- 1 Select the slab or roof slab, right-click, and click Hole ► Remove.
- 2 Select any edge of the hole to remove.

Creating Slab/Roof Slab Interference Conditions

Just as you can use another object to define the perimeter of a hole you want to add to a slab or a roof slab, you can also modify the geometry of a slab/roof slab by using another object to create an interference condition within the slab/roof slab. Unlike the object used to add a hole, which has no connection to the slab/roof slab and can be erased after the hole is added, the object used to create an interference condition remains partially or wholly embedded in the slab/roof slab, cutting out and replacing a part of its geometry. All interference conditions are subtractive in this sense, but the shrinkwrap effect option you use to create the interference condition (Additive or Subtractive) determines whether the outline of the interference condition is included in or excluded from the shrink wrap outline of the slab/roof slab in plan view.

Typically, after creating interference conditions for a slab/roof slab, you freeze the layer where the interfering objects are placed. If you move or edit the objects, the slab/roof slab updates accordingly.

NOTE Objects used as interference conditions are not included for the Area in the LIST command or in a Schedule Query result.

Use the following procedure to create either additive or subtractive interference conditions for a slab or roof slab. If you want to create both additive and subtractive interference conditions, you need to perform the procedure separately for each type.

- 1 Create one or more objects in the actual location where you want the interference condition positioned in relation to the slab/roof slab.
- 2 Select the slab/roof slab.
- 3 Right-click, and click Interference Condition ► Add.
- 4 Select the objects to use as interference conditions, and press *ENTER*.

NOTE AEC objects from externally referenced (xref) files can be added to a slab/roof slab as interference conditions so long as the following conditions are met:

- The object is a three-dimensional (3D) body
 - The xref is found
 - The xref is read/write
 - The xref is not locked or opened by another user
 - The xref is loaded
-

5 Specify the desired shrinkwrap effect:

If you want to...	Then...
include the interference condition(s) within the shrink wrap outline in plan view	enter a (Additive).
exclude the interference condition(s) from the shrink wrap outline in plan view	enter s (Subtractive).

The selected objects are added to the slab/roof slab as either additive or subtractive interference conditions. You can delete an interference condition or change its shrinkwrap effect using the Interference Conditions worksheet, which is accessed from the Properties palette for the slab/roof slab.

Removing Slab/Roof Slab Interference Conditions

Use this procedure to remove an interference condition from a slab or roof slab. Note that only the interference condition is removed; the object from which the interference condition was created remains in the drawing.

- 1 Select the slab/roof slab, right-click, and click Interference Condition ► Remove.
- 2 Select the objects to remove as interference conditions, and press *ENTER*.

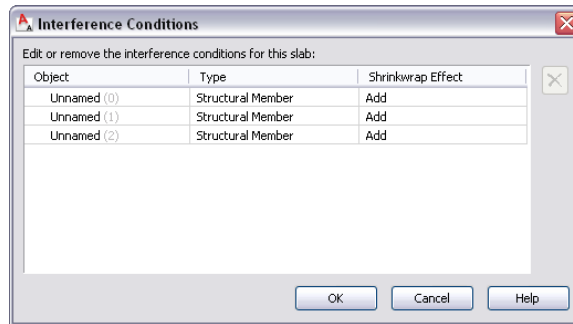

NOTE You can also remove interference conditions through the Interference Conditions worksheet. For more information, see [Editing Slab/Roof Slab Interference Conditions](#) on page 1642.

Editing Slab/Roof Slab Interference Conditions

Objects applied as interference conditions in slabs and roof slabs can be edited like any other objects, using grips, context menu options, or the Properties palette. If you move or edit the objects, the slab/roof slab updates accordingly. You can also change the setting that determines whether an interference condition is added to or subtracted from the shrink wrap outline of the slab/roof slab in plan view by using the following procedure.

- 1 Select the slab or roof slab, right-click, and click Properties.

2 On the Properties palette, under Advanced, click the value for Interferences.

3 On the Interference Conditions worksheet, click the Shrinkwrap Effect value you want to change, and select a different value from the pull-down menu.

4 Click OK.

NOTE You can also use this worksheet to remove an interference condition by right-clicking its Object or Type value and then clicking Remove. The alternate method is to use the context menu of the slab/roof slab, as explained under [Removing Slab/Roof Slab Interference Conditions](#) on page 1642. When you remove an interference condition, you remove the association between the slab or roof slab and the object that was used to create the interference condition. The object itself is not removed from the drawing.

Creating Slab/Roof Slab Body Modifiers

Like interference conditions, body modifiers let you modify the geometry of a slab or roof slab by incorporating another three-dimensional (3D) object. However, where interference conditions always subtract from the mass of a slab/roof slab and affect only components that they touch, body modifiers can be used to add to, subtract from, or completely replace a specific component. If a slab/roof slab has only one component, then the body modifier applies to the entire slab/roof slab.

You can create a body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

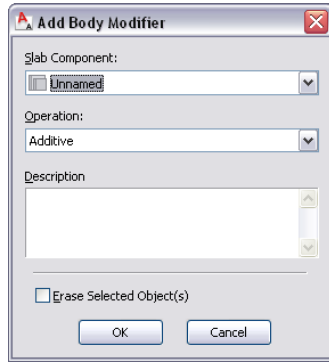

After you create a body modifier from an object, you can delete the original object. However, if you have created a complex object, such as a mass group comprising many mass elements, you may want to retain the object in the drawing until you are sure you have the results you want for the slab/roof slab.

NOTE Objects used as interference conditions are not included for the Area in the LIST command or in a Schedule Query result.

To create a body modifier for a slab or roof slab:

- 1 Create one or more objects in the location where you want the body modifier positioned in relation to the slab/roof slab.
- 2 Select to slab/roof slab you want to modify, right-click, and click Body Modifiers ► Add.

3 Select the objects to be applied as body modifiers, and press *ENTER*.

4 On the Add Body Modifier worksheet, specify the following:

- For Slab Component (or Roof Slab Component), select the component to which you want the body modifier applied.
- For Operation, select Additive, Subtractive, or Replace, depending on whether you want the body modifier added to the selected component, subtracted from it, or used to replace the entire component.
- For Description, enter a text description of the body modifier(s) you are applying.

5 If you do not want the outline of the object(s) to be visible in the drawing, select Erase Selected Object(s).

6 Click OK.

Editing a Slab/Roof Slab Body Modifier in Place

Use this procedure to edit the shape of a body modifier that is attached to a slab or a roof slab. You can edit the body using grips to edit faces, using Boolean commands to add or remove other objects from the body modifier, and other editing commands to change its shape.

1 Select the slab or roof slab that has the body modifier you want to change, right-click, and click Body Modifiers ► Edit In Place.

A temporary mass element is created for you to edit the geometry of the body modifier. If the slab/roof slab contains multiple body modifiers, a mass element is created for each body modifier. If an object was not originally a mass element (for example, if you used a structural member as a body modifier), the object becomes a temporary Free Form mass element with faces that you can edit.

2 **NOTE** After you perform an editing task from the context menu, you may need to select a profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select a profile, and right-click to display the context menu.

Edit the body modifier:

If you want to ...

Then ...

change the shape of a body modifier that is a Free Form mass element

select the body modifier. Select a Face grip to activate edge grips for the face. Move the grips to the desired locations. Continue editing other faces in the same manner.

If you want to ...	Then ...
change the shape of a body modifier that is a conventional mass element	select the body modifier. Select grips and move them to change the shape of the body modifier. The grips that are available depend on the type of mass element used as a body modifier and the current view direction.
add an object to a body modifier	place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Union. Select the object, and press <i>ENTER</i> . Enter <i>y</i> (Yes) to keep the object in the drawing, or press <i>ENTER</i> to erase it.
subtract an object from a body modifier	place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Subtract. Select the object, and press <i>ENTER</i> . Enter <i>y</i> (Yes) to keep the object in the drawing, or press <i>ENTER</i> to erase it.
create a body modifier that is the intersection of the original body modifier with another object	place the object in the location where it is needed. Select the body modifier, right-click, and click Boolean ► Intersect. Select the object, and press <i>ENTER</i> . Enter <i>y</i> (Yes) to keep the object in the drawing, or press <i>ENTER</i> to erase it.
trim a body modifier	select the body modifier, right-click, and click Trim. Specify the points that define the trim plane, and select the side of the body modifier to be trimmed. The trimmed body modifier is converted to a Free Form mass element.
divide the face of a body modifier into two faces	select the body modifier, right-click, and click Split Face. Specify the points that define the edge created by splitting the faces.
join two faces that are on the same plane into a single face	select the body modifier, right-click, and click Join Faces. Select the edge that separates the coplanar faces.
remove a body modifier	select the object that forms the body modifier, and press <i>DELETE</i> .
3 Save or discard the changes:	
If you want to ...	Then ...
restore the body modifier to its original shape	select the body modifier, and click  .

If you want to ...**Then ...**

save the changes to the body modifier

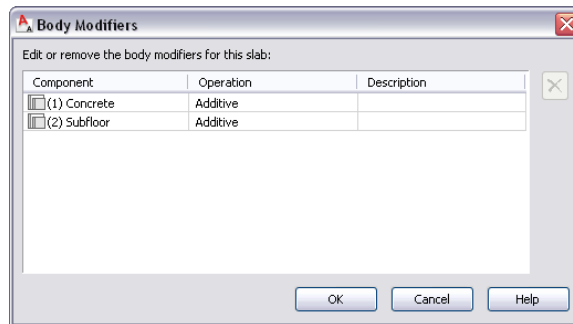

select the body modifier, and click . The body modifier uses the edited mass element to define its geometry.

Managing Slab/Roof Slab Body Modifiers

Use this procedure to edit or remove three-dimensional (3D) body modifiers from a slab or a roof slab. You can change the component to which the body modifier is applied or the way it is applied (whether it adds to, subtracts from, or replaces the selected component). You can also enter or edit the descriptions of body modifiers.

NOTE To remove a body modifier from a slab/roof slab component and restore the modifier as a mass element that you can edit or apply to other slabs/roof slabs, see [Restoring a Slab/Roof Slab Body Modifier to a Mass Element](#) on page 1647.

- 1 Double-click the slab or roof slab you want to change.
- 2 On the Properties palette, under Advanced, click the value for Body Modifiers.

- 3 Select a body modifier, and change its settings:

If you want to ...**Then ...**

apply the body modifier to a different slab/roof slab component

select a different component for Component.

change the operation used to apply the body modifier to the slab/roof slab component

select a different operation for Operation:

- Select Additive to add the body modifier to the component.
- Select Subtract to subtract the shape of the body modifier from the component.
- Select Replace to replace the component with the body modifier.

delete the body modifier from the slab/roof slab component

select the body modifier, and click , or right-click, and click Remove.

If you want to ...	Then ...
enter a description of the body modifier	click Description, enter text, and press <i>ENTER</i> .

4 Click OK.

Restoring a Slab/Roof Slab Body Modifier to a Mass Element

Use this procedure to remove a body modifier from a slab or a roof slab and add it to the drawing as a mass element. Restoring a body modifier to a mass element enables you to modify the shape as a mass element and then add it to the slab/roof slab again as a body modifier. You can also restore the body modifier to a mass element while leaving the body modifier still applied to the slab/roof slab. This is useful if you want to create other slabs/roof slabs with the same shape.

If the object used to create the body modifier was a conventional mass element, it is restored to that mass element. For example, a Gable mass element is restored as a Gable mass element. However, if the body modifier was created from another object, such as a structural member, or was edited using Boolean operations or face editing commands, the body modifier is restored as a Free Form mass element.

1 Select the slab or roof slab you want to change, right-click, and click Body Modifiers ► Restore.

2 **NOTE** This procedure restores all body modifiers attached to a slab/roof slab.

Create mass elements from the body modifiers:

If you want to ...	Then ...
create mass elements from the body modifiers while keeping the body modifiers attached to the slab/roof slab	press <i>ENTER</i> .
remove <i>all</i> body modifiers from the slab/roof slab, and create mass elements from their shapes	enter <i>y</i> (Yes), and press <i>ENTER</i> .

Specifying the Material of a Slab/Roof Slab

Use this procedure to select a different material for components of an individual slab or roof slab.

To change the materials assigned to all slabs/roof slabs of the same style, see [Specifying the Materials of a Slab or Roof Slab Style](#) on page 1659.

NOTE If a material assignment does not determine the display properties of the component, you can change the properties of the display component as described in [Specifying the Display Properties of a Slab/Roof Slab](#) on page 1648.

1 Select the slab or roof slab you want to change, right-click, and click Edit Object Display.

2 To verify that the material assignment determines the display properties of the component, click the Display Properties tab, select the display representation on which to display the changes,

and click  .

3 Click the Layer/Color/Linetype tab, verify that By Material is selected for the component, and click OK.

4 Click the Materials tab.

5 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING When you edit a material definition from this dialog box, any changes you make will apply to all objects that are assigned the material.

6 Click OK.

Specifying the Display Properties of a Slab/Roof Slab

Use this procedure to change the following properties of the display components of an individual slab or roof slab:

- Visibility (display component is on or off)
- By Material (material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

To change these display properties for all slabs/roof slabs of the same style, see [Specifying the Display Properties of a Slab or Roof Slab Style](#) on page 1661.

NOTE If a material assignment determines the display properties of a component, you can change the properties by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Material of a Slab/Roof Slab](#) on page 1647.

1 Select the slab or roof slab you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 Click the Layer/Color/Linetype tab.

5 Select the component to change, and select a different setting for the property.

6 Click OK twice.

Specifying the Hatching of a Slab/Roof Slab

Use this procedure to specify the hatching of the components of a slab or roof slab. Hatching is displayed only in display representations that are used in the Top view (plan view) of a drawing.

To change the hatching for all slabs/roof slabs of the same style, see [Specifying the Hatching of a Slab/Roof Slab Style](#) on page 1663.

NOTE If a material assignment determines the hatching properties of a slab display component, you can change the hatching of the display component by clearing By Material or by overriding the material assignment with a different material. For more information, see [Specifying the Material of a Slab/Roof Slab](#) on page 1647.

- 1 Select the slab or roof slab you want to change, right-click, and click Edit Object Display.

NOTE You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

- 2 On the Display Properties tab, select the display representation for which you want to change a property, and select Style Override.

- 3 If necessary, click .

- 4 On the Hatching tab, select the display component, and click the setting for Pattern.

- 5 Select the hatching for the display component:

If you want to...	Then...
specify a hatching pattern that is available in the software	select Predefined for Type, and select a pattern.
specify a custom pattern	select Custom for Type, and enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
specify single hatching	select User-Defined for Type, and clear Double Hatch.
specify double hatching	select User-Defined for Type, and select Double Hatch.
specify solid fill	select Solid Fill for Type.

- 6 Click OK.

- 7 Click the setting for Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

- 8 Click the setting for Angle, and enter the angle for the selected pattern.

- 9 Click the setting for Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the slab/roof slab, regardless of its rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

- 10 Click the setting for X Offset, and enter an offset value.
- 11 Click the setting for Y Offset, and enter an offset value.
- 12 Click OK twice.

Specifying the Cut Plane Height of a Slab/Roof Slab

Use this procedure to specify the cut plane height of a slab or roof slab.

If the value you specify for the cut plane height is greater than zero, you must specify the layer, color, and linetype for the elements above and below the cut plane height. This is especially important for slabs/roof slabs with interference conditions or body modifiers.

To change the cut plane height for all slabs/roof slabs of the same style, see [Specifying the Cut Plane Height of a Slab/Roof Slab Style](#) on page 1664.

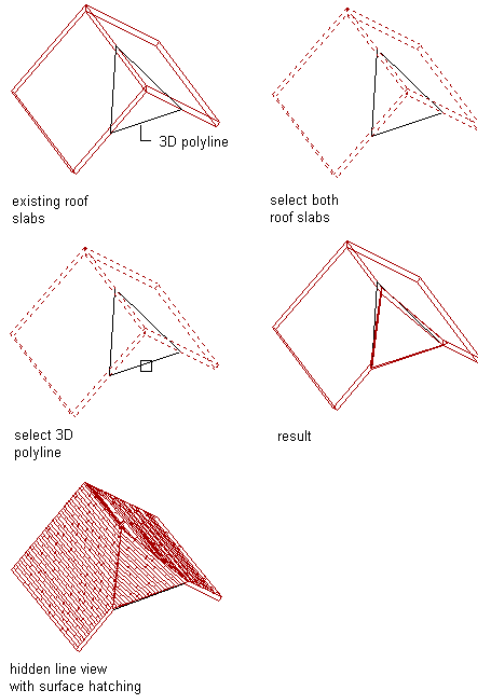

- 1 Select the slab or roof slab you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 Click the Other tab.
- 5 Select Override Display Configuration Cut Plane, and enter a value for Cut Plane Height.
- 6 Click OK twice.

Creating a Clipped Gable Roof

Use this procedure to modify two roof slabs to add a third slab, creating a clipped gable roof.

- 1 Create a gable roof with two roof slabs.
- 2 In an isometric view, draw a 3D polyline in the shape and location of the clipped roof slab.
- 3 Enter **roofslab**.
- 4 Enter **e** (Edit).
- 5 Enter **x** (Xcut).
- 6 Select the two roof slabs and press *ENTER*.
- 7 Select the 3D polyline and press *ENTER* twice.

Creating a clipped gable roof

NOTE You can edit the outside edge of the new roof slab to change it from square to plumb. For more information, see [Changing Slab/Roof Slab Edges](#) on page 1630.

Creating a Dormer in a Roof Slab

Use this procedure to add a dormer to a roof slab. You must first create the roof slabs, walls, and all other parts of the dormer, so that an appropriate hole can be cut in the roof slab. The walls you create for the dormer must include a back segment, so that a complete hole for the dormer can be cut in the roof slab.

Adding a dormer to a roof slab

- 1 Create the walls for the dormer, including a closing rear wall.
- 2 Open the tool palette that contains the roof slab tool you want to use.
(You may have to scroll to display the desired tool.)
- 3 Right-click the tool, and click Apply Tool Properties to ► Linework, Walls and Roof.
- 4 Select the walls, and press *ENTER*.
- 5 Miter the roof slab edges as required.
- 6 Move the structure so that the walls and roof slabs of the dormer fully penetrate the existing roof slab in the correct position.
- 7 Select the roof slab to add the dormer to, right-click, and click Roof Dormer.
- 8 Select the objects that form the dormer, and press *ENTER*.
- 9 When prompted to slice the walls with the roof slab, press *ENTER* to slice the walls, or enter **n** (No) to leave the walls as they are.
- 10 Erase the wall at the rear of the dormer.

Slab and Roof Slab Styles

A slab or roof slab style is a set of parameters that determines the appearance and other characteristics of the slab or roof slab object to which it is assigned. By editing a style, you can control the properties of all objects that use that style, without having to change the properties of each such object in a drawing. For slabs and roof slabs, the style controls the following properties:

- default dimensions, including thickness
- default edge conditions, including fascia and soffit styles

- default display properties, including fascia and soffit
- physical components (concrete, metal deck, and so on)
- materials assigned to components of slabs

The default slab and roof slab tools provided with the software use standard styles. You can use these as provided, edit the standard styles in the Style Manager, or create your own styles and use them to make new tools.

Using Materials in Slab/Roof Slab Styles

You can control how slabs/roof slabs of a particular style are displayed in a drawing by assigning materials to the slab/roof slab components in the style. The components are then displayed using the display properties of the assigned materials. For more information see [Material Components and Display Properties](#) on page 610.

AutoCAD Architecture provides predefined materials for common design purposes. You can use these materials as provided, modify them to meet your project requirements, or define new materials. For more information about materials and how to define them, see [Creating and Editing Material Definitions](#) on page 624 and [Specifying the Material of a Slab/Roof Slab](#) on page 1647.

Creating Tools from Slab/Roof Slab Styles

You can create a slab or roof slab tool from a slab or roof slab style by dragging the style from the Style Manager onto a tool palette. The default settings provided by the style are then applied to any object created with that tool. For more information, see [Using Tools to Create Slabs and Roof Slabs](#) on page 1602.

Managing Slab/Roof Slab Styles

To create, copy, edit, or purge styles for slabs and roof slabs, you use the Style Manager, which you can access from the Format menu or from the Properties palette for slab/roof slab tools or objects. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information, see [Style Manager](#) on page 589.

Creating a Slab or Roof Slab Style

Use this procedure to create a slab or roof slab style. You can start by using the default properties of the standard style, or you can copy an existing style to use as your template. You then edit the style properties to customize the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Styles or Roof Slab Styles.
- 3 Create a style:

If you want to...	Then ...
create a style with default properties	right-click Slab/Roof Slab Styles, and click New.
create a style from an existing style	right-click the slab/roof slab style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new style, and press *ENTER*.

5 To specify or edit the properties of the new style, use the tabs on the right pane of the Style Manager as described in the following table.

If you want to ...	Then ...
enter a description of the style	click the General tab, and enter a description.
specify the physical components of the slab/roof slab	see Specifying the Components of a Slab or Roof Slab Style on page 1654.
specify either a fixed or variable thickness or offset for the slab/roof slab or its components	see Specifying the Thickness and Offset of a Slab/Roof Slab Component on page 1657.
assign materials to the display components of the style	see Assigning Materials to a Slab/Roof Slab Style on page 1660 and Turning on Materials for a Slab/Roof Slab Style on page 1662.
add classifications to the style	see Adding Classifications to a Slab or Roof Slab Style on page 1664.
specify hatching, cut plane properties, and other display properties of the style	see Specifying the Display Properties of a Slab or Roof Slab Style on page 1661.
add notes and files to the style	see Attaching Notes and Files to a Slab or Roof Slab Style on page 1665.

6 If you want to create a tool that uses the new style, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Slab or Roof Slab Tool](#) on page 1611.

7 Click OK.

Specifying the Components of a Slab or Roof Slab Style

Slab or roof slab components are the physical structures of the slab/roof slab, such as concrete, metal deck, insulation, and so on.

Slab/Roof Slab Components and Their Properties

Each component in a slab or roof slab style corresponds to a structural component or material of a slab/roof slab. When you create a component, you specify values for the following properties of the component:

- **Name** (generally identifies the material used, such as concrete, metal deck, or insulation)
- **Thickness** (analogous to the Width property of a wall component; can be a fixed value or a variable)
- **Thickness Offset** (specifies the position of the component within the slab/roof slab, relative to the slab/roof slab baseline or to adjacent slab/roof slab components; can be a fixed value or a variable)

Using Components from Other Slab/Roof Slab Styles

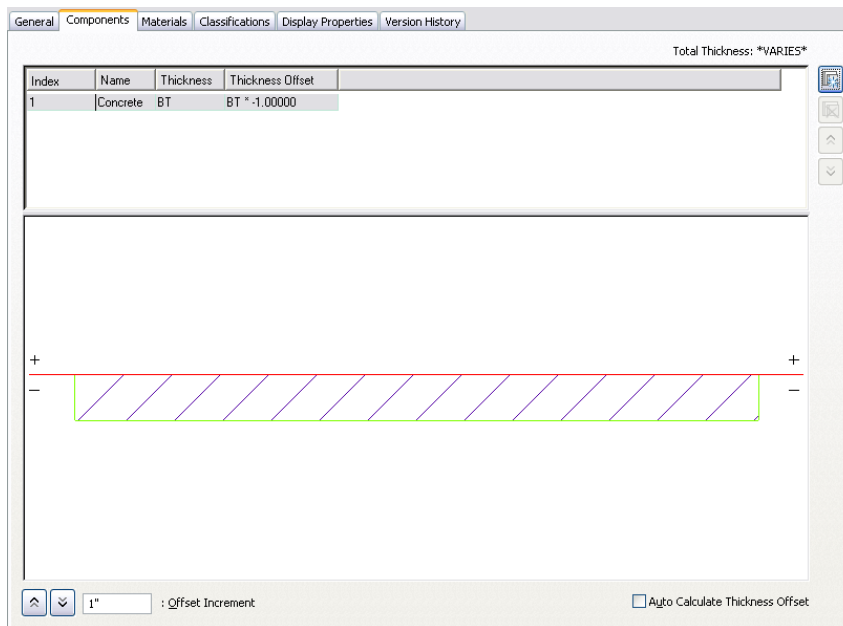

In addition to creating new components from scratch within a slab or roof slab style, you can also paste in components you have copied from a different style of the same type. That is, you can paste components from one slab style into another slab style, or components from one roof slab style into another roof slab style.

Components Tab

Use the Components tab of the Style Manager for the following tasks:

- Add or remove slab/roof slab components and edit their properties.
- View the components as you create and configure them.
- Change the order of components relative to other components in the style.

Specifying the properties of slab components

Creating or Editing a Component in a Slab/Roof Slab Style

Use this procedure to create a slab or roof slab component, or to edit existing components in a slab/roof slab style.

You can also add components to a style by pasting in components you have copied from other styles of the same type.

TIP Only the first 20 components of a slab/roof slab style are controlled by the display system. It is suggested that you limit the number of components to 20, since any additional components would be controlled by material assignment only.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.

3 Select the style that you want to change.

4 Click the Components tab.

5 To add a new component, click .

If no existing component was selected, the new component is assigned an Index number of 2, but otherwise has the same values as the first component in the list. If an existing component was selected, the new component is a duplicate of the selected component, except that its Index number is 1 higher. In either case, you can edit the properties of the new component as described in the following steps.

6 To edit the name of a selected component, click in the Name column, and enter a new name.

7 To specify the thickness of a component, double-click its Thickness value, and then do one of the following:

If you want to ...

Then ...

specify a fixed thickness that cannot be edited when you add or edit objects of this style

enter a new value for Thickness.

specify a variable thickness based on a Base Thickness (BT) value that can be determined when you add or edit objects of this style

click  to display text boxes that let you specify a formula that defines how the Base Thickness variable is used to calculate component thickness. For more information, see [Specifying the Thickness and Offset of a Slab/Roof Slab Component](#) on page 1657.

8 To specify the offset distance between the component and the slab/roof slab baseline, double-click the Thickness Offset value for the component, and then do one of the following:

If you want to ...

Then ...

move the component up or down by a specified increment

click  or  in the lower-left corner of the Components tab to offset the component by the Offset Increment value that you specify. The selected component is highlighted in green in the viewer.

let the software calculate the offset

select Auto Calculate Thickness Offset.

specify a fixed offset

enter a value for Thickness Offset.

specify a variable offset that is calculated from values that you specify

click  in the Thickness Offset column to display text boxes that let you specify a formula that defines how the Base Thickness variable is used to calculate component thickness. For more information, see [Specifying the Thickness and Offset of a Slab/Roof Slab Component](#) on page 1657.

9 Repeat steps 5 through 8 to add more components to the style.

- 10 To change the order of components in the style, select a component, and click  or  at the upper-right side of the tab to move the component to the desired position relative to the other components.

The Index numbers update to reflect the new order.

- 11 Click OK.

Adding a Component from Another Slab or Roof Slab Style

Use this procedure to copy a slab/roof slab component from one style and add it to another style of the same type that you are creating or editing.

TIP Only the first 20 components of a slab/roof slab style are controlled by the display system. It is suggested that you limit the number of components to 20, since any additional components would be controlled by material assignment only.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style that contains the component you want to copy:

If you want to ...	Then ...
--------------------	----------

view the components for a style in the current drawing

in the left pane of the Style Manager, select a style. The right pane lists the components and their properties and displays the style in the viewer.

view the components for a style in another drawing

click , navigate to the drawing you want, click Open, and then select a style in the left pane of the Style Manager.

- 4 On the Components tab for the selected style, right-click the desired component, and click Copy.
- 5 In the left pane of the Style Manager, select the style to which you want to add the component:
- 6 Move the cursor onto the Components tab, right-click, and click Paste.

You can now edit or delete the new components as needed. For more information, see [Creating or Editing a Component in a Slab/Roof Slab Style](#) on page 1655 and [Removing a Component from a Slab/Roof Slab Style](#) on page 1659.

- 7 Click OK to save the style with the new component.

Specifying the Thickness and Offset of a Slab/Roof Slab Component

When you create or edit a slab or roof slab component in a style, you can enter values that establish a fixed thickness and a fixed offset from the slab/roof slab baseline. If all the components in a slab/roof slab style use these fixed values, then you cannot change the thickness for an object of that style when you add one to a drawing. (The Thickness value on the Properties palette is read-only, and no Thickness grip is available on the object itself.)

Specifying slab component offsets

Alternatively, when you specify the Thickness or Thickness Offset values for a slab/roof slab component, you can use a variable called Base Thickness (BT), which has a default value of 4" but can be changed at the time you add the slab/roof slab to a drawing or subsequently, either through the Properties palette or by grip editing. You can use the Base Thickness variable by itself, or as part of a formula that will be used to calculate the component thickness or offset.

For example, if you want to create a style in which a 2" paving component is positioned directly above a paving base of variable thickness whose bottom edge is the same as the slab baseline, you would specify the Thickness and Thickness Offset values as follows:

Index	Name	Thickness	Thickness Offset
1	Paving	2"	BT
2	Paving B...	BT	0"

For more complicated positioning relationships involving the Base Thickness variable, you can construct formulas for calculating the Thickness and Thickness Offset values. For example, if you know you want .5" rebar to be positioned in the middle of a concrete layer with a fixed thickness of 6", you might configure the components in the slab style as follows:

Index	Name	Thickness	Thickness Offset
1	Concrete	6"	0"
2	Rebar	1/2"	2 3/4"

However, if you want the rebar to be positioned in the middle of the concrete component, regardless of its thickness, you can configure the components as follows, where the concrete thickness is specified as a variable (BT), and the offset of the rebar component is specified as one half of the concrete thickness, whatever that may be, minus half the thickness of the rebar (1/4").

Index	Name	Thickness	Thickness Offset
1	Concrete	BT	0"
2	Rebar	1/2"	-1/4"+ BT / 2.00000

To specify a formula using the Base Thickness variable, click the Thickness or Thickness Offset value for the

component, and then click  to display the text boxes for the formula as shown.

The formula can be as simple as the one shown, in which only the Base Thickness is used, or it can specify a value to be added to the Base Thickness, or a further mathematical operation involving the Base Thickness. (Note that the operation drop-down menu and the operand box at the far right are only available if Base

Thickness is selected.) In the case of the 1/2" rebar positioned in the middle of a variable thickness concrete slab, the formula for the rebar Thickness Offset would be constructed as follows:

After you have entered the desired formula, press *Enter* to dismiss the text boxes and transfer the formula to the Thickness or Thickness Offset value for the selected component.

Removing a Component from a Slab/Roof Slab Style

Use this procedure to delete a component from a slab or roof slab style. When you remove a component from a style, the component is also removed from all existing objects that use that style.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style that you want to change.
- 4 Click the Components tab.
- 5 Select the slab/roof slab component you want to remove, and click .
- 6 Click OK.

Specifying the Materials of a Slab or Roof Slab Style

A slab or roof slab object consists of a number of components whose display properties can be determined by the materials assigned to them.

You assign one material to each display component of the object. For example, you might assign a floor tile material to a slab body and a concrete material to a slab edge.

If you want to use the display properties of a slab/roof slab object or style, instead of using material display properties, you can turn off the material assignments in the display properties of the object or its style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in Plan view. The Surface Hatch component of a material is used to hatch all object surfaces in 3D model views and elevations.

For a complete list of material components and their description, see [Material Components and Display Properties](#) on page 610.

Roof slabs with assigned materials

Slab/Roof Slab Materials and Display Components

The following table identifies the material component that corresponds to each slab/roof slab component.

Display Representations	Slab/Roof Slab Display Component	Material Display Component
Plan, Plan High Detail, Plan Low Detail, Reflected Plan, Screened	Below Cut Plane Body Shrinkwrap	
	Above Cut Plane Body Shrinkwrap	None
	Below Cut Plane Outline	None
	Above Cut Plane Outline	None
	Cut Plane Shrinkwrap	None
	Cut Plane Shrinkwrap Hatch	None
	Boundary	Plan Linework
	Hatch	Plan Hatch
	Baseline	None
	Fascia	Plan Linework
	Soffit	Plan Linework
	Pivot Point	None
	Model	Baseline
Slab		3D Body
Fascia		3D Body
Soffit		3D Body
Pivot Point		None

Assigning Materials to a Slab/Roof Slab Style

Use this procedure to assign materials to the individual components of a slab or roof slab style. The components will then use the display properties of the materials instead of the style display properties.

You can assign a material to any physical component of the slab/roof slab. Custom components and components that are only symbolic do not use materials for their display properties. For example, the slab/roof slab body is a physical component, while the pivot point is a symbolic component.

NOTE Although fascias and soffits are physical components of slabs/roof slabs, they are defined in the slab or roof slab edge style, and not in the slab or roof slab style. For information on assigning materials to edge styles, see [Assigning Materials to a Slab/Roof Slab Edge Style](#) on page 1674.

NOTE If a material assignment does not determine the display properties of a slab/roof slab component, you can change the display properties of the style as described in [Specifying the Display Properties of a Slab or Roof Slab Style](#) on page 1661.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click the Materials tab.
- 10 Click the component you want to change, click its current material definition, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Any changes you make to the material definition in this dialog will apply to all objects that are assigned the material.

- 11 Click OK.

Specifying the Display Properties of a Slab or Roof Slab Style

In most cases, you want the appearance of slabs or roof slabs that use the same style to be consistent throughout a drawing. To achieve this, you specify the following display properties in each style:

- The layer, color, and linetype of slab/roof slab components
- The hatching used for the surface of the slab/roof slab in plan views
- The cut plane height

Components with display properties include dimensions for slab/roof slab thickness, edge conditions for the fascia and soffit, line work, cut planes, cut lines, 3D shading factors, baseline, and pivot point. The display properties of the fascia and soffit are also controlled by the slab or roof slab style, although the geometry of these components is controlled through edge styles.

You can also use materials to control the display properties of the physical components of a slab/roof slab. Symbolic components, such as the pivot point, are not controlled by materials. For more information about using materials in slabs and roof slabs, see [Specifying the Materials of a Slab or Roof Slab Style](#) on page 1659.

Specifying the Layer, Color, and Linetype of a Slab/Roof Slab Style

Use this procedure to change the following display properties for display components of a slab or roof slab style:

- Visibility (component is on or off)
- By material (material assigned to the display component determines its display properties)
- Layer
- Color
- Linetype
- Lineweight
- Linetype Scale

NOTE If a material assignment determines the properties of components in the slab/roof slab style, you can change the properties of the display component by clearing By Material, or by overriding the material assignment with a different material. For more information, see [Assigning Materials to a Slab/Roof Slab Style](#) on page 1660.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK.

Turning on Materials for a Slab/Roof Slab Style

Use this procedure to turn on material assignments for individual display representations in a slab or roof slab style.

For more information about using materials to control the display of slab/roof slab components, see [Specifying the Materials of a Slab or Roof Slab Style](#) on page 1659.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click .

7 Click the Layer/Color/Linetype tab.

8 Select By Material for each component to be controlled by the material. The By Material check box is unavailable for components that cannot be assigned a material.

When you select By Material for a display component, all other settings in the dialog box are unavailable. Since the display properties are now taken from the material definition, you can no longer set them directly in the display properties of the slab/roof slab style.

9 Click OK.

Specifying the Hatching of a Slab/Roof Slab Style

Use this procedure to specify the hatching of a slab or roof slab style. Hatching is displayed only in display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

1 Open a tool palette that has a slab or roof slab tool.

2 Right-click the tool, and click Slab Styles or Roof Slab Styles.

3 Select the style you want to edit.

4 Click the Display Properties tab.

5 Select the display representation in which to display the changes, and select Style Override.

6 If necessary, click  .

7 Click the Hatching tab.

8 Click the setting for Pattern.

9 Select the hatching pattern:

If you want to...	Then...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and then clear Double Hatch.
select double hatching	select User-defined for Type, and then select Double Hatch.
select solid fill	select Solid Fill for Type.

10 Click OK.

11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

12 Click Angle, and enter the angle for the selected pattern.

13 Click Orientation, and specify how the hatching is to be oriented:

If you want to...	Then...
orient the hatching to the slab/roof slab, regardless of its rotation	select object.
orient the hatching to the World Coordinate System	select global.

14 Click OK twice.

Specifying the Cut Plane Height of a Slab/Roof Slab Style

Use this procedure to specify the cut plane height of a slab or roof slab style.

If the value you specify for the cut plane height is greater than zero, you must specify the layer, color, and linetype for the elements above and below the cut plane height. This is especially important when interference conditions or body modifiers are present.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.
- 6 If necessary, click .
- 7 Click the Other tab.
- 8 Select Override Display Configuration Cut Plane, and enter a value for Cut Plan Height.
- 9 Click OK twice.

Adding Classifications to a Slab or Roof Slab Style

Use this procedure to specify classifications for any classification definition applied to a slab or roof slab style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style you want to edit.
- 4 Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to slab/roof slab styles.
- 5 For each classification definition, select the classification you want to apply to the current style.
- 6 Click OK.

Defining a Slab/Roof Slab Style as Bounding for Associative Spaces

Use this procedure to define a slab or roof slab style that can bound associative spaces.

When a style is set as bounding, by default all objects of that style will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

By default, this setting is checked.

You can override the bounding setting for the style in an individual slab or roof slab if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Styles.
- 3 Select a slab style.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Slab or Roof Slab Style

Use this procedure to enter notes and attach reference files to a slab or roof slab style. You can also edit notes and edit or detach reference files from the style.

- 1 Open a tool palette that has a slab or roof slab tool.
- 2 Right-click the tool, and click Slab Styles or Roof Slab Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the style, enter it under Description.
- 6 Click Notes.
- 7 To add or edit a note, click the Notes tab, and enter the note or edits.
- 8 To attach, edit, or detach a reference file, click the Reference Docs tab:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Click OK when you are finished editing.
detach a reference file	select the file name, click Delete, and click OK.

- 9 Click OK.

Slab and Roof Slab Edge Styles

Slab and roof slab edge styles control the appearance of the edges of slab and roof slab objects. Using edge styles, you can specify dimensions, such as the overhang length, and the orientation and angle of the edges. You can also specify a fascia and soffit for the edge style.

Components of Slab/Roof Slab Edge Styles

The slab/roof slab edge style defines the appearance of slab/roof slab edges. Each style consists of two optional components: a fascia and a soffit.

A fascia is a shape applied to the outside face of a slab/roof slab edge. A soffit is a shape applied to the underside of an edge overhang.

You can create fascia and soffit components by defining profiles that provide the two-dimensional (2D) geometry of the component whose shape is then extruded along the slab/roof slab edge.

The fascia component follows the orientation of the slab edge (plumb or square cut). The soffit component, however, is always oriented to the horizontal. Either component can have a positive or negative angle, relative to its base orientation.

The +/- directions for edge component angles remain the same regardless of their orientation in the *XY* plane. They always follow the slab/roof slab slope, so that, for example, a +30° soffit and a +30° slab/roof slab would be parallel to each other. Similarly, a +10° (plumb cut) fascia and a -10° soffit would meet at a right angle. Mirroring a slab/roof slab maintains the same angle signs for all components.

Controlling the Placement of the Fascia and Soffit on Slab/Roof Slab Edges

The fascia profile is drawn at actual size, except when you select Auto-Adjust. If the slab/roof slab edge is sloped relative to the ground plane, then the length is measured parallel to that slope, and not plumb with the ground. When you select Auto-Adjust to Edge Height, the fascia profile is scaled about its insertion point so that its lowest *Y* axis point aligns with the bottom of the slab/roof slab edge.

NOTE Slope offsets are measured relative to the slab/roof slab edge angle from the ground plane, and not relative to the world UCS.

The soffit profile is drawn at actual size, except when you select Auto-Adjust. The soffit angle is measured about its insertion point, using the local *X* axis of the profile.

When you select Auto-Adjust to Overhang Depth, the soffit profile is scaled about the insertion point, so that the furthest *X* axis point aligns with a plumb line from the slab/roof slab baseline or perimeter line. Auto-Adjust scaling is adjusted by the horizontal offset from the baseline dimension.

Display Properties of the Fascia and Soffit

In most cases, you want the appearance of fascias or soffits that use the same edge style to be consistent throughout a drawing. To achieve this, you specify the following display properties in each slab/roof slab edge style:

- The layer, color, and linetype of slab/roof slab edge components
- The hatching used for the surface of slab/roof slab edges in plan views
- The cut plane height

Slab edge components with display properties include dimensions for slab thickness, fascia and soffit, vertical and horizontal offsets, line work, cut planes, cut lines, 3D shading factors, baseline, slab, and pivot point. The display properties of the fascia and soffit are also controlled by slab/roof slab style, although the geometry of these components is controlled through slab/roof slab edge styles.

Materials in Slab/Roof Slab Edges

You can assign materials to a slab or roof slab edge. These materials are then displayed in wireframe or rendered views. Materials have specific settings for individual components of a slab or roof slab edge, such as the fascia and soffit.

Viewing Slab Edge detail in 2D wireframe and rendered views

AutoCAD Architecture provides predefined materials for common design purposes. These materials contain settings for slabs and slab edges that you can use “as is” or modify for special designs. You can also create materials from scratch. For more information, see [Specifying the Materials of a Slab or Roof Slab Style](#) on page 1659.

Managing Slab/Roof Slab Edge Styles

To create, import, export, or edit styles, you use the Style Manager. The Style Manager provides a central location where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Creating a Slab or Roof Slab Edge Style

Use this procedure to create a new slab or roof slab edge style. You can start by using the default properties of the standard style, or you can copy an existing style to use as your template. You then edit the style properties to customize the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Edge Styles or Roof Slab Edge Styles.
- 3 Create a slab/roof slab edge style:

If you want to...	Then...
create a style with default properties	right-click Slab Edge Styles or Roof Slab Edge Styles, and click New.
create a style from an existing style	right-click the style you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the new style, and press *ENTER*.
- 5 To specify or edit the properties of the new style, use the tabs on the right pane of the Style Manager as described in the following table:

If you want to...	Then...
enter a description of the style	click the General tab, and enter a description.
specify the overhang, edge cut, and angle for the style	see Specifying the Overhang, Edge Cut, and Angle of a Slab/Roof Slab Edge Style on page 1668.

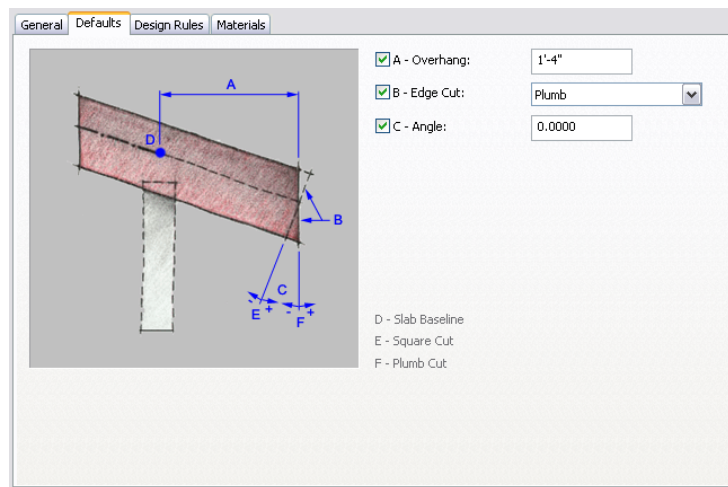

If you want to...	Then...
specify soffits and fascias for the style	see Specifying a Fascia and a Soffit for a Slab/Roof Slab Edge Style on page 1671.
assign materials to the display components of the style	see Assigning Materials to a Slab/Roof Slab Edge Style on page 1674.
turn on materials for the style	see Turning on Materials for a Slab/Roof Slab Edge Style on page 1674.
add notes and files to the style	see Attaching Notes and Files to a Slab/Roof Slab Edge Style on page 1675.

6 When you finish specifying the properties of the style, click OK twice.

Specifying the Overhang, Edge Cut, and Angle of a Slab/Roof Slab Edge Style

Use this procedure to specify the default overhang depth, edge cut, and edge angle for slab or roof slab edges using this edge style.

- 1 Select a slab or roof slab, right-click, and click Edit Slab Edge Style or Edit Roof Slab Edge Style.
- 2 Select an edge of the slab/roof slab.
- 3 Click the Defaults tab.

4 Specify the overhang, edge cut, and angle of the edge:

If you want to...	Then...
specify the overhang of the slab/roof slab	enter a value for Overhang.
specify the orientation of the edge cut	select a setting for Edge Cut: <ul style="list-style-type: none"> ■ Select Square to cut the edge 90 degrees with the plane of the slab/roof slab.

If you want to...

Then...

- Select Plumb to cut the edge perpendicular to the ground.

specify the angle of the edge

enter a value for Angle. A positive value moves the bottom of the edge out and a negative value moves the bottom of the edge in.

Specifying square and plumb edges

5 Click OK.

Creating Profiles for the Fascia and Soffit

Use this procedure to create a profile for the fascia and soffit.

The profile is made up of closed polylines. To represent solid fascia or soffits, such as a wood fascia, you can create a profile from a single polyline. To represent fascia or soffits that are extruded, such as aluminum soffits, you can create a profile from concentric polylines that can include one or more voids. The outer polyline, or ring, becomes the exposed shape, and the inner polyline, if used, becomes the void. You can create multiple voids by adding more inner closed polylines. The polylines are proportional in size and shape to each other and to the slab.

You can draw these polylines anywhere in the drawing and use any convenient scale relative to your final fascia or soffit size. One method for sizing the polylines relative to the slab/roof slab edge is to draw them by snapping to an existing fascia, and then move your completed polylines to an open area of the drawing to create the profile.

Assigning a profile as a fascia

Assigning a profile as a soffit

- 1 Draw closed or open polylines representing the fascia or soffit.
- 2 Select the polylines, right-click, and click Convert to ► Profile Definition.
- 3 Select the outermost polyline.
- 4 Enter **a** (Add ring) as needed.
- 5 Select an inner polyline as needed.
- 6 Repeat steps 3 and 4 as needed to add more voids to the profile.
- 7 Specify the insertion point for the fascia or soffit. (The insertion point is typically the lower-left corner.)
- 8 Enter **n** (New), enter a name for the profile, and click OK.

Controlling Profile Edges and Extrusion

Use this procedure to specify the following parameters for a profile:

- the position of each edge in a profile (left, right, back, discard, none)
- the axis along which an object is extruded from the shape of a profile

These settings determine how surface hatching is applied to objects created from the profile and how the objects are extruded from the two-dimensional (2D) profile.

NOTE Objects already created from the profile change when you change profile edges or the axis of extrusion.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand Profile Definition.
- 3 Select the profile you want to change.
- 4 Click the Profile Edges tab.
- 5 Select an edge, and specify its position:

If you want to...	Then...
let the software determine the position of edges	click Calculate Default Edge Positions. You can then override the position of individual edges, if necessary.
select a position for an edge	select the setting for Edge, and select a new position.
exclude an edge from surface hatching	select the setting for Edge, and select None.
discard an edge	select the setting for Edge, and select Discard.

6 Specify the axis of extrusion based on the type of object created from the profile:

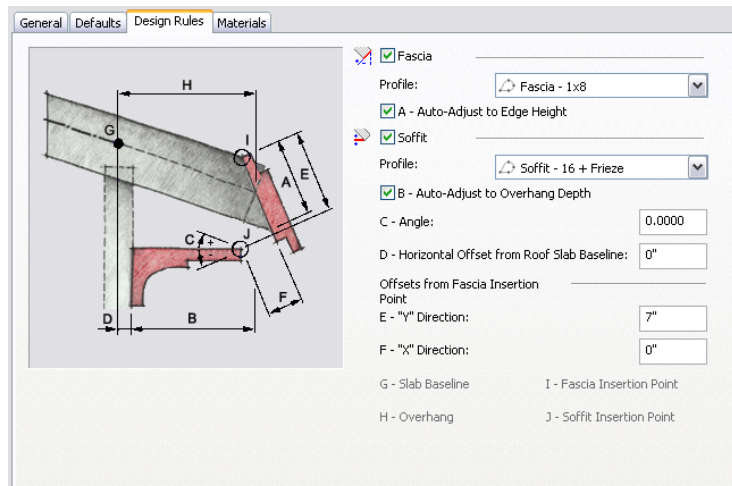

If you want to...	Then...
create a roof slab or slab fascia	select X for Extrusion Direction.
create a slab soffit	select Y for Extrusion Direction.
extrude mass elements	select Z for Extrusion Direction.

7 Click OK.

Specifying a Fascia and a Soffit for a Slab/Roof Slab Edge Style

Use this procedure to specify a fascia and a soffit for a slab or roof slab edge style. The drawing must contain profiles for the fascia and soffit. For more information, see [Creating Profiles for the Fascia and Soffit](#) on page 1669.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Edge Styles or Roof Slab Edge Styles.
- 3 Select the slab/roof slab edge style that you want to edit.
- 4 Click the Design Rules tab.

5 Select Fascia, and select a profile that defines the geometry of the fascia.

If you select *NONE*, display component settings apply to the slab/roof slab edge line or plane where the fascia is located.

6 Specify how the fascia is to be scaled on the slab/roof slab edge:

If you want to...	Then...
scale the fascia to fit the height of the edge	select Auto-Adjust to Edge Height to scale the fascia to edge height.
use the fascia at its drawn size	clear Auto-Adjust to Edge Height.

7 Select Soffit, and select a profile that defines the geometry of the soffit.

If you select *NONE*, display component settings apply to the slab/roof slab edge line or plane where the soffit is located.

8 Specify how the soffit is to be scaled on the slab/roof slab overhang:

If you want to...	Then...
scale the soffit to fit the depth of the overhang	select Auto-Adjust to Overhang Depth.
use the soffit at its drawn size	clear Auto-Adjust to Overhang Depth.

9 Specify the placement of the soffit:

If you want to...	Then...
specify the soffit angle of the slab/roof slab edge	enter a value for the Angle, with zero being horizontal. A positive value slopes the soffit up from the insertion point, and a negative value slopes the soffit down.
specify the horizontal offset from the slab/roof slab baseline or perimeter line for the slab edge	enter a value for Horizontal Offset from [Slab/Roof Slab] Baseline. (This option is available only if you select Auto-Adjust to Overhang Depth.)
specify the soffit offsets from the insertion point of the fascia	enter a value for "X" Direction and "Y" Direction.

10 Click OK.

Editing the Geometry of Fascia and Soffits

Use this procedure to edit the geometry of the profile used to define the fascia and soffit of a slab or roof slab edge style. You can also add a profile to the fascia or soffit of an edge style that does not currently use a profile to define its shape.

NOTE If you want to replace the geometry of the profile with newly drawn polylines, draw them before you start this procedure.

1 Select the slab or roof slab that has the style you want to change.

2 Add or edit a profile:

If you want to...	Then...
add an existing profile to the style	right-click, and click Add Edge Profiles. Select an edge. Select the name of the profile for the fascia or soffit, and click OK.
create a profile and add it to the style	right-click, and click Add Edge Profiles. Select an edge. Select Start from scratch for Fascia or Soffit Profile Definition, enter a name for the new profile, and click OK. A rectangle profile is created for you to edit.

If you want to...	Then...
edit the existing profile for the style	select the slab, right-click, and click Edit Edge Profile in Place.

NOTE If you are prompted about the selected edge not having an edge style and overhang, click Yes.

3 If you receive a message that the profile is not drawn to size, click Yes.

The area of the slab/roof slab edge defined by the profile is selected and hatched in the drawing.

NOTE After you perform an editing task from the context menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select the profile, and right-click to display the context menu.

4 Edit the profile as necessary:

If you want to...	Then...
change the shape of the perimeter of the profile or its rings	select the profile, and use edge and vertex grips to adjust the shape. The Edge grip has two edit modes: Stretch and Move. The default mode is Stretch, and the direction of the stretch depends on the orientation of edges connected to the selected edge. For example, if the edges at both ends of the selected edge are parallel to each other, the grip edit mode is Stretch (Parallel) and the stretch direction is limited to the direction of the parallel edges. If the connected edges are not parallel, the grip edit mode is Stretch (Offset) and the stretch direction is perpendicular to the direction of the selected edge. The Move edit mode allows an unconstrained move of the selected edge.
add vertices to the profile	select the profile, right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .
remove vertices from the profile	select the profile, right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .
replace an existing ring of the profile with new geometry	select the profile, right-click, and click Replace Ring. Select the ring to replace, and select the new geometry. Press <i>ENTER</i> to keep the geometry, or enter n (No) to erase it.

5 Save or discard the changes:

If you want to...	Then...
restore the profile to its original shape	select the profile, and click  .

If you want to...	Then...
save the changes to the current profile	select the profile, and click  . The slab/roof slab style uses the edited profile to define its geometry. Any other objects or styles that use this profile are also updated with the edited geometry.
save the changes to a new profile definition	select the profile, right-click, and click Save as New Profile. Enter a name for the new profile definition, and click OK. The slab/roof slab uses the new profile to define its geometry. Any other objects of this style are updated with the new geometry. Other styles or objects that use the original profile are not affected.

Assigning Materials to a Slab/Roof Slab Edge Style

Use this procedure to assign materials to individual components of a slab or roof slab edge style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Edge Styles or Roof Slab Edge Styles.
- 3 Select the style to which to assign materials.
- 4 Click the Materials tab.
- 5 Select the edge component to which to assign a material, and click its current material definition.
- 6 Select a material definition from the list.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Any changes you make to the material definition in this dialog will apply to all objects that are assigned the material.

- 7 Click OK.

Turning on Materials for a Slab/Roof Slab Edge Style

Use this procedure to turn on material assignments for individual display representations in a slab or roof slab edge style. Display components for edges are not turned on in the edge style, but rather in the slab or roof slab style that uses them.

For information on creating and assigning materials, see [Specifying the Materials of a Slab or Roof Slab Style](#) on page 1659.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Styles or Roof Slab Styles.
- 3 Select the style that contains the edges you want to turn on.
- 4 Click the Display Properties tab.
- 5 Select the display representation in which to display the changes, and select Style Override.

- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for each component to be controlled by the material.
If the setting for By Material is not available, the display of this component cannot be determined by a material.
- 9 Click OK twice.

Attaching Notes and Files to a Slab/Roof Slab Edge Style

Use this procedure to enter notes and attach reference files to a slab or roof slab edge style. You can also edit notes and edit or detach reference files from the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Slab Edge Styles or Roof Slab Edge Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the edge style, enter it under Description.
- 6 Click Notes.
- 7 To add or edit a note, click the Notes tab, and enter the note.
- 8 To attach, edit, or detach a reference file, click the Reference Docs tab:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Click OK when you are finished editing.
detach a reference file	select the file name, click Delete, and click OK.

- 9 Click OK.

Structural Members

29

A structural member is an object that can represent a beam, brace, or column in a drawing. All the beams, braces, and columns that you create are sub-types of a single structural member object.

Structural Members

A structural member is an object that can represent a beam, brace, or column in a drawing. All the beams, braces, and columns that you create are sub-types of a single structural member object.

Creating Structural Members

You create a structural member in AutoCAD Architecture by extruding a structural shape along a path. The style that you use to create the structural member provides the shape. The shape, similar to a profile, is a 2-dimensional cross-section of a structural member. You define the extrusion path (axis) of the member when you specify start and endpoints for the member or when you convert linework to a member.

Creating a structural member

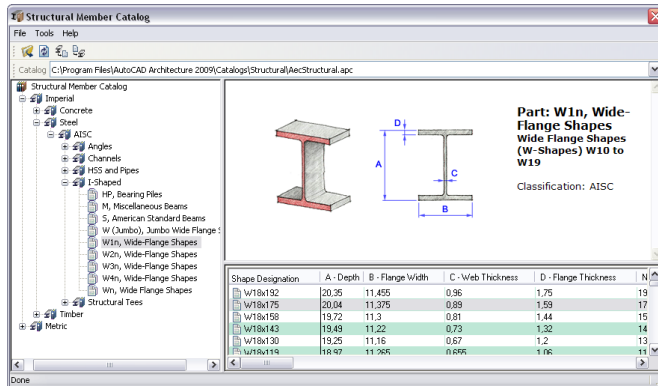

Connecting Structural Members

Connections between structural members are supported. Structural members are considered connected when an endpoint of one member lies on an endpoint or along the axis of another. With some exceptions, you have the option of maintaining or breaking these connections when you move a member using its Location grip. Connections between structural members are also recognized across external reference (xref) drawings, and you can use objects in an xref to position and establish trim planes for members you are adding. For example, while working in one drawing, you can open an xref containing a column grid and use it to lay out columns or beams. If you edit the xref in-place, connections between structural members are maintained just as they would be in the host drawing. For more information on the behavior of connections during edits, see [Using Grips To Edit Structural Members](#) on page 1715.

Creating Styles with the Structural Member Catalog and Structural Member Style Wizard

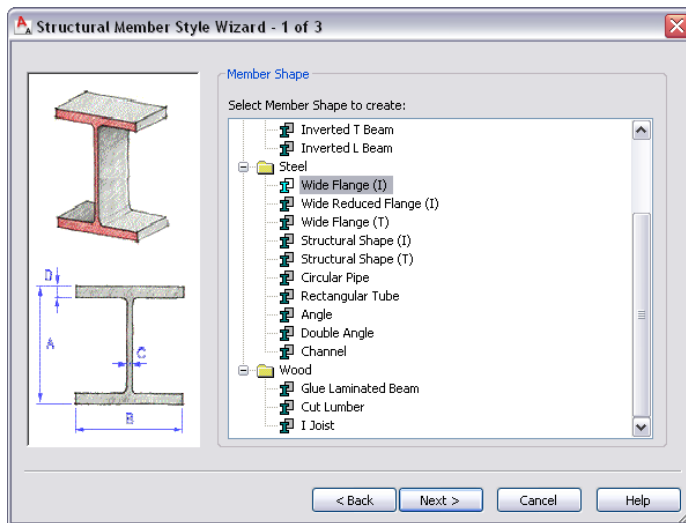

To create styles for most standard beams, braces, and columns, you can use the Structural Member Catalog included in AutoCAD Architecture. The catalog contains specifications for industry-standard concrete, steel, and timber structural shapes organized in a Windows® Explorer-like tree view. You can browse the catalog, select a shape, and create a style.

Structural Member Catalog

If you know the type, shape, and shape dimensions of the member that you want to create, you can quickly enter the information in the Structural Member Style wizard to create a style. You can create a structural member shape within a style that is based on any of the member shapes in the catalog.

Structural Member Style Wizard

After you create structural member styles, you can drag them from the Style Manager onto tool palettes to create structural member tools.

Adding Graphics to Structural Members

You can add blocks to the display of structural members as components in display representations. For example, you can create blocks that represent stiffener plates and add them to beams or create blocks that represent clip angles and add them to members.

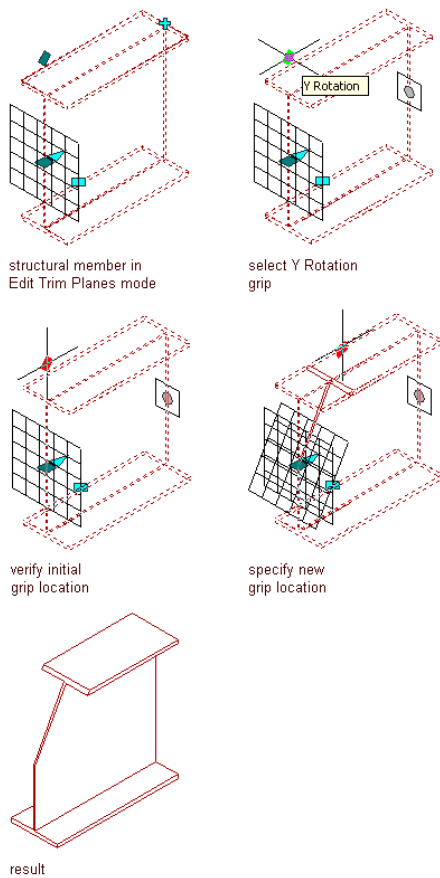

Beam with added stiffener plates

Trimming Structural Members

Structural members are trimmed using objects called trim planes, which let you clean up joints between multiple structural members or between structural members and other objects. Using the Properties palette for a structural member tool, you can create specific trim planes that are applied when you add a new member with the tool. Or you can specify that trim planes be created automatically when you connect the new member to an existing structural member in a drawing. Once a member has been added to a drawing, you can edit its trim planes or add new ones. Additional trim planes can be defined on the member itself or in relation to an edge of another object. For more information, see [Trimming Structural Members](#) on page 1727.

Trimming a structural member with a trim plane

Creating Column Grids

When you create a column, you can attach it to a grid. You can also create a column grid with the structural column grid tool that is included in AutoCAD Architecture. The tool creates a grid with columns pre-anchored to nodes on the grid. For more information, see [Creating a Column Grid](#) on page 1829.

Materials in Structural Members

In AutoCAD Architecture, you can assign materials to a structural member. These materials are displayed in wireframe and working shade views, or when rendered. Materials have specific settings for the physical components of a structural member.

AutoCAD Architecture provides a large number of predefined materials for all common design purposes, which contain settings for structural members. You can use these predefined materials, or modify them to your special designs. You can also create your own materials from scratch.

For more information, see [Specifying the Materials of a Structural Member Style](#) on page 1747.

Creating Custom Structural Members

You can use the styles from the Structural Member Catalog and Structural Member Style wizard to create structural members for most of your design needs. However, your project requirements may require you to create structural members that cannot be created from a shape in the catalog or created with the wizard. For example, you may want to create:

- a column with a shape that tapers from start to end
- a composite column created from a steel shape encased in a concrete shape
- a rigid frame created from multiple tapering shapes extruded along the path of the frame
- a structural member with a custom shape that cannot be created in the catalog or with the wizard

To create custom structural members, you use the design rules within a structural member style to extrude one or more shapes along the path of the member. You can use shapes created in the catalog or with the wizard, or you can create your own custom shapes.

Predefined Custom Structural Member Styles

You can access predefined styles for custom structural members from the *Member Styles* and *Bar Joists Styles* drawings located in the `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial` folder.

Process Overview: Creating Structural Members with the Structural Member Catalog or Structural Member Style Wizard

This process overview describes how you can create structural members with styles that you create in the Structural Member Catalog or with the Structural Member Style wizard. This overview assumes that you need to create your own structural member styles and tools to create structural members. If you have a tool palette of structural member tools, see [Using Structural Member Tools to Create Structural Members](#) on page 1695.

The process of creating a structural member from the catalog or with the wizard has three steps:

- 1 Create a structural member style in the Structural Member Catalog or with the Structural Member Style wizard.
If you know the type, shape, and shape dimensions of the member that you want to create, you can quickly enter the information in the Structural Member Style wizard to create a style. Alternatively, browse the Structural Member Catalog and select a shape to create a style.
- 2 Drag the style from the Style Manager onto a tool palette to create a structural member tool.

- 3 Create a structural member or convert linework to a structural member with the tool that you created in step 2.

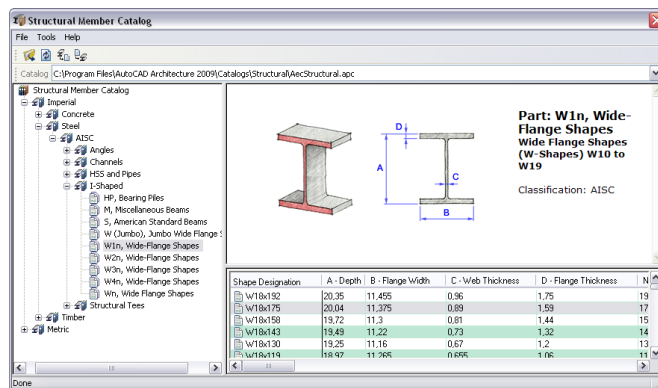

Creating Structural Member Styles in the Structural Member Catalog

The Structural Member Catalog contains specifications for different types and sizes of standard structural shapes. You can browse the catalog, select a shape, and create a structural member style that contains the selected shape. When you create a structural member with the style, the style provides the shape of the member.

Organization of the Structural Member Catalog

The left pane of the Structural Member Catalog contains standard structural shapes organized in a Windows® Explorer-like tree view. Several industry standard specifications are organized in the tree, first by imperial or metric units, and then by material.

Structural Member Catalog

Browsing the Catalog

You can open all the levels in the tree pane under a unit and material to view the different structural shape types available in the catalog. When you select a shape type in the tree view, a preview image of the shape with its dimensions displays in the upper right pane. All the available sizes of the shape type display in the lower right pane.

If you have a structural member in a drawing with a style created in the catalog, you can locate the catalog shape contained in that style from the member.

Creating Structural Member Styles from Catalog Shapes

When you create a structural member style in the catalog, the dimensions of the catalog shape that you select define and store the shape in the style.

For example, the dimensions of the steel beam selected in the previous illustration include its depth (d), flange width (bf), flange thickness (tf), and web thickness (tw). When you create a style, these dimensions create the following shape that is stored in the style.

Wide-flange structural shape cross-sectional parameters

When you create a beam in your drawing with this style, the style provides the shape of the beam. You determine the length, start and end offsets, justification, and roll of the beam when you create the beam.

Contents of the Structural Member Catalog

When you display the Structural Member Catalog, a default catalog file, *-AecStructural.apc*, provides the catalog content. This file is located in: *C:\Program Files\AutoCAD Architecture 2009\Catalogs\Structural*.

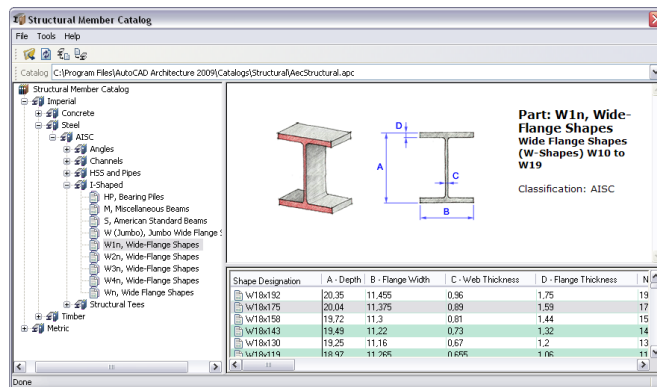

In the future, additional catalog files that you can open in the catalog may become available on the Autodesk web site, or you may create your own catalog files.

Opening the Structural Member Catalog

Use this procedure to open the Structural Member Catalog.

- 1 Click **Format** menu ► **Structural Members** ► **Catalog**.

Opening the Structural Member Catalog

- 2 Move and resize the Structural Member Catalog, or resize the left and right panes within the catalog as needed to view catalog information.

- 3 Click  to close the Structural Member Catalog.

Creating a Style from a Shape in the Structural Member Catalog

Use this procedure to create a structural member style from a shape that you select in the Structural Member Catalog.

1 Click Format menu ► Structural Members ► Catalog.

A tree view in the left pane of the catalog lists the available shapes.

2 Expand Imperial or Metric in the tree view.

3 Expand the type of material (Concrete, Steel, or Timber) for the structural shape that you want to create with the style.

4 Expand the shape that you want to create.

Depending on the member, you may need to expand one or more levels in the tree.

5 Select the shape type of the member that you want to create.

In the top right pane, a preview of the shape displays.

In the bottom right pane, a list of the available sizes of the selected shape display. The following shapes may take a significant amount of time to display:

- Imperial ► Steel ► AISC ► HSS and Pipes ► HSS, Small Hollow Structural Sections
- Metric ► Steel ► CISC ► Angles ► L, Angle Shapes
- Metric ► Steel ► CISC ► I-Shaped ► W, Wide Flange Shapes
- Metric ► Steel ► CISC ► I-Shaped ► WWF, Welded Wide Flange Shapes
- Metric ► Steel ► CISC ► Structural Tees ► WT, Tee Shapes

6 Under Shape Designation in the bottom right pane, select the shape size that you want to use to create your style, right-click, and click Generate Member Style.

7 Enter a style name, if necessary, and click OK.

The name of the shape is used as the default style name. Special characters in the shape name, such as quotation marks, are substituted with underscores. If you change the default style name, you cannot use any of the following special characters in your style name:

- Less-than and greater-than symbols (< >)
- Forward slashes and backslashes (/ \)
- Quotation marks (")
- Colons (:)
- Semicolons (;)
- Question marks (?)
- Commas (,)
- Asterisks (*)
- Vertical bars (|)
- Equal signs (=)
- Back quotes (`)

8 Continue creating structural member styles, or click  to close the Structural Member Catalog.

You can access the style that you created in the Style Manager, create a new structural member tool from the style, modify an existing tool to use that style, or apply the style to an existing member.

Locating a Shape in the Structural Member Catalog from a Structural Member in a Drawing

Use this procedure to locate a shape in the Structural Member catalog from a shape contained in the style of a structural member in a drawing. You may find this command useful if you created a style from a shape in the catalog and did not name it with the same name as the catalog shape.

- 1 Click Format menu ► Structural Members ► Catalog.
- 2 On the Tools menu in the Structural Member Catalog, click Locate.
- 3 Select the structural member in the drawing that you want to select in the catalog.

The shape that you located from the existing member is selected in the Structural Member Catalog.

Opening a Catalog File in the Structural Member Catalog

Use this procedure to open a new catalog file in the Structural Member Catalog.

- 1 Click Format menu ► Structural Members ► Catalog.
- 2 Specify the location of the new catalog file:

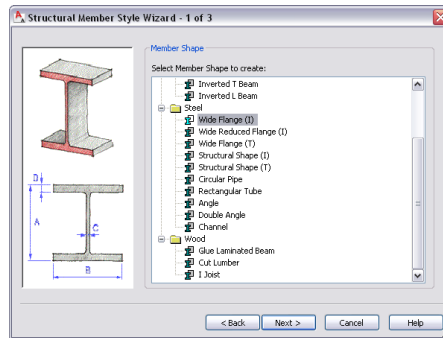

If you...	Then...
know the location and name of the catalog file	enter the full path and name of the catalog file in the Catalog bar under the Structural Member Catalog toolbar.
want to browse your hard disk or server for a catalog	on the File menu in the Structural Member Catalog, click Open. Select a new catalog file, and click Open.

Creating a Structural Member Style with the Structural Member Style Wizard

Use this procedure to create a structural member style with the Structural Member Style wizard. You can create a structural member shape within the style that is based on any of the 19 different shape types in the Structural Member Catalog. The current drawing units determine the units of the style that you create.

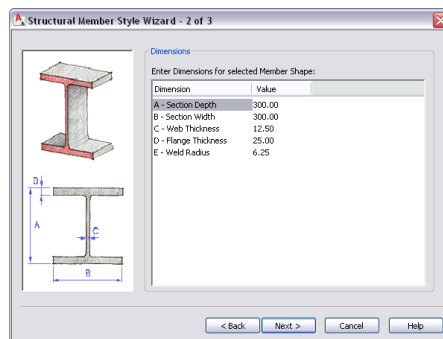

- 1 Click Format menu ► Structural Members ► Wizard.
- 2 Select the type of structural member shape that you want to create, and click Next.

Selecting a structural member shape type

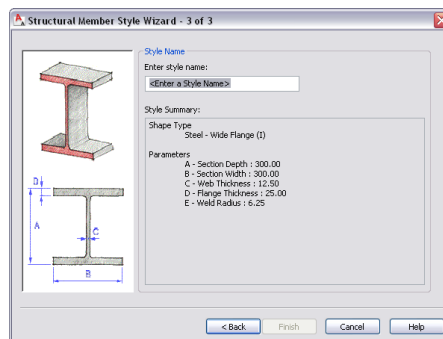

3 Enter dimensions for the shape, and click Next.

Entering the structural member dimensions

4 Enter a name for the structural member style, and click Finish.

Entering a structural member style name

You cannot use the following special characters in your style names:

- Less-than and greater-than symbols (< >)
- Forward slashes and backslashes (/ \)
- Quotation marks (")
- Colons (:)
- Semicolons (;)
- Question marks (?)
- Commas (,)

- Asterisks (*)
- Vertical bars (|)
- Equal signs (=)
- Back quotes (`)

You can access the style that you created in the Style Manager, create a new structural member tool from the style, modify an existing tool to use that style, or apply the style to an existing member.

Creating Structural Member Tools

You can create structural member tools and add them to tool palettes. Tool palettes in AutoCAD Architecture let you quickly place beams, braces, and columns by selecting a structural member tool with a specific style and other predefined properties.

If you created structural member styles in the Structural Member Catalog or with the Structural Member Style wizard, you can drag the styles from the Style Manager to tool palettes and then customize the properties of the new tools.

You can also use any of the following methods to create structural member tools:

- Drag a structural member that has the properties you want to a tool palette.
- Copy an existing tool in the current palette, paste it onto the current palette or a different palette, and then customize the properties of the new tool.
- Drag a tool from the Content Browser to a tool palette and then customize the properties of the new tool.

Creating a Beam Tool

Use this procedure to create a structural beam tool and add it to a tool palette.

- 1 Open the tool palette on which you want to add a tool.
- 2 Create the tool:

If you want to...	Then...
create a tool from a structural member style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
create a tool from a beam in the drawing	select the beam, and drag it to the tool palette.
copy a tool in the current palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

If you want to...	Then...
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

- 3 Right-click the new tool, and click Properties.
- 4 Enter a name for the tool.
- 5 Click the setting for Description, enter a description of the tool, and click OK.
The description displays in the tooltip when you select the tool from the tool palette, and describes the tool if you store it in a tool catalog in the Content Browser.
- 6 Expand Basic, and expand General.
- 7 Enter a description of the beams that you can create using this beam tool.
- 8 If you do not want to use the layer assignments specified in the layer key style used in the drawing, specify a layer key and any layer key overrides.
- 9 Select a structural member style, and select a style location, if not the current drawing.
The style provides the shape of the beam.

10 Specify a value for Bound spaces:

If you want to...	Then...
allow the beam to be used as a bounding object for associative spaces	select Yes.
prevent the beam from being used as a bounding object for associative spaces	select No.
use the bounding setting from the beam style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

11 Specify a value for Trim automatically:

If you want...	Then...
the geometry of the beam to be automatically trimmed to any other structural members, other architectural objects, or linework to which it is logically connected	select Yes.
prevent the geometry of the beam from being trimmed automatically	select No.
use the trim setting from the beam style	select By Style.

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

12 Expand Dimensions.

13 Specify offsets:

If you want to...	Then...
offset the beam on its extruded axis at the start point of the beam	enter a value for Start offset. A positive value shortens the beam on its axis, while a negative value lengthens the beam on its axis.
offset the beam on its extruded axis at the endpoint of the beam	enter a value for End offset. A positive value lengthens the beam on its axis, while a negative value shortens the beam on its axis.

14 Enter a value for Roll.

This value specifies the orientation of the beam relative to its extruded axis in terms of degrees of roll. A positive value rolls the beam counterclockwise when viewed from its end to its start.

15 If Layout type is Fill, and you want beams to be added to the selected edge of a column grid, slab, roof slab, or wall at an angle other than the default of 90 degrees, enter a value for Angle relative to selected object.

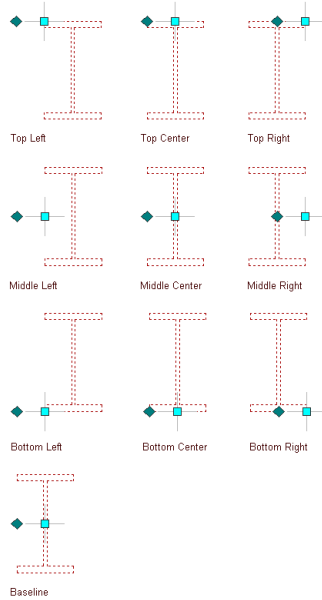

16 Select a Layout type to specify how a beam is positioned in relation to a highlighted edge of a column grid, slab, roof slab, or wall:

If you want to position the beam...	Then...
along the highlighted edge of the object	select Edge for Layout type.
within the boundaries of the object (from one edge to an opposite edge or edges)	select Fill for Layout type.

17 Specify the beam justification, which positions the beam shape in relation to its extruded axis when you draw the beam:

If you want to...	Then...
position the axis of the beam along the centroid of the beam shape	select Baseline for Justify. NOTE This applies to members created with styles from the Structural Member Catalog only.
position the axis of the beam along one of 9 positions on the beam shape	select one of the 9 positions for Justify. NOTE These positions are defined at a roll of zero, viewing the beam from the end to the start.

Justification options for a beam

18 To specify the justification of members with multiple shapes and segments created with this tool, select a setting for Justify using overall extents:

If you want to justify the member...	Then...
based on the largest cross-sectional extent of the member's lowest priority shapes	select Yes. The justification is applied ONLY to the lowest priority shape definitions, and is calculated based on the node (vertex) of the member with the greatest cross section.
at each node, based on all shapes	select No. The justification is calculated based on the cross-sectional extents at each node, and applied to all the shapes without regard to priority.

For more information about members with multiple shapes and segments, see [Creating Custom Structural Members](#) on page 1757.

19 If Layout type is Fill, and you want to array multiple beams between two existing beams or within a column grid, slab, roof slab, or wall, expand Layout and select Yes for Array.

20 Specify the layout method for the array:

If you want to array beams...	Then...
so that they create a specific number of equal-sized bays	select Space evenly for Layout method, and enter a value for Number of bays.
at a specific distance from each other	select Repeat for Layout method, and enter a value for Bay size.

21 Click OK.

Creating a Brace Tool

Use this procedure to create a structural brace tool and add it to a tool palette.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a structural member style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
create a tool from a brace in the drawing	select the brace, and drag it to the tool palette.
copy a tool in the current palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

The description displays in the tooltip when you select the tool from the tool palette, and describes the tool if you store it in a tool catalog in the Content Browser.

6 Expand Basic, and expand General.

7 Enter a description of the braces that you can create using this brace tool.

8 If you do not want to use the layer assignments specified in the layer key style used in the drawing, specify a layer key and any layer key overrides.

9 Select a structural member style, and select a style location, if not the current drawing.

The style provides the shape of the brace.

10 Specify a value for Bound spaces:

If you want to...	Then...
allow the brace to be used as a bounding object for associative spaces	select Yes.
prevent the brace from being used as a bounding object for associative spaces	select No.
use the bounding setting from the brace style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

11 Specify a value for Trim automatically:

If you want...	Then...
the geometry of the brace to be automatically trimmed to any other structural members, other architectural objects, or linework to which it is logically connected	select Yes.
prevent the geometry of the brace from being trimmed automatically	select No.
use the trim setting from the brace style	select By Style.

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

12 Expand Dimensions.

13 Specify offsets:

If you want to...	Then...
offset the brace on its extruded axis at the start point of the brace	enter a value for Start offset. A positive value shortens the brace on its axis, while a negative value lengthens the brace on its axis.
offset the brace on its extruded axis at the endpoint of the brace	enter a value for End offset. A positive value lengthens the brace on its axis, while a negative value shortens the brace on its axis.

14 Enter a value for Roll.

This value specifies the orientation of the brace relative to its extruded axis in terms of degrees of roll. A positive value rolls the brace counterclockwise when viewed from its end to its start.

15 Specify the brace justification, which positions the brace shape in relation to its extruded axis when you draw the brace:

If you want to...	Then...
position the axis of the brace along the centroid of the brace shape	select Baseline for Justify. NOTE This applies to members created with styles from the Structural Member Catalog only.
position the axis of the brace along one of 9 positions on the brace shape	select one of the 9 positions for Justify. NOTE These positions are defined at a roll of zero, viewing the beam from the end to the start.

Justification options for a brace

16 To specify the justification of braces with multiple shapes and segments created with this tool, select a setting for Justify using overall extents:

If you want to...

Then...

justify the brace based on the largest cross-sectional extent of the member's lowest priority shapes

select Yes. The justification is applied ONLY to the lowest priority shape definitions, and is calculated based on the node (vertex) of the member with the greatest cross section.

justify the brace at each node, based on all shapes

select No. The justification is calculated based on the cross-sectional extents at each node, and is applied to all the shapes without regard to priority.

For more information about members with multiple shapes and segments, see [Creating Custom Structural Members](#) on page 1757.

17 Specify the rise, which is the vertical distance between the start point and endpoint of the brace:

If you want to...

Then...

specify the rise of the brace before you draw it

select No for Specify Rise on Screen. For Method, select either Angle, Distance, or Height. If you select Angle, enter a value for Distance along first member (measured from the point where the two members are connected to the point on the first member where you want the brace to start) and a value for Angle from first member. If you select Distance, enter values for both Distance along first member and Distance along second member. If you select Height, enter a value for Rise.

specify the rise of the brace by specifying a 3D endpoint for the end of the brace

select Yes for Specify Rise on Screen.

18 Click OK.

Creating a Column Tool

Use this procedure to create a structural column tool and add it to a tool palette.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a structural member style in the Style Manager	on the Format menu, click Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
create a tool from a column in the drawing	select the column, and drag it to the tool palette.
copy a tool in the current palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

The description displays in the tooltip when you select the tool from the tool palette, and describes the tool if you store it in a tool catalog in the Content Browser.

6 Expand Basic, and expand General.

7 Enter a description of the columns that you can create using this column tool.

8 If you do not want to use the layer assignments specified in the layer key style used in the drawing, specify a layer key and any layer key overrides.

9 Select a structural member style, and select a style location, if not the current drawing.

The style provides the shape of the column.

10 Specify a value for Bound spaces:

If you want to...	Then...
allow the column to be used as a bounding object for associative spaces	select Yes.
prevent the column from being used as a bounding object for associative spaces	select No.

If you want to...	Then...
use the bounding setting from the column style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

11 Specify a value for Trim automatically:

If you want...	Then...
the geometry of the column to be automatically trimmed to any other structural members, other architectural objects, or linework to which it is logically connected	select Yes.
prevent the geometry of the column from being trimmed automatically	select No.
use the trim setting from the column style	select By Style.

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

12 Expand Dimensions.

13 Specify offsets:

If you want to...	Then...
offset the column on its extruded axis at the start point of the column	enter a value for Start offset. A positive value shortens the column on its axis, while a negative value lengthens the column on its axis.
offset the column on its extruded axis at the endpoint of the column	enter a value for End offset. A positive value lengthens the column on its axis, while a negative value shortens the column on its axis.

14 Specify the roll of the column (how it is oriented relative to its extruded axis):

If you want to...	Then...
specify the roll of the column before you insert it	select No for Specify on Screen, and enter a value for Roll.
specify the roll of the column when you insert it	select Yes for Specify on Screen.

This value specifies the orientation of the column relative to its extruded axis in terms of degrees of roll. A positive value rolls the column counterclockwise when viewed from the end (top) to the start (bottom) of the column.

15 Specify the column justification, which positions the column shape in relation to its extruded axis when you draw the column:

If you want to...

Then...

position the axis of the column along the centroid of the column shape

select Baseline for Justify.

NOTE This applies to members created with styles from the Structural Member Catalog only.

position the axis of the column along one of 9 positions on the column shape

select one of the 9 positions for Justify.

NOTE These positions are defined at a roll of zero, viewing the column from the top to the bottom.

16 To specify the justification of members with multiple shapes and segments created with this tool, select a setting for Justify using overall extents:

If you want to...

Then...

justify the member based on the largest cross-sectional extent of the member's lowest priority shapes

select Yes. The justification is applied ONLY to the lowest priority shape definitions, and is calculated based on the node (vertex) of the member with the greatest cross section.

justify the member at each node, based on all shapes.

select No. The justification is calculated based on the cross-sectional extents at each node, and is applied to all the shapes without regard to priority.

For more information about members with multiple shapes and segments, see [Creating Custom Structural Members](#) on page 1757.

17 Click OK.

Using Structural Member Tools to Create Structural Members

Tool palettes in AutoCAD Architecture let you quickly place beams, braces, and columns by selecting a structural member tool with a specific style and other predefined properties. You can also use structural member tools to convert linework to structural members and to apply the settings of a structural member tool to existing structural members.

Custom palettes created by you or your CAD manager may contain structural member tools from styles created in the Structural Member Catalog or Structural Member Style wizard. These palettes may be customized for your projects or office standards.

The default tool palettes in the workspace contain sample structural member tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain structural member tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog
- My Tool catalog

When you create structural members using structural member tools, you can use the default settings of the tool, or you can specify settings for any structural member properties that are not controlled by the style.

IMPORTANT Columns grids that have numerous columns attached to them can take longer than expected to display on screen. This is because structural members carry additional information that may be used for structural analysis.

Creating a Beam

Use this procedure to add one or more new beams that have the property settings specified in the structural beam tool that you select. You can add a beam anywhere in the drawing area by specifying a start point and an endpoint, or you can position and size a beam in relation to an edge of an existing object. The style specified in the tool provides the beam shape, which is extruded along the path you define in the drawing area.

To specify settings when you add a beam, see [Creating Beams with User-Specified Settings](#) on page 1697.

Creating a beam

- 1 Open the tool palette that contains the structural beam tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

- 2 If you want to offset the new beam(s) from the elevation of the current level, double-click the Elevation value on the application status bar at the bottom of the workspace, enter an elevation value (or specify a point on an existing object in the drawing area), click OK, and then click the Z-snap button to the right of the Elevation Value.
- 3 Position the new beam(s) in the drawing area:

If you want to...	Then...
create a single beam independent of other objects	specify a start point and an endpoint for the beam, and then press <i>ENTER</i> .
create multiple beams independent of other objects but connected to each other using the endpoint of one beam as the start point of the next beam	specify a start point and an endpoint, and then specify additional endpoints as required. Press <i>ENTER</i> to end the command.
create a beam that is connected to an existing structural member	specify a start point and an endpoint, one of which must be on the axis or the endpoint of the existing member. Press <i>ENTER</i> to end the command.
add beams along one or more edges of a slab, roof slab, or wall	move the cursor over an edge of the object to display a preview of the beam, and then click to add a beam along that edge, or press <i>Ctrl</i> and click to add beams

If you want to...

Then...

along all edges of the object. Press *ENTER* to end the command.

add beams along one or more segments of a column grid

move the cursor over a segment of the grid to display a preview of the beam, and then click to add a beam along that segment; or press *Ctrl* and click to add beams along all segments in that grid line; or press *Ctrl* twice and click to add beams along all segments in the grid. Press *ENTER* to end the command.

NOTE If you want to add a beam that spans an object from edge to edge rather than lying along one of its edges, you can change the Layout type setting from Edge to Fill on the Properties palette. For more information on property settings for beam tools, see [Creating Beams with User-Specified Settings](#) on page 1697.

Creating Beams with User-Specified Settings

Use this procedure to add one or more new beams with property settings that you specify. You can add a beam anywhere in the drawing area by specifying a start point and an endpoint, or you can position and size a beam in relation to an existing object. You can also create multiple beams, either one at a time (connected endpoint to start point) or arrayed within boundaries defined by other beams or by column grids, slabs, roof slabs, or walls. The style specified in the tool provides the beam shape, which is extruded along the paths you define in the drawing area.

Creating a beam

Optionally, offset the beam from its start point or endpoint.

Offsetting a beam

1 Open the tool palette that contains the structural beam tool you want to use, and select the tool.

(You may have to scroll to display the desired tool).

2 On the Properties palette, under General, click Style, and select a structural beam style.

3 Specify a value for Bound spaces:

If you want to...	Then...
allow the beam to be used as a bounding object for associative spaces	select Yes.
prevent the beam from being used as a bounding object for associative spaces	select No.
use the bounding setting from the beam style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

4 Specify a value for Trim automatically:

If you want...	Then...
the geometry of the beam to be automatically trimmed to any other structural members, other architectural objects, or linework to which it is logically connected	select Yes.
prevent the geometry of the beam from being trimmed automatically	select No.
use the trim setting from the beam style	select By Style.

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

5 Expand Dimensions.

6 Specify offsets:

If you want to...	Then...
offset the beam on its extruded axis at the start point of the beam	enter a value for Start offset. A positive value shortens the beam on its axis, while a negative value lengthens the beam on its axis.
offset the beam on its extruded axis at the endpoint of the beam	enter a value for End offset. A positive value lengthens the beam on its axis, while a negative value shortens the beam on its axis.

7 Enter a value for Roll.

This value specifies the orientation of the beam relative to its extruded axis in terms of degrees of roll. A positive value rolls the beam counterclockwise when viewed from its end to its start.

8 Specify the beam justification, which positions the beam shape in relation to its extruded axis when you draw the beam:

If you want to...

Then...

position the axis of the beam along the centroid of the beam shape

select Baseline for Justify.

NOTE This applies to members created with styles from the Structural Member Catalog only.

position the axis of the beam along one of 9 positions on the beam shape

select one of the 9 positions for Justify.

NOTE These positions are defined at a roll of zero, viewing the beam from the end to the start.

Justification options for a beam

9 Select a Layout type to specify how a beam is positioned in relation to a highlighted edge of a column grid, slab, roof slab, or wall:

If you want to position the beam...

Then...

along the highlighted edge of the object

select Edge for Layout type.

If you want to position the beam...**Then...**

within the boundaries of the object (from one edge to an opposite edge or edges)

select Fill for Layout type.

10 If Layout type is Fill, and you want to array multiple beams between 2 existing beams or within a column grid, slab, roof slab, or wall, expand Layout and select Yes for Array.

11 Specify the layout method for the array:

If you want to array beams...**Then...**

so that they create a specific number of equal-sized bays

select Space evenly for Layout method, and enter a value for Number of bays.

at a specific distance from each other

select Repeat for Layout method, and enter a value for Bay size.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

12 If you want to offset the new beams from the elevation of the current level, double-click the Elevation value on the application status bar at the bottom of the workspace, enter an elevation value (or specify a point on an existing object in the drawing area), click OK, and then click the Z-snap button to the right of the Elevation value.

Adding a beam to a single segment**Adding beams to one grid line**

Adding beams to all grid lines

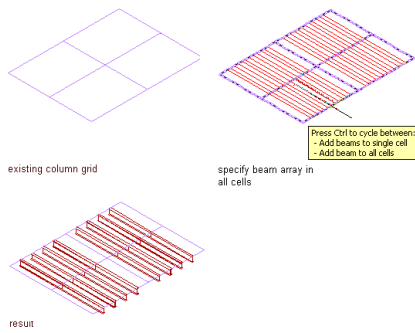

Adding a beam to a specified point

Adding a beam array to a single cell

Adding a beam array to all cells

13 Position the new beams in the drawing area:

If you want to...	Then...
create a single beam independent of other objects	specify a start point and an endpoint for the beam, and then press <i>ENTER</i> .
create multiple beams independent of other objects but connected to each other using the endpoint of one beam as the start point of the next beam	specify a start point and an endpoint, and then specify additional endpoints as required. Press <i>ENTER</i> to end the command.
create a beam that is connected to an existing structural member	specify a start point and an endpoint, one of which must be on the axis or the endpoint of the existing member. Press <i>ENTER</i> to end the command.
add a beam along one or more edges of a slab, roof slab, or wall (assuming Layout type is Edge)	move the cursor over an edge of the object until a preview of the beam is displayed, and then click to add a beam along that edge, or press <i>Ctrl</i> and click to add beams along all edges of the object. Press <i>ENTER</i> to end the command.
add a beam along one or more segments of a column grid (assuming Layout type is Edge)	move the cursor over a segment of the grid until a preview of the beam is displayed, and then click to add a beam along that segment; or press <i>Ctrl</i> and click to add beams along all segments in that grid line; or press <i>Ctrl</i> twice and click to add beams along all segments in the grid. Press <i>ENTER</i> to end the command.
add a beam that spans a slab, roof slab, wall, or column grid cell from edge to edge at an angle of 90 degrees (assuming Layout type is Fill)	move the cursor over the object edge or column grid segment until a preview of the beam is displayed in the desired position perpendicular to the edge/segment, and then click. Press <i>ENTER</i> to end the command.
add a beam that spans a slab, roof slab, wall, or column grid cell from edge to edge at an angle other than 90 degrees (assuming Layout type is Fill)	move the cursor over the object edge or column grid segment until a preview of the beam is displayed, enter a value for the desired angle, press <i>ENTER</i> , and then click. Press <i>ENTER</i> to end the command.
array beams between 2 structural members (assuming Array is Yes)	move the cursor over one of the structural members until its baseline is displayed, click that member, specify a point on the second member, and press <i>ENTER</i> . New beams are arrayed according to the Layout Method selected on the Properties palette and at an angle determined by the point you specify on the second member. Press <i>ENTER</i> to end the command.
array beams perpendicularly within a slab, roof slab, wall, or one or more cells of a column grid (assuming Array is Yes)	move the cursor over an edge until a preview of the array is displayed, and click. New beams are arrayed perpendicular to the selected edge according to the Layout Method selected on the Properties palette. If you want to add the array to all cells of a column grid,

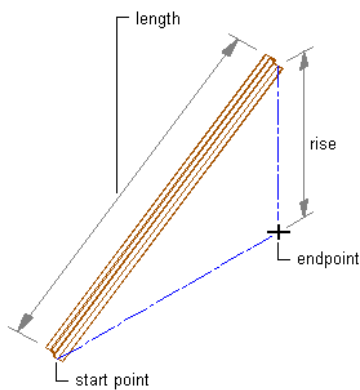

If you want to...	Then...
array beams at an angle other than 90 degrees within a slab, roof slab, wall, or one or more cells of a column grid (assuming Array is Yes)	press <i>Ctrl</i> before clicking. Press <i>ENTER</i> to end the command. move the cursor over an edge until a preview of the array is displayed, enter a value for the desired angle, press <i>ENTER</i> , and then click. New beams are arrayed at the specified angle according to the Layout Method selected on the Properties palette. If you want to add the array to all cells of a column grid, press <i>Ctrl</i> before clicking. Press <i>ENTER</i> to end the command.

Creating a Brace

Use this procedure to add a new brace that has the properties specified in the structural brace tool that you select. The style specified in the tool provides the brace shape, which is extruded along the path you define by specifying a start point and an endpoint.

To specify your own settings when you add a brace, see [Creating a Brace with User-Specified Settings](#) on page 1704.

Creating a brace

- 1 Open the tool palette that contains the structural brace tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

- 2 Specify the start point of the brace.
- 3 Specify an endpoint:

If you want to...	Then...
create a single brace	specify the endpoint of the brace, and press <i>ENTER</i> .
create additional braces	continue to specify brace start points and endpoints, and press <i>ENTER</i> .

Creating a Brace with User-Specified Settings

Use this procedure to add a new brace with property settings that you specify. The style specified in the tool provides the brace shape, which is extruded along the path you define by specifying a start point and an endpoint.

Creating a brace

Optionally, offset the brace from its start point or endpoint.

Offsetting a brace

- 1 Open the tool palette that contains the structural brace tool you want to use, and select the tool.
(You may have to scroll to display the desired tool).
- 2 On the Properties palette, under General, click Style, and select a structural brace style.
- 3 Specify a value for Bound spaces:

If you want to...	Then...
allow the brace to be used as a bounding object for associative spaces	select Yes.
prevent the brace from being used as a bounding object for associative spaces	select No.
use the bounding setting from the brace style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

4 Specify a value for Trim automatically:

If you want...	Then...
the geometry of the brace to be automatically trimmed to any other structural members, other architectural objects, or linework to which it is logically connected	select Yes.
prevent the geometry of the brace from being trimmed automatically	select No.
use the trim setting from the brace style	select By Style.

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

5 Expand Dimensions.

6 Specify offsets:

If you want to...	Then...
offset the brace on its extruded axis at the start point of the brace	enter a value for Start offset. A positive value shortens the brace on its axis, while a negative value lengthens the brace on its axis.
offset the brace on its extruded axis at the endpoint of the brace	enter a value for End offset. A positive value lengthens the brace on its axis, while a negative value shortens the brace on its axis.

7 Enter a value for Roll.

This value specifies the orientation of the brace relative to its extruded axis in terms of degrees of roll. A positive value rolls the brace counterclockwise when viewed from its end to its start.

8 Specify the brace justification, which positions the brace shape in relation to its extruded axis when you draw the brace:

If you want to...	Then...
position the axis of the brace along the centroid of the brace shape	select Baseline for Justify. NOTE This applies to members created with styles from the Structural Member Catalog only.
position the axis of the brace along one of 9 positions on the brace shape	select one of the 9 positions for Justify. NOTE These positions are defined at a roll of zero, viewing the beam from the end to the start.

Justification options for a brace

9 Specify the rise, which is the vertical distance between the start point and endpoint of the brace:

If you want to...

Then...

specify the rise of the brace before you draw it

select No for Specify rise on screen. For Method, select either Angle, Distance, or Height. If you select Angle, enter a value for Distance along first member (measured from the point where the two members are connected to the point on the first member where you want the brace to start) and a value for Angle from first member. If you select Distance, enter values for both Distance along first member and Distance along second member. If you select Height, enter a value for Rise.

specify the rise of the brace by specifying a 3D endpoint for the end of the brace.

select Yes for Specify Rise on Screen.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

10 In the drawing area, specify the start point of the brace.

11 Specify an endpoint for the brace:

- If you entered a value for Rise in step 9, then the endpoint of the brace is the X and Y coordinates of the endpoint that you selected. The Z coordinate equals the Z coordinate of the start point plus the value for the rise.
- If you selected Specify rise on screen in step 9, the endpoint of the brace is the 3D point that you selected.

12 Continue adding braces, and press *ENTER*.

Creating a Freestanding Column

Use this procedure to add a new freestanding column that has the property settings specified in the structural column tool that you select. The style specified in the tool provides the column shape. When you specify an insert point for the column, the shape is extruded in a positive direction along the current UCS Z-axis to a height determined by the Start offset, End offset, and Logical length properties of the tool.

To specify settings when you add a column, see [Creating a Freestanding Column with User-Specified Settings](#) on page 1707.

Creating a column

1 Open the tool palette that contains the structural column tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

2 Specify the insert point for the column.

3 If the Properties palette value for Specify roll on screen is Yes, move the cursor to roll the column around its extruded axis as desired, and then click; or enter a value for the roll angle, and press *ENTER*.

A positive value rolls the column counterclockwise around its extruded axis when viewed from its end (top) to its start (bottom).

4 Specify an insert point for another column, or press *ENTER* to end the command.

Creating a Freestanding Column with User-Specified Settings

Use this procedure to create a new freestanding column with property settings that you specify. The style specified in the tool provides the column shape. When you specify an insert point for the column, the shape is extruded in a positive direction along the current UCS Z-axis to a height determined by the Start offset, End offset, and Logical length properties you specify.

Creating a free-standing column

Optionally, offset the column from its start point or endpoint.

Offsetting a column

1 Open the tool palette that contains the structural column tool you want to use, and select the tool.

(You may have to scroll to display the desired tool).

2 On the Properties palette, under General, click Style, and select a structural column style.

3 Specify a value for Bound spaces:

If you want to...

Then...

allow the column to be used as a bounding object for associative spaces

select Yes.

prevent the column from being used as a bounding object for associative spaces

select No.

use the bounding setting from the column style

select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

4 Specify a value for Trim automatically:

If you want...

Then...

the geometry of the column to be automatically trimmed to any other structural members, other archi-

select Yes.

If you want...	Then...
-----------------------	----------------

structural objects, or linework to which it is logically connected

prevent the geometry of the column from being trimmed automatically	select No.
---	------------

use the trim setting from the column style	select By Style.
--	------------------

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

5 Expand Dimensions.

6 Specify offsets:

If you want to...	Then...
--------------------------	----------------

offset the column on its extruded axis at the start point of the column	enter a value for Start offset. A positive value shortens the column on its axis, while a negative value lengthens the column on its axis.
---	--

offset the column on its extruded axis at the endpoint of the column	enter a value for End offset. A negative value lengthens the column on its axis, while a positive value shortens the column on its axis.
--	--

7 Enter a value for Logical length.

The logical length of the column is the length (height) of the column before offsets are applied.

8 Select Yes or No for Specify roll on screen:

If you want to...	Then...
--------------------------	----------------

specify the roll of the column before you insert it	select No for Specify Roll on Screen, and enter a value for Roll.
---	---

specify the roll of the column when you insert it	select Yes for Specify Roll on Screen, and specify the roll as explained in step 10.
---	--

A positive value rolls the column counterclockwise around its extruded axis when viewed from its end (top) to its start (bottom).

9 Specify the column justification, which positions the column shape in relation to its extruded axis when you draw the column:

If you want to...	Then...
--------------------------	----------------

position the extruded axis of the column at the centroid of the column shape	select Baseline for Justify.
--	------------------------------

NOTE This applies to members created with styles from the Structural Member Catalog only.

If you want to...**Then...**

position the extruded axis of the column along one of 9 positions on the column shape

select one of the 9 positions for Justify.

NOTE These positions are defined at a roll of zero, viewing the column from the top to the bottom.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

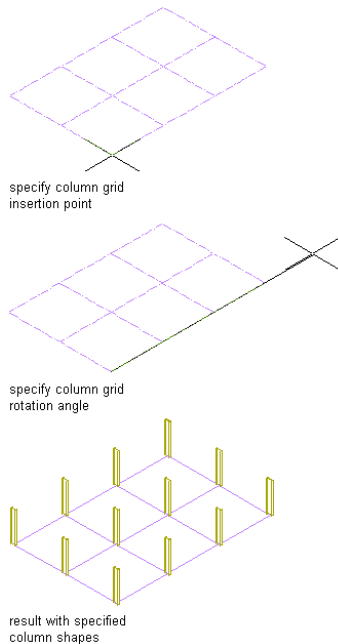

- 10 In the drawing area, specify the insert point for the column.
- 11 If you selected Yes for Specify roll on screen, move the cursor to roll the column around its extruded axis as desired, and then click; or enter a value for degrees of roll, and press *ENTER*.
- 12 Specify an insert point for another column, or press *ENTER* to end the command.

Creating Grid-Anchored Columns

Use this procedure to create a column that is anchored to a grid and has the property settings specified in the structural column tool that you select. The style specified in the tool provides the column shape. When you specify an insert point on the grid, the shape is extruded in a positive direction along the current UCS Z-axis to a height determined by the Start offset, End offset, and Logical length properties of the tool. To specify your own settings when you anchor a column to a grid, see [Creating Grid-Anchored Columns with User-Specified Settings](#) on page 1711.

To create a column grid with pre-anchored columns, see [Creating a Column Grid](#) on page 1829.

Creating a column grid with specified column shapes

- 1 Open the tool palette that contains the structural column tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

2 Move the cursor over the grid so that the grid is highlighted and the list of column-add options is displayed. (You press *Ctrl* to cycle through the options.)

3 Specify the insert point for the column on the grid.

If you want to...

Then...

add a column at a particular node in the grid

move the cursor over the node (or near it), and click. A column is added to the node nearest to the cursor position.

add a column to all nodes in the grid

press *Ctrl*, and click.

add a column at a particular point on or within the grid

press *Ctrl* twice, move the cursor to the point where you want to add the column, and click. If the Properties palette value for Specify roll on screen is Yes, move the cursor to roll the column around its extruded axis as desired, and then click; or enter a value for the roll angle, and press *ENTER*.

A positive value rolls the column counterclockwise around its extruded axis when viewed from its end (top) to its start (bottom).

4 When you are finished adding columns to the grid, press *ENTER* to end the command.

IMPORTANT Column grids that have numerous columns attached to them can take longer than expected to display on screen. This is because structural members carry additional information that may be used for structural analysis.

Creating Grid-Anchored Columns with User-Specified Settings

Use this procedure to anchor a column to a grid as you create it, with property settings that you specify. The style specified in the tool provides the column shape. When you specify an insert point on the grid, the shape is extruded in a positive direction along the current UCS Z-axis to a height determined by the Start offset, End offset, and Logical length properties of the tool.

To create a column grid with pre-anchored columns, see [Creating a Column Grid](#) on page 1829.

Add a column to a single node of a column grid

Add columns to all nodes of a column grid

Add a column to a single point on a column grid

1 Open the tool palette that contains the structural column tool you want to use, and select the tool.

(You may have to scroll to display the desired tool).

2 Select the grid.

3 On the Properties palette, under General, click Style, and select a structural column style.

4 Specify a value for Bound spaces:

If you want to...	Then...
allow the column to be used as a bounding object for associative spaces	select Yes.
prevent the column from being used as a bounding object for associative spaces	select No.
use the bounding setting from the column style	select By Style.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

5 Specify a value for Trim automatically:

If you want...	Then...
the geometry of the column to be automatically trimmed to any other structural members, other architectural objects, or linework to which it is logically connected	select Yes.

If you want...	Then...
prevent the geometry of the column from being trimmed automatically	select No.
use the trim setting from the column style	select By Style.

NOTE This setting affects only the structural member being added. Adding a new structural member will not change the geometry of an existing structural member, regardless of the setting for Trim automatically.

6 Expand Dimensions.

7 Specify offsets:

If you want to...	Then...
offset the column on its extruded axis at the start point of the column	enter a value for Start offset. A positive value shortens the column on its axis, while a negative value lengthens the column on its axis.
offset the column on its extruded axis at the endpoint of the column	enter a value for End offset. A negative value lengthens the column on its axis, while a positive value shortens the column on its axis.

8 Enter a value for Logical length.

The logical length of the column is the length (height) of the column before offsets are applied.

9 Select Yes or No for Specify roll on screen:

If you want to...	Then...
specify the roll of the column before you insert it	select No for Specify Roll on Screen, and enter a value for Roll.
specify the roll of the column when you insert it	select Yes for Specify Roll on Screen, and specify the roll as explained in step 12.

A positive value rolls the column counterclockwise around its extruded axis when viewed from its end (top) to its start (bottom).

10 Specify the column justification, which positions the column shape in relation to its extruded axis when you draw the column:

If you want to...	Then...
position the axis of the column along the centroid of the column shape	select Baseline for Justify. NOTE This applies to members created with styles from the Structural Member Catalog only.
position the axis of the column along one of 9 positions on the column shape	select one of the 9 positions for Justify.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

11 Move the cursor over the grid so that the grid is highlighted and the list of column-add options is displayed. (You press *Ctrl* to cycle through the options.)

12 Specify the insert point for the column on the grid.

If you want to...	Then...
add a column at a particular node in the grid	move the cursor over the node (or near it), and click. A column is added to the node nearest to the cursor position.
add a column to all nodes in the grid	press <i>Ctrl</i> , and click.
add a column at a particular point on or within the grid	press <i>Ctrl</i> twice, move the cursor to the point where you want to add the column, and click. If the Properties palette value for Specify roll on screen is Yes, move the cursor to roll the column around its extruded axis as desired, and then click; or enter a value for the roll angle, and press <i>ENTER</i> . A positive value rolls the column counterclockwise around its extruded axis when viewed from its end (top) to its start (bottom).

13 When you are finished adding columns to the grid, press *enter* to end the command.

NOTE Column grids that have numerous columns attached to them can take longer than expected to display on screen. This is because structural members carry additional information that may be used for structural analysis.

Creating a Structural Member from Linework

Use this procedure to convert any of the following objects to structural members with structural member tools:

- Arcs
- Lines
- Open polylines
- Open polylines with arc segments

NOTE Converting an arc to a structural member is the only method of creating a curved structural member. For more information about curved structural members, see [About Curved Structural Members](#) on page 1725.

When you use a tool to convert linework to a structural member, the style specified in the tool provides the shape of the member. The linework defines the extrusion path for the shape. You can convert multiple lines to create multiple members, convert curved lines to create curved members, and convert multi-segmented lines to create multi-segmented members.

1 Open the tool palette that contains the structural member tool you want to use.

(You may have to scroll to display the desired tool).

2 Right-click a structural member tool, and click Apply Tool Properties to Linework.

3 Select the linework to convert, and press *ENTER*.

NOTE You cannot convert a closed polyline (a polyline with a start node that coincides with its end node) to a structural member.

A worksheet opens appropriate to the tool you selected.

4 Clear One Member Per Polyline Segment to create a structural member for each segment.

5 Select Erase Layout Geometry to erase the linework, and click OK.

If you created a structural member by converting a polyline, the initial orientation of the structural member is set to the UCS that was current when you drew the polyline. You can change the orientation by adjusting the Roll property of the member.

Editing Structural Members

After you create a structural member, you can change any properties of the member that you specified when you created it and make additional modifications. You can change the start and end offsets of a member, or add or remove them. You can change the length, justification, and location of a member, specifying whether its connections with other structural members are maintained. For a curved structural member, you can change the radius.

You can change the geometry of a structural member by trimming it. By changing the structural member type, you can change a brace to beam, or a column to a brace. By changing the style of a structural member, you can change its shape.

AutoCAD Architecture offers several methods for editing structural members:

- You can directly edit structural members using grips for dimensions and other physical characteristics.
- For grip edit operations where you are changing a dimension or an angle, the Dynamic Input feature lets you enter a precise value instead of moving a grip. When this feature is active (click DYN on the application status bar), selecting a grip displays a text box in which you can enter the desired value for the associated dimension or angle. For more information, see “Use Dynamic Input” in AutoCAD Help.
- You can change structural member settings on the Properties palette. You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.
- You can select editing commands from the context menu for a selected structural member.

Using Grips To Edit Structural Members

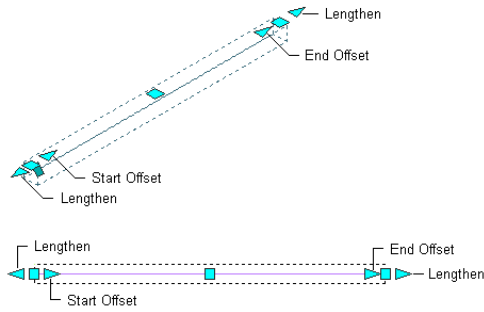

Refer to the illustrations and steps in this topic to use grips to edit structural members.

NOTE If the value of Trim automatically (on the Properties palette) is Yes for each of 2 connected structural members, then any kind of grip edit to either member will result in a mitered joint between them.

Editing Structural Member Dimensions

- 1 Select the structural member.
- 2 Select the grip for the dimension you want to change.

Grips for length, start offset, and end offset of a straight beam or brace

Grips for length, start offset, and end offset of a straight column

Grips for start and end angles, radius, and start and end offsets of a curved beam or brace

Grips for start and end angles, radius, and start and end offsets of a curved column

3 Move the grip until the dimension value you want is displayed, and click once; or enter a value.

Changing the Location of a Structural Member

1 Select the structural member.

Select the Location grip to change the location of the structural member, or the Roll grip to change its roll (the rotation of the member around its extruded axis).

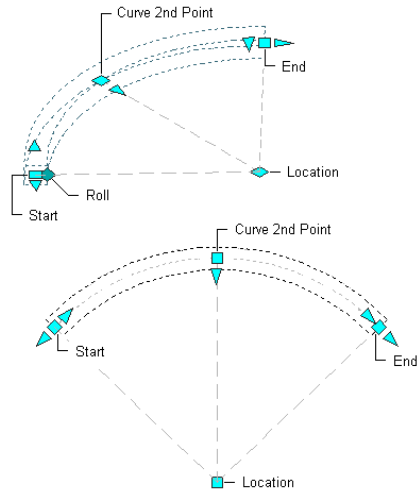

Location and roll grips for a straight beam or brace

Location and roll grips for a straight column

Location and roll grips for a curved beam or brace

Location and roll grips for a curved column

In Model view, the Location grip has six edit options you can cycle through by pressing *CTRL*. For each plane in which you can move the member (*XY*, *YZ*, or *XZ*), you have the option of maintaining or breaking connections with other structural members.

When you choose to maintain connections, all connections are not necessarily maintained for every type of move. Maintenance of connections depends on whether the move is in or out of plane, how the members are connected, and which type of members are involved. Generally, columns take precedence over beams and braces in determining how connected members behave when one is moved. This behavior is summarized in the following table:

If you specify Main- tain Connections when moving ...	Then ...
---	----------

a column	<p>other columns, beams, and braces connected to an endpoint of the column will also move, changing length and orientation as necessary to maintain the connection. (This is also true for any other members connected along the length of a member that is endpoint-connected to the column.) Structural members connected along the length of the column will only extend or shorten to remain connected; they will not change orientation unless the column is moved out of plane. For example, if a column is moved in the <i>XY</i> plane, beams or braces connected along its length will stay connected, even though their orientation changes.</p>
----------	--

**If you specify Main-
tain Connections
when moving ...** **Then ...**

a beam or a brace other beams and braces connected to an endpoint of the beam or brace will also move, changing length and orientation as necessary to maintain the connection. Structural members connected along the length of the beam or brace will only extend or shorten to remain connected; they will not change orientation unless the beam is moved out of plane. For example, if a ridge beam is moved vertically, rafters connected along its length will stay connected, even though their orientation changes.

The default edit mode is to maintain connections for moves along the *XY* plane. In Plan view, the Location grip is restricted to movement in one plane, but you still have the option to maintain or break connections.

- 2** Move the grip until the dimension value you want is displayed, and click once; or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the structural member along a specific direction. If you enter a value for either of the dimension directions in the current edit mode and then press *TAB*, the movement of the structural member is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the structural member is constrained to the *Y* dimension direction.

- 3** Right-click, and click Deselect All to turn off grips.

NOTE When you shift-select the Location grips of end-connected beams, the common endpoint moves approximately twice as far as the grip you move. In the example shown below, if you shift-select the two vertical beams in the structure on the left, and then move a grip toward the right, the result is a configuration like the one at the top right. To get a configuration like the one at the bottom right, you would select all five beams using a crossing selection or a crossing polygon, and then use the **Stretch** command. (For more information, see “STRETCH Command” and “SELECT Command” in AutoCAD Help.) Beams may also move twice as far as you might expect when they are attached to columns on a column grid, and the grid, columns, and beams are all selected. If you select and move only the grid, the columns and beams will move with it, maintaining their same relative positions. For instructions on selecting one object when other objects are superimposed on it, see “Select Objects Individually” in AutoCAD Help.

Changing the Structural Member Length

Use this procedure to change the length of a structural member. You can also change the structural member length on the Properties palette.

- 1 Select the structural member.
- 2 Select a Lengthen grip, move the grip until the length value you want is displayed, and click once.

Changing the length of a beam structural member with grips

After selecting a grip, you can also enter a value to increase or decrease the length of the structural member.

Changing the Structural Member Start and End Offsets

Use this procedure to offset a structural member from the start point or endpoint of its path. You can remove or change existing offsets, or add new offsets to the start point or endpoint of a structural member. You can also change the structural member start and end offsets on the Properties palette.

- 1 Select the structural member.
- 2 Select a Start Offset grip, move the grip until the start offset value you want is displayed, and click once.
A positive start offset value shortens the member on its axis (path), while a negative start offset value lengthens the member on its axis.

Change the end offset of a beam structural member with grips

- 3 Select an End Offset grip, move the grip until the end offset value you want is displayed, and click once.

A positive end offset lengthens the member on its axis, while a negative end offset shortens the member on its axis.

After selecting a grip, you can also enter a value to increase or decrease the start or end offset of the structural member.

Changing the Structural Member Start Point and Endpoint

Use this procedure to change a structural member start point or endpoint. You can also change the structural member start and endpoints on the Properties palette.

- 1 Select the structural member.
- 2 Select a Start or End grip, move the grip until the length value you want is displayed, and click once.

Moving the Start grip in the positive direction shortens the member on its axis (path), while moving the Start grip in the negative direction lengthens the member on its axis.

Moving the End grip in the positive direction lengthens the member on its axis (path), while moving the End grip in the negative direction shortens the member on its axis.

Change the end of a beam structural member with grips

3 Select a Start or End grip, move the grip until the length value you want is displayed, and click once.

After selecting a grip, you can also enter a value to increase or decrease the length of the structural member.

Changing the Structural Member Roll

Use this procedure to change the orientation of a structural member relative to its extruded axis by specifying a number of degrees to roll it. A positive value rolls the member counterclockwise when viewed from its end to its start.

1 Select the structural member.

2 Select the Roll grip, move it until the desired number of degrees is displayed, and click once; or enter a value, and press *ENTER*.

A positive value rolls the member about its axis in a counterclockwise direction when viewed from its end to its start.

Changing beam orientation with the Roll grip

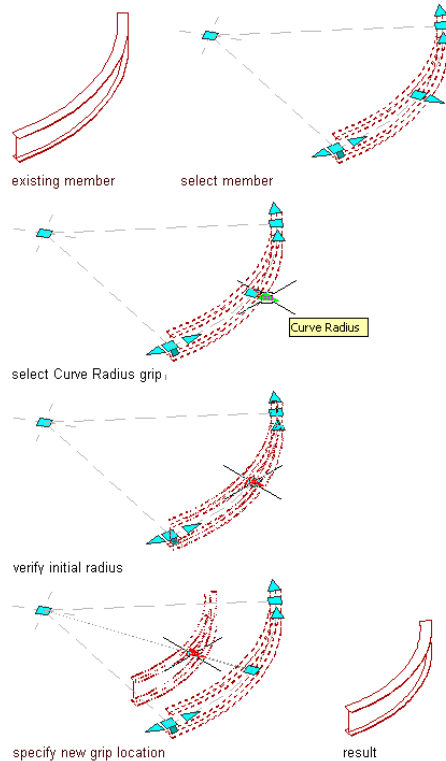

Changing the Radius of a Curved Structural Member

Use this procedure to change the radius of a curved structural member. You can also change the structural member radius on the Properties palette. For more information about curved structural members, see [About Curved Structural Members](#) on page 1725.

- 1 Select the structural member.
- 2 Select a Curve Radius grip, move the grip until the radius value you want is displayed, and click once.

Change the curve radius of a curved beam structural member with grips

About Curved Structural Members

The smoothness (tessellation) of curved edges is controlled by the FACETDEV variable. This variable sets the number of facets to display on curved AEC objects. The default value is 1/2" for drawings created from imperial templates and is 12.7 mm for drawings created from metric templates.

The number you specify for facet deviation defines the maximum distance from the chord to the arc—the chord being an edge that is created from faceting the curve to the true mathematical arc. The facet deviation has a range of greater than zero (0) and no upper limit.

The minimum number of facets is 8. For example, if you create a cylinder mass element to have a 1' radius, and specify 1' for FACETDEV, the cylinder has 8 faces.

The plan representation of individual curved components of columns uses the true curved representation of the member shapes. The above and below cut components will always be faceted.

The maximum number of facets is controlled by the FACETMAX variable. This variable can be set from 100 to 10,000. Note that using a small value for FACETDEV and a large value for FACETMAX will adversely affect drawing performance.

To specify the facet deviation values for the current drawing, see [Specifying the Display Resolution of Objects with Facets](#) on page 169. The settings apply to all curved objects in the drawing, including curved structural members.

Changing the Structural Member Justification

Use this procedure to change the justification of a structural member. Justification positions the shape of a structural member in relation to its extruded axis. Changing the justification of an existing member moves the member and can affect how the member relates to other objects, such as how a column is positioned in relation to a column grid when it is anchored to the grid.

Justification options for a beam

You can also specify the justification of structural members with multiple shapes and segments. For more information about these members, see [Creating Custom Structural Members](#) on page 1757.

- 1 Select the structural member to change, and double-click it.
- 2 On the Properties palette, expand Basic, and expand Dimensions.
- 3 Select a setting for Justification:

If you want to...

Then...

position the axis of the member along the centroid of the member shape

select Baseline for Justify.

NOTE This applies to members created with styles from the Structural Member Catalog only.

position the axis of the member along one of 9 positions on the member shape

select one of the 9 positions for Justify.

4 To specify the justification of members with multiple shapes and segments created with this tool, select a setting for Justify using overall extents:

If you want to...	Then...
justify the member based on the largest cross-sectional extent of the member's lowest priority shapes	select Yes. The justification is applied ONLY to the lowest priority shape definitions, and is calculated based on the node (vertex) of the member with the greatest cross section.
justify the member at each node, based on all shapes.	select No. The justification is calculated based on the cross-sectional extents at each node, and is applied to all the shapes without regard to priority.

Changing the Structural Member Type

Use this procedure to change the type of one or more structural members. Because beams, braces, and columns are sub-types of a single structural member object, you can change a beam to a brace, a column to a beam, or a brace to a beam.

- 1 Select the structural members to change, and double-click one of them.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a setting for Member type: Beam, Brace, or Column.

Trimming Structural Members

Structural members can be trimmed using 2-dimensional objects called trim planes. You can manually add a trim plane for a structural member either by defining its position in relation to the member itself (using the Trim Planes worksheet available from the Properties palette), or by selecting a plane defined (or implied) by another structural member, an architectural object of another type, or linework. You can also configure structural member styles and insertion tools so that a trim plane is created automatically when an endpoint of a new structural member is logically connected to an existing structural member or other object (see [Creating a Structural Member Style in the Style Manager](#) on page 1746).

You can add multiple trim planes to individual structural members, allowing you to clean up joints between multiple structural members. For example, use multiple trim planes to angle both ends of a brace in a diagonally braced frame.

Trim planes can be edited using the Trim Planes worksheet or grip-edited. You can remove trim planes from a structural member to restore it to its original dimensions.

NOTE Although trim planes are depicted as square grids when selected for editing, they are actually infinite planes; thus you cannot use them to notch, cope, or cut holes in structural members.

Trimming a structural member with a trim plane

Adding a Trim Plane to a Structural Member

You can add any number of trim planes to a structural member. When you add a trim plane to one or more structural members, you define the position of the trim plane relative to the structural member that you are trimming.

When defining trim planes, you can:

- Define the position of the trim plane relative to the start or end of the extruded axis of the member.
- Offset the trim plane in the X direction to move the origin of the trim plane along the extruded axis of the member.

Offsetting a trim plane in the X direction

structural member in
Edit Trim Planes mode

select X Offset
grip

verify initial
grip location

specify new
grip location

result

- Offset the trim plane in the *Y* and *Z* directions to move the origin of the trim plane perpendicular to the extruded axis of the member in the *Y* and/or *Z* direction.
- Rotate the trim plane around its *Y* axis to specify a cutting plane angle.

Rotating a trim plane about its Y axis

structural member in Edit Trim Planes mode

select Y Rotation grip

verify initial grip location

specify new grip location

result

- Rotate the trim plane around its Z axis to specify a cutting plane angle.

Rotating a trim plane about its Z axis

structural member in Edit Trim Planes mode

select Z Rotation grip

verify initial grip location

specify new grip location

result

- 1 Select the structural member you want to change, and double-click.
- 2 On the Properties palette, expand Advanced.
- 3 Click the setting for Trim planes.

4 Click .

5 Specify settings to position the trim plane:

If you want to...	Then...
offset the trim plane from the start point or endpoint of the member	select Start or End under Offset.
offset the trim plane in the X direction along the extruded axis of the member	enter an X value for Offset.
offset the trim plane in the Y and Z directions to position the trim plane perpendicular to the extruded axis of the member	enter Y and Z values for Offset.
rotate the trim plane around its Y or Z axis	enter Y and Z values for Rotation.

6 To copy a trim plane, select the trim plane, and click Copy.

7 Continue adding trim planes, and click OK.

Adding a Trim Plane Based on Another Object or Linework

Use this procedure to generate trim planes for one or more structural members based on a plane defined (or implied) by another structural member, an architectural object of another type, linework, or any 2 points you specify. The edge, face, or line that defines the trim plane does not have to intersect the members selected for trimming. The trim plane is projected perpendicular to the current UCS *XY* plane. Selected members are extended or trimmed to the trim plane, depending on whether they intersect it.

Extending a structural member to another structural member

- 1 Select the structural member(s) you want to extend or trim.
- 2 Right-click, and click Trim Planes ► Add Trim Plane.
- 3 Define the trim plane:

If you want to...

Then...

define a trim plane independent of any existing objects

press *ENTER*, specify the start point and endpoint of the trim plane, and then click the side on which you want to remove members.

use the edge or face of an existing object or linework as the trim plane

select the object or linework, and then click the side on which you want members removed. If you want to trim to the face of an object rather than its edge, press *Ctrl* before selecting the object.

Mitering Structural Members with Trim Planes

Use this procedure to generate trim planes that produce a mitered joint between 2 structural members that are connected at their endpoints.

NOTE If the value of Trim automatically (on the Properties palette) is Yes for each of the connected structural members, then any kind of grip edit to either member will result in a mitered joint between them.

Mitering two structural members with coincident endpoints

- 1 Select one of the structural member(s) you want to miter.
- 2 Right-click, and click Trim Planes ► Miter.
- 3 Select the other structural member.

Changing a Structural Member Trim Plane

After you add one or more trim planes to a structural member, you can change the orientation of the trim planes. You can also grip-edit trim planes to move and rotate them.

- 1 Select the structural member you want to change, and double-click.
- 2 On the Properties palette, expand Advanced.
- 3 Click the setting for Trim planes.
- 4 Change any of the trim plane settings:

If you want to...	Then...
change the start or end offset of the trim plane	select Start or End under Offset.
change the trim plane offset in the X direction along the extruded axis of the member	change the X value for Offset.
change the trim plane offset in the Y and Z directions to position the trim plane perpendicular to the extruded axis of the member	change the Y and Z values for Offset.
change the rotation of the trim plane around the Y or Z axis	change Y and Z values for Rotation.

NOTE If you rotate a trim plane between 90 and 270 degrees, the opposite end of the structural member is completely removed.

- 5 Click OK.

Removing a Trim Plane from a Structural Member

Use this procedure to remove a trim plane from a structural member. When you remove all trim planes from a structural member, the structural member is restored to its original dimensions.

- 1 Select the structural member you want to change, and double-click.
- 2 On the Properties palette, expand Advanced.

- 3 Click the setting for Trim planes.
- 4 Select the trim plane that you want to remove.
- 5 Click Remove.
- 6 Click OK.

Changing the Style of a Structural Member

Use this procedure to select a different structural member style for one or more structural members. The style of a structural member provides its shape, so changing the style of a member changes its shape.

- 1 Select the structural members to change, and double-click one of them.
- 2 Expand Basic, and expand General.
- 3 Select a different style.

Applying Tool Properties to a Structural Member

Use this procedure to apply the properties of a structural member tool to one or more members of the same tool type (beam, brace, or column) in a drawing. The properties include any settings specified in the tool you select.

- 1 Open the tool palette that you want to use.
(You may have to scroll to display the desired tool.)
- 2 Right-click a structural member tool, and click Apply Tool Properties to ► <Beam, Brace, or Column>.
- 3 Select the structural members that coincide with the tool, and press *ENTER*.
- 4 Edit the properties of the structural member on the Properties palette, if needed.

Specifying the Cut Plane Display of a Structural Member

Use this procedure to specify the properties of one or more cut planes for an individual structural member. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the structural member you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all structural members in the drawing, select Drawing default setting. To apply changes to all structural members of this style, select Structural Member Style:<style name>. For more information on styles, see [Structural Member Styles](#) on page 1746.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.

- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object. (Alternatively, you can click the value, click , and specify 2 points in the drawing area to define the new height.)
- 8 Specify whether to display the true cut body of the structural member.
- 9 Specify whether to display object components both above and below the cut plane.

You can also access and modify these same cut plane settings through the structural member's context menu, as follows:

- 1 Select the structural member you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
- 3 Select the display representation where you want the changes to appear, and select Object Override.
The display representation in bold is the current display representation.

- 4 If necessary, click .
- 5 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.
- 6 Click OK twice.

Specifying the Display of Custom Block Components of a Structural Member

Use this procedure to specify the display of custom block components for an individual structural member in a particular display representation. If you are going to use custom graphics for a new component, draw the component and save it as a block before you start this procedure.

- 1 Double-click the structural member.
- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all structural members in the drawing, select Drawing default setting. To apply changes to all structural members of this style, select Structural Member Style:<style name>. For more information on styles, see [Structural Member Styles](#) on page 1746.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced, and for Custom block display, click  (the number in parentheses indicates the number of blocks currently attached to the structural member).
- 7 If you want to turn off the display of custom blocks for this structural member without removing them, select Disable Custom Blocks.
- 8 Specify whether to add, edit, or remove a block component:

If you want to...	Then...
add a new block component	click Add, and then click Select Block, select the block, and click OK.
edit an existing block component	select the component to edit, and click Edit.

If you want to...	Then...
remove an existing block component	select the block, click Remove, and click OK.

9 Select a setting for Position Along (x) to position the block in a location along the X-axis of the member.

10 Specify an insertion offset of the block in the X, Y, and Z directions.

11 Specify whether you want repeat the block display along the X-axis of the member:

If you want to...	Then...
repeat the display of the block along the X-axis of the member	select Repeat Block Display.
offset the repeated blocks from the start or endpoint of the member	enter values for Start Offset and End Offset.
specify the space between the repeated blocks	enter a value for space between.
increase the spacing between repeated blocks so the insertion point of the last block is at the end offset distance from the end of the member	select Fit, and select Space Evenly.
scale the block so the extents of all the blocks fit between the start and end offset distances	select Fit, and select Scale to Fit.

12 Specify whether to mirror the block in the X, Y, or Z direction:

If you want to...	Then...
create a mirror of the block in the X direction	select Mirror X.
create a mirror of the block in the Y direction	select Mirror Y.
create a mirror of the block in the Z direction	select Mirror Z.

13 Click OK twice.

you can also add offsets between members to display them as you typically would in a top view framing plan. Note that the Use Member Offsets check box applies only to the start and end offsets. The Offset value below the check box applies only to structural braces, and allows you to offset them horizontally so that they are visible even when positioned directly underneath a beam.

Specifying the Offsets for a Structural Member in Plan Low Detail

Use this procedure to specify offset values for a selected structural member in the Plan Low Detail display representation.

Adding offsets between members lets you display them as you typically would in a top view framing plan. Note that the Use Member Offsets check box applies only to the start and end offsets.

1 Double-click the structural member.

- 2 Click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all structural members in the drawing, select Drawing default setting. To apply changes to all structural members of this style, select Structural Member Style:<style name>. For more information on styles, see [Structural Member Styles](#) on page 1746.

- 5 For Display representation, select Plan Low Detail.

- 6 If necessary, expand Object Display Properties ► Advanced, and click  Offsets.
- 7 For Use Member Offsets, specify whether you want to use the start and end offsets of the member.
- 8 If you did not select Use Member Offsets, enter values for Start Offset and End Offset.
- 9 For Offset, enter the horizontal offset distance you want to use to make structural braces visible even when positioned directly underneath a beam.
- 10 Click OK.

Attaching Hyperlinks, Notes, and Files to a Structural Member

Use this procedure to enter notes and attach hyperlinks and reference files to a structural member. You can also edit notes and edit or detach reference files from a structural member.

- 1 Double-click the structural member.
- 2 In the Properties palette, click the Extended Data tab.
- 3 Click the setting for Hyperlink.
- 4 Specify the link, and click OK.
- 5 Click the setting for Notes.
- 6 Enter the note, and click OK.
- 7 Click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click  , select a file, and click Open.
edit the description of a reference file	enter your comments under Description for the document you are describing.
edit a reference file	double-click the reference file name to start the application needed to edit it.
detach a reference file	select the file name, and click Delete.

- 8 Click OK.

Working with Structural Member Body Modifiers

Body modifiers use the three-dimensional (3D) geometry of an object, such as a mass element or a mass group, to add to or subtract from a structural member. You can also use a body modifier to replace a structural member.

After you create a body modifier from an object, you can delete the original object. However, if you have created a complex object, such as a mass group comprising many mass elements, you may want to retain the object in the drawing until you are sure you have the results you want for the structural member.

Adding a Body Modifier to a Structural Member

Use this procedure to create a body modifier and add it to a structural member.

You can create a three-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

The following illustration shows you how to use an angle as a body modifier to add to a beam.

Adding a body modifier to a structural member

- 1 Place the object in the location where you want to add the body modifier to the structural member.
- 2 Select the structural member you want to change with the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to add to the structural member.
- 4 In the Add body Modifier dialog box, select Additive for Operation.

- 5 Enter a description for the body modifier.
- 6 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 7 Click OK.

Subtracting a Body Modifier from a Structural Member

Use this procedure to create a three-dimensional (3D) body modifier and subtract it from a structural member.

You can create a three-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

The following illustration shows you how to use a box mass element as a body modifier to cope a beam.

Subtracting a body modifier from a structural member

- 1 Place the object in the location where you want to subtract the body modifier from the structural member.
- 2 Select the structural member you want to change with the body modifier, right-click, and click Body Modifiers ► Add.
- 3 Select the object to subtract from the structural member.
- 4 In the Add body Modifier dialog box, select Subtractive for Operation.

- 5 Enter a description for the body modifier.
- 6 Select Erase Selected Object(s) if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 7 Click OK.

Replacing a Structural Member with a Body Modifier

Use this procedure to create a three-dimensional (3D) body modifier and replace a structural member with the modifier.

You can create a three-dimensional (3D) body modifier from a mass element, a mass group, or any other AEC object with mass. You can also create body modifiers from ACIS solids or blocks that form 3D bodies. You must place the object in the location you want in the drawing before defining the object as a body modifier.

The following illustration shows you how to use a mass group as a body modifier to replace a beam.

Replacing a structural member with a body modifier

- 1 Place the object in the location where you want to replace the structural member with the body modifier.
- 2 Select the structural member you want to change with the body modifier, right-click, and click **Body Modifiers** ► **Add**.
- 3 Select the object to replace the structural member.
- 4 In the Add body Modifier dialog box, select **Replace** for Operation.

- 5 Enter a description for the body modifier.
- 6 Select **Erase Selected Object(s)** if you do not want to keep the original object, or clear this option to keep the object in the drawing.
- 7 Click **OK**.

Editing the Geometry of a Body Modifier

Use this procedure to edit the shape of a body modifier that is attached to a structural member. You can edit the body using grips to edit faces, using Boolean commands to add or remove other objects from the body modifier, and other editing commands to change its shape.

- 1 Select the structural member that has the body modifier you want to change, right-click, and click **Body Modifiers** ► **Edit in Place**.

A temporary mass element is created for you to edit the geometry of the body modifier. If the wall contains multiple body modifiers, a mass element is created for each body modifier. If the object was not originally a mass element (for example, if you used a slab as a body modifier), the object becomes a temporary Free Form mass element with faces that you can edit.

- 2 **NOTE** After you perform an editing task from the shortcut menu, you may need to select a profile again to perform another editing task. If you do not see the editing commands that you expect on the shortcut menu, select a profile, and right-click to display the shortcut menu.

Edit the body modifier:

If you want to ...

Then ...

change the shape of a body modifier that is a Free Form mass element

select the body modifier. Select a Face grip to activate edge grips for the face. Move the grips to the desired locations. Continue editing other faces in the same manner.

change the shape of a body modifier that is a conventional mass element

select the body modifier. Select grips and move them to change the shape of the body modifier. The grips that are available depend on the type of mass element used as a body modifier and the current view direction.

add an object to a body modifier

place the object in the location where it is needed. Select the body modifier, right-click, and click **Boolean** ► **Union**. Select the object, and press **ENTER**. Enter **y** (Yes) to keep the object in the drawing, or press **ENTER** to erase it.

subtract an object from a body modifier

place the object in the location where it is needed. Select the body modifier, right-click, and click **Boolean** ► **Subtract**. Select the object, and press **ENTER**. Enter **y** (Yes) to keep the object in the drawing, or press **ENTER** to erase it.

create a body modifier that is the intersection of the original body modifier with another object

place the object in the location where it is needed. Select the body modifier, right-click, and click **Boolean** ► **Intersect**. Select the object, and press **ENTER**. Enter **y** (Yes) to keep the object in the drawing, or press **ENTER** to erase it.

trim a body modifier

select the body modifier, right-click, and click **Trim**. Specify the points that define the trim plane, and select the side of the body modifier to be trimmed. The

If you want to ...	Then ...
	trimmed body modifier is converted to a Free Form mass element.
divide the face of a body modifier into two faces	select the body modifier, right-click, and click Split Face. Specify the points that define the edge created by splitting the faces.
join two faces that are on the same plane into a single face	select the body modifier, right-click, and click Join Faces. Select the edge that separates the coplanar faces.
remove a body modifier	select the object that forms the body modifier, and press <i>DELETE</i> .

3 Save or discard the changes:

If you want to ...	Then ...
restore the body modifier to its original shape	select the body modifier, and click  .
save the changes to the body modifier	select the body modifier, and click  . The body modifier uses the edited mass element to define its geometry.

Managing Body Modifiers

Use this procedure to edit or remove three-dimensional (3D) body modifiers from a structural member. You can select a different operation, or you can enter or edit the descriptions of body modifiers.

NOTE To remove a body modifier from a structural member and restore the modifier as a mass element that you can edit or apply to other structural members, see [Restoring a Body Modifier to a Mass Element](#) on page 1743.

- 1 Double-click the structural member you want to change.
- 2 Expand Advanced, and expand Worksheets.
- 3 Click the setting for Body modifiers.
- 4 Select a body modifier, and change its settings:

If you want to ...	Then ...
apply the body modifier to a different structural member	select a different structural member.
change the operation used to apply the body modifier to the structural member	select a different operation for Operation: <ul style="list-style-type: none"> ■ Select Additive to add the body modifier to the structural member

If you want to ...	Then ...
	<ul style="list-style-type: none"> ■ Select Subtract to subtract the shape of the body modifier from the structural member ■ Select Replace to replace the structural member with the body modifier.
delete the body modifier from the structural member	select the body modifier, and click  .
enter a description of the body modifier	click Description, enter text, and press <i>ENTER</i> .

5 Click OK.

Restoring a Body Modifier to a Mass Element

Use this procedure to remove a body modifier from a structural member and add it to the drawing as a mass element. Restoring a body modifier to a mass element enables you to modify the shape as a mass element and then add it to the structural member again as a body modifier. You can also restore the body modifier to a mass element while leaving the body modifier still applied to the structural member. This is useful if you want to create other structural members with the same shape.

If the object used to create the body modifier was a conventional mass element, it is restored to that mass element. For example, a cylinder mass element is restored as a cylinder mass element. However, if the body modifier was created from another object, such as a slab, or was edited using Boolean operations or face editing commands, the body modifier is restored as a Free Form mass element.

1 Select the structural member you want to change, right-click, and click Body Modifiers ► Restore.

2 **NOTE** This procedure restores all body modifiers attached to a structural member.

Create mass elements from the body modifiers:

If you want to ...	Then ...
create mass elements from the body modifiers while keeping the body modifiers attached to the structural member	press <i>ENTER</i> .
remove <i>all</i> body modifiers from the structural member, and create mass elements from their shapes	enter <i>y</i> (Yes), and press <i>ENTER</i> .

Working with Structural Member Interference Conditions

You can modify the geometry of a Structural Member by using another object to create an interference condition within the structural member. For example, you can create a hole in a structural member. Unlike the object used to add a hole, which has no connection to the structural member and can be erased after the hole is added, the object used to create an interference condition remains partially or wholly embedded in the structural member, cutting out and replacing a part of its geometry. All interference conditions are subtractive in this sense, but the option you use to create the interference condition (Add or Subtract)

determines whether the outline of the interference condition is included or excluded from the shrink wrap outline of the structural member in plan view.

Creating Structural Member Interference Conditions

Use the following procedure to create structural member interference conditions. Typically, after creating interference conditions for a structural member, you freeze the layer where the interfering objects are placed. If you move or edit the objects, the structural member updates accordingly.

NOTE Objects used as interference conditions are not included for the Area in the LIST command or in a Schedule Query result.

To create interference conditions for a structural member:

- 1 Create one or more objects in the actual location where you want the interference condition positioned in relation to the structural member.
- 2 Select the structural member.
- 3 Select an interference condition option:

If you want to...	Then...
include the interference condition within the shrink wrap outline in plan view	right-click, and click Interference Condition ► Add.
exclude the interference condition from the shrink wrap outline in plan view	right-click, and click Interference Condition ► Subtract.

- 4 Select the objects to use as interference conditions, and press *ENTER*.

NOTE AEC objects from externally referenced (xref) files can be added to a structural member as interference conditions so long as the following conditions are met:

- The object is a three-dimensional (3D) body
 - The xref is found
 - The xref is read/write
 - The xref is not locked or opened by another user
 - The xref is loaded
-

Removing Structural Member Interference Conditions

Use this procedure to remove an interference condition from a structural member. Note that only the interference condition is removed; the object from which the interference condition was created remains in the drawing.

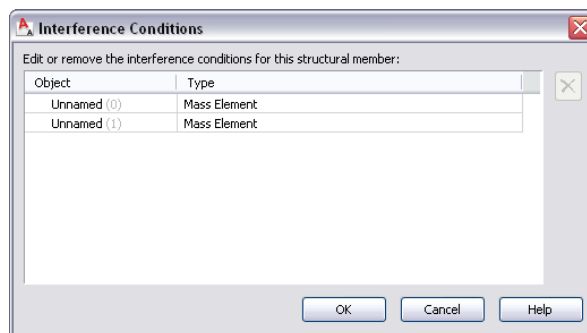

- 1 Select the structural member, right-click, and click Interference Condition ► Remove.
- 2 Select the objects to remove as interference conditions, and press *ENTER*.

NOTE You can also remove interference conditions through the Interference Conditions worksheet. For more information, see [Editing Structural Member Interference Conditions](#) on page 1745.

Editing Structural Member Interference Conditions

Objects applied as interference conditions in structural members be edited like any other objects, using grips, context menu options, or the Properties palette. If you move or edit the objects, the structural member updates accordingly. You can also change the setting that determines whether an interference condition is added to or subtracted from the shrink wrap outline of the structural member in plan view by using the following procedure.

- 1 Select the structural member, right-click, and click Properties.
- 2 On the Properties palette, under Advanced, click the value for Interferences.

- 3 On the Interference Conditions worksheet, click the Shrinkwrap Effect value you want to change, and select a different value from the pull-down menu.
- 4 Click OK.

NOTE You can also use this worksheet to remove an interference condition by right-clicking its Object or Type value and then clicking Remove. The alternate method is to use the context menu of the structural member, as explained under [Removing Slab/Roof Slab Interference Conditions](#) on page 1642. When you remove an interference condition, you remove the association between the structural member and the object that was used to create the interference condition. The object itself is not removed from the drawing.

Structural Member Styles

A structural member style is a group of properties assigned to a structural member that determines the shape and other characteristics of the structural member. You can use structural member styles to represent standard structural member types for specific jobs and drawings or for office standards. When you create or modify a structural member style, the structural members using the style have the settings and characteristics of the style.

Usually you create structural member styles from the Structural Member Catalog or with the Structural Member wizard and drag them from the Style Manager onto a tool palette. You can also create your own structural member styles for custom structural members that you cannot create from the catalog or with the wizard. For more information, see [Creating Custom Structural Members](#) on page 1757.

Creating Tools from Structural Member Styles

You can create a structural member tool from any structural member style. Usually, you want to create structural members tools from styles that you create in the Structural Member Catalog or with the Structural Member Style wizard. However, you can also create a structural member tool from a style that you create in the Style Manager. You can save the style to a drawing file and create a structural member tool with the style. You can then specify default settings for any structural member created with that tool. For more information, see [Creating Structural Member Tools](#) on page 1686.

Managing Structural Member Styles

To create, edit, copy, or purge structural member styles, you access the Style Manager. The Style Manager provides a central location in AutoCAD Architecture where you can work with styles from multiple drawings and templates. For more information about using the Style Manager, see [Style Manager](#) on page 589.

Creating a Structural Member Style in the Style Manager

Use this procedure to create a structural member style in the Style Manager. You can create a style using default style properties, by copying an existing style. After you create the style, you edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Structural Member Styles.
- 3 Create a structural member style:

If you want to...	Then...
create a style with default properties	right-click Structural Member Styles, and click New.
create a style from an existing style	right-click the structural member style you want to copy, and click Copy. Right-click, and click Paste.

4 Enter a name for the new structural member style, and press *ENTER*.

5 Edit the new structural member style:

If you want to...	Then...
enter a description of the style	click the General tab, and enter a description.
specify whether a member with this style will automatically trim to existing members when added to a drawing and whether its trim planes will be adjusted automatically if it is grip edited directly, or if its endpoints move in response to grip-editing of a logically connected member	click the Design Rules tab, and select or clear Trim Members Automatically. This option is selected by default for new styles. The setting can be overridden in the tool or object properties.
change the design rules of the style to create a custom structural member	see Creating Custom Structural Members on page 1757.
specify materials for the components of the style	see Specifying the Materials of a Structural Member Style on page 1747.
specify hatching, cut plane properties, and other display properties of the style	see Specifying the Display Properties of a Structural Member Style on page 1749.
add classifications to a structural member style	see Specifying Classifications for a Structural Member Style on page 1756.
add notes and files to the style	see Attaching Notes and Files to a Structural Member Style on page 1757.

6 Click OK.

7 If you want to assign the style to a structural member tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating Structural Member Tools](#) on page 1686.

8 Click OK.

Specifying the Materials of a Structural Member Style

A structural member consists of a number of components whose display properties can be determined by the materials assigned to each component. When you assign materials to a structural member style, you assign one material to each physical component of the structural member. You assign materials to components in each display representation where you want the materials to be used.

If you want to use the display properties of the structural member style, instead of using material display properties, you can turn off the material assignments in the display properties of the structural member style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component of a material is used to hatch all object surfaces in three dimensional (3D) model views and in elevations.

Structural Member Materials and Display Components

The following table identifies the material component that corresponds to each structural member component:

Structural Member Component	Material Component
Elevation, Elevation High Detail	
Visible Comp 1-10	Plan Linework
Model, Model High Detail, Model Low Detail	
Component 1 - 10	3D Body
Plan, Plan Low Detail, Plan High Detail, Plan Presentation, Plan Screened	
Visible Comp 1-10	Plan Linework
Hatch 1 - 20	Plan Hatch
Reflected, Reflected Screened	
Visible Comp 1-10	Plan Linework

Assigning Materials to a Structural Member Style

Use this procedure to assign materials to the individual components of a structural member style. When you assign a material to a structural member component, the component uses the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the structural member. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, all structural member components are physical components that you can assign materials. The connection and axis are symbols, and you cannot assign materials to them.

NOTE If a material assignment does not determine the display properties of a structural member component, you can change the display properties of the structural member style as described in [Specifying the Display Properties of a Structural Member Style](#) on page 1749.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select By Material for any component to which you want to assign a material, and click OK.

If the setting for By Material is not available, the display of this component cannot be determined by a material.

9 Click the Materials tab.

10 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Although you can edit a material definition from this dialog box, any changes you make to the material definition apply to all objects that are assigned the material.

11 Click OK.

Specifying the Display Properties of a Structural Member Style

In most cases, you can assign materials to structural member components so that the appearance of structural members that belong to the same style is consistent throughout a drawing and with other structural members and objects that use the same materials.

If a component cannot be assigned a material, or if you do not want to use materials but still want consistency among structural members of the same style, you can specify the display properties of the structural member components in the structural member style:

- Layer, color, and linetype of structural member components
- Hatching used with each component
- Cut plane height and the display of components relative to the cut plane
- Other specific structural member display information, such as whether custom blocks are added to the display of the structural member

You can also use the Display tab of the Properties palette to change the display property settings for a selected object display component in the current display representation. For more information, see [Using the Properties Palette to Change Display Properties](#) on page 538.

About Structural Member Display Representations

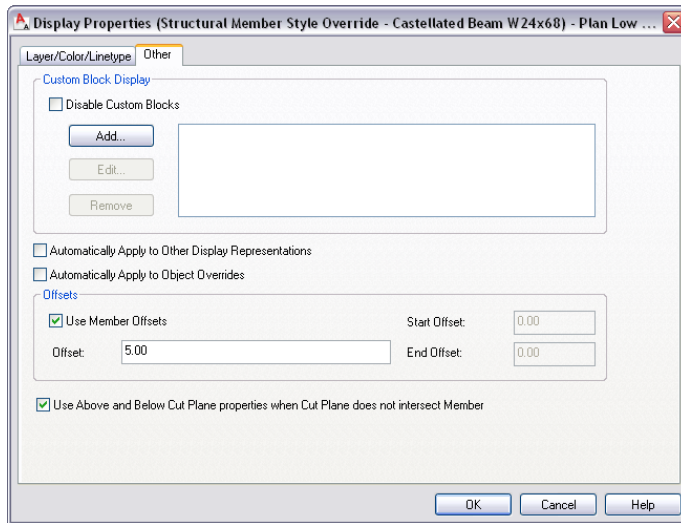

Structural member geometry is created by a shape contained in the style of the structural member that is extruded along the axis of the member. Each shape can have different levels of detail in its geometry, allowing different displays of the structural member that the shape is defining. If you look at the display representations of a structural member, you see that there may be more than one of the same representation. Each representation displays the structural shape in a different level of detail.

For example, you can use the Plan, Plan High Detail, and Plan Low Detail structural member representations to display a plan view of a structural member.

Displaying a structural member with the Plan High Detail, Plan Low Detail, and Plan display representations

The Plan Low Detail display representation displays the member with simple lines and arcs. You can use this display representation to create a top view framing plan where you want a single line representation of a column. The Plan Low Detail display representation includes two display components, Beam Sketch and Brace Sketch. You can change the display properties of these components, such as layer, color, and linetype, to differentiate the display of beams and braces. On the Other tab of the style override dialog box for this display representation, you can also add offsets between members to display them as you typically would in a top view framing plan. Note that the Use Member Offsets check box applies only to the start and end offsets. The Offset value below the check box applies only to structural braces, and allows you to offset them horizontally so that they are visible even when positioned directly underneath a beam.

The Plan and Plan High Detail display representations display the previous column using closed polylines. Both representations display the column geometry, but the Plan High Detail representation is more detailed, including fillets in the column display. Use the Plan representation to improve performance while modeling, and the Plan High Detail representation to display an added level of detail for detail drawings.

The following table lists the structural member display representations and their uses:

Use this display representation...	To...
Elevation	display an elevation view of a structural member with simplified geometry for better performance when modeling.

Use this display representation...	To...
Elevation High Detail	display an elevation view of a structural member in full detail.
Logical	display the extruded axis of a structural member and connections between members. Connections are automatically established between members when they touch endpoint to endpoint or endpoint to a point on the extruded axis of another member.
Model	display a 3D structural member with simplified geometry for better performance when modeling.
Model High Detail	display a 3D structural member in full detail for large scale details.
Plan	display a 2D structural member in less detail than the Plan High Detail representation to improve performance. Members display as closed polylines, rather than lines and arcs as in the Plan Low Detail representation.
Plan High Detail	display a 2D structural member in full detail.
Plan Low Detail	display a 2D structural member with simple lines and arcs to create a top view framing plan. Includes a Beam Sketch and Brace Sketch display component to differentiate beams and braces in plan view.
Plan Presentation	display a 2D structural member with solid hatching (poche) for plan view presentation drawings.
Plan Screened	display a 2D structural member in the screened portion of a screened floor plan, with components and hatching visibly lighter than some other objects.
Reflected	display a 2D structural member in a reflected ceiling plan.
Reflected Screened	display a 2D structural member in the screened portion of a screened reflected ceiling plan with components and hatching visibly lighter than some other objects.

Specifying the Layer, Color, and Linetype of a Structural Member Style

Use this procedure to change the following display properties of the components of a structural member style:

- Visibility (component is on or off)
- By material (material assigned to the display component determines its display properties)

- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

NOTE If a material assignment determines the display properties of components in the structural member style, you can change the properties of the display component by clearing By Material. You can also override the material assignment with a different material. For more information, see [Assigning Materials to a Structural Member Style](#) on page 1748.

NOTE For multi-component structural members, hidden lines are calculated one component at a time.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the structural member style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Layer/Color/Linetype tab.
- 8 Select the component to change, and select a different setting for the property.
- 9 Click OK twice.

Specifying the Hatching for Components of a Structural Member Style

Use this procedure to specify the hatching of the components of a structural member style. Structural member hatching is displayed only in display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the structural member style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click  .
- 7 Click the Hatching tab.
- 8 Select a component, and click the setting for Pattern.
- 9 Select the hatching for the component:

If you want to...

Then...

select a hatching pattern that is available in the software

select Predefined for Type, and then select a pattern.

If you want to...	Then...
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

10 Click OK.

11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

12 Click Angle, and enter the angle for the selected pattern.

13 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

14 Click OK twice.

Specifying the Cut Plane Elevation of a Structural Member Style

Use this procedure to specify the cut plane elevation of a structural member style. The cut plane settings you specify in the structural member style override the cut plane settings in any display configuration applied to a viewport.

NOTE If the cut plane does not intersect the structural member, all visible and hidden components display. If the cut plane does intersect the member, only the cross section of the components of the structural member displays. These are the actual member shapes unless you select Do True Cut.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the structural member style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 If necessary, click .
- 7 Click the Other tab.
- 8 Select Override Display Configuration Cut Plane.
- 9 Enter a value for Cut Plane Elevation.
- 10 Click OK twice.

Using Custom Blocks to Add Graphics to a Structural Member Style

You can add custom blocks to the display of a structural member as a component in a display representation. For example, you can add stiffener plates to beams as a custom blocks or add clip angles to members as a custom blocks.

Adding stiffener plates to a beam

Custom blocks can be either 2D or 3D. When you add a custom block, you can specify several rules for positioning and scaling the new component. Each custom block also appears in the display properties component list so that you can control its layer, color, and linetype. For more information, see [Adding Custom Blocks as a Display Component in a Structural Member Style](#) on page 1754.

Be sure to set the properties of the objects used to create your custom blocks to ByBlock. Otherwise, you cannot control these objects through the display properties. For more information about ByBlock, see “Control the Color and Linetype Properties in Blocks” in AutoCAD help.

To change these display properties for all structural members of the same structural member style, see [Specifying the Display Properties of a Structural Member Style](#) on page 1749.

Adding Custom Blocks as a Display Component in a Structural Member Style

Use this procedure to add or edit custom block components in the display representation of a structural member style.

- 1 Create a 2D or 3D block for the component that you want to add to the structural member.
Create the block in the same plane as the structural member that you use to represent structural member. For more information about custom blocks, see [Using Custom Blocks to Add Graphics to a Structural Member Style](#) on page 1754.
- 2 Open a tool palette that has a structural member tool.
- 3 Right-click a structural member tool, and click Structural Member Styles.
- 4 Select the structural member style that you want to change.
- 5 Click the Display Properties tab.
The display representation in bold is the current display representation.
- 6 Select the display representation where you want the changes to appear, and select Object Override.
- 7 If necessary, click .
- 8 Click the Other tab.
- 9 Under Custom Block Display, click Add.
- 10 Click Select Block and select the block you created.
- 11 Select a setting for Position Along (x) to position the block in a location along the X-axis of the member.

12 Specify an insertion offset of the block in the X, Y, and Z directions.

13 Specify whether you want repeat the block display along the X-axis of the member:

If you want to...	Then...
repeat the display of the block along the X-axis of the member	select Repeat Block Display.
offset the repeated blocks from the start or endpoint of the member	enter values for Start Offset and End Offset.
specify the space between the repeated blocks	enter a value for space between.
increase the spacing between repeated blocks so the insertion point of the last block is at the end offset distance from the end of the member	select Fit, and select Space Evenly.
scale the block so the extents of all the blocks fit between the start and end offset distances	select Fit, and select Scale to Fit.

14 Specify whether to mirror the block in the X, Y, or Z direction:

If you want to...	Then...
create a mirror of the block in the X direction	select Mirror X.
create a mirror of the block in the Y direction	select Mirror Y.
create a mirror of the block in the Z direction	select Mirror Z.

15 Click OK twice.

Turning Off Custom Blocks in a Structural Member Style

Use this procedure to turn off the display of custom blocks without removing them from the structural member style.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the structural member style that you want to change.
- 4 Click the Display Properties tab.
The display representation in bold is the current display representation.
- 5 Select the display representation where you want to turn off custom blocks, and select Object Override.
- 6 If necessary, click  .
- 7 Click the Other tab.
- 8 Under Custom Block Display, select Disable Custom Blocks.
- 9 Click OK twice.

Removing Custom Blocks from a Structural Member Style

Use this procedure to remove custom blocks from the display of a structural member.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the structural member style that you want to change.
- 4 Click the Display Properties tab.
The display representation in bold is the current display representation.
- 5 Select the display representation where you want to turn off custom blocks, and select Object Override.
- 6 If necessary, click .
- 7 Click the Other tab.
- 8 Under Custom Block Display, select the block and click Remove.
- 9 Click OK twice.

Specifying Classifications for a Structural Member Style

Use this procedure to specify classifications for any classification definition applied to a structural member style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the style that you want to change.
- 4 Click the Classifications tab.
By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to structural member styles.
- 5 For each classification definition, select the classification you want to apply to the current structural member style.
- 6 Click OK.

Defining a Structural Member Style as Bounding for Associative Spaces

Use this procedure to define a structural member style that can bound associative spaces.

When a structural member style is set as bounding, by default all beams, braces, and columns that have the style assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding setting from the structural member style in an individual beam, brace, or column, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Structural Member Styles.
- 3 Select a structural member style.
- 4 Click the General tab.

- 5 Select the check box for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Structural Member Style

Use this procedure to enter notes and attach reference files to a structural member style. You can also edit notes and edit or detach reference files from a structural member style.

- 1 Open a tool palette that has a structural member tool.
- 2 Right-click a structural member tool, and click Structural Member Styles.
- 3 Select the structural member style you want to change.
- 4 Click the General tab.
- 5 To add a description to the structural member style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Text Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 9 Click OK.

Creating Custom Structural Members

You can specify design rules within a structural member style to create a custom structural member. The design rules allow you to specify one or more shapes to extrude along the path (axis) of a structural member. You can assign and position a start and end shape for each segment of a structural member.

Creating Single-Segmented Custom Structural Members

A single-segment member can start and end with the same shape, or you can specify different start and end shapes. For example, you can create a tapered column by assigning different start and end shapes to a single-segment column.

Creating a tapered column

You can also assign different shapes to the same single-segment member by adding a component to the member. By adding a component in the design rules and assigning different shapes to the same segment, you can create a structural member with overlapping shapes. For example, you can create a concrete encased steel column by adding a component with a steel column shape to a concrete column.

Creating a composite steel and concrete column

Creating Multi-Segmented Custom Structural Members

For multi-segmented structural members, you can assign different shapes to each segment of the member as components of the member. A series of nodes (starting at 0 at the start point of the member) correspond to each vertex of the member path. By assigning different shapes to segments between nodes on the member path, you can create a structural member that transforms from one shape to different shapes along the member path. For example, you can use this method to create a rigid frame.

Creating the rigid frame

Creating Custom Shapes for Structural Members

When you create custom structural members, you can use the shapes contained in styles that you create from the Structural Member Catalog or Structural Member Style wizard, or you can create your own custom shapes. When you create a custom shape, you can only add it to a structural members in the design rules of the structural member style.

Understanding the Design Rules of a Structural Member

Use this procedure to access and understand the options in the design rules of a structural member.

- 1 Select a structural member, right-click, and click Edit Member Style.
- 2 Click Design Rules.
- 3 On the Design Rules tab, click Show Details.

You can use the following options in the design rules to create custom members:

This option...	Allows you to...
Component	add multiple components to a structural member. Each component includes a name and can include a start and end shape and a priority. You can remove and copy the components of a structural member.
Start Shape and End Shape	select a shape and a set of parameters to the start and end of a structural member component. The component shapes can be the same shape or a different shape. If End Shape is using the Start Shape, an asterisk (*) displays next to the end shape. To transform the shape of the member along the member path, the end shape must be explicitly set.
Priority	assign a priority to a component. Components that start and end at a common node are mitered based on their priorities. Components with the same priority are factored into the miter angle between the components. Components with different priorities are not factored into the miter angle. Components with the lowest priority will affect the justification of the member when Justify Overall Extents is cleared on the Dimensions tab in the properties of the member.

This option...	Allows you to...
Name	select shapes that you assign to the start and end of the member or member segment. You can select shapes contained in structural member styles, or custom shapes that you create.
Relative to	define the position of the shape relative to the start or end of the member.
Node	place shapes on the member path relative to the start or end of the member. To place shapes on the member path, assign them to nodes on the member path. A single segment member has two nodes; the start point and the endpoint of the member. Multi-segmented members have additional nodes located at each vertex of the member path, allowing you to assign different shapes to the start and end of each segment of the member. If you place shapes on the member path relative to the start of the member, then the start point of the member path is Node 0. The first vertex on the member path is Node 1, and so on until the endpoint of the member path is defined as the final node. If you place shapes on the member path relative to the end of the member, then the endpoint of the member is Node 0.
Scale	scale the shape.
Mirror	mirror the shape.
Rotation	rotate the shape.
X	offset the shape in the X direction along the member path.
Y	offset the shape in the Y direction perpendicular to the member path.
Z	offset the shape in the Z direction perpendicular to the member path.

4 Click Add to add a component to a structural member.

A component with the same values as the preceding component is added to the design rules.

5 Click Copy to copy a component.

6 Click Remove to remove a component.

7 Click OK.

Changing the Shape in the Style of a Structural Member

Use this procedure to change the shape that is extruded along the axis of a structural member created from a single shape. You can create a new shape for the structural member by creating a custom shape, or by creating a new style from the Structural Member Catalog that contains a shape.

- 1 Create a structural member with a single shape.

For more information, see [Using Structural Member Tools to Create Structural Members](#) on page 1695.

- 2 Create a new shape for the structural member:

If you want to create...	Then...
a custom shape for the member	create a custom shape. See Creating a Custom Shape for a Structural Member on page 1772.
a shape from the Structural Member Catalog	create a structural member style in the Structural Member Catalog that contains the shape. See Creating a Style from a Shape in the Structural Member Catalog on page 1682.

- 3 Select the structural member, right-click, and click Edit Member Style.

- 4 Click the Design Rules tab.

- 5 In the Name list under Start Shape, select the shape that you created in step 2.

If you created a custom shape in step 2, the name of the shape displays in the Name list. If you created a style from the Structural Member Catalog, the shape displays in the Name list with the name of the shape that you selected in the catalog to create the style, not with the style name that you created.

- 6 Click OK.

Adding a Shape to a Structural Member

Use this procedure to add one or more shapes to a structural member in the design rules of the structural member style. You can create a new shape to add to the structural member by creating a custom shape, or by creating a new style from the Structural Member Catalog that contains a shape.

- 1 Create a structural member with a single shape.

For more information, see [Using Structural Member Tools to Create Structural Members](#) on page 1695.

- 2 Create a new shape to add to the structural member:

If you want to...	Then...
create a custom shape for the member	create a custom shape. See Creating a Custom Shape for a Structural Member on page 1772.
create a shape from the Structural Member Catalog	create a structural member style in the Structural Member Catalog that contains the shape. See Creating a Style from a Shape in the Structural Member Catalog on page 1682.

3 Select the structural member, right-click, and click Edit Member Style.

4 Click the Design Rules tab.

5 Click Add.

A new component is added to the structural member.

6 Type a name for each component under Component.

7 For the new component, from the Name list under Start Shape, select the shape that you created in step 2.

If you created a custom shape in step 2, the name of the shape is displayed in the Name list. If you created a style from the Structural Member Catalog, the shape is displayed in the Name list with the name of the shape that you selected in the catalog to create the style, not with the style name that you typed.

8 Click OK.

The structural member is redrawn with the new shape added to its geometry.

Process Overview: Creating a Single-Component Structural Member (Tapered Column)

Use this example to create a tapered column, a single-component structural member that starts with one shape and ends with another.

Creating a tapered column

The process of creating this tapered column has four steps:

- 1 Create two structural member styles in the Structural Member Catalog that contain the start and end shapes to taper over the length (height) of the column.
- 2 Create a Tapered Column tool.
- 3 Create a column with the tapered column style.
- 4 Specify design rules in the tapered column style to add the start and end shapes in the styles that you created in step 1 to the tapered column.

Creating Start and End Shapes for the Tapered Column

Use this procedure to create two styles that contain the start and end shapes for the tapered column. The first style contains the start shape for the column and the second style contains the end shape for the column.

- 1 On the Format menu, click Structural Member Catalog.

- 2 Expand Imperial in the tree view in the left pane of the Structural Member Catalog.
- 3 Expand Steel, AISC, and then I-Shaped.
- 4 Select Wn, Wide-Flange Shapes.
- 5 Right-click W8X31 in the lower right pane of the Structural Member Catalog, and click Generate Member Style.
- 6 Enter W8X31, and click OK.
- 7 Select W1n, Wide-Flange Shapes in the tree view in the left pane.
- 8 Right-click W14X43 in the lower right pane of the Structural Member Catalog, and click Generate Member Style.
- 9 Enter W14X43 and click OK.
- 10 Click  to close the Structural Member Catalog.

Creating the Tapered Column Tool

Use this procedure to create a tapered column tool. Save the style for the tapered column in the *Member Styles (Imperial).dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`.

- 1 Click Format menu ► Style Manager.
- 2 On the File menu, click Open drawing.
- 3 Open *Member Styles (Imperial).dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`.
- 4 Expand Architectural Objects, right-click Structural Member Styles, and click New.
- 5 Enter Tapered Column for the name, and press *ENTER*.
- 6 Click OK to close the Style Manager.
- 7 Click OK to save changes to the *Member Styles (Imperial).dwg*.
- 8 In the title bar of the tool palettes set, click , and then click New Palette.
- 9 Enter Structural, and press *ENTER*.
- 10 Open the Design palette, select the Structural Column tool, right-click, and click Copy.
- 11 Open the Structural palette, right-click, and click Paste.
- 12 Select the new tool, right-click, and click Properties.
- 13 Enter Tapered Column for the Name.
- 14 Click the setting for Description.
- 15 Enter Creates a tapered column, and click OK.
- 16 Expand Basic, and expand General.
- 17 Click Style location.
- 18 Select Browse, select the *Member Styles.dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 20092009\enu\Styles\Imperial`, and click Open.
- 19 Click Style and select Tapered Column.
- 20 Click OK.

Creating a Column with the Tapered Column Tool

Use this procedure to create a column with the tapered column tool that you created.

- 1 Select the Tapered Column tool from the tool palette.
- 2 Press *ENTER* to create a column that is not anchored to a grid.
- 3 Specify the insert point of the column.
- 4 Specify the roll, which is the rotation around the extruded axis of the column, and press *ENTER*.

Adding the Start and End Shapes to the Tapered Column

Use this procedure to add the start and end shapes to the tapered column and transform them along the member path.

- 1 Select the column, right-click, and click Edit Member Style.
- 2 Click Design Rules.
- 3 Click Show Details.
- 4 Select Unnamed under Component, and enter Component 1.
- 5 Under Start Shape, select W8X31 from the Name list.
- 6 Scroll to the end of the Design Rules dialog box to display the End Shape parameters.
- 7 Under End Shape, select W14X43 from the Name list.
- 8 Click OK.

The complete tapered column displays in your drawing.

Process Overview: Creating a Multi-Component Structural Member (Composite Column)

Use this example to create a steel column encased in concrete, a multi-component structural member with a single segment. The steel column shape is one component of the member, the concrete column shape another.

Creating a composite steel and concrete column

The process of creating this composite column has four steps:

- 1 Create two structural member styles: one that contains the shape for the concrete column and one that contains the shape for the steel column.
- 2 Create a Composite Column tool.
- 3 Create a column with the composite column style.
- 4 Specify design rules in the composite column style to add the concrete and steel shapes to the column.

Creating the Steel and Concrete Shapes for the Composite Column

Use this procedure to create two styles: one that contains the steel shape and one that contains the concrete shape.

- 1 On the Format menu, click Structural Member Catalog.
- 2 Expand Imperial in the tree view in the left pane of the Structural Member Catalog.
- 3 Expand Steel, AISC, and then I-Shaped.
- 4 Select Wn, Wide-Flange Shapes.
- 5 Right-click W8X31 in the lower right pane of the Structural Member Catalog, and click Generate Member Style.
- 6 Enter W8X31, and click OK.
- 7 Expand Concrete, and then Pre-Cast.
- 8 Select Rectangular Columns.
- 9 Right-click 16X16 in the lower right pane of the Structural Member Catalog, and click Generate Member Style.
- 10 Enter 16X16 and click OK.
- 11 Click  to close the Structural Member Catalog.

Creating the Composite Column Tool

Use this procedure to create a composite column tool. Save the style for the composite column in the *Member Styles (Imperial).dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`.

- 1 Click Format menu ► Style Manager.
- 2 On the File menu, click Open drawing.
- 3 Open *Member Styles (Imperial).dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`.
- 4 Expand Architectural Objects, right-click Structural Member Styles, and click New.
- 5 Enter Composite Column for the name, and press *ENTER*.
- 6 Click OK to close the Style Manager.
- 7 Click OK to save changes to the *Member Styles (Imperial).dwg*.
- 8 In the title bar of the tool palettes set, click , and then click New Palette.
- 9 Enter Structural, and press *ENTER*.
- 10 Open the Design palette, select the Structural Column tool, right-click, and click Copy.
- 11 Open the Structural palette, right-click, and click Paste.

- 12 Select the new tool, right-click, and click Properties.
- 13 Enter Composite Column for the Name.
- 14 Click the setting for Description.
- 15 Enter Creates a composite column, and click OK.
- 16 Expand Basic, and expand General.
- 17 Click Style location.
- 18 Select Browse, select the *Member Styles.dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`, and click Open.
- 19 Click Style and select Composite Column.
- 20 Click OK.

Creating a Column with the Composite Column Tool

Use this procedure to create a column with the composite column tool that you created.

- 1 Select the Composite Column tool from the tool palette.
- 2 Press *ENTER* to create a column that is not anchored to a grid.
- 3 Specify the insertion point of the column.
- 4 Specify the roll, or rotation around the extruded axis of the column, and press *ENTER*.

Adding the Steel and Concrete Shapes to the Composite Column

Use this procedure to add the steel and concrete shapes to the composite column.

- 1 Select the column, right-click, and click Edit Member Style.
- 2 Click Design Rules.
- 3 Click Show Details.
- 4 Select Unnamed under Component, and enter Component 1.
- 5 Under Start Shape, select 16X16 from the Name list.
- 6 Click Add.
A new component is added to the design rules of the column. By default, the start and end shapes are the same as the preceding component.
- 7 Select Unnamed under Component, and enter Component 2.
- 8 Under Start Shape for Component 2, select W8X31 from the Name list.
Do not change the other Start Shape parameters.
- 9 Click OK.
The composite column displays in your drawing.

Process Overview: Creating a Multi-Component Structural Member Using Multiple Segments (Rigid Frame)

Use this example to create a rigid frame, a multi-segmented structural member created from multiple shapes that transform at each vertex of the structural member path.

To create the rigid frame, you convert a multi-segmented polyline to a structural member and assign different start and end shapes to each segment of the member as components in the design rules of the rigid frame style. A series of nodes correspond to the start point, vertices, and the endpoint of the member path. By assigning different shapes to segments between nodes on the member path, the rigid frame transforms from one shape to several shapes along its path.

Assign shapes to the rigid frame member relative to the start of the member. The start point is defined as Node 0. The first vertex of the member is defined as Node 1, the next vertex is Node 2, and so on until the endpoint of the member, which is defined as the end node.

NOTE If you assign shapes relative to the end of the member, the endpoint of the member is defined as Node 0.

Identifying nodes on the member path

Creating the rigid frame

polyline converted to rigid frame

The process of creating this rigid frame has seven steps:

- 1 Create two styles in the Structural Member Catalog that contain the shapes that transform over the path of the rigid frame.
- 2 Create a rigid frame style and tool.
- 3 Draw a multi-segmented polyline path for the rigid frame and use the rigid frame tool to convert the path to a structural member.
- 4 Create the first leg of the rigid frame by assigning start and end shapes to the first segment of the frame.
- 5 Create the first rafter of the rigid frame by assigning start and end shapes to the second segment of the frame.

- 6 Create the second rafter of the rigid frame by assigning start and end shapes to the third segment of the frame.
- 7 Create the second leg of the rigid frame by assigning start and end shapes to the fourth segment of the frame.

Creating Shapes for the Rigid Frame

Use this procedure to create two styles that contain the two shapes that transform over the path of the rigid frame.

- 1 On the Format menu, click Structural Member Catalog.
- 2 Expand Imperial in the tree view in the left pane of the Structural Member Catalog.
- 3 Expand Steel, AISC, and then I-Shaped.
- 4 Select Wn, Wide-Flange Shapes.
- 5 Right-click W8X31 in the lower right pane of the Structural Member Catalog, and click Generate Member Style.
- 6 Enter W8X31, and click OK.
- 7 Select W1n, Wide-Flange Shapes in the tree view in the left pane.
- 8 Right-click W14X43 in the lower right pane of the Structural Member Catalog, and click Generate Member Style.
- 9 Enter W14X43 and click OK.
- 10 Click  to close the Structural Member Catalog.

Creating the Rigid Frame Tool

Use this procedure to create a rigid frame tool. Save the style for the rigid frame in the *Member Styles (Imperial).dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`.

- 1 Click Format menu ► Style Manager.
- 2 On the File menu, click Open drawing.
- 3 Open *Member Styles (Imperial).dwg* located in `\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial`.
- 4 Expand Architectural Objects, right-click Structural Member Styles, and click New.
- 5 Enter Rigid Frame for the name, and press *ENTER*.
- 6 Click OK to close the Style Manager.
- 7 Click OK to save changes to the *Member Styles (Imperial).dwg*.
- 8 In the title bar of the tool palettes set, click , and then click New Palette.
- 9 Enter Structural, and press *ENTER*.
- 10 Open the Design palette, select the Structural Column tool, right-click, and click Copy.
- 11 Open the Structural palette, right-click, and click Paste.
- 12 Select the new tool, right-click, and click Properties.
- 13 Enter Rigid Frame for the Name.
- 14 Click the setting for Description.
- 15 Enter Creates a rigid frame, and click OK.

- 16 Expand Basic, and expand General.
- 17 Click Style location.
- 18 Select Browse, select the *Member Styles.dwg* located in *\Documents and Settings\All Users\Application Data\Autodesk\ACD-A 2009\enu\Styles\Imperial*, and click Open.
- 19 Click Style and select Rigid Frame.
- 20 Click OK.

Drawing the Rigid Frame Path and Converting it to a Structural Member

Use this procedure to draw a polyline path in the shape of the rigid frame, and then convert it with the Rigid Frame tool you created in Step 2.

- 1 In plan view, draw a polyline path for the rigid frame.

Drawing the rigid frame path

- 2 On the Structural palette, select the Rigid Frame tool.
- 3 Right-click, select Apply Tool Properties to, and select Linework.
- 4 Select the polyline that you created in step 1.
- 5 Enter y (Yes) to leave the original polyline in the drawing and press *ENTER*.

Creating the First Leg of the Rigid Frame

Use this procedure to create the first leg of the rigid frame by assigning a different start and end shape to the first segment of the rigid frame member.

Creating the first leg of the rigid frame

- 1 Select the rigid frame, right-click, and click Edit Member Style.
- 2 Click Design Rules.
- 3 Click Show Details.
- 4 Select Unnamed under Component, and enter Leg 1.
- 5 Under Start Shape, in the Name list, select W8X31.

6 Select Start for Relative to.

7 Enter 0 for Node.

Node 0 is relative to the start point of the member path.

8 Enter 90 for Rotation.

9 Scroll to the end of the Design Rules dialog box to display the End Shape parameters for Leg 1.

10 Under End Shape, in the Name list, select W14X43.

11 Select Start for Relative to.

12 Enter 1 for Node.

Node 1 corresponds to the vertex formed by the endpoint of the first segment of the member path and the start point of the second segment of the member path.

Creating the First Rafter of the Rigid Frame

Use this procedure to create the first rafter of the rigid frame by assigning a different start and end shape to the second segment of the rigid frame member.

Creating the first rafter of the rigid frame

1 Click Add to add a second component to the structural member.

2 Select Unnamed under Component, and enter Rafter 1.

3 Under Start Shape, in the Name list, select W14X43.

4 Select Start for Relative to.

5 Enter 1 for Node.

6 Scroll to the end of the Design Rules dialog box to display the End Shape parameters for Rafter 1.

7 Under End Shape, in the Name list, select W8X31.

8 Select Start for Relative to.

9 Enter 2 for Node.

Creating the Second Rafter of the Rigid Frame

Use this procedure to create the second rafter of the rigid frame by assigning a different start and end shape to the third segment of the rigid frame member.

Creating the second rafter of the rigid frame

1 Click Add to add a third component to the structural member.

2 Select Unnamed under Component, and enter Rafter 2.

- 3 Under Start Shape, in the Name list, select W8X31.
- 4 Select Start for Relative to.
- 5 Enter 2 for Node.
- 6 Scroll to the end of the Design Rules dialog box to display the End Shape parameters for Rafter 2.
- 7 Under End Shape, in the Name list, select W14X43.
- 8 Select Start for Relative to.
- 9 Enter 3 for Node.

Creating the Second Leg of the Rigid Frame

Use this procedure to create the second leg of the rigid frame by assigning a different start and end shape to the final segment of the rigid frame member.

Creating the second leg of the rigid frame

- 1 Click Add to add a fourth component to the structural member.
- 2 Select Unnamed under Component, and enter Leg 2.
- 3 Under Start Shape, in the Name list, select W14X43.
- 4 Select Start for Relative to.
- 5 Enter 3 for Node.
- 6 Scroll to the end of the Design Rules dialog box to display the End Shape parameters for Leg 2.
- 7 Under End Shape, in the Name list, select W8X31.
- 8 Select Start for Relative to.
- 9 Enter 4 for Node.
- 10 Click OK.

The complete rigid frame displays in your drawing.

Creating Custom Shapes for Structural Members

If you want to design a member with one or more shapes that are not available from the Structural Member Catalog and cannot be created using the Structural Member Style Wizard, you can use the Style Manager to create custom shapes.

When you create a custom shape, you can define three separate geometries (Low Detail, Medium Detail, and High Detail) to accommodate the different levels of detail in different display representations (for example, Plan Low Detail, Plan, and Plan High Detail). The geometries for the new shape can be set entirely from linework in the drawing area, or you can use an existing custom shape definition as a template and edit it to redefine any of its geometries.

Hollow core concrete plank display representations example

Once you have created a custom shape, it is added to the list of Structural Member Shape Definitions in the Style Manager. You can then create a new style from the shape, or you can assign the shape to an existing structural member style by adding it as a component in the design rules of the style. You can also edit, copy, paste, and purge shape definitions just as you can other styles. For more information on these operations, see [Style Manager](#) on page 589.

Creating a Custom Shape for a Structural Member

Use this procedure to create a custom shape for a structural member based on linework you have drawn or otherwise inserted in the drawing area.

1 In the drawing area, create three geometries to define the Plan Low Detail, Plan, and Plan High Detail display representations of the shape. You can draw entirely new geometries, or you can insert geometries from existing shape definitions (see [Inserting a Custom Shape in a Drawing](#) on page 1773.)

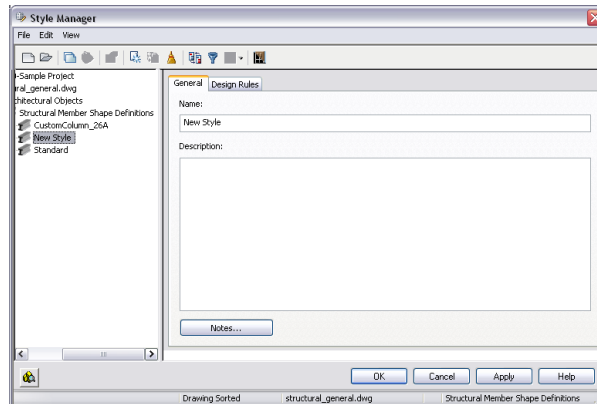

For Plan Low Detail, you can use lines, arcs, circles, or polylines. For Plan and Plan High Detail, use closed polylines, splines, ellipses, or circles. Note that these entities must not intersect.

2 Click Format menu ► Structural Members ► Member Shapes.

The Style Manager is displayed with the Architectural Objects folder open and Structural Member Shape Definitions selected

3 Right-click Structural Member Shape Definitions, and click New

4 In the right pane of the Style Manager, click the General tab.

5 Enter a name and description for the new shape, and then click the Design Rules tab.

6 For Shape Geometry, select Low Detail, and then click .

7 In the drawing area, select the line(s), arc(s), circle(s), or polyline(s) to define the Plan Low Detail display representation for the new shape, and then press *ENTER*.

8 Select an insertion point.

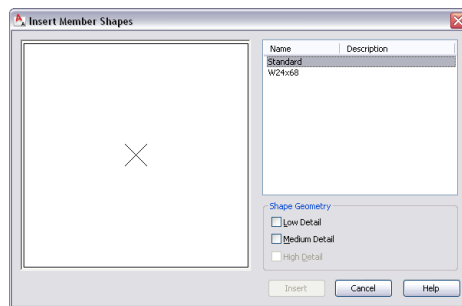

The low detail shape is displayed in the viewer under the Design Rules tab.

- 9 For Shape Geometry, select Medium Detail, and then click  .
- 10 In the drawing area, select a closed polyline, spline, ellipse, or circle to define the Plan display representation for the selected shape designation.
- 11 Select an insertion point, or enter **c** (Centroid) or **p** (Previous Point) to position the selected shape in the viewer.
- 12 For Shape Geometry, select High Detail, and then click  .
- 13 In the drawing area, select a closed polyline, spline, ellipse, or circle to define the Plan High Detail display representation for the shape.
- 14 Select an insertion point, or enter **c** (Centroid) or **p** (Previous Point) to position the selected shape in the viewer.
- 15 If you want to create a new structural member style from the shape, click  , enter a name for the new style, and click OK.
- 16 Click OK to add the new shape to the list of Structural Member Shape Definitions and dismiss the Style Manager.
- The new shape can now be added to existing structural member styles. For more information, see [Adding a Shape to a Structural Member](#) on page 1761.

Inserting a Custom Shape in a Drawing

Use this procedure to insert one or more of the geometries defined for a custom shape into a drawing. The geometry can then be edited or used as is to define one of the display representations for another custom member shape you are creating or editing.

- 1 On the Format menu, select click Structural Members ► Insert Member Shape.

- 2 In the right pane of the Insert Member Shapes worksheet, select a custom member shape.
- 3 Click one or more of the Shape Geometry check boxes.
The geometry for each selected shape designation is highlighted in the viewer.
- 4 Click Insert.
The geometry defined for each of the selected shape designations is inserted into the drawing area.

Design Utilities

Anchors

30

Anchors create links between different objects. Anchors are often used to connect an object, such as a column or a structural element, to a grid or layout curve. Anchors can also be used to anchor architectural objects to each other, or to linework objects, like lines and circles.

Anchors

An anchor links an AEC object to another object or to a layout curve or grid. You can create anchors between objects and also remove anchors from objects. AEC objects can be anchored to each other, to AutoCAD objects like lines and circles, or to layout curves or grids.

Automatic and user-defined anchors enable you to use anchors for many different purposes.

Automatic and User-Defined Anchors

Automatic anchors are set by the program. Certain objects are by default anchored to other objects. For example, doors and windows are usually anchored to walls. Curtain wall units or window assemblies might be anchored to curtain walls. Although these anchors are inserted automatically, when you place the objects their behavior can differ slightly. For example, a door that is anchored to a wall can be moved to an unconnected wall. The door cannot, however, be moved outside a wall and stand alone. To do this, you must remove the anchor between door and wall. The anchor of a column to a column grid behaves differently: you can move the column inside the grid, but you cannot move the column to another grid without first removing the anchor.

User-defined anchors are manual links that you can create between two objects. Most anchors are used with layout curves, layout grids, or volumes. You can also attach anchors to other AEC objects or AutoCAD objects.

Anchoring objects to a layout curve can be useful for positioning washbasins along a wall or rafters along a roof. Anchoring objects to layout grids can help you to position columns on a column grid, planters on a sidewalk grid, or tile accents on a floor tile grid. For information about layout curves or grids, see [Using Layout Curves](#) on page 1800 and [Using Layout Grids](#) on page 1810.

Types of User-Defined Anchors

There are six different types of anchors that you can use to attach objects:

If you want to...	Then...
attach AEC objects to other AEC objects	use object anchors.
attach AEC objects to the base curve of other objects, such as lines, arcs, circles, mass elements, polylines, roofs, or walls	use curve anchors.
attach objects to nodes on layout curves or grids with leaders	use leader anchors.
attach objects to nodes on layout curves or grids	use node anchors.
attach objects to cell positions on 2D layout grids and 3D volume grids	use cell anchors.
attach objects to volumes on 3D grids	use volume anchors.

Working with Object Anchors

You can use object anchors to attach an AEC object to the base curve of another AEC object. When an AEC object is anchored to another AEC object, it will be moved together with the anchoring object. When the anchoring object is deleted, the anchored object will be deleted, too. Changes that are made to the anchored object, however, will not be replicated in the anchoring object.

When the anchored object is selected, a temporary graphic displays the anchor. The temporary anchor graphic contains a trigger grip to release the object anchor.

Mass element anchored to a wall

Adding Object Anchors

Use this procedure to create an object anchor between two AEC objects.

Creating an object anchor

1 On the command line, enter **ObjectAnchorAttach**.

2 Select the AEC object that should be anchored to another AEC object, and press ENTER.

3 Select the anchoring AEC object.

An object anchor is added. When you select the anchored object, you can see the anchoring connection.

Releasing Object Anchors

Use this procedure to release an object anchor between two AEC objects.

Releasing an object anchor

1 Select the AEC object that is anchored to another AEC object.

2 Click the Release Object Anchor grip on the anchor line.

The object anchor is removed.

Working with Curve Anchors

You can use curve anchors to attach AEC objects to the base curve of other AEC objects or linework, such as lines, arcs, circles, mass elements, polylines, roofs, or walls. The movement of an object that is anchored to another object with a curve anchor is constrained by the object to which it is anchored. Curve anchors are best suited for attaching objects to linear objects like lines, arcs, or walls as opposed to grids or layout volumes.

Adding Curve Anchors

Use this procedure to add a curve anchor to attach objects to the base of other objects.

Anchoring an object to a layout curve

1 Open the tool palette that you want to use, and select a Curve Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Curve Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Curve Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **CurveAnchor** on the command line.

2 Enter **at** (Attach object), and select the object to be anchored.

3 Select a point on the curve that you want to anchor the object to.

The object is anchored to the curve at the X position. When the object is first placed, the Y and Z positions are 0.

4 Press **ENTER**.

Changing the Position of Objects Anchored to Curves

Use this procedure to change the position of objects anchored to curves. You can change the position of an anchored object relative to the curve in the X , Y , and Z directions. You can also rotate and flip the object along its axes.

Moving an object along a layout curve in the X direction

movement in a negative
x direction

movement in a positive
x direction

Moving an object along a layout curve in the Y direction

movement in a negative
y direction

movement in a positive
y direction

Moving an object along a layout curve in the Z direction

NOTE The positioning of multi-view blocks assumes that the insertion point of the multi-view block is at its midpoint.

- 1 Double-click the anchored object.
- 2 On the Properties palette, expand Basic, and expand Location on Curve.

TIP You can also access commands to change the position of the anchored object from the context menu. Select the anchored object, right-click, and click Curve Anchor. From the submenu, choose the desired command to manipulate the anchored object in relation to its anchoring curve.

- 3 Click Anchor.
- 4 Change the position along the X axis:

If you want to...

Then...

change the X reference point on the curve

select Start of curve, Midpoint of curve, or End of curve for From.

specify the X distance between the reference point on the curve and the anchored object

enter a value for Distance.

If you want to...	Then...
select from which point on the anchored object the X distance to the curve is measured	select Start edge of object, Center of object, or End edge of object for To.

5 Change the position along the Y axis:

If you want to...	Then...
change the Y reference point on the curve	select Left edge of curve width, Center of curve width, or Right edge of curve width for From.
specify the Y distance between the reference point on the curve and the anchored object	enter a value for Distance.
select from which point on the anchored object the Y distance to the curve is measured	select Front of object, Center of object, or Back of object for To.

6 Change the position along the Z axis (vertical):

If you want to...	Then...
change the Z reference point on the curve	select Bottom of curve height, Center of curve height, or Top of curve height for From.
specify the Z distance between the reference point on the curve and the anchored object	enter a value for Distance.
select from which point on the anchored object the Z distance to the curve is measured	select Bottom of object, Center of object, or Top of object for To.

7 To change the rotation of the anchored object, enter values for the X and Z rotation.

8 To flip the object along one of the axes, select Flip X, Flip Y, or Flip Z.

9 Click OK.

Anchoring Objects to New Curves

Use this procedure to anchor objects to new curves. You can anchor an object to a new object without first releasing the previous anchor. The new anchor is of the same type as the previous one; in this case, it is a curve anchor.

1 Open the tool palette that you want to use, and select a Curve Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Curve Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Curve Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **CurveAnchor** on the command line.

2 Enter **s** (Set curve), and select anchored objects.

NOTE You can select only AEC objects here.

3 Press *ENTER*.

4 Select a new object to anchor the object to.

NOTE You can select AEC objects and AutoCAD objects here.

5 Press *ENTER*.

Working with Leader Anchors

You can use leader anchors to anchor objects to nodes on layout curves or grids with leaders. The movement of the anchored object is constrained by the leader on the anchor.

For information about creating layout curves or grids and nodes, see [Using Layout Curves](#) on page 1800 and [Using Layout Grids](#) on page 1810.

Adding Leader Anchors

Use this procedure to add leader anchors to your drawing. An object can be anchored to only one node at a time. When you try to anchor it to a second node, the object is released from the first node. You can, however, anchor any number of objects to a single layout node.

1 Open the tool palette that you want to use, and select a Leader Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Leader Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Leader Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **LeaderAnchor** on the command line.

2 Enter **a** (Attach object), select the object to be anchored, and then specify a point on or near a node on a layout curve, layout grid, or volume grid.

The object is anchored to the node that you selected. By default, the leader anchor is created at a direction of 0 from the node and has first and second extensions of 1 inch (25.4 mm). These extensions are measured from the node to the center of the anchored object.

3 Press *ENTER*.

Changing the Position of Objects Anchored to Layout Nodes with Leader Anchors

Use this procedure to change the position of objects anchored to layout nodes with leader anchors. You can change the coordinate system, orientation, and rotation of an object anchored to a layout node. You can also define offsets from the node.

1 Double-click the object anchored to a layout node.

2 On the Properties palette, expand Basic, and expand Location from Node.

TIP You can also access commands to change the position of the anchored object from the context menu. Select the anchored object, right-click, and click Leader Anchor. From the submenu, choose the desired command to manipulate the anchored object in relation to its anchoring node and leader.

3 Click Anchor.

4 Specify changes in the position or orientation of anchored objects:

If you want to...	Then...
specify an offset from the object to the node	specify insertion offset values for the X, Y, or Z position.
anchor the object to the center of the node	select Center on Node.
have the anchored object use the coordinate system of the node	select Use Node Coordinate System.
not have the anchored object use the coordinate system of the node	specify X, Y, or Z normals for the anchored object.
change the rotation angle of the anchored object	specify values for the X, Y, or Z rotation angles.
flip the object along the X, Y, or Z axes	select Flip X, Flip Y, or Flip Z.
change the angle of the leader to the node	specify a value for Angle to Node.
change the offset of the leader start grip from the center of the base curve of the layout node	enter an offset value for First Extension.
change the offset of the leader end grip from the center of the base curve of the anchored object	enter an offset value for Second Extension.

NOTE By default the leader extensions are slightly offset so as not to overlap the leader grip with the object location grip.

5 Click OK.

Grip-Editing Leaders

Use this procedure to grip-edit leaders. A leader anchor connects an object to a layout node with a leader between the two. You can change the length and shape of the leader.

A leader consists of one segment or several segments. You can change the leader shape by grip-editing the object.

You can use grips to add segments to existing leaders.

1 Select the anchored object.

2 Move the leader grip to move the leader in the appropriate direction.

3 After you release the leader, select the anchored object again.

An additional leader grip is added at the point from which the leader originally started.

- 4 Move the leader grip at the start of the leader line to add another segment to the leader.
- 5 Repeat this procedure until the leader has all the segments you need.
You can later edit the leader in the same way you edit an AutoCAD polyline.

Extending Leaders

Use this procedure to extend the leader line beyond the first and last grip points on the leader line.

- 1 Double-click the anchored object.
- 2 On the Properties palette, expand Basic, and expand Location from Node.
- 3 Click Anchor.
- 4 Edit the leader line:

If you want to extend...	Then...
the start point of the leader line	in the First Extension field, enter the extension value.
the endpoint of the leader line	in the Second Extension field, enter the extension value.

- 5 Click OK.

Copying Objects to All Layout Nodes

Use this procedure to copy objects to all layout nodes. You can select an AEC object and, instead of manually anchoring it to a layout node, you can copy the object and anchor one copy to each node on a layout curve or grid.

TIP If you want the leader to be displayed in the same way at every node, first anchor the object to a single node. Adjust the leader attributes (direction, extension, or properties), and then use the Copy to Nodes option. Next, select the object that is anchored to the single node, and select the layout curve or grid.

- 1 Anchor an object to a layout node, as described in [Adding Leader Anchors](#) on page 1785.
- 2 Open the tool palette that you want to use, and select a Leader Anchor tool.
If necessary, scroll to display the tool that you want to use.
A Leader Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Leader Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.
- 3 To copy the anchored object to every node on the layout curve or grid, enter **c** (Copy to Nodes).
- 4 Select the object that you want to copy and anchor to every node on the layout curve or grid.
- 5 Select the layout curve or grid.

NOTE Alternatively, enter **LeaderAnchor** on the command line.

If an existing object is anchored to any of the nodes, you are prompted to specify whether you want to skip nodes that already have something anchored to them. Enter **y** to avoid duplicate anchored objects on those nodes.

Working with Node Anchors

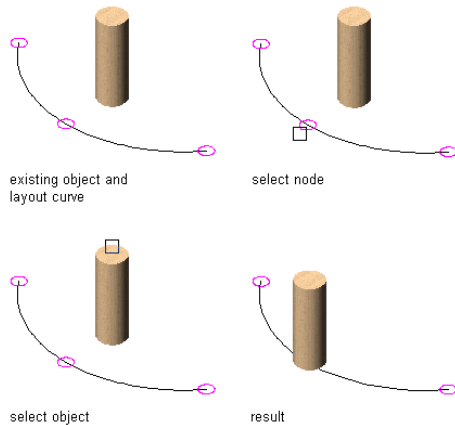

You can use node anchors to attach objects to nodes on layout curves or grids. Anchoring objects to a layout curve might be useful for positioning washbasins along a wall or rafters along a roof. Anchoring objects to layout grids might help you to position columns on a column grid, planters on a sidewalk grid, or tile accents on a floor tile grid.

WARNING When you change the position of an object that is anchored to a curve, the anchored object needs to stay on the curve. Keeping the association between the object and the node prevents all objects that are being moved from attaching to the same node.

Adding Node Anchors

Use this procedure to add node anchors. You can add as many node anchors in your drawing as you have layout nodes. An individual object can be anchored to only one layout node. If you try to anchor an object to a second node, the first anchor is released. You can, however, anchor several objects to the same layout node and edit them individually.

Anchoring an object to a layout curve node

1 Open the tool palette that you want to use, and select a Node Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Node Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Node Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **NodeAnchor** on the command line.

2 Enter **a** (Attach object), and select the object to be anchored.

3 Specify a point on or near a node on a layout curve or grid.

4 Press **ENTER**.

Changing the Position of Objects Anchored to Layout Nodes with Node Anchors

Use this procedure to change the position of objects anchored to layout nodes with node anchors. You can change the coordinate system and orientation of an object anchored to a layout node. You can also define offsets from the node.

- 1 Double-click the anchored object.
- 2 On the Properties palette, expand Basic, and expand Location from Node.

TIP You can also access commands to change the position of the anchored object from the context menu. Select the anchored object, right-click, and click Node Anchor. From the submenu, choose the desired command to manipulate the anchored object in relation to its anchoring node.

- 3 Click Anchor.
- 4 Change the position or orientation of the anchored object:

If you want to...	Then...
specify an offset from the object to the node	specify offset values for the X, Y, or Z position.
anchor the object to the center of the node	select Center on Node.
have the anchored object use the coordinate system of the node	select Use Node Coordinate System.
not have the anchored object use the coordinate system of the node	specify X, Y, or Z normals for the anchored object.
flip the object along the X, Y, or Z axes	select Flip X, Flip Y, or Flip Z.

- 5 Click OK.

Anchoring Objects to Different Nodes

Use this procedure to anchor objects to different nodes. You can attach an anchored object to another node on the same layout curve or grid, or to another layout curve or grid altogether.

Moving an anchored object to another layout curve node

NOTE If you want to move an anchored object to a different node on the same layout curve or grid, you can also drag the object to the node.

1 Open the tool palette that you want to use, and select a Node Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Node Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Node Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **NodeAnchor** on the command line.

2 Enter **s** (Set node), and select the anchored object.

3 Press **ENTER**.

4 Select the node you want to anchor the object to.

5 Press **ENTER**.

Copying Objects to All Layout Nodes

Use this procedure to copy objects to all layout nodes. You can select an AEC object and, instead of manually anchoring it to a layout node, you can copy the object and anchor one copy to each node on the layout curve or grid.

Copying an object to all layout curve nodes

1 Anchor an object to a layout node, as described in [Adding Node Anchors](#) on page 1788.

2 Open the tool palette that you want to use, and select a Node Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Node Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Node Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **NodeAnchor** on the command line.

3 To copy the object to every node on the layout curve or grid, enter **c** (Copy to each node).

4 Select the object that you want to copy and anchor to every node on the layout curve or grid.

5 Select the layout curve or grid.

If an object is already anchored to any of the nodes, you are prompted to specify whether you want to skip nodes that already have something anchored to them. Enter **y** (Yes) to avoid duplicate anchored objects on those nodes.

Working with Cell Anchors

A cell is a subdivision of a layout grid or volume grid. A cell anchor attaches objects to cell positions on layout grids and volume grids. When an object is anchored to a cell, the object is resized to fit the cell size. When the grid or volume itself is resized, you can decide whether the anchored object is updated accordingly or remains its original size.

Adding Cell Anchors

Use this procedure to add cell anchors. You can add cell anchors to objects to connect them to cells in layout grids and volume grids.

Anchoring an object to a layout grid cell

NOTE There is no rule that determines which cell the object attaches to when you anchor it. You can turn on the Node display component to display the cell nodes of the layout grid or volume for easier cell selection. You can also move the object after you anchor it to the layout grid or volume.

1 Open the tool palette that you want to use, and select a Cell Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Cell Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Cell Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **CellAnchor** on the command line.

2 Enter **a** (Attach object), and select the object to be anchored.

3 Specify a point on or near a cell of a layout grid or volume grid.

The object is automatically scaled to fill the entire cell.

4 Press **ENTER**.

Changing the Position and Size of Objects Anchored to Layout Cells

Use this procedure to change the position and size of objects anchored to layout cells. You can change the coordinate system and orientation of an object anchored to a layout cell. You can also define insertion and size offsets and indicate whether the object should be resized when the cell is resized.

- 1 Double-click the anchored object.
- 2 On the Properties palette, expand Basic, and expand Location in Cell.

TIP You can also access commands to change the position of the anchored object from the context menu. Select the anchored object, right-click, and click Cell Anchor. From the submenu, choose the desired command to manipulate the anchored object in relation to its anchoring grid cell.

- 3 Click Anchor.
- 4 Change the position or orientation of anchored objects:

If you want to...	Then...
specify an offset from the object to the cell	specify offset values for the X, Y, or Z position.
anchor the object to the center of the cell	select Center on Cell.
have the anchored object use the coordinate system of the cell	select Use Cell Coordinate System.
not have the anchored object use the coordinate system of the cell	clear Use Cell Coordinate System, and specify X, Y, or Z normals for the anchored object.
flip the object along the X, Y, or Z axes	select Flip X, Flip Y, or Flip Z.

- 5 Specify how an anchored object is resized to fit the edges of the cell:

If you want to...	Then...
resize the object every time the cell is resized	select Apply Resize.
not resize object every time the cell is resized	clear Apply Resize.
specify a distance between the anchored object and the cell	enter an appropriate negative value for Size Offset.
extend the anchored object beyond the cell edges	enter an appropriate positive value for Size Offset.

- 6 Click OK.

Anchoring Objects to a Different Cell

You can attach an anchored object to another cell in the same layout grid or volume grid, or to another grid altogether.

- 1 Open the tool palette that you want to use, and select a Cell Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Cell Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Cell Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **CellAnchor** on the command line.

2 Enter **se** (Set cell), and select the object.

3 Press **ENTER**.

4 Select the cell you want to anchor the object to.

The object is moved to the new cell. If the new cell is different in size from the original one, the object is resized accordingly.

NOTE You can also drag the object if you want to move an anchored object to a different cell on the same layout grid or volume grid.

Copying Objects to All Layout Cells

Use this procedure to copy objects to all layout cells. You can select an AEC object and, instead of manually anchoring it to a layout cell, you can copy the object and anchor one copy to each cell on the layout grid or volume grid.

1 Open the tool palette that you want to use, and select a Cell Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Cell Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Cell Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **CellAnchor** on the command line.

2 To copy the anchored object to every cell in the layout grid or volume grid, enter **c** (Copy to each cell).

3 Select the object.

4 Select the layout grid or volume grid that you want to copy and anchor the object to.

If an object is already anchored to any of the cells, you are prompted to specify whether you want to skip cells that already have something anchored to them. Enter **y** (Yes) to avoid duplicate anchored objects appear in those cells.

Working with Volume Anchors

You can use volume anchors to attach objects to volumes in 3D volume grids. The movement of an object that is anchored to a volume grid is constrained by that volume grid.

When an object is anchored to a volume inside a volume grid, the object is resized to fit the volume size. When the volume itself is resized, you can decide whether the anchored object is updated accordingly or remains its original size.

Adding Volume Anchors

Use this procedure to add volume anchors. You can add volume anchors to objects to connect them to volume grids.

Anchoring an object to a volume grid

1 Open the tool palette that you want to use, and select a Volume Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Volume Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Volume Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **VolumeAnchor** on the command line.

2 Enter **a** (Attach object), and select the object to be anchored.

3 Specify a point on or near a volume in a volume grid.

The object is scaled to fill the entire volume.

4 Press **ENTER**.

Changing the Position and Size of Objects Anchored to Volumes

Use this procedure to change the position and size of objects anchored to volumes. You can change the coordinate system and orientation of an object anchored to a volume. You can also define insertion and size offsets and indicate whether the object should be resized when the volume is resized.

1 Double-click the anchored object.

2 On the Properties palette, expand Basic, and expand Location in volume.

TIP You can also access commands to change the position of the anchored object from the context menu. Select the anchored object, right-click, and click Volume Anchor. From the submenu, choose the desired command to manipulate the anchored object in relation to its anchoring volume grid.

3 Click Anchor.

4 Change the position or orientation of anchored objects:

If you want to...	Then...
specify an offset from the object to the volume	specify offset values for the X, Y, or Z position.
anchor the object to the center of the volume	select Center on Node.
have the anchored object use the coordinate system of the volume grid	select Use Node Coordinate System.
not have the anchored object use the coordinate system of the volume grid	clear Use Node Coordinate System, and specify X, Y, or Z normals for the anchored object.
flip the object along the X, Y, or Z axes	select Flip X, Flip Y, or Flip Z.

5 Specify how an anchored object is resized to fit the edges of the volume:

If you want to...	Then...
resize the object every time the volume is resized	select Apply Resize.
not resize the object every time the volume is resized	clear Apply Resize.
specify a distance between the anchored object and the volume	enter an appropriate negative value for Size Offset.
extend the anchored object beyond the volume edges	enter an appropriate positive value for Size Offset.

6 Click OK.

Anchoring Objects to a Different Volume

Use this procedure to anchor objects to a different volume. You can attach an anchored object to another volume in the same volume grid, or to another volume grid.

NOTE If you want to move an anchored object to a different volume on the same volume grid, you can also drag it there.

1 Open the tool palette that you want to use, and select a Volume Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Volume Anchor tool is located in the Content Browser in the Stock Tool Catalog. Open the Content Browser and select the Stock Tool Catalog. Browse to the Parametric Layout and Anchoring category, and drag the Volume Anchor tool into the drawing area or to a tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

NOTE Alternatively, enter **VolumeAnchor** on the command line.

2 Enter **s** (Set volume), and select the anchored object.

3 Press **ENTER**.

4 Select the volume you want to anchor the object to.

The object is moved to the new volume. If the new volume is different in size from the original one, the object is resized accordingly.

Copying Objects to All Layout Volumes

Use this procedure to copy objects to all layout volumes. You can select an AEC object and, instead of manually anchoring it to a volume, you can copy the object and anchor one copy to each volume on the volume grid.

1 Open the tool palette that you want to use, and select a Volume Anchor tool.

If necessary, scroll to display the tool that you want to use.

A Volume Anchor tool is located in the Parametric Layout and Anchoring Tools category in the Stock Tool catalog. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

2 To copy the anchored object to every volume in the volume grid, enter c (Copy to each volume).

3 Select the object that you want to copy and anchor to every volume in the volume grid.

4 Select the volume grid.

If an object is already anchored to any of the volumes, you are prompted to specify whether you want to skip volumes that already have something anchored to them. Enter y (Yes) to avoid duplicate anchored objects on those volumes.

Releasing and Positioning Anchored Objects

You can release and position anchored objects. Release an anchored object from another object to remove the relationship between the objects. Position an anchored object to offset it from the object it is anchored to.

Releasing Anchored Objects

Use this procedure to release objects from anchors and remove the anchoring relationship. Any anchored object can be released, including a railing that is anchored to a stair object or a window that is anchored to a wall.

- Right-click the anchored object, and click Anchor ► Release.

Positioning Anchored Objects

Use this procedure to position anchored objects. You can position an object with anchors to offset it from the object that it is anchored to.

1 Right-click the anchored object, and change the position of the anchored object:

If you want to...

Then...

specify the X position

click Set X Position.

specify the Y position

click Set Y Position.

If you want to...	Then...
specify the Z position	click Set Z Position.
specify the end position	click Set Anchored End.
specify the rotation	click Set Rotation.
flip the X position	click Flip X.
flip the Y position	click Flip Y.
flip the Z position	click Flip Z.

2 Enter an XYZ coordinate value for the desired offset position.

Entering a coordinate for the offset distance is equivalent to setting all three of the individual position offsets.

Creating an Anchor Tool

Use this procedure to create an anchor tool and add it to a tool palette. You may want to create your own anchor tools if you are placing multiple anchors of specific styles with additional properties that you want to be the same every time you add an anchor of each type.

You can use any of the following methods to create an anchor tool:

- Drag a copy of a tool from another palette to the current palette, and then customize the properties of the new tool.
- Copy an existing tool in the current palette, and then customize the properties of the new tool.
- Drag a tool from the Content Browser to a tool palette, and then customize the properties of the new tool.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to...	Then...
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 Click OK.

Layout Curves and Grids

31

Three types of layout objects help you to position objects relative to each other: layout curves, two-dimensional (2D) layout grids, and three-dimensional (3D) layout volumes (also called volume grids). Each type of layout object has anchors to which you can attach objects. All use nodes as anchor points. Layout grids and layout volumes also provide cells as anchoring points for cell anchors and volume anchors. For more information, see [Anchors](#) on page 1777.

Layout Curves and Grids

Three types of layout objects help you to position objects relative to each other: layout curves, two-dimensional (2D) layout grids, and three-dimensional (3D) layout volumes (also called volume grids). Each type of layout object has anchors to which you can attach objects. All use nodes as anchor points. Layout grids and layout volumes also provide cells as anchoring points for cell anchors and volume anchors. For more information, see [Anchors](#) on page 1777.

Layout Curve

By defining an object as a layout curve and placing nodes along the curve, you can position objects precisely along a path. Layout curves are useful for positioning wash basins along a wall or rafters along a roof.

Layout Grid

A layout grid is an arrangement of rectangular or radial spaces, called *bays*, that are delineated with parallel or radial lines. Use a two-dimensional (2D) layout grid to position objects in a grid pattern. Anchoring objects to layout grids might help you to position planters in a sidewalk grid, or tile accents in a floor tile grid.

Layout Volume

A layout volume (also called a volume grid) is a three-dimensional (3D) arrangement of rectangular spaces. Use three-dimensional (3D) layout volumes to position objects on a multilevel grid. Changing the size of a layout volume changes the spacing of objects attached to that grid and can also change the size and height of objects attached to that grid.

Using Layout Curves

Use a layout curve to anchor objects along a path. You can define the following objects as layout curves:

- Walls
- Curtain walls
- Window assemblies
- Spaces
- Mass elements
- Roofs
- Lines
- Arcs
- Circles
- Ellipses
- Polygons
- Polylines
- Splines

Layout curves are best suited for objects with linear geometry, such as polylines, walls, or splines. If you need nodes on a two-dimensional (2D) object, consider using a layout grid instead.

Creating a Layout Curve Tool

Use this procedure to create a layout curve tool and add it to a tool palette. You may want to create your own layout curve tools if you are placing multiple layout curves of a specific style and they all have the same properties.

1 Open the tool palette where you want to add the tool.

2 Create the tool:

If you want to...	Then...
create a tool from a layout curve in the drawing	select the object, and drag it to the tool palette.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

- 3 Right-click the new tool, and click Properties.
- 4 For Name, enter the name you want displayed for this tool's tooltip. This name will also be displayed with the tool if it is published to a catalog in the Content Browser.
- 5 For Description, click in the text box, and then enter the description you want displayed for this tool's tooltip. This description will also be displayed with the tool if it is published to a catalog in the Content Browser.
- 6 Expand Basic, and expand General.
- 7 Under General, click the Description text box, enter a description of the tool, and click OK.
- 8 For Layer key, click the text box, select a layer key, and click OK.
- 9 For Layer overrides, click the text box, select a layer key override, and click OK.
- 10 Under Dimensions, specify a Layout type
- 11 Specify the number of nodes, or enter a spacing value.
- 12 Click OK.

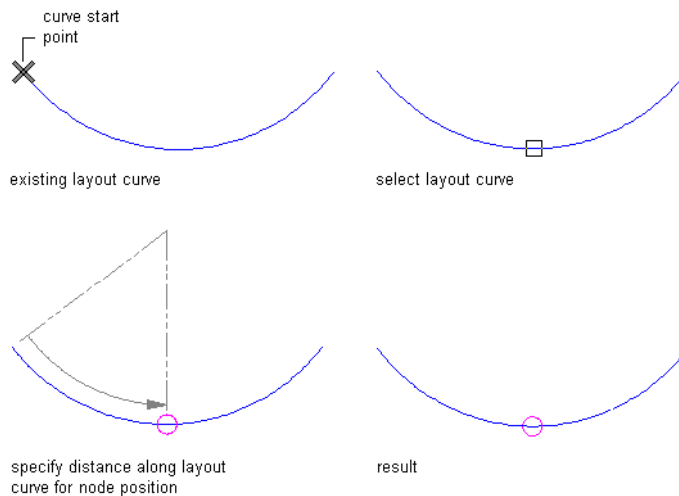

Adding Layout Curves

Use this procedure to define an object as a layout curve. The spacing between anchor nodes determines the spacing between objects that you attach to the layout curve, even if you change the geometry of the layout curve.

The following spacing options are available:

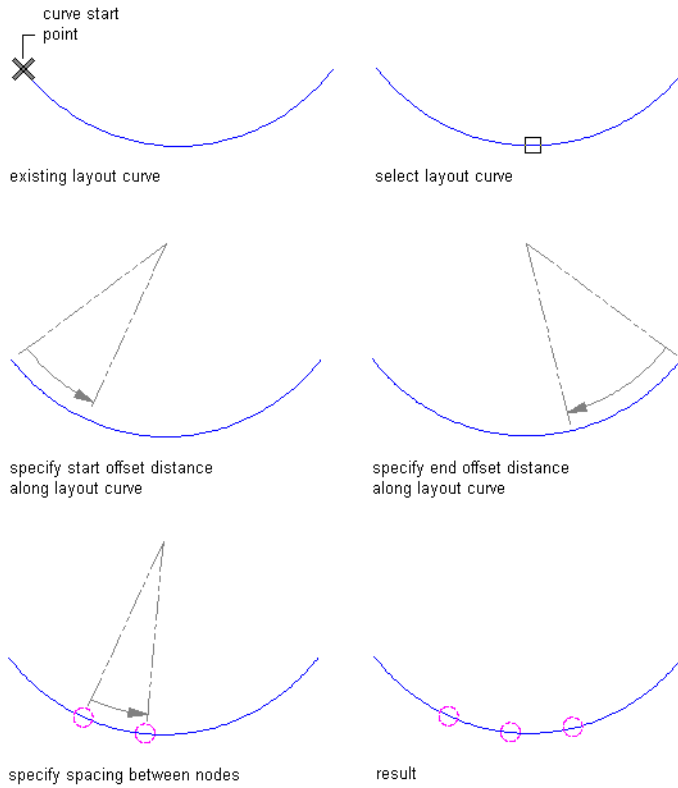

- **Manual:** You specify the position of each node along the layout curve.

Manually placing a node on a layout curve

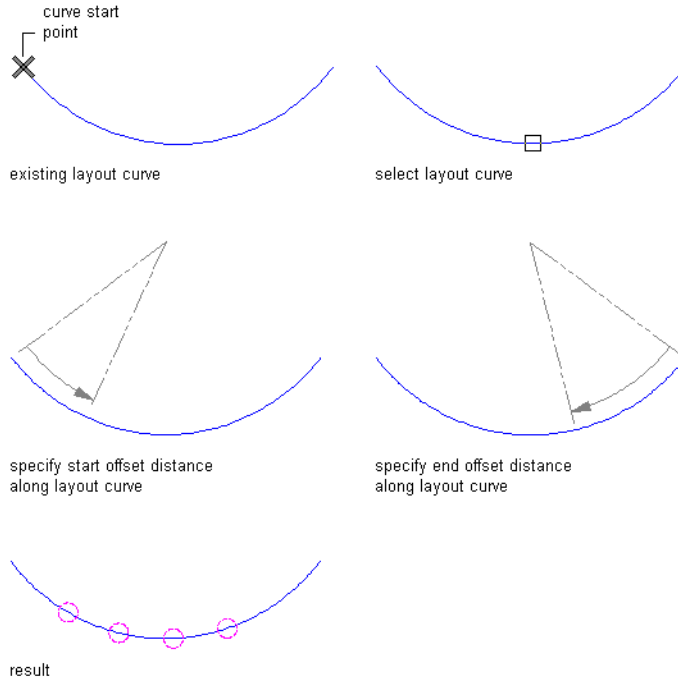

- **Repeat:** You specify equidistant spacing between nodes along the layout curve. The number of anchor nodes is determined by the length of the layout curve. As the length of the curve changes, nodes are added or subtracted accordingly. The spacing of the nodes remains fixed.

Placing nodes at repeat spacing on a layout curve

- **Space Evenly:** You specify the number of nodes along the curve. The space between nodes is determined by the length of the layout curve. As the length of the curve changes, the spacing between nodes is lengthened or shortened accordingly. The number of nodes remains fixed.

Placing nodes at even spacing on a layout curve

- 1 Open the tool palette that contains the layout curve tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

If there are no layout curve tools available on tool palettes in the workspace, you can use the Content Browser to access the Stock Tool catalog, which contains a layout curve tool under Parametric Layout and Anchoring Tools. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

- 2 Select the object to define as a layout curve.

- 3 Place nodes along the layout curve:

If you want to...	Then...
Place nodes at locations that you specify	press <i>ENTER</i> . Enter the number of nodes, and specify the locations of nodes by selecting them or by entering distances from the start point of the curve.
Repeat nodes at fixed intervals along the curve	enter <i>r</i> (Repeat). Specify the start and end offsets of the first and last nodes, and specify the spacing between nodes.
Space a fixed number of nodes along the curve	enter <i>s</i> (Space evenly). Specify the start and end offsets of the first and last nodes, and specify the number of nodes.

Adding Nodes to Layout Curves

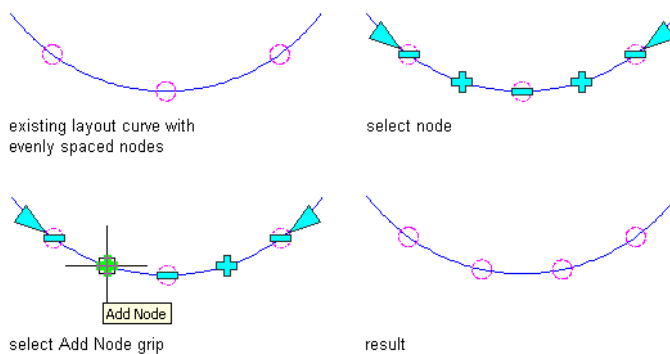

Use this procedure to add nodes to layout curves.

Layout curve with evenly spaced node grips

You can add nodes only to those layout curves that have manually spaced or evenly spaced nodes. Layout curves with nodes at fixed repeated spacing cannot be changed without changing either the length of the curve or the spacing of the first node. For more information, see [Changing the Spacing Mode of Layout Curves](#) on page 1807.

Adding a node to a layout curve using grips

- 1 Select the layout curve by selecting one of the node anchors.
- 2 Click an Add Node grip.
 - If you have added a node to a layout curve with manually spaced nodes, the new node is inserted at the specified position. The position of the other nodes remains unchanged.
 - If you have added a node to a layout curve with evenly spaced nodes, the new node is added and all nodes are recalculated, so that they are evenly spaced again.
- 3 Right-click, and click Deselect All to turn off grips.

Removing Nodes from Layout Curves

Use this procedure to remove nodes from layout curves.

You can remove nodes from only those layout curves that have manually spaced or evenly spaced nodes. Layout curves with nodes at fixed repeated spacing cannot be changed without changing either the length of the curve or the spacing of the first node.

Removing a node from a layout curve using grips

1 Select the layout curve by selecting one of the node anchors.

2 Click a Remove Node grip.

- If you have removed a node from a layout curve with manual nodes, the node is removed from the specified position. The position of the other nodes remains unchanged.
- If you have removed a node from a layout curve with evenly spaced nodes, the node is removed from the specified position and the remaining nodes are recalculated, so that they are evenly spaced again.

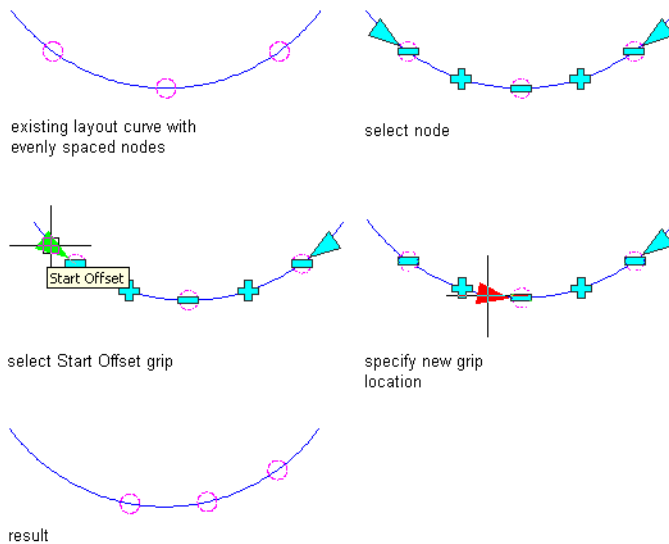

3 Right-click, and click Deselect All to turn off grips.

Changing the Offsets of Layout Curves

Use this procedure to change the start and end offsets of layout curves.

You can change the offsets for evenly spaced and repeated layout curves. By repositioning the offset grips, you can move the start or end offset to any position on the layout curve. You cannot extend an offset beyond the bounds of the curve.

Changing the start offset node location of a layout curve using grips

1 Select a layout curve by selecting one of the node anchors.

2 Click an Offset grip.

- 3 Move the grip to the desired location, and click once; or enter a value on the command line, and press *ENTER*.
- 4 Right-click, and click Deselect All to turn off grips.

Changing the Node Spacing of a Layout Curve

Use this procedure to change the spacing between nodes on a layout curve with fixed repeated spacing.

Layout curve with evenly spaced node grips

Changing the node spacing of a layout curve using grips

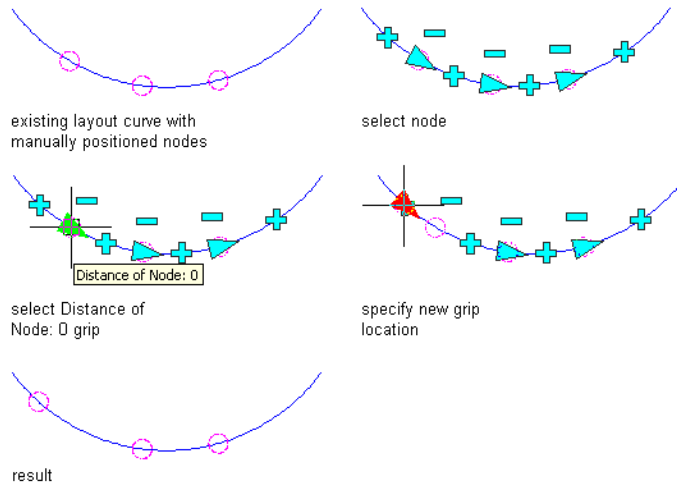

- 1 Select a layout curve by selecting one of the node anchors.
- 2 Click the Spacing grip.
The Spacing grip is attached to the first node of the layout curve.
- 3 Move the grip to the desired location, and click once; or enter a value on the command line, and press *ENTER*.
If you move the grip to the left to decrease the space between nodes, the number of nodes increases. If you move the grip to the right to increase the space between nodes, the number of nodes decreases.
- 4 Right-click, and click Deselect All to turn off grips.

Changing the Node Positions on a Layout Curve

Use this procedure to change the positions of nodes on a layout curve with manual node placement.

Changing a node position on a layout curve using grips

- 1 Select a layout curve by selecting one of the node anchors.
- 2 Click a Node Distance grip.
- 3 Move the grip to the desired location, and click once; or enter a value on the command line, and press *ENTER*.
- 4 Right-click, and click Deselect All to turn off grips.

Changing the Spacing Mode of Layout Curves

Use this procedure to change how nodes are positioned along a layout curve. For more information, see [Adding Layout Curves](#) on page 1801.

For example, you can change the mode so that a curve with manually spaced nodes becomes a curve with evenly spaced nodes. If you want to add nodes to a layout curve with a fixed number of nodes, you must first convert the layout curve to manually spaced or evenly spaced mode.

You can also change the layout mode on the Properties palette.

- 1 Select the layout curve by selecting one of the node anchors.
- 2 Right-click, and click Layout Mode.
- 3 Select the desired mode, and press *ENTER*.
 - If you are changing a layout curve with manually spaced nodes to a curve with nodes at fixed repeated spacing, you are prompted for start and end offsets, and the distance between nodes. If there are too few nodes on the curve to fill it, new nodes are created at the specified distance.
 - If you are changing a layout curve with manually spaced nodes to a curve with evenly spaced nodes, you are prompted for start and end offsets for the curve. The existing nodes are distributed evenly on the curve.
 - If you are changing a curve with nodes placed at a fixed repeated spacing value to a curve with manually spaced nodes, there is no visible change. However, the nodes have been converted to manual nodes, so that you now can add nodes to and remove nodes from the curve.
 - If you are changing a curve with nodes placed at a fixed repeated spacing value to a curve with evenly spaced nodes, you are prompted for start and end offsets. The existing nodes

are then recalculated and distributed evenly. You can now add nodes to and remove nodes from the curve.

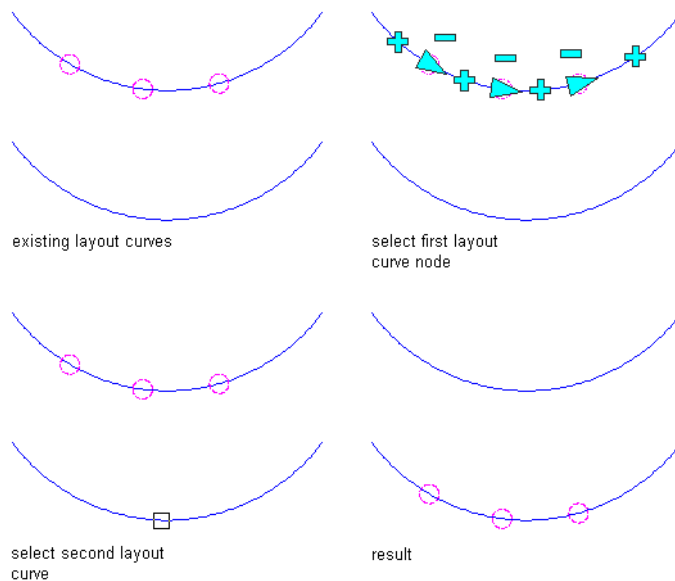

- If you are changing a curve with evenly spaced nodes to a curve with manually spaced nodes, there is no visible change. If you change the curve, however, the nodes remain fixed and are no longer redistributed evenly.
- If you are changing a curve with evenly spaced nodes to a curve with nodes placed at fixed repeated spacing, you are prompted for start and end offsets, and the distance between nodes. If there are too few nodes on the curve to fill it, new nodes are created at the specified distance.

Switching Layout Curves

Use this procedure to move a layout curve from one object to another object. The layout mode is retained in this action. If the layout curve was inserted originally with evenly spaced nodes, the nodes remain evenly spaced on the new object.

If you switch the curve to an object that already contains a layout curve, the two curves are not merged. They are still separate objects and can be edited separately.

Switching nodes from one layout curve to another

- 1 Select the layout curve by selecting one of the node anchors.
- 2 Right-click, and click Switch Curve.
- 3 Select the object to which to attach the layout curve.

The layout curve is moved to the new object.

Changing the Display Properties of Layout Curves

Use this procedure to change the display properties of the nodes on a layout curve. Display properties you can change include the following:

- Visibility (display component is on or off)

- Layer
- Color
- Linetype
- Lineweight
- Linetype scale
- Node size

- 1 Select the layout curve that you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 Click the Layer/Color/Linetype tab.
- 5 Select the component to change, and select a different setting for the property.
- 6 Click OK twice.

Changing the Node Radius for a Layout Curve

Use this procedure to change the node radius for a layout curve by editing its display properties.

- 1 Double-click the layout curve you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all layout curves in the drawing, select Drawing default setting.

- 5 If necessary, expand Object Display Properties ► Advanced.
- 6 Click the value for Node radius, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new radius.)

You can also access and modify the node radius property through the layout curve's context menu, as follows:

- 1 Select the layout curve, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Other tab, and then change the radius as needed.
- 5 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Layout Curve

Use this procedure to attach hyperlinks, notes, or files to a layout curve. You can also edit hyperlinks and notes, and edit or detach reference files from a layout curve.

- 1 Select the layout curve to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

For more information, see “Add Hyperlinks to a Drawing” in AutoCAD help.

TIP The quickest way to locate and view an AutoCAD topic referenced in AutoCAD Architecture 2009 Help is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

- 4 Click OK.
- 5 To add a note, click the setting for Notes, and enter the note.
- 6 Click OK.
- 7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 8 Click OK.

Using Layout Grids

Use a layout grid to arrange objects in a 2D grid pattern. You can create a radial or rectangular layout grid. You can anchor objects to the intersection of the grid lines (node anchors) or to the center of the grid bays (cell anchors).

NOTE By default, the markers for node anchors and cell anchors are not displayed when you insert a grid. To display them, turn these components on in the Entity Display. For information about turning on display components, see [Changing the Display Properties of Layout Curves](#) on page 1808.

Changing the size of a grid changes the spacing of objects anchored to that grid and can also change the size of objects anchored to that grid. You can use a clipping profile to define a boundary around a layout grid or to make a hole in a layout grid. The layout grid is not displayed outside a boundary or inside a hole. Use closed polylines to define the boundary or hole. For example, you can use a clipping profile to cut a hole in a reflected ceiling grid.

Creating a Layout Grid Tool

Use this procedure to create a 2D layout grid tool and add it to a tool palette. You may want to create your own layout grid tools if you are placing multiple layout grids of a specific style and they all have the same properties.

1 Open the tool palette where you want to add the tool.

2 Create the tool:

If you want to...	Then...
create a tool from a layout grid in the drawing	select the object, and drag it to the tool palette.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the tool palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 For Name, enter the name you want displayed for this tool's tooltip. This name will also be displayed with the tool if it is published to a catalog in the Content Browser.

5 For Description, click in the text box, and then enter the description you want displayed for this tool's tooltip. This description will also be displayed with the tool if it is published to a catalog in the Content Browser.

6 Expand Basic, and expand General.

7 Under General, click the Description text box, enter a description of the tool, and click OK.

8 For Layer key, click the text box, select a layer key, and click OK.

9 For Layer overrides, click the text box, select a layer key override, and click OK.

10 Expand Dimensions.

11 Click Yes to specify the dimension of the grid on the drawing screen as you are creating it.

12 Click No to specify numerical values for the Width, Depth, and Height of the grid.

13 Expand X Axis, and specify a Layout type, a Bay size, and Start and End offsets.

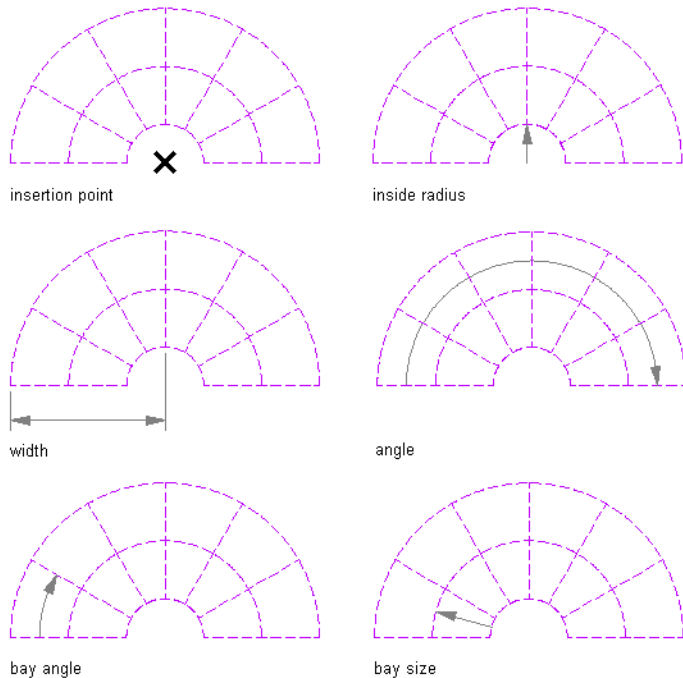

14 Expand Y Axis, and specify a Layout type, a Bay size, and Start and End offsets.

15 Click OK.

Adding Radial Layout Grids

Use this procedure to create a 2D radial layout grid.

Radial layout grid parameters

1 Open the tool palette that contains the layout grid 2D tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

If there are no layout grid 2D tools available on tool palettes in the workspace, you can use the Content Browser to access the Stock Tool catalog, which contains a layout grid 2D tool under Parametric Layout and Anchoring Tools. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

2 In the Properties palette, expand Basic, and expand General.

3 Click the setting for Description, enter a description of the grid, and click OK.

4 Select Radial for Shape.

5 Specify the boundary object attached to the grid.

6 Expand Dimensions.

7 Select Yes to specify dimensions on the drawing screen.

8 Select No to specify dimensions on the Properties palette.

- Enter the width of the grid.

- Enter the angular dimension of the grid.

9 Expand X Axis.

10 Select Space evenly for Layout type, and enter a value for Number of bays.

11 Select Repeat for Layout type, and enter a value for Bay size.

12 Enter a value for Inside radius.

13 Enter a value for End offset.

14 Expand Y Axis.

15 Select Space evenly for Layout type, and enter a value for Number of bays.

16 Select Repeat for Layout type, and enter a value for Bay angle.

- 17 Enter a value for Start angle offset.
- 18 Enter a value for End angle offset.
- 19 Specify an insertion point in the drawing for the center of the radial layout grid.
- 20 Specify the rotation of the radial grid about the insertion point.

Changing Radial Layout Grids

Use this procedure to change the angle or size of a radial layout grid. You can also change the number and size of the grid bays.

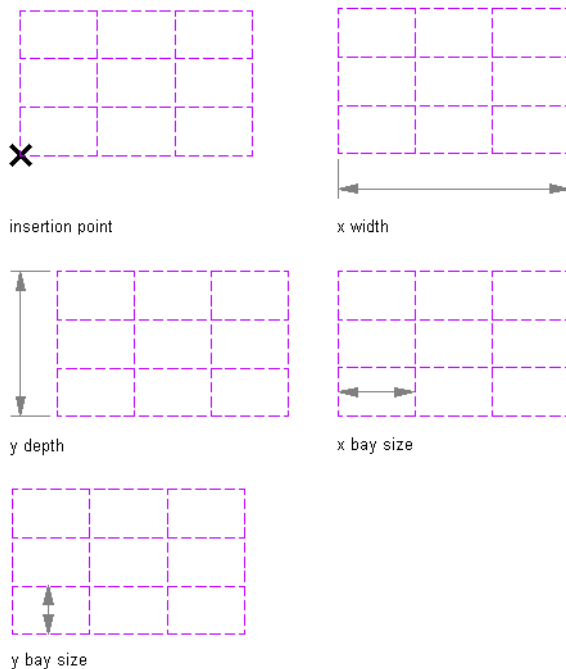

If you use grips to stretch a radial layout grid, the behavior of the radial layout grid depends on the spacing type of each axis. The overall size of the grid “jumps” in directions that are specified to use a certain bay size with repeat spacing because the exact bay size is maintained. The overall size changes in directions that are specified to be evenly spaced or manually spaced.

- 1 Select one or more 2D layout grids, right-click, and click Modify Layout Grid (2D).
- 2 In the Properties palette, expand Basic, and expand General.
- 3 Enter a new value for the radius, angle, and inside radius.
- 4 Enter a new value for the X bay size.
- 5 Change the repeat spacing value, or enter a new value for the bay angle.

Adding Rectangular Layout Grids

Use this procedure to add rectangular layout grids.

Rectangular layout grid parameters

- 1 Open the tool palette that contains the layout grid 2D tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

If there are no layout grid 2D tools available on tool palettes in the workspace, you can use the Content Browser to access the Stock Tool catalog, which contains a layout grid 2D tool under Parametric Layout and Anchoring Tools. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

- 2 In the Properties palette, expand Basic, and expand General.
- 3 Select Rectangular for Shape.
- 4 Enter a value for the X width and the Y depth.
- 5 Select the repeat spacing option and enter a value, or enter a value for the X and Y bay size.
- 6 Specify an insertion point in the drawing for the lower-left corner of the rectangular layout grid.
- 7 Specify the rotation of the rectangular grid about the insertion point.

Changing Rectangular Layout Grids

Use this procedure to change the angle or size of a rectangular layout grid. You can also change the number and size of the grid bays.

If you use grips to stretch a rectangular layout grid, the behavior of the rectangular layout grid depends on the spacing type of each axis. The overall size of the grid “jumps” in directions that are specified to use a specific bay size with repeat spacing because the exact bay size is maintained. The overall size changes in directions that are specified to be evenly spaced or manually spaced.

- 1 Select one or more 2D layout grids, right-click, and click Modify Layout Grid (2D).
- 2 In the Properties palette, expand Basic, and expand General.
- 3 Enter a new X width and Y depth value.
- 4 Select the repeat spacing option and enter a value, or enter a new X and Y bay size value.

Adding Grid Lines to Layout Grids

Use this procedure to add grid lines to a grid. You can separately add grid lines on the X plane and on the Y plane.

NOTE You can add lines only to grids inserted with manually spaced lines or evenly spaced lines. Layout grids with lines placed at a fixed repeated spacing value cannot be changed manually. For information about grid modes, see [Changing the Spacing Mode of Layout Grids](#) on page 1815.

- 1 Select the layout grid, right-click, and add a grid line:

If you want to add...

Then...

a grid line to the X plane of the grid

select X-axis on the shortcut menu, and then click Add Grid Line.

a grid line to the Y plane of the grid

select Y-axis on the shortcut menu, and then click Add Grid Line.

2 Specify the distance of the new grid line from the start of the grid.

- If you have added a line to a layout grid with manually spaced lines, the new line is inserted on the specified position. The position of the other lines remains unchanged. The grid size changes accordingly.
- If you have added a line to a layout grid with evenly spaced lines, the new line is inserted and all lines are recalculated, so that they are evenly distributed again. The grid size remains unchanged.

Removing Grid Lines from Layout Grids

Use this procedure to remove individual grid lines from a grid. You can separately remove grid lines from the *X* plane and the *Y* plane.

NOTE You can remove lines only from grids that have been inserted with manually spaced lines or evenly spaced lines. Layout grids with lines placed at a fixed repeated spacing value cannot be changed. For information about grid modes, see [Changing the Spacing Mode of Layout Grids](#) on page 1815.

1 Select the layout grid, right-click, and remove a grid line:

If you want to remove...

Then...

a grid line from the *X* plane of the grid

select *X*-axis on the shortcut menu, and then click Remove Grid Line.

a grid line from the *Y* plane of the grid

select *Y*-axis on the shortcut menu, and then click Remove Grid Line.

2 Click the grid line to be removed from the grid.

- If you have removed a line from a layout grid with manually spaced lines, the specified line is removed from the grid. The position of the other lines remains unchanged.
- If you have removed a line from a layout grid with evenly spaced lines, the specified line is removed from the grid. All remaining lines are recalculated, so that they are evenly distributed again.

Changing the Spacing Mode of Layout Grids

Use this procedure to change the spacing mode of a radius or rectangular layout grid. Layout grids can have three different spacing modes. These modes are set separately for the *X* and *Y* planes:

- **Manual:** You specify the position of each line on the layout grid.
- **Repeat:** You specify equidistant spacing between lines on the layout grid. The number of lines is determined by the size of the layout grid. As the size of the grid changes, lines are added or subtracted accordingly. The distance between the lines remains fixed.
- **Space Evenly:** You specify the number of lines on the grid. The space between the lines is determined by the size of the layout grid. As the size of the grid changes, the spacing between the lines is lengthened or shortened accordingly. The number of lines remains fixed.

By default, layout grids are inserted with evenly spaced lines.

1 Select the layout grid, right-click, and specify a spacing mode:

If you want to change...	Then...
the spacing mode of the <i>X</i> plane of the grid	select X-axis on the shortcut menu, and then click Layout Mode.
the spacing mode of the <i>Y</i> plane of the grid	select Y-axis on the shortcut menu, and then click Layout Mode.

2 Select the desired mode, and press *ENTER*.

- If you are changing a layout grid with manually spaced lines to a grid with lines placed at a fixed repeated spacing value, you are prompted for start and end offsets, and the distance between the lines. If there are too few lines on the grid to fill it according to your specifications, new lines are created.
- If you are changing a layout grid with manually spaced lines to a grid with evenly spaced lines, you are prompted for start and end offsets for the grid. The existing lines are distributed evenly on the grid.
- If you are changing a layout grid with lines placed at a fixed repeated spacing value to a grid with manually spaced lines, there is no visible change, but the lines have been converted to manual lines, so that you now can add lines to and remove lines from the grid.
- If you are changing a layout grid with lines placed at a fixed repeated spacing value to a grid with evenly spaced lines, you are prompted for start and end offsets. The existing lines are then recalculated and distributed evenly. You can now add lines to and remove lines from the grid.
- If you are changing a grid with evenly spaced lines to a grid with manually spaced lines, there is no visible change. However, if you change the grid, the lines remain fixed and are not distributed evenly anymore.
- If you are changing a grid with evenly spaced lines to a grid with lines placed at a fixed repeated spacing value, you are prompted for start and end offsets, and the distance between the lines. If there are too few lines on the grid to fill the grid according to your specifications, new lines are created.

Changing the Display Properties of Layout Grids

Use this procedure to change any of the following display properties of the nodes on a layout grid:

- Visibility (display component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale
- Node size

1 Select the layout grid that you want to change, right-click, and click Edit Object Display.

- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 Click the Layer/Color/Linetype tab.
- 5 Select the component to change, and select a different setting for the property.
- 6 Click OK twice.

Changing the Node Radius for a Layout Grid

Use this procedure to change the node radius for a layout grid by editing its display properties.

- 1 Double-click the layout grid you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all layout grids in the drawing, select Drawing default setting.

- 5 If necessary, expand Object Display Properties ► Advanced.
- 6 Click the value for Node radius, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new radius.)

You can also access and modify the node radius property through the layout grid's context menu, as follows:

- 1 Select the layout grid, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Other tab, and then change the radius as needed.
- 5 Click OK twice.

Creating and Removing Boundaries for Layout Grids

Use this procedure to create a boundary around a 2D layout grid. Areas of the grid outside the boundary are not shown. However, objects anchored to the grid outside the boundary are still displayed. Boundaries are useful when you need to create a grid in an irregularly shaped area.

You can also remove a boundary to redisplay the entire grid.

- 1 Draw a closed polyline to define the grid boundary.
- 2 Select a layout grid, right-click, and click Clip.
- 3 Enter *s* (Set boundary), select the layout grid, and press *ENTER*.
- 4 Select the closed polyline for the boundary of the layout grid, and press *ENTER*.
- 5 To remove a grid boundary, erase the polyline that defines the boundary.

Creating Holes in Layout Grids

Use this procedure to create a hole in a layout grid. The area of the grid within the hole is not displayed.

- 1 Draw a closed polyline to define the hole.
- 2 Select a layout grid, right-click, and click Clip.
- 3 Enter **a** (Add hole), select the layout grid, and press *ENTER*.
- 4 Select the closed polyline for the hole, and press *ENTER*.

A hole is cut in the layout grid.

Removing Holes from Layout Grids

Use this procedure to remove holes that you have created in layout grids.

- 1 Select a layout grid, right-click, and click Clip.
- 2 Enter **r** (Remove hole), select a layout grid, and press *ENTER*.
- 3 Select the closed polyline of the hole.

Changing the Location of Layout Grids

Use this procedure to change the location of layout grids. You can relocate a layout grid by changing the coordinate values of its insertion point. The layout grid also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the layout grid are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the layout grid by aligning its normal with another axis. You can also rotate the layout grid on its plane by changing the rotation angle.

For information about WCS and UCS, see “Use Coordinates and Coordinate Systems” in AutoCAD help.

- 1 Select the layout grid that you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the layout grid:

If you want to...	Then...
relocate the layout grid	enter new coordinate values under Insertion Point.
locate the layout grid on the <i>XY</i> plane	make the normal of the layout curve parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the layout grid on the <i>YZ</i> plane	make the normal of the layout grid parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the layout grid on the <i>XZ</i> plane	make the normal of the layout grid parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .

If you want to...	Then...
change the rotation of the layout grid	enter a new value for Rotation Angle.

5 Click OK.

Attaching Hyperlinks, Notes, or Files to a Layout Grid

Use this procedure to attach hyperlinks, notes, or files to a layout grid. You can also edit hyperlinks and notes, and edit or detach reference files from a layout grid.

1 Select the layout grid to which to attach information.

2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

For more information, see “Add Hyperlinks to a Drawing” in AutoCAD help.

4 Click OK.

5 To add a note, click the setting for Notes, and enter the note.

6 Click OK.

7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

8 Click OK.

Using Layout Volumes

Use a layout volume to arrange objects in a 3D grid. Changing the size of a layout volume changes the spacing of objects attached to that volume and can also change the size and height of objects attached to that volume.

Creating a Layout Volume Tool

Use this procedure to create a layout volume tool and add it to a tool palette. You may want to create your own layout volume tools if you are placing multiple layout volumes of a specific style and they all have the same properties.

1 Open the tool palette where you want to add the tool.

2 Create the tool:

If you want to...	Then...
create a tool from a layout volume in the drawing	select the object, and drag it to the tool palette.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 For Name, enter the name you want displayed for this tool's tooltip. This name will also be displayed with the tool if it is published to a catalog in the Content Browser.

5 For Description, click in the text box, and then enter the description you want displayed for this tool's tooltip. This description will also be displayed with the tool if it is published to a catalog in the Content Browser.

6 Expand Basic, and expand General.

7 Under General, click the Description text box, enter a description of the tool, and click OK.

8 For Layer key, click the text box, select a layer key, and click OK.

9 For Layer overrides, click the text box, select a layer key override, and click OK.

10 Expand Dimensions.

11 Click Yes to specify the dimension of the grid on the drawing screen as you are creating it.

12 Click No to specify numerical values on the Properties palette, and enter values for Width, Depth, and Height

13 Expand X Axis.

14 Select Space evenly for Layout type, and enter a value for Number of bays.

15 Select Repeat for Layout type, and enter a value for Bay size.

16 Enter a value for Start offset.

17 Enter a value for End offset.

18 Expand Y Axis.

19 Select Space evenly for Layout type, and enter a value for Number of bays.

20 Select Repeat for Layout type, and enter a value for Bay angle.

21 Enter a value for Start offset.

22 Enter a value for End offset.

23 Expand Z Axis.

24 Select Space evenly or Repeat for Layout type.

25 Enter a value for Start offset.

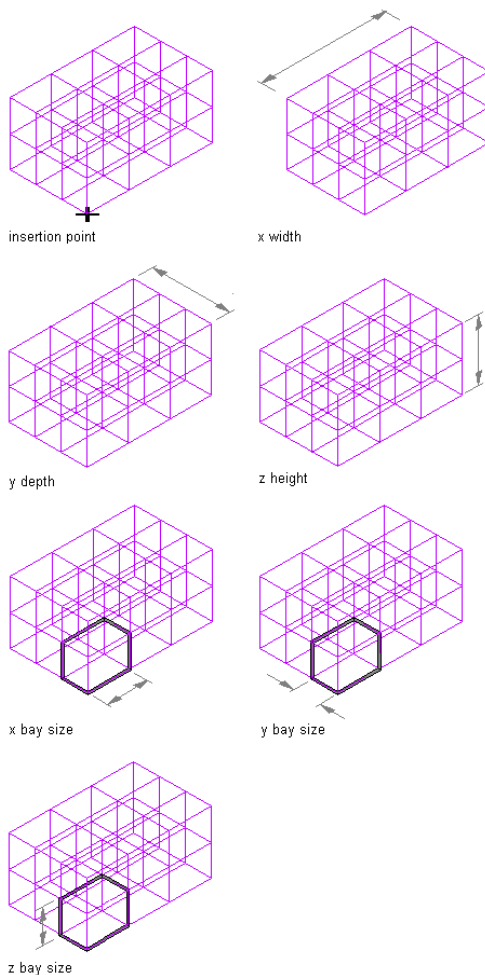

26 Enter a value for End offset.

27 Click OK.

Adding Layout Volumes

Use this procedure to add a layout volume, which is a three-dimensional (3D) layout grid.

Layout volume parameters

1 Open the tool palette that contains the volume layout tool you want to use, and select the tool.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

If there are no volume layout tools available on tool palettes in the workspace, you can use the Content Browser to access the Stock Tool catalog, which contains a volume layout tool under Parametric Layout and Anchoring Tools. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.

2 Select the volume layout tool.

3 In the Properties palette, expand Basic, and expand General.

4 Enter a value for the X width, Y depth and the Z height.

5 Select the repeat spacing option and enter a value, or enter a value for the X, Y, and Z bay size.

6 Specify an insertion point in the drawing for the lower-left corner of the rectangular layout grid.

7 Specify the rotation of the rectangular grid about the insertion point.

Changing Layout Volumes

Use this procedure to change the angle or size of three-dimensional (3D) layout volumes. You can also change the number and size of the grid bays.

If you use grips to stretch a layout volume, the behavior of the layout volume depends on the spacing type of each axis. The overall size of the grid “jumps” in directions that are specified to use a certain bay size with repeat spacing because the exact bay size is maintained. The overall size changes in directions that are specified to be evenly spaced or manually spaced.

- 1 Select one or more 3D volume grids, right-click, and click Modify Layout Volume (3D).
- 2 In the Properties palette, expand Basic, and expand General.
- 3 Enter a new X width, Y depth, and Z height value.
- 4 Select the repeat spacing option and enter a value, or enter a new X, Y, and Z bay size value.

Adding Grid Lines to Layout Volumes

Use this procedure to add grid lines to a layout volume. You can add grid lines on the X, Y, and Z planes separately.

NOTE You can add lines only to volumes inserted with manually spaced lines or evenly spaced lines. Layout volumes with lines placed at a fixed repeated spacing value cannot be changed. For information about grid modes, see [Changing the Spacing Mode of Layout Grids](#) on page 1815.

- 1 Select the layout volume.
- 2 Specify the axis to which to add the grid line:

If you want to add...

Then...

a grid line to the X plane of the volume

right-click, and click X axis ► Add Grid Line.

a grid line to the Y plane of the volume

right-click, and click Y axis ► Add Grid Line.

a grid line to the Z plane of the volume

right-click, and click Z axis ► Add Grid Line.

- 3 Specify the distance of the new grid line from the start of the grid.
 - If you have added a line to a layout volume with manually spaced lines, the new line is inserted at the specified position. The position of the other lines remains unchanged. The grid size changes accordingly.
 - If you have added a line to a layout volume with evenly spaced lines, the new line is inserted and all lines are recalculated, so that they are evenly distributed again. The grid size remains unchanged.

Removing Grid Lines from Layout Volumes

Use this procedure to remove individual grid lines from a volume. You can remove grid lines from the X, Y, and Z planes separately.

NOTE You can remove lines only from volumes which have been inserted with manually spaced lines or evenly spaced lines. Layout volumes with lines placed at a fixed repeated spacing value cannot be changed. For information about grid modes, see [Changing the Spacing Mode of Layout Grids](#) on page 1815.

1 Select the layout volume.

2 Specify the axis from which to remove the grid line:

If you want to remove...	Then...
a grid line from the X plane of the volume	right-click, and click X axis ► Remove Grid Line.
a grid line from the Y plane of the volume	right-click, and click Y axis ► Remove Grid Line.
a grid line from the Z plane of the volume	right-click, and click Z axis ► Remove Grid Line.

3 Click the grid line to be removed from the volume.

- If you have removed a line from a layout volume with manually spaced lines, the specified line is removed from the volume. The position of the other lines remains unchanged.
- If you have removed a line from a layout volume with evenly spaced lines, the specified line is removed from the volume. All remaining lines are recalculated, so that they are evenly distributed again.

Changing the Spacing Mode of Layout Volumes

Use this procedure to change how nodes are positioned along a layout volume. For more information, see [Adding Layout Volumes](#) on page 1821.

For example, you can change the mode so that a volume with manually spaced nodes becomes a volume with evenly spaced nodes. If you want to add nodes to a layout volume with a fixed number of nodes, you must first convert the layout volume to the manually spaced or evenly spaced mode.

You can also change the layout mode on the Properties palette.

1 Select the layout volume by selecting one of the node anchors.

2 Right-click, and click Layout Mode.

3 Select the desired mode, and press *ENTER*.

- If you are changing a layout volume with manually spaced nodes to a volume with nodes placed at a fixed repeated spacing value, you are prompted for start and end offsets, and the distance between the nodes. If there are too few nodes on the curve to fill it, new nodes are created at the specified distance.
- If you are changing a layout volume with manually spaced nodes to a volume with evenly spaced nodes, you are prompted for start and end offsets for the volume. The existing nodes are distributed evenly on the volume.
- If you are changing a volume with nodes placed at a fixed repeated spacing value to a volume with manually spaced nodes, there is no visible change. However, the nodes have been converted to manual nodes, so that you now can add nodes to and remove nodes from the volume.
- If you are changing a volume with nodes placed at a fixed repeated spacing value to a volume with evenly spaced nodes, you are prompted for start and end offsets. The existing nodes

are than recalculated and distributed evenly. You can now add nodes to and remove nodes from the volume.

- If you are changing a volume with evenly spaced nodes to a volume with manually spaced nodes, there is no visible change. If you change the volume, however, the nodes remain fixed and are no longer redistributed evenly.
- If you are changing a volume with evenly spaced nodes to a volume with nodes placed at a fixed repeated spacing value, you are prompted for start and end offsets, and the distance between the nodes. If there are too few nodes on the curve to fill it, new nodes are created at the specified distance.

Changing the Display Properties of Layout Volumes

Use this procedure to change any of the following display properties of the nodes on a layout volume:

- Visibility (display component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale
- Node size

1 Select the layout volume that you want to change, right-click, and click Edit Object Display.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 Click the Layer/Color/Linetype tab.

5 Select the component to change, and select a different setting for the property.

6 Click OK twice.

Changing the Node Radius for a Layout Volume

Use this procedure to change the node radius for a layout volume by editing its display properties.

1 Double-click the layout volume you want to change.

2 On the Properties palette, click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all layout volumes in the drawing, select Drawing default setting.

5 If necessary, expand Object Display Properties ► Advanced.

- 6 Click the value for Node radius, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new radius.)

You can also access and modify the node radius property through the layout volume's context menu, as follows:

- 1 Select the layout volume, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Other tab, and then change the radius as needed.
- 5 Click OK twice.

Changing the Location of Layout Volumes

Use this procedure to change the location of layout volumes. You can relocate a layout volume by changing the coordinate values of its insertion point. The layout volume also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the layout volume are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the layout volume by aligning its normal with another axis. You can also rotate the layout volume on its plane by changing the rotation angle.

For information about WCS and UCS, see “Use Coordinates and Coordinate Systems” in AutoCAD help.

- 1 Select the layout volume that you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the layout volume:

If you want to...	Then...
relocate the layout volume	enter new coordinate values under Insertion Point.
locate the layout volume on the <i>XY</i> plane	make the normal of the layout volume parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the layout volume on the <i>YZ</i> plane	make the normal of the layout volume parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the layout volume on the <i>XZ</i> plane	make the normal of the layout volume parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the layout volume	enter a new value for Rotation Angle.

- 5 Click OK.

Attaching Hyperlinks, Notes, or Files to a Layout Volume

Use this procedure to attach hyperlinks, notes, or files to a layout volume. You can also edit hyperlinks and notes, and edit or detach reference files from a layout volume.

- 1 Select the layout volume to which to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
For more information, see “Add Hyperlinks to a Drawing” in AutoCAD help.
- 4 Click OK.
- 5 To add a note, click the setting for Notes, and enter the note.
- 6 Click OK.
- 7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 8 Click OK.

Grids

32

Grids are AEC objects on which you can anchor other objects, such as columns, and constrain their locations.

Grids

Grids are AEC objects on which you can anchor other objects, such as columns, and constrain their locations. Grids are useful in the design and documentation phases of a project.

Types of Grids

There are several types of grids, each with its own purpose:

Layout grids help you position objects relative to each other in your building design. For more information about layout grids, see [Layout Curves and Grids](#) on page 1799.

Column grids are layout grids that place a column at each intersection of the grid as you add it to your drawing. They are unique also in that they have automatic labeling tools. For more information about columns, see [Creating a Freestanding Column](#) on page 1707 or [Creating Grid-Anchored Columns](#) on page 1710.

Ceiling grids are specialized layout grids that represent suspended ceiling systems or cassette ceilings. They can be anchored to a space object at ceiling height.

All of these grid types share some common features.

Layout Types for Grids

There are 3 different layout types that control the spacing of lines in a grid. Layout type is specified separately for the X and Y planes.

- **Manual:** You specify the position of each line on the grid.
- **Repeat (Fixed Bay Size):** You specify equidistant spacing between lines on the grid. The number of lines is determined by the size of the grid. As the size of the grid changes, lines are added or subtracted accordingly. The distance between lines remains fixed.
- **Space Evenly:** You specify the number of lines on the grid. The space between lines is determined by the size of the grid. As the size of the grid changes, the spacing between lines is lengthened or shortened accordingly. The number of lines remains fixed.

NOTE By default, grids are inserted with evenly spaced lines.

Anchoring Objects to Grids

Grids can be used to anchor other objects. This is most visible in column grids, where special functionality allows you to anchor columns to the grid during insertion. Once the grid is inserted, you can add other objects to it as well.

There are 2 anchoring mechanisms available for grids:

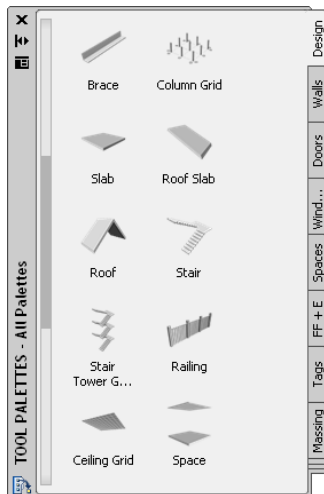

- Anchoring objects to a grid cell (Cell Anchor)
- Anchoring objects to a grid intersection (Node Anchor)

For more information about anchoring objects, see [Anchors](#) on page 1777.

Using Column Grid Tools to Create Column Grids

Tools in the software let you quickly place column grids using a structural column grid tool with specific predefined properties. You can use the default settings of the tool, or you can change the properties. You can also use structural column grid tools to convert linework to column grids, and to apply the settings of a structural column grid tool to existing column grids.

Tool palettes containing structural column grid tools

The default tool palettes in the workspace contain sample structural column grid tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain structural column grid tools that you can add to your tool palettes:

- AutoCAD Architecture Stock Tool catalog
- AutoCAD Architecture Sample Palette catalog

Custom palettes created by your CAD manager or other users may also contain structural column grid tools with column grid properties that are customized for your projects or office standards.

Creating a Column Grid

Use this procedure to add a new column grid that has the properties specified in the structural column grid tool that you select. To specify settings when you add a column grid, see [Creating a Column Grid with User-Specified Settings](#) on page 1829.

- 1 Open the tool palette that contains the structural column grid tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)
- 2 Specify the insertion point of the column grid.
- 3 Specify the rotation of the column grid, and press *ENTER*.
- 4 Continue adding column grids, and press *ENTER*.

Creating a Column Grid with User-Specified Settings

Use this procedure to add a column grid with settings that you specify. Column grids can be either rectangular or radial.

Rectangular grid

Radial grid

- 1 Open the tool palette that you want to use, and select a structural column grid tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a shape, either Rectangular or Radial.
- 4 Expand Dimensions.
- 5 If you have selected a rectangular grid shape, specify the settings:

If you want to...

Then...

define the width of the grid

expand Dimensions, and enter a value for X - Width.

If you want to...	Then...
define the depth of the grid	expand Dimensions, and enter a value for Y - Depth.
lay out the grid with evenly spaced bays along the X direction	expand X Axis, select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay size along the X direction	expand X Axis, select Repeat for Layout type, and enter a value for Bay size.
specify the offset distance from the start point along the X direction of the grid	expand X Axis, and enter a value for Start offset. The offset distance may be used to reduce the effective grid size.
specify the offset distance from the end point along the X direction of the grid	expand X Axis, and enter a value for End offset. The offset distance may be used to reduce the effective grid size.
lay out the grid with evenly spaced bays along the Y direction	expand Y Axis, select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay size along the Y direction	expand Y Axis, select Repeat for Layout type, and enter a value for Bay size.
specify the offset distance from the start point along the Y direction of the grid	expand Y Axis, and enter a value for Start offset. The offset distance may be used to reduce the effective grid size.
specify the offset distance from the end point along the Y direction of the grid	expand Y Axis, and enter a value for End offset. The offset distance may be used to reduce the effective grid size.
6 If you have selected a radial grid shape, specify the settings:	
If you want to...	Then...
define the width of the grid	expand Dimensions, and enter a value for X - Width.
define the angle of the grid	expand Dimensions, and enter a value for A - Angle.
lay out the grid with evenly spaced bays along the X direction	expand X Axis, select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay size along the X direction	expand X Axis, select Repeat for Layout type, and enter a value for Bay size.
specify the inside radius of the grid	expand X Axis, and enter a value for Inside radius.

If you want to...	Then...
specify the offset distance from the end point along the X direction of the grid	expand X Axis, and enter a value for End offset. The offset distance may be used to reduce the effective grid size.
lay out the grid with evenly spaced bays along the Y direction	expand Y Axis, select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay angle along the Y direction	expand Y Axis, select Repeat for Layout type, and enter a value for Bay angle.
specify the offset angle from the start angle along the X direction grid curve	expand Y Axis, and enter a value for Start angle offset. The offset angle may be used to reduce the grid size.
specify the offset angle from the end angle along the X direction grid curve	expand Y Axis, and enter a value for End angle offset. The offset distance may be used to reduce the grid size.

7 To add columns to the grid intersection during insertion, expand Column, and specify a style for the structural member.

If you choose to add columns, you can specify the dimensions of the column:

- Start offset
- End offset
- Logical length
- Justify
- Justify using overall extents

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

8 In the drawing area, specify the insertion point of the column grid.

9 Specify the rotation angle of the grid, and press *ENTER*.

10 Continue adding column grids, and press *ENTER*.

Creating a Column Grid from a Layout Grid

Use this procedure to convert a two-dimensional (2D) layout grid to a column grid that has the properties of the structural column grid tool you select. You can edit these properties after creating the column grid.

1 Open the tool palette that contains the column grid tool you want to use.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

2 Right-click the tool, and click Apply Tool Properties to ► Layout Grid 2D.

3 Select the layout grid to convert, and press *ENTER*.

- 4 When prompted to erase the original geometry, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the column grid in the Properties palette, if necessary.

Creating a Column Grid from Linework

Use this procedure to convert custom linework to a column grid that has the properties of the structural column grid tool you select. You can edit these properties after creating the column grid.

- 1 Open the tool palette that contains the column grid tool you want to use.

TIP You may have to scroll to display the desired tool. After selecting it, you can move or hide the Properties palette to expose more of the drawing area.

- 2 Right-click a structural column grid tool, and click Apply Tool Properties to ► Linework.
- 3 Select the linework to convert, and press *ENTER*.
- 4 When prompted to erase the original linework, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.
- 5 Edit the properties of the column grid in the Properties palette, if necessary.

Creating a Column Grid Dynamically

Use this procedure to create column grids dynamically by specifying their dimensions on screen as you draw them.

- 1 Open the tool palette that contains the column grid tool you want to use.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Dimensions, and select Yes for Specify on screen.
- 3 To add columns to the grid during insertion, expand Column, and select the desired column style.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

- 4 Specify the insertion point for the grid in the drawing.
- 5 Specify the overall size of the grid by dragging the cursor to the desired size and clicking once.
- 6 Drag the crosshairs inside the resulting shape vertically and horizontally to define the correct number of bays in the column grid.

NOTE The closer the crosshairs go to the left and bottom of the grid, the more spaces are created.

- 7 Click once to confirm the number of vertical and horizontal bays.
- 8 Specify the rotation angle of the grid, and press *ENTER*.

The column grid is inserted into the drawing according to your specifications.

Creating a Structural Column Grid Tool

Use this procedure to create a structural column grid tool and add it to a tool palette. You may want to create your own structural column grid tools if you are placing multiple column grids of a specific style, and they all have the same properties.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a column grid in the drawing	select the object, and drag it to the tool palette.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 Expand Basic, and expand General.

7 Click the setting for Description, enter a description of the column grid created from this tool, and click OK.

8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.

9 Select a column grid shape.

10 Specify the settings for the dimensions of the grid.

For more information, see [Creating a Column Grid with User-Specified Settings](#) on page 1829.

11 Click OK.

Working with Column Grids

After you have created column grids in your drawing, you can customize them for your project. You can add labels, extend grid lines, and add dimensions to the grids.

Labeling Column Grids

You can label existing column grids in the X direction and the Y direction.

1 Select the column grid you want to label, right-click, and click Label.

2 Specify the grid location for labels:

If you want to...	Then...
add labels to the X axis of the grid	click the X - Labeling tab.
add labels to the Y axis of the grid	click the Y - Labeling tab.

3 Enter a starting number or letter for the label under Number in the table.

Each grid line in the X direction or the Y direction is listed in the table. If Automatically Calculate Values for Labels is selected, numbers or letters are consecutively assigned to the remaining grid lines in the order you specify (ascending or descending).

NOTE To renumber a grid, enter a new value in the first location. The remaining values are updated if Automatically Calculate Values for Labels is selected.

4 If you do not want to use certain characters in the sequence, select Never Use Characters, and enter the characters, separated by commas.

5 To change the label symbol, click Bubble.

6 Select a new label symbol from the MvBlockDef Select dialog box, and click OK.

Any multi-view block currently defined in the drawing can be used.

7 Click Generate New Bubbles On Exit to update the bubbles.

8 Specify the location of bubbles:

If you want to...	Then...
place bubbles in the X direction of the grid	select Top and/or Bottom.
place bubbles in the Y direction of the grid	select Left and/or Right.

9 Enter a value for Extension.

Extension is the length of the bubble lines from the grid to the bubble.

10 Click OK.

Labeling a column grid

Extending Column Grid Lines Beyond the Grid Boundary or Limits

Use this procedure to label 2 sides of a column grid and have the lines of the other 2 sides extend beyond the edge of the column grid rectangle.

- 1 Label the 2 sides of the column grid.
For more information, see [Labeling Column Grids](#) on page 1833.
- 2 Create a multi-view block definition that has no view blocks.
For more information, see [Creating a New Multi-View Block Definition](#) on page 1898.
- 3 Select the column grid, right-click, and click Label.
- 4 Click the Labeling tab for the axis you wish to extend.
- 5 Under Bubble Parameter, select the side (Left or Right, Top or Bottom) that has not been labeled, but do not clear a side that is already labeled, or the bubbles will be removed from that side.
- 6 Click Bubble, select the new multi-view block you created, and then click OK.
- 7 Clear Generate New Bubbles On Exit.
- 8 Click OK.

Dimensioning Column Grids

Use this procedure to dimension column grids and set the distance between the dimensions and the grid. For this, you can use the automatic AEC Dimension.

Dimensioning Column Grids with Automatic AEC Dimension

When you dimension a column grid with an automatic AEC dimension, the resulting dimension is associative. When you update the grid, the dimension is updated accordingly. Also, you can choose an AEC dimension style. For more information, see [AEC Dimensions](#) on page 2243.

With an AEC dimension, you cannot display angle dimensions or edit individual dimension chains.

- 1 Select the column grid you want to dimension.
- 2 Right-click, and click AEC Dimension.
- 3 On the Properties palette, expand Basic, and expand General.
- 4 Select a style.

NOTE Be sure to select an AEC dimension style that contains dimensioning points for grids. For more information about AEC dimension contents, see [Associative Dimensions from Objects](#) on page 2247.

- 5 Click to specify the position of the AEC dimension.
The dimension can, for example, be placed above or below the column grid.
 - To set the direction of the dimension, drag the mouse. The extension lines are drawn in the opposite direction.
 - If you want to align the dimension, enter **a** on the command line, and select the geometry to align to.
 - If you want a user-defined angle for the dimension, enter **r** and enter the rotation angle on the command line.

NOTE The angle you specify here is calculated in relation to the UCS, and not to the dimensioned grid.

Editing Column Grids

You can change column grids by modifying the overall dimensions of the grid, the number and position of grid lines, as well as the location of the grid within the drawing. You can also set a clipping boundary for the grid and use that to mask the grid or insert a hole into the grid.

NOTE You cannot change the shape of an existing column grid, such as changing a radial grid to a rectangular grid.

Changing the Dimensions of a Column Grid

Use this procedure to change the overall dimensions of a column grid. A rectangular grid is defined by its width and depth. A radial grid is defined by its radius, angle, and optionally, its inner radius.

- 1 Double-click the column grid to which you want to make changes.
- 2 Expand General, and expand Dimensions.
- 3 Modify the desired settings:

If you want to...	Then...
change the dimensions of a rectangular column grid	enter new values for X - Width and Y - Depth.
change the dimensions of a radial column grid	enter new values for X - Width and A - Angle.

TIP You can also change the size of a grid by dragging its grip points. When you have a manual grid, you drag the individual lines, and not the grid.

Changing the Lines of a Column Grid

Apart from the overall dimensions of a column grid, you can also change the number and position of grid lines on the X and Y axes. There are 3 different layout types that control the spacing of lines in a grid. Layout type is specified separately for the X and Y planes on the Properties palette for the grid.

- **Manual:** You specify the position of each line on the grid.
- **Repeat (Fixed Bay Size):** You specify equidistant spacing between lines on the grid. The number of lines is determined by the size of the grid. As the size of the grid changes, lines are added or subtracted accordingly. The distance between lines remains fixed.
- **Space Evenly:** You specify the number of lines on the grid. The space between lines is determined by the size of the grid. As the size of the grid changes, the spacing between lines is lengthened or shortened accordingly. The number of lines remains fixed.

NOTE By default, grids are inserted with evenly spaced lines.

The procedures for adding or removing grid lines vary depending on the Layout type in effect, as explained in the following sections.

Adding Lines to a Column Grid

In some cases, you need to add lines to an existing grid. Depending on the Layout type in effect, you do this in different ways.

Adding Lines to a Column Grid with Evenly Spaced Lines

Use this procedure to add lines to a grid with evenly spaced lines. The lines will always be distributed evenly along the grid axis. If you need non-regular lines with different spacing between them, open the grid's Properties palette, and change the Layout type to Manual.

1 Double-click the column grid to which you want to add lines.

2 Expand Dimensions.

3 Add grid lines:

If you want to...	Then...
add grid lines to the X axis of the grid	expand X Axis, and enter a value for Number of bays. The number of grid lines increases to create the specified number of bays, while the overall size of the grid remains the same.
add grid lines to the Y axis of the grid	expand Y Axis, and enter a value for Number of bays. The number of grid lines increases to create the specified number of bays, while the overall size of the grid remains the same.

Adding Grid Lines to a Manual Column Grid

Use this procedure to add lines to a manual grid. A manual grid allows maximum control over the grid, but requires that you define the exact number and position of grid lines.

1 Double-click the column grid to which you want to add lines.

2 Expand Dimensions.

3 Add grid lines:

If you want to...	Then...
add grid lines to the X axis of the grid	expand X Axis, select Manual for Layout type, and click on the value for Bays.
add grid lines to the Y axis of the grid	expand Y Axis, select Manual for Layout type, and click on the value for Bays.

The Bays worksheet lists all bays on the selected axis, their distance from the start point of the grid, and the spacing between the grid lines that define the bays.

4 To add a line, click under the last number in the Bays list.

A new line is inserted with default values for distance and spacing. You can edit these values by clicking them and entering new values.

NOTE You cannot enter a line number for the new line. The line number is provided by the application after you close the worksheet.

5 Click OK.

Adding Grid Lines to a Column Grid with Fixed Bay Size

Use this procedure to add lines to a grid with bays of a fixed size. Normally, in a grid with fixed bays, the distance between the grid lines is more important than the number of grid lines.

To add lines to a grid with a fixed bay size, you have 2 options:

- Enlarge the overall grid size (for more information, see [Changing the Dimensions of a Column Grid](#) on page 1836).
- Decrease the size of the bays.

TIP In cases where the number of lines is important for the grid, change the Layout type of the grid from Repeat to Space evenly or Manual.

1 Double-click the column grid to which you want to add lines.

2 Expand Dimensions.

3 Add grid lines:

If you want to...	Then...
add grid lines to the X axis of the grid	expand X Axis, and enter a value for Bay size.
add grid lines to the Y axis of the grid	expand Y Axis, and enter a value for Bay size.

If you enter a value that reduces the size of the bays, the number of grid lines increases as the extra bays are added to the grid.

Removing Lines from a Column Grid

You can remove individual grid lines from column grids. The method used will depend on the layout type of the specific column grid.

Removing Lines from a Column Grid with Evenly Spaced Lines

Use this procedure to remove lines from a grid with evenly spaced lines. The lines will always be distributed evenly along the grid axis. To remove a particular line and have all the other lines stay in their original places, open the grid's Properties palette, and change the Layout type to Manual.

1 Double-click the column grid from which you want to remove lines.

2 Expand Dimensions.

3 Remove grid lines:

If you want to...	Then...
remove grid lines from the X axis of the grid	expand X Axis, and enter a smaller value for Number of bays. The number of grid lines decreases to create the specified number of bays, while the overall size of the grid remains the same.
remove grid lines from the Y axis of the grid	expand Y Axis, and enter a smaller value for Number of bays. The number of grid lines decreases to create the specified number of bays, while the overall size of the grid remains the same.

Removing Grid Lines from a Manual Column Grid

Use this procedure to remove grid lines from a manual grid. On a manual grid, you can remove each line individually.

- 1 Double-click the column grid from which you want to remove lines.
- 2 Expand Dimensions.
- 3 Remove grid lines:

If you want to...	Then...
remove grid lines from the X axis of the grid	expand X Axis, select Manual for Layout type, and click the value for Bays.
remove grid lines from the Y axis of the grid	expand Y Axis, select Manual for Layout type, and click the value for Bays.

The Bays worksheet lists all bays on the selected axis, their distance from the start point of the grid, and the spacing between the grid lines that define the bays.

- 4 To remove a line, click the bay number in the Bays list, and click Remove.
- 5 Click OK.

The bay is deleted from the grid, and the grid size is reduced accordingly.

Removing Lines from a Column Grid with Fixed Bay Size

Use this procedure to remove lines from a grid with fixed bays. Normally, in a grid with fixed bays, the distance between the grid lines is more important than the number of grid lines.

To remove lines from a grid with a fixed bay size, you have 2 options:

- Decrease the overall grid size (for more information, see [Changing the Dimensions of a Column Grid](#) on page 1836).
- Increase the size of the bays

TIP In cases where the number of lines is important for the grid, change the Layout type of the grid from Repeat to Space evenly or Manual.

- 1 Double-click the column grid from which you want to remove lines.
- 2 Expand Dimensions.
- 3 Remove grid lines:

If you want to...	Then...
remove grid lines from the X axis of the grid	expand X Axis, and enter a value for Bay size.
remove grid lines from the Y axis of the grid	expand Y Axis, and enter a value for Bay size.

If you enter a value that increases the size of the bays, the number of grid lines decreases as the extra bays are removed from the grid.

Changing the Position of Column Grid Lines

You can change the position of individual lines in column grids for which the Layout type is Manual. (Grids with a Layout type of Repeat or Space evenly calculate line position according to the number of bays or the size of the grid.) A manual grid has grip points for every line. You can use either the grip points or the Bays worksheet to change the position of a grid line.

Using Grip Points to Move Column Grid Lines

Use this procedure to move a column grid line by dragging the grip points of the line. Manual grids have a pair of grip points for the start point and endpoint of each line.

- 1 Select the grid where you want to move grid lines.

For each line in the grid, a pair of grip points (start point and endpoint) is displayed.

TIP If your grid displays only four lines for the corners of the grid, the Layout type needs to be changed to Manual on the grid's Properties palette.

- 2 Use the grip points to drag the lines in either a horizontal or vertical direction.
 - If you move a grid line beyond the grid border, the grid is enlarged accordingly.
 - If you move one of the border lines to the inside of the grid, the grid is decreased accordingly.

Changing the Position of Column Grid Lines by Editing Grid Bays

Use this procedure to reposition grid lines by editing the number and spacing of grid bays using the Bays worksheet.

- 1 Double-click the column grid where you want to move lines.
- 2 Expand Dimensions.
- 3 Edit grid bays:

If you want to...	Then...
edit grid bays along the X axis	expand X Axis, and click the value for Bays.
edit grid bays along the Y axis	expand Y Axis, and click the value for Bays.

The Bays worksheet lists all bays on the selected axis, their distance from the start point of the grid, and the spacing of each bay.

- 4 To change a bay, click one of its measuring values in the list, and edit the value.
- 5 Click OK.

The line positions have changed according to your specifications.

Attaching Clipping Profiles to Column Grids

You can attach a clipping profile to define a mask around a column grid or to make a hole in a column grid. You could, for example, create a mask to define a column grid for an irregularly shaped room, or exclude parts of a room from the column grid.

NOTE To attach a clipping profile, you must first draw a closed polyline with the desired boundary or hole shape.

Masking Column Grids

Use this procedure to mask a column grid. A mask is a polyline shape that defines the boundaries of a column grid. Those parts of the grid outside the boundary are not displayed.

- 1 Draw a closed polyline with the boundary or hole shape you want.
- 2 Select the grid you want to mask.
- 3 On the Properties palette, expand General.
- 4 Choose Select object for Boundary.
- 5 Select the closed polyline you want to use as a mask.
- 6 Right-click, and click Deselect All to turn off the grid grips.

The parts of the column grid that are outside the masking polyline are no longer displayed.

TIP If columns are connected to the invisible part of the grid, they are still displayed after masking. If necessary, you can delete them.

TIP If you want to restore the original grid shape, select None for Boundary in the Properties palette.

Creating Holes in Column Grids

Use this procedure to create a hole in an existing column grid. The hole is created from a closed polyline placed within the boundaries of the grid. Any parts of the grid inside the hole are not displayed.

- 1 If it does not already exist within the boundaries of the grid, draw a closed polyline in the shape of the desired hole.
- 2 Select the grid, right-click, and click Clip.
- 3 Enter **a** (Add Hole), and press *ENTER*.
- 4 Select the grid again, and press *ENTER*.
- 5 Select a closed polyline for the hole.
A hole is cut in the column grid.
- 6 Press *ENTER* to end the command.

TIP If columns are connected to the hole in the grid, they are still displayed. If necessary, you can delete them.

Removing Holes from Column Grids

Use this procedure to remove holes you have created in column grids.

- 1 Select the grid from which you want to remove holes, right-click, and click Clip.
- 2 Enter **r** (Remove Hole) and press *ENTER*.
- 3 Select the grid again, and press *ENTER*.
- 4 Select the closed polyline of the hole.

The hole is removed from the layout grid. The polyline, however, remains in the drawing. If necessary, you can delete it.

Attaching Hyperlinks, Notes, or Files to a Column Grid

Use this procedure to attach hyperlinks, notes, or files to a column grid. You can also edit hyperlinks and notes, and edit or detach reference files from a column grid.

- 1 Select the column grid to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

For more information, see “Add Hyperlinks to a Drawing” in AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

- 4 Click OK.
- 5 To add a note, click the setting for Notes, and enter the note.
- 6 Click OK.
- 7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 8 Click OK twice.

Changing the Location of Column Grids

Use this procedure to change the location of column grids. You can relocate a column grid by changing the coordinate values of its insertion point. The column grid also has an orientation with respect to the world

coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the column grid are parallel to the XY plane, its normal is parallel to the Z axis. You can change the orientation of the column grid by aligning its normal with another axis. You can also rotate the column grid on its plane by changing the rotation angle.

For more information about the world coordinate system, see “Use World and User Coordinate Systems in 3D” in AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic referenced is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

- 1 Select the column grid that you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the column grid:

If you want to...	Then...
relocate the column grid	enter new coordinate values under Insertion Point.
locate the column grid on the XY plane	make the normal of the column grid parallel to the Z axis: under Normal, enter 1 for Z, and enter 0 for X and Y.
locate the column grid on the YZ plane	make the normal of the column grid parallel to the X axis: under Normal, enter 1 for X, and enter 0 for Y and Z.
locate the column grid on the XZ plane	make the normal of the column grid parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.
change the rotation of the column grid	enter a new value for Rotation Angle.

- 5 Click OK.

Changing the Display of Column Grids

Use this procedure to change any of the following display properties for lines, node markers, or cell markers in a column grid:

- Visibility (display component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

- 1 Select the column grid you want to change, right-click, and click Edit Object Display.

- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 Click the Layer/Color/Linetype tab.
- 5 Select the component to change, and select a different setting for the property.
- 6 Click OK twice.

Changing the Node Radius for a Column Grid

Use this procedure to change the node radius for a column grid by editing its display properties.

- 1 Double-click the column grid you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all column grids in the drawing, select Drawing default setting.

- 5 If necessary, expand Object Display Properties ► Advanced.
- 6 Click the value for Node radius, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new radius.)

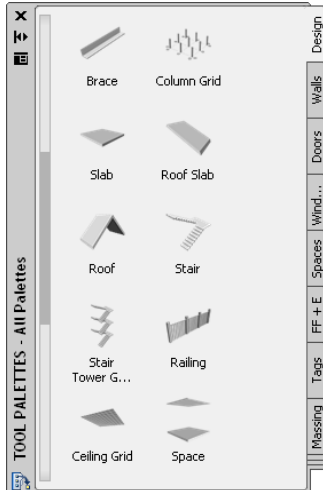

You can also access and modify the node radius property through the column grid's context menu, as follows:

- 1 Select the column grid, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Other tab, and then change the radius as needed.
- 5 Click OK twice.

Using Ceiling Grid Tools to Create Ceiling Grids

Tools in the software let you quickly place ceiling grids using a ceiling grid tool with a specific ceiling grid style and other predefined properties. You can use the default settings of the tool, or you can change its properties. You can also use ceiling grid tools to convert linework to ceiling grids and to apply the settings of a ceiling grid tool to existing ceiling grids.

Tool palettes containing ceiling grid tools

The default tool palettes in the workspace contain sample ceiling grid tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain ceiling grid tools that you can add to your tool palettes:

- AutoCAD Architecture Stock Tool catalog
- AutoCAD Architecture Sample Palette catalog

Custom palettes created by your CAD manager or other users may also contain ceiling grid tools with ceiling grid properties that are customized for your projects or office standards.

Creating a Ceiling Grid

Use this procedure to add a new ceiling grid that has the properties specified in the ceiling grid tool that you select. To specify settings when you add a ceiling grid, see [Creating a Ceiling Grid with User-Specified Settings](#) on page 1845.

- 1 Open the tool palette that contains the ceiling grid tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)
- 2 Specify the insertion point of the ceiling grid.
- 3 Specify the rotation of the ceiling grid, and press *ENTER*.
- 4 Continue adding ceiling grids, and press *ENTER*.

Creating a Ceiling Grid with User-Specified Settings

Use this procedure to add a ceiling grid with settings that you specify on the Properties palette. Spaces and closed polylines can be used as boundaries for ceiling grids.

- 1 Open the tool palette that you want to use, and select a ceiling grid tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.

3 Select a boundary:

If you want to...	Then...
place a ceiling grid within a space	click Select object for Boundary, and select a space in the drawing.
place a ceiling grid within a closed polyline	click Select object for Boundary, and select a closed polyline in the drawing.

4 Expand Dimensions, and select No for Specify on screen.

5 Specify the settings:

If you want to...	Then...
define the width of the grid	enter a value for X - Width.
define the depth of the grid	enter a value for Y - Depth.
lay out the grid with evenly spaced bays along the X direction	expand X Axis, select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay size along the X direction	expand X Axis, select Repeat for Layout type, and enter a value for Bay size.
specify the offset distance from the start point along the X direction of the grid	expand X Axis, and enter a value for Start offset. The offset distance may be used to reduce the effective grid size.
specify the offset distance from the endpoint along the X direction of the grid	expand X Axis, and enter a value for End offset. The offset distance may be used to reduce the effective grid size.
lay out the grid with evenly spaced bays along the Y direction	expand Y Axis, select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay size along the Y direction	expand Y Axis, select Repeat for Layout type, and enter a value for Bay size.
specify the offset distance from the start point along the Y direction of the grid	expand Y Axis, and enter a value for Start offset. The offset distance may be used to reduce the effective grid size.
specify the offset distance from the endpoint along the Y direction of the grid	expand Y Axis, and enter a value for End offset. The offset distance may be used to reduce the effective grid size.

TIP After specifying the desired settings, you can move or hide the Properties palette to expose more of the drawing area.

6 In the drawing area, specify the insertion point of the ceiling grid.

7 Specify the rotation angle of the grid, and press *ENTER*.

8 Continue adding ceiling grids, and press *ENTER*.

Creating a Ceiling Grid from a Layout Grid

Use this procedure to convert a two-dimensional (2D) layout grid to a ceiling grid that has the properties of the ceiling grid tool you select. You can edit these properties after creating the ceiling grid.

1 Open the tool palette that contains the ceiling grid tool you want to use.

(You may have to scroll to display the desired tool.)

2 Right-click the ceiling grid tool, and click Apply Tool Properties to ► Layout Grids.

3 Select the layout grid to convert, and press *ENTER*.

4 When prompted to erase the original geometry, press *ENTER* to erase the linework, or enter *n* (No) to keep it.

5 Edit the properties of the ceiling grid in the Properties palette, if necessary.

Creating a Ceiling Grid from Linework

Use this procedure to convert custom linework to a ceiling grid that has the properties of the ceiling grid tool you select. You can edit these properties after creating the ceiling grid.

1 Open the tool palette that contains the ceiling grid tool you want to use.

(You may have to scroll to display the desired tool.)

2 Right-click a ceiling grid tool, and click Apply Tool Properties to ► Linework.

3 Select the linework to convert, and press *ENTER*.

4 When prompted to erase the original linework, press *ENTER* to keep the linework, or enter *y* (Yes) to erase it.

5 Edit the properties of the ceiling grid in the Properties palette, if necessary.

Creating a Ceiling Grid Dynamically

Use this procedure to create ceiling grids dynamically by specifying their dimensions on the screen as you draw them.

1 Open the tool palette that contains the ceiling grid tool you want to use, and select the tool.

(You may have to scroll to display the desired tool.)

2 On the Properties palette, expand Dimensions, and select Yes for Specify on screen.

3 Expand X Axis and Y Axis, and specify the settings:

If you want to...

Then...

lay out the grid with evenly spaced bays along the X direction

select Space evenly for Layout type, and enter a value for Number of bays.

lay out the grid with a fixed bay size along the X direction

select Repeat for Layout type, and enter a value for Bay size.

If you want to...	Then...
specify the offset distance from the start point along the X direction of the grid	enter a value for Start offset. The offset distance may be used to reduce the effective grid size.
specify the offset distance from the endpoint along the X direction of the grid	enter a value for End offset. The offset distance may be used to reduce the effective grid size.
lay out the grid with evenly spaced bays along the Y direction	select Space evenly for Layout type, and enter a value for Number of bays.
lay out the grid with a fixed bay size along the Y direction	enter a value for Bay size.
specify the offset distance from the start point along the Y direction of the grid	enter a value for Start offset. The offset distance may be used to reduce the effective grid size.
specify the offset distance from the endpoint along the Y direction of the grid	enter a value for End offset. The offset distance may be used to reduce the effective grid size.

- 4 Specify an insertion point in the drawing.
- 5 Specify the overall size of the grid by dragging the cursor to the desired size and clicking once.
- 6 Specify the rotation angle for the grid, and press *ENTER*.

Creating a Ceiling Grid with a Clipping Boundary

Use this procedure to create a ceiling grid within a closed polyline or a space object. If the ceiling grid is within a space, the grid is created at the ceiling height of the space.

- 1 Open the tool palette that contains the ceiling grid tool you want to use, and select the tool. (You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Click the setting for Boundary.
- 4 Click Select object, and then select an existing space or a closed polyline in the drawing.
- 5 Specify an insertion point in the drawing.

NOTE The insertion point of the ceiling grid is the lower-left corner of the ceiling grid if the rotation is set to 0 degrees.

- 6 Specify the overall size of the grid by dragging the cursor to the desired size and clicking once. Drag the cursor along the X axis to specify the number of bays along the X direction, and drag the cursor along the Y axis to specify the number of bays along the Y direction.
- 7 Specify the rotation angle of the grid, and press *ENTER*. The grid is displayed only within the space or closed polyline.

Creating a ceiling grid from a polyline

NOTE In some templates, the ceiling grid object is turned off in a number of plan views. It is displayed in most model views, however, so if you cannot see your grid in top view, switch to a model view to make sure it is there. For more information about turning on the display of ceiling grids in plan view, see [Display System](#) on page 537.

Creating a Ceiling Grid Tool

Use this procedure to create a ceiling grid tool and add it to a tool palette. You may want to create your own ceiling grid tools if you are placing multiple ceiling grids of a specific style, and they all have the same properties.

- 1 Open the tool palette on which you want to add a tool.
- 2 Create the tool:

If you want to...	Then...
create a tool from a ceiling grid in the drawing	select the object, and drag it to the tool palette.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

- 3 Right-click the new tool, and click Properties.
- 4 Enter a name for the tool.
- 5 Click the setting for Description, enter a description of the tool, and click OK.
- 6 Expand Basic, and expand General.
- 7 Click the setting for Description, enter a description of the ceiling grid created from this tool, and click OK.
- 8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.
- 9 Specify the settings for the dimensions of the grid.
For more information, see [Creating a Ceiling Grid with User-Specified Settings](#) on page 1845.
- 10 Click OK.

Editing Ceiling Grids

You can change existing ceiling grids in different ways. You can change the overall dimensions of the grid, the number and position of grid lines, and the location of the grid within the drawing. You can also specify a clipping boundary for the grid and use that to mask the grid or insert a hole into the grid.

Changing the Dimensions of a Ceiling Grid

Use this procedure to change the overall dimensions of a ceiling grid. A ceiling grid is defined by its width and depth.

- 1 Double-click the ceiling grid you want to change.
- 2 Expand General, and expand Dimensions.
- 3 Modify the values for X - Width or Y - Depth.

TIP You can also change the size of a grid by dragging its grip points. Note that when you have a manual grid, you are dragging the individual lines, and not the grid.

Changing the Lines of a Ceiling Grid

Apart from the overall dimensions of a ceiling grid, you can also change the number and position of grid lines on the X and Y axes. There are 3 different layout types that control the spacing of lines in a grid. Layout type is specified separately for the X and Y planes on the Properties palette for the grid.

- **Manual:** You specify the position of each line on the grid.
- **Repeat (Fixed Bay Size):** You specify equidistant spacing between lines on the grid. The number of lines is determined by the size of the grid. As the size of the grid changes, lines are added or subtracted accordingly. The distance between lines remains fixed.
- **Space Evenly:** You specify the number of lines on the grid. The space between lines is determined by the size of the grid. As the size of the grid changes, the spacing between lines is lengthened or shortened accordingly. The number of lines remains fixed.

NOTE By default, grids are inserted with evenly spaced lines.

The procedures for adding or removing grid lines vary depending on the Layout type in effect, as explained in the following sections.

Adding Lines to a Ceiling Grid

In some cases, you need to add lines to an existing grid. Depending on the Layout type in effect, you do this in different ways.

Adding Lines to a Ceiling Grid with Evenly Spaced Lines

Use this procedure to add lines to a grid with evenly spaced lines. The lines will always be distributed evenly along the grid axis. If you need non-regular lines with different spacing between them, open the grid's Properties palette, and change the Layout type to Manual.

- 1 Double-click the ceiling grid to which you want to add lines.
- 2 Expand Dimensions.
- 3 Add grid lines:

If you want to...	Then...
add grid lines to the X axis of the grid	expand X Axis, and enter a value for Number of bays. The number of grid lines increases to create the specified number of bays, while the overall size of the grid remains the same.
add grid lines to the Y axis of the grid	expand Y Axis, and enter a value for Number of bays. The number of grid lines increases to create the specified number of bays, while the overall size of the grid remains the same.

Your grid has been updated accordingly, with the new number of grid lines distributed evenly along the grid axis.

TIP To add lines to the ceiling grid, you can also right-click the grid, and click X Axis/Y Axis ► Add Grid Line.

Adding Lines to a Manual Ceiling Grid

Use this procedure to add lines to a manual grid. A manual grid allows maximum control over the grid, but requires that you specify the exact number and position of grid lines.

- 1 Double-click the ceiling grid to which you want to add lines.
- 2 On the Properties palette, expand Dimensions.
- 3 Add grid lines:

If you want to...	Then...
add grid lines to the X axis of the grid	expand X Axis, select Manual for Layout type, and click on the value for Bays.
add grid lines to the Y axis of the grid	expand Y Axis, select Manual for Layout type, and click on the value for Bays.

The Bays worksheet lists all of the bays on the selected axis, their distance from the start point of the grid, and the spacing between the grid lines that define the bays.

- 4 To add a line, click under the last number in the Bays list.
A new line is inserted with default values for distance and spacing. You can edit these values by clicking them and entering new values.

NOTE You cannot enter a line number for the new line. The line number is provided by the application after you close the worksheet.

- 5 Click OK.

TIP To add lines to the ceiling grid, you can also right-click the grid, and click X Axis/Y Axis ► Add Grid Line.

Adding Lines to a Ceiling Grid with Fixed Bay Size

Use this procedure to add lines to a grid with fixed bays. Normally, in a grid with fixed bays, the distance between the grid lines is more important than the number of grid lines.

To add lines to a grid with a fixed bay size, you have 2 options:

- Enlarge the overall grid size (for more information, see [Changing the Dimensions of a Ceiling Grid](#) on page 1850).
- Decrease the size of the bays

TIP In cases where the number of lines is important for the grid, change the Layout type of the grid from Repeat to Space evenly or Manual.

1 Double-click the ceiling grid to which you want to add lines.

2 Expand Dimensions.

3 Add grid lines:

If you want to...	Then...
add grid lines to the X axis of the grid	expand X Axis, and enter a value for Bay size.
add grid lines to the Y axis of the grid	expand Y Axis, and enter a value for Bay size.

If you enter a value that reduces the size of the bays, the number of grid lines increases as the extra bays are added to the grid.

A number of new lines have been added by decreasing the size of the individual bays.

Removing Lines from a Ceiling Grid

In the same way that lines can be added to a ceiling grid, they can also be removed.

Removing Lines from a Ceiling Grid with Evenly Spaced Lines

Use this procedure to remove lines from a grid with evenly spaced lines. The lines will always be distributed evenly along the grid axis. To remove a particular line and have all the other lines stay in their original places, open the grid's Properties palette, and change the Layout type to Manual.

1 Double-click the ceiling grid from which you want to remove lines.

2 Expand Dimensions.

3 Remove grid lines:

If you want to...	Then...
remove grid lines from the X axis of the grid	expand X Axis, and enter a smaller value for Number of bays. The number of grid lines decreases to create the specified number of bays, while the overall size of the grid remains the same.

If you want to...	Then...
remove grid lines from the Y axis of the grid	expand Y Axis, and enter a smaller value for Number of bays. The number of grid lines decreases to create the specified number of bays, while the overall size of the grid remains the same.

Your grid has been updated accordingly, with the new number of grid lines distributed evenly along the grid axis.

TIP To remove lines from a ceiling grid, you can also right-click the grid, and click X Axis/Y Axis ► Remove Grid Line.

Removing Lines from a Manual Ceiling Grid

Use this procedure to remove grid lines from a manual grid. On a manual grid, you can remove each line individually.

- 1 Double-click the ceiling grid from which you want to remove lines.
- 2 Expand Dimensions.
- 3 Remove grid lines:

If you want to...	Then...
remove grid lines from the X axis of the grid	expand X Axis, select Manual for Layout type, and click on the value for Bays.
remove grid lines from the Y axis of the grid	expand Y Axis, select Manual for Layout type, and click on the value for Bays.

The Bays worksheet lists all the bays on the selected axis, their distance from the start point of the grid, and the spacing between the grid lines that define the bays.

- 4 To remove a line, click the bay number in the Bays list, and click Remove.
- 5 Click OK.

The bay is deleted from the grid, and the grid size is reduced accordingly.

TIP To remove lines from a ceiling grid, you can also use right-click the grid, and click X Axis/Y Axis ► Remove Grid Line.

Removing Lines from a Ceiling Grid with Fixed Bay Size

Use this procedure to remove lines from a grid with bays of fixed size. Normally, in a grid with fixed bays, the distance between the grid lines is more important factor than the number of grid lines.

To remove lines from a grid with a fixed bay size, you have 2 options:

- Decrease the overall grid size (for more information, see Changing the Dimensions of a Ceiling Grid).
- Increase the size of the bays.

TIP In cases where the number of lines is important for the grid, change the Layout type of the grid from Repeat to Space evenly or Manual.

1 Double-click the ceiling grid from which you want to remove lines.

2 Expand Dimensions.

3 Remove grid lines:

If you want to...	Then...
remove grid lines from the X axis of the grid	expand X Axis, and enter a value for Bay size.
remove grid lines from the Y axis of the grid	expand Y Axis, and enter a value for Bay size.

If you enter a value that increases the size of the bays, the number of grid lines decreases as the extra bays are removed from the grid.

A number of lines have been removed by increasing the size of the individual bays.

Changing the Position of Ceiling Grid Lines

You can change the position of individual lines in ceiling grids for which the Layout type is Manual. (Grids with a Layout type of Repeat or Space evenly calculate line position according to the number of bays or the size of the grid.) A manual grid has grip points for every line. You can use either the grip points or the Bays worksheet to change the position of a grid line.

Using Grip Points to Move Ceiling Grid Lines

Use this procedure to move a ceiling grid line by dragging the grip points of the line. Manual grids have a pair of grip points for the start point and end point of each line.

1 Select the grid where you want to move grid lines.

For each line in the grid, a pair of grip points (start point and end point) is displayed.

TIP If your grid displays only four lines for the corners of the grid, the Layout type needs to be changed to Manual on the grid's Properties palette.

2 Use the grip points to drag the lines in either horizontal or vertical direction.

- If you move a grid line beyond the grid border, the grid is enlarged accordingly.
- If you move one of the border lines of the grid to the inside of the grid, the grid is decreased accordingly.

Changing the Position of Ceiling Grid Lines by Editing Grid Bays

Use this procedure to reposition grid lines by editing the number and spacing of grid bays using the Bays worksheet.

1 Double-click the ceiling grid where you want to move lines.

2 On the Properties palette, expand Dimensions.

3 Edit grid bays:

If you want to...	Then...
edit grid bays along the X axis	expand X Axis, and click the value for Bays.
edit grid bays along the Y axis	expand Y Axis, and click the value for Bays.

The Bays worksheet lists all bays on the selected axis, their distance from the start point of the grid, and the spacing of each bay.

4 To change a bay, click one of its measuring values in the list, and edit the value.

5 Click OK.

The line positions have changed according to your settings.

Attaching Clipping Profiles to Ceiling Grids

You can attach a clipping profile to define a mask around a ceiling grid or to make a hole in a ceiling grid. You could, for example, create a mask to define a ceiling grid for an irregularly shaped room, or exclude parts of a room from the ceiling grid.

For a mask, you can use closed polylines and spaces. For more information, see [Creating a Ceiling Grid with a Clipping Boundary](#) on page 1848.

NOTE To attach a clipping profile, you must first draw a closed polyline or space with the desired boundary or hole shape.

Masking Ceiling Grids

Use this procedure to mask a ceiling grid. A mask is a polyline shape or space that defines the boundaries of a ceiling grid. Those parts of the grid outside the boundary are not displayed.

- 1 Draw a closed polyline with the boundary or hole shape you want.
- 2 Select the grid you want to mask.
- 3 On the Properties palette, expand General.
- 4 Choose Select object for Boundary.
- 5 Select the closed polyline or space you want to use as a mask.
- 6 Right-click, and click Deselect All to turn off the grid grips.

The parts of the ceiling grid that are outside the masking polyline or space are no longer displayed.

TIP If you want to restore the original grid shape, select None for Boundary on the Properties palette.

Creating Holes in Ceiling Grids

Use this procedure to create a hole in an existing ceiling grid. The hole is created from a closed polyline or AEC object placed within the boundaries of the grid. Any parts of the grid inside the hole are not displayed.

- 1 If it does not already exist within the boundaries of the grid, draw a closed polyline in the shape of the desired hole.
- 2 Select the grid, right-click, and click Clip.

- 3 Enter **a** (Add Hole), and press *ENTER*.
- 4 Select the grid again, and press *ENTER*.
- 5 Select a closed polyline or AEC object for the hole.
A hole is cut in the ceiling grid.
- 6 Press *ENTER* to end the command.

Adding a hole to a ceiling grid

Removing Holes from Ceiling Grids

Use this procedure to remove holes you have created in ceiling grids.

- 1 Select the grid from which you want to remove holes, right-click, and click **Clip**.
- 2 Enter **r** (Remove Hole) and press *ENTER*.
- 3 Select the desired ceiling grid, and press *ENTER*.
- 4 Select the closed polyline of the hole.

The hole is removed from the ceiling grid. The polyline, however, remains in the drawing. If necessary, you can delete it.

Removing a hole from a ceiling grid

Attaching Hyperlinks, Notes, or Files to a Ceiling Grid

Use this procedure to attach hyperlinks, notes, or files to a ceiling grid. You can also edit hyperlinks and notes, and edit or detach reference files from a ceiling grid.

- 1 Select the ceiling grid to which you want to attach information.
- 2 On the Properties palette, click the **Extended Data** tab.
- 3 To add a hyperlink, click the setting for **Hyperlink**, and specify the link.
For more information, see “Add Hyperlinks to a Drawing” in AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic is to click the **Search** tab in the Help window, select the **Search titles only** option, and then copy and paste or type in the AutoCAD topic name, and click **List Topics**.

- 4 Click **OK**.
- 5 To add a note, click the setting for **Notes**, and enter the note.
- 6 Click **OK**.

7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

8 Click OK twice.

Changing the Location of Ceiling Grids

Use this procedure to change the location of ceiling grids. You can relocate an existing ceiling grid by changing the coordinate values of its insertion point. The ceiling grid also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the ceiling grid are parallel to the XY plane, its normal is parallel to the Z axis. You can change the orientation of the ceiling grid by aligning its normal with another axis. You can also rotate the ceiling grid on its plane by changing the rotation angle.

For more information about the world coordinate system, see “Use World and User Coordinate Systems in 3D” in AutoCAD help.

TIP The quickest way to locate and view an AutoCAD topic is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

- 1 Select the ceiling grid that you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Select Additional information.
- 4 Specify the location of the ceiling grid:

If you want to...	Then...
relocate the ceiling grid	enter new coordinate values under Insertion Point.
locate the ceiling grid on the XY plane	make the normal of the ceiling grid parallel to the Z axis: under Normal, enter 1 for Z and enter 0 for X and Y.
locate the ceiling grid on the YZ plane	make the normal of the ceiling grid parallel to the X axis: under Normal, enter 1 for X, and enter 0 for Y and Z.
locate the ceiling grid on the XZ plane	make the normal of the ceiling grid parallel to the Y axis: under Normal, enter 1 for Y, and enter 0 for X and Z.

If you want to...	Then...
change the rotation of the ceiling grid	enter a new value for Rotation Angle.

5 Click OK.

Changing the Display of Ceiling Grids

Use this procedure to change any of the following display properties for lines, node markers, or cell markers in a ceiling grid:

- Visibility (display component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

1 Select the ceiling grid you want to change, right-click, and click Edit Object Display.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 Click the Layer/Color/Linetype tab.

5 Select the component to change, and select a different setting for the property.

6 Click OK twice.

Changing the Node Radius for a Ceiling Grid

Use this procedure to change the node radius for a ceiling grid by editing its display properties.

1 Double-click the ceiling grid you want to change.

2 On the Properties palette, click the Display tab.

3 Under the General category, for Display component, verify that *NONE* is selected.

4 For Display controlled by, select This object.

NOTE To apply your changes to all ceiling grids in the drawing, select Drawing default setting.

5 If necessary, expand Object Display Properties ► Advanced.

6 Click the value for Node radius, and enter a new value. (Alternatively, you can click  and specify 2 points in the drawing area to set the new radius.)

You can also access and modify the node radius property through the ceiling grid's context menu, as follows:

1 Select the ceiling grid, right-click, and click Edit Object Display.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 In the Display Properties dialog, click the Other tab, and then change the radius as needed.

5 Click OK twice.

Detail Drafting Tools

33

AutoCAD Architecture includes a number of easily accessible tools designed to help you work more intuitively and effectively with linework in detail drawings.

Construction Lines

Construction lines (also known as xlines) are temporary linework entities that can be used as references when creating and positioning other objects or linework. For example, you can use construction lines to prepare multiple views of the same item, or create temporary intersections to serve as object snaps.

Construction lines are either circles or straight lines that extend to infinity in both directions. In either case, they do not change the total area of the drawing and have no effect on zooming or viewports. You can move, rotate, copy, or delete construction lines just like other objects.

The regular AutoCAD construction line functionality is still available via the XLINE command. However, the AutoCAD Architecture construction line feature is designed to give you a more intuitive way of drawing construction lines based on the geometry of existing objects or linework. No command line entry is required.

You access the Construction Line command by clicking the  button on the Shapes toolbar. The XLINE layer key is used by default for all construction lines created with this command.

In most cases, you would probably want to draw construction lines based on segments of existing objects, but you can also draw them by specifying any two points in the drawing area, without regard to existing objects or linework.

Creating Construction Lines From Existing Objects/Linework

Use this procedure to create a construction line based on the geometry of any straight, arced, or circular segment of any object or linework, except hatches, splines, and ellipses. If based on a straight segment, the resulting construction line is a straight line that extends to infinity in both directions; if based on an arced or circular segment, the construction line is a circle.

- 1 On the Shapes toolbar, click  .
- 2 In the drawing area, move the cursor over the segment on which you want to base your construction line (the “construction line base”).
A preview of the construction line is displayed.

- 3 Click to display an offset indicator, which dynamically shows the distance between the preview line and the construction line base.
- 4 Either drag the preview line to the desired distance, and click to position the construction line, or enter the desired distance and press *ENTER*.

Drawing a construction line at a zero offset based on a straight wall segment

Drawing a construction line at a zero offset based on a arc wall segment

Drawing a construction line at a specified offset based on a straight wall segment

The resulting construction line displays three grips when selected. You can move the line by moving the middle grip, or you can change its orientation by moving either of the end grips.

Creating Construction Lines Independently

Use this procedure to create a straight construction line that passes through any two points of your choice.

- 1 On the Shapes toolbar, click .
- 2 Press *ENTER*.
- 3 In the drawing area, specify the first point that you want the construction line to pass through. (This will be the root or conceptual midpoint of the construction line.)
- 4 Specify a second point.

Drawing a construction line by specifying points

The construction line is displayed. If you select it, three grips are displayed. You can move the line by moving the middle grip, or you can change its orientation by moving either of the end grips.

Hatch Productivity Tools

The context menu for hatches includes options that allow you to easily reposition hatches relative to their origins, generate AEC Polygons to provide boundaries for non-bounded hatches, and redefine hatch boundaries based on other selected closed-boundary linework.

Repositioning a Hatch

Use this procedure to align brick and masonry hatch patterns within a boundary so that whole units display along a particular edge.

- 1 Select the hatch.
- 2 Right-click, and click Set Origin.
- 3 Specify an endpoint on the boundary, and press *ENTER*.

The hatch is repositioned with its origin at the endpoint you specified.

Repositioning a hatch within a boundary

Generating a Hatch Boundary

Use this procedure to generate a boundary for a hatch whose original boundary has been deleted or moved during the course of other drawing operations. The boundary generated by this procedure is an AEC Polygon, which is created with the POLYGON layer key. AEC Polygons are also created for any islands within the selected hatch. These AEC Polygons remain selected after you generate the boundary, so you can directly manipulate them into the desired configuration. You can then apply the hatch to the new boundary configuration using the Set Boundary option, as described under [Redefining a Hatch Boundary](#) on page 1865.

- 1 Select the hatch.
- 2 Right-click, and select Generate Boundary.
All grips are displayed for any AEC Polygons created.

TIP If you want to generate a polyline copy of an AEC Polygon created by this process, select the AEC Polygon, right-click, and click Convert To ► Polyline.

Generating a hatch boundary

existing hatch

with grips

result

Redefining a Hatch Boundary

Use this procedure to redefine the boundaries of associative or non-associative hatches based on any selected closed-boundary linework. In cases where a non-associative hatch originally filled closed-boundary linework, but the linework was subsequently stretched or moved, this procedure lets you expand or reposition the hatch to fill the new boundary.

You can also use this procedure to extend or move a hatch from one boundary to others. (If you do not also select the linework currently bounding the hatch, the hatch is moved from the original boundary to the other boundaries that you select.) The linework you select for the new hatch boundaries can be AEC Polygons, closed polylines, circles, text, or multiline text (Mtext).

- 1 Select the hatch.
- 2 Right-click, and click Set Boundary.
- 3 Select the linework, and press *ENTER*.
- 4 Press *ENTER* to keep the selected linework, or enter *y* (Yes) to erase it.

The selected hatch is applied within all selected boundaries.

Transferring a hatch from one boundary to another

and boundaries

select hatch

select boundaries

result

NOTE If a hatch was originally created as associative, its associativity is *not* transferred to other linework to which the hatch is applied using the Set Boundary option. And if the original boundary itself is one of the boundaries selected during the operation, the association between the boundary and the hatch is discontinued.

AEC Modify Tools

You can perform a variety of editing operations on linework components and certain architectural objects using AEC Modify tools. Some of these tools, such as Trim, Obscure and Merge, can be used on any of the following objects and are available from the context menu regardless of whether any objects of these types are selected:

- Hatches
- Polylines
- Circles
- Arcs
- Text/Multiline text (Mtext)
- Spaces
- AEC Polygons
- Mass element extrusions
- Any of the above when embedded in blocks

Although some of the AEC Modify Tools can only be applied to the types of objects listed above, objects of any type can be used as reference points or boundaries for the editing operations. For example, linework can be trimmed or extended in relation to architectural objects such as walls. Likewise, architectural objects can be used to define a cropping boundary or an area to subtract from linework. Architectural objects can also be included as part of a collection of objects for which a shrinkwrap outline is generated.

When you work with architectural objects, such as windows and doors, you can use Array, Reposition From, Space Evenly, and Center tools in this suite in addition to linework and profile-based objects. When you select an architectural object and right-click, the AEC Modify tool that is available for the object displays on the context menu.

Trimming Linework or Profile-Based Objects

Use this procedure to trim hatches, lines, polylines, arcs, circles, AEC Polygons, mass element extrusions, spaces, or any block-based content (including detail components) made up of these types of linework or objects.

- 1 Select the linework, object, or block to trim.

- 2 Right-click and click AEC Modify Tools ► Trim.

- 3 Specify two points to establish the trim line.

The trim line changes color once the second point is selected, as does all linework (except hatches) on the side of the trim line where the cursor is positioned.

- 4 Click the side of the trim line where the region you want to remove is located.

All linework on the selected side of the trim line is removed, and boundaries for any closed polylines on the other side are redrawn along the trim line.

Trimming a block

Trimming Linework or Profile-Based Objects to an Edge

Use this procedure to trim one or more lines, polylines, arcs, circles, hatches, AEC Polygons, mass element extrusions, or spaces precisely to a selected edge or side of any straight segment of AEC linework. This feature lets you easily trim linework to components of walls.

TIP If you need to trim linework to the edge of an arced segment of an object, use either the Crop option (see [Cropping Linework or Profile-Based Objects](#) on page 1875) or the Subtract option (see [Subtracting from Linework and Profile-Based Objects](#) on page 1872). The Crop option removes linework outside the implied boundary of the arc, while the Subtract option removes linework inside the implied boundary of the arc.

- 1 Select the linework or object to trim.
- 2 Right-click, and click AEC Modify Tools ► Trim.
- 3 Press *ENTER*.
- 4 Move the cursor over the edge or line to which you want to trim the selected linework or object.
- 5 Click when the trim line displays.
- 6 Click the side of the trim line you want trimmed.
All selected linework is trimmed to the edge you selected.

Trimming linework to the edge of a wall

Extending Linework to an Edge

Use this procedure to extend one or more lines, open polylines, or arcs precisely to an implied edge of a straight or arced segment of any object, or to an implied extension of that segment.

- 1 Select the linework you want to extend.
- 2 Right-click and click AEC Modify Tools ► Extend.
- 3 Move the cursor over the edge or line to which you want to extend the selected linework, and click when a temporary line is displayed extending along and beyond the edge/line in both directions.
- 4 Click any point on the linework you want to extend, or click the edge or line to which you want to extend the linework.

The linework is extended to the edge. If you selected multiple lines, clicking on any one of them extends them all.

Extending linework to the edge of a wall

Dividing Linework and Profile-Based Objects

Use this procedure to divide linework, AEC Polygons, mass element extrusions, spaces, or a block containing any of these objects into two (or more) parts defined by a divide line you draw. The parts on either side of the line are then separately selectable. If a closed-boundary object is divided into two parts using this option, both parts are recreated as closed. If an open polyline in a zigzag pattern is divided along its length, many selectable segments are created.

- 1 Select the linework, object, or block you want to divide.
- 2 Right-click, and click AEC Modify Tools ► Divide.
- 3 Specify two points to establish the divide line. In the case of a closed-boundary object, the points can be inside or outside the boundaries; the divide line is automatically extended until it intersects all boundaries of the selected object.

The divided parts of the linework or object on either side of the divide line are now selectable. Note that the divide line is no longer visible once the second point is selected.

Dividing a space object

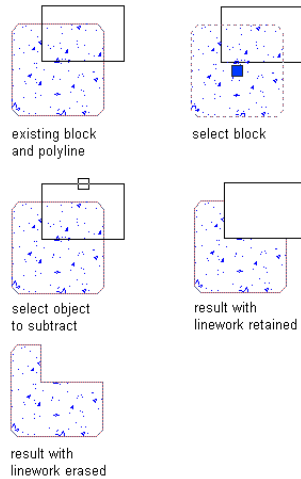

Subtracting from Linework and Profile-Based Objects

Use this procedure to subtract a selected part from linework, AEC Polygons, mass element extrusions, spaces, or from a block containing any of these objects, without having to redraw any of the remaining components. You can also specify the corners of a rectangle as the subtraction. The part to be subtracted can contain or be delineated by lines, polylines (closed or open), arcs, circles, text, or hatches. If the subtraction removes part of a closed polyline, the polyline is recreated as closed. If the subtraction bisects a closed polyline, both parts are recreated as separate closed polylines. However, in cases where the subtraction bisects a hatch, the hatch remains a single linework entity that you can select by clicking either “part.”

NOTE Anything subtracted by this operation is actually deleted from the drawing. If you only want to hide linework from view, you may want to use the Obscure command instead. For more information, see [Obscuring Regions of Linework](#) on page 1873.

- 1 If it does not already exist, draw the linework that delineates what you want to subtract.
- 2 Select the linework or object from which to subtract the delineated part.
- 3 Right-click, and click AEC Modify Tools ► Subtract.
- 4 Press *ENTER* and specify a rectangular shape to be subtracted from the object.
- 5 Alternately, select the linework delineating the part you want to subtract and press *ENTER*.
- 6 Press *ENTER* to keep the selected linework, or enter *y* (Yes) to erase it.

Subtracting part of a block with an existing polyline

Subtracting part of a block by specifying rectangle corners

Obscuring Regions of Linework

Use this procedure to obscure or “hide” a region of linework in relation to other linework. This feature is chiefly useful when you want to indicate that one entity extends behind or beneath another entity that you want to display in the foreground. The obscured linework is placed on the layer specified by the HIDDEN layer key. Once you have begun the Obscure command, you can also specify two corners of a rectangle to use.

- 1 Select the linework to hide (the linework “being obscured”).
- 2 Right-click, and click AEC Modify Tools ► Obscure.
- 3 Select the “obscuring linework” (that is, the linework behind which you want to hide the originally selected linework), and press *ENTER*.

The obscured region is delineated with a dashed line. You can select it (or its component segments) separately from the linework it was part of before being obscured.

Obscuring linework with a block

4 Alternately, press *ENTER* and specify a rectangular shape to obscure the object.

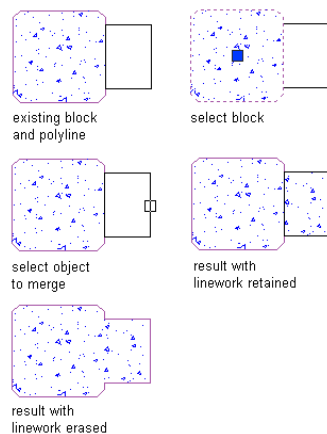

Merging Linework or Profile-Based Objects

Use this procedure to merge contiguous closed polylines, circles, hatches, AEC Polygons, mass element extrusions, spaces, or blocks into a single closed-boundary object or linework entity.

- 1 Select the linework or object to which you want to add one or more other linework entities or objects.
- 2 Right-click, and click AEC Modify Tools ► Merge.
- 3 Select the linework/object(s) you want to merge with the originally selected linework/object, and press *ENTER*.
- 4 Press *ENTER* to keep the selected linework, or enter *y* (Yes) to erase it.

All selected linework and/or objects are merged into a single entity of the type you selected first. That is, if you select an AEC Polygon in Step 1 and a space object in Step 3, the resulting entity is an AEC Polygon.

Merging a region with a block

5 Alternately, press *ENTER* after Step 2 and specify a rectangular shape to merge with the linework or object.

Cropping Linework or Profile-Based Objects

Use this procedure to crop linework or a profile-based object to a smaller area with a boundary you define. You can crop hatches, lines, polylines, arcs, circles, AEC Polygons, mass element extrusions, spaces, and/or blocks. Neither the linework to be cropped nor the linework that defines the new boundary needs to have closed boundaries. For example, you can use a v-shaped polyline to crop a circle, or you can use a circle to crop a v-shaped polyline. Once you have begun the Crop command, you can also specify two corners of a rectangle to crop the linework or objects.

- 1 Draw the linework that defines the new boundary to which you want to crop the existing linework.
- 2 Right-click, and click AEC Modify Tools ► Crop.
- 3 Select the linework to crop and press *ENTER*.
- 4 Select the linework you want to define the new boundary (the linework you drew in Step 1), and press *ENTER*.
- 5 Press *ENTER* to keep the selected linework (the crop boundary), or enter *y* (Yes) to erase it.

All of the originally selected linework outside the crop boundary is erased. If you choose to erase the crop boundary, boundaries are redrawn for any closed-boundary entities inside the crop area, but any open-boundary objects that have been cropped remain open.

Cropping a block with a polyline

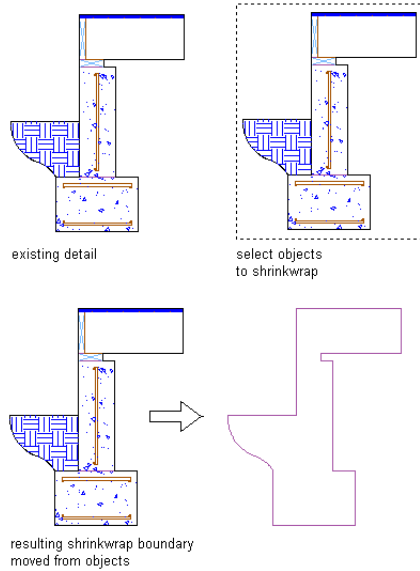

- 6 Alternately, press *ENTER* after Step 2 and specify a rectangular shape to crop the linework or object.

Shrinkwrapping Linework

Use this procedure to automatically create a profile or shrinkwrap outline around any collection of contiguous linework entities, including architectural objects. The visual result of the procedure is similar to merging the entities (see [Merging Linework or Profile-Based Objects](#) on page 1874), but in this case the outline you create is a separately selectable entity. Unlike the other AEC Linework Tools, the Shrinkwrap tool is accessed from the General tool palette. The `AecLineworkShrinkwrap` command the tool invokes is wrapped in a DesignCenter command to accommodate layer keying (that is, shrinkwrap polylines created using this tool are automatically placed on a particular layer as specified by the associated layer key).

- 1 Open the Basic tool palette, and click the Shrink Wrap tool.
- 2 Select all of the objects you want to shrinkwrap.

3 Press *ENTER*.

All objects within the shrinkwrap remain selected. You can now select and move the shrinkwrap profile independently of the linework it encloses.

Creating Arrays

Use this procedure to create an array of identical linework (such as hatches and polylines), architectural objects (such as doors and walls), AEC polygons, or profile-based objects (such as mass element extrusions, and spaces). You can also array any block-based content (including detail components) made up of these types of linework and objects.

- 1 Select the linework, object, or block to array.
- 2 Right-click and click AEC Modify Tools ► Array.
- 3 Select an edge and drag the cursor to specify the direction of the array for a rectangular array. The number of objects you are adding to the array is displayed in the tooltip as Array Count.

Array a block

- 4 Enter a value for the distance offset between each instance of the linework or object, and press *ENTER*.

Alternately, for a polar array, specify two points to establish the angle of the array, enter a value for the distance offset between the linework or object, and press *ENTER*.

5 Click in the drawing area to specify the endpoint of the array.

For more information on arrays, see “Array Dialog Box” in AutoCAD Help.

Repositioning from a Reference Point

Use this procedure to reposition architectural objects, linework, or blocks from a specific reference point in your drawing. For example, if you have a kitchen island that you want repositioned 6'-0" from existing cabinetry, you can place the island using the interior edge of the cabinet as a reference point. You can also use this procedure with hatches, lines, polylines, arcs, circles, AEC Polygons, mass element extrusions, spaces, or any block-based content (including detail components and DesignCenter content) made up of these types of linework or objects.

- 1 Select the linework, object, or block to reposition.
- 2 Right-click and click AEC Modify Tools ► Reposition From.
- 3 Select an existing edge from which to reposition the object, or specify two points to define a reference edge.
- 4 Select the object to be repositioned, and enter a value for the distance between it and the reference edge.
- 5 Press *ENTER*.

Evenly Spacing Linework or Objects

Use this procedure to space a collection of existing architectural objects, linework, or blocks at an equal distance from each other. For example, if you have windows along walls that are not colinear, you can space the windows evenly across the entire facade by specifying points along an axis. You can use this procedure with hatches, lines, polylines, arcs, circles, AEC Polygons, mass element extrusions, spaces, or any block-based content (including detail components) made up of these types of linework or objects.

- 1 Select the linework, object, or block to space.
- 2 Right-click and click AEC Modify Tools ► Space Evenly.
- 3 Select an edge as the axis along which to space all the objects evenly, and specify a start point and an endpoint along the edge; or press *ENTER*, and specify two points between which the objects will be spaced evenly from each other.

NOTE For example, if you select two objects to be spaced between two points, the spacing of the objects is from the specified start point to the center of the first object, from the center of the first object to the center of the second object, and from the center of the second object to the specified endpoint.

Centering Linework or Objects

Use this procedure to center any of the following between two points: architectural objects, hatches, lines, polylines, arcs, circles, AEC Polygons, mass element extrusions, spaces, or any block-based content (including detail components) made up of these types of linework or objects.

- 1 Select the linework, object or block to center.
- 2 Right-click and click AEC Modify Tools ► Center.

3 Select an existing edge as an axis, and then specify two points between which to center the object on that axis; or press *ENTER*, and specify any two points between which to center the object.

Mask Blocks

34

A mask block is a two-dimensional (2D) block that covers, or “masks,” part of the graphic display of an AEC object in a plan view. You can use mask blocks to clean up or correct objects in your drawings or to create custom 2D shapes from predefined drawing objects, such as walls or grids.

Mask Blocks

A mask block is a two-dimensional (2D) block that covers, or “masks,” part of the graphic display of an AEC object in a plan view. You can use mask blocks to clean up or correct objects in your drawings or to create custom 2D shapes from predefined drawing objects, such as walls or grids.

For example, attach a light fixture as a mask block to a ceiling grid in a plan view. If the light fixture is bigger than one or more of the ceiling grid bays, the light fixture masks, or covers, the ceiling grid lines that would visibly pass through the light fixture if it had been defined as a regular AutoCAD block.

Before you can begin to mask objects in your plan view drawings, you must have an existing mask block or a mask block definition created in your drawing. You can find predefined mask blocks on the Drafting tool palette and in the AutoCAD Architecture Stock Tool catalog. You can also create a mask block with the AEC Content Wizard. For more information about custom content, see [Creating an AEC Content Masking Block for DesignCenter](#) on page 2610.

After you have selected a mask block, add it to your drawing in plan view. Adding the mask block to your drawing is like adding a regular AutoCAD block: specify an insertion point or scale factors and a rotation angle. The mask block and the object that you want to mask must be coplanar; that is, for the mask object to cover the other object, they must be on the same plane.

After you insert a mask block in your drawing, attach the objects to be masked. The mask block clips the graphics of the objects that you are masking when the objects regenerate themselves in a plan view. Only the objects that you attach to the mask block are clipped. The masked objects are plotted as you see them on your screen.

If you change your drawing from a 2D view to a three-dimensional (3D) view, the mask block is still displayed, but it no longer masks the objects that are attached to it. You can detach the mask block from the objects at any time. You can also import and export mask block definitions. If you create a mask block definition that you decide not to use in your drawings, you can purge it.

Creating Mask Block Definitions

You can define a mask block by selecting a closed polyline in the drawing and defining it as a mask block, by copying and editing an existing mask block, or by using the AEC Content Wizard.

Use the AEC Content Wizard to save mask blocks in content drawings for convenient reuse. For more information, see [Creating an AEC Content Masking Block for DesignCenter](#) on page 2610.

Managing Mask Block Definitions

To create, edit, copy, or purge mask block definitions, use the Style Manager. The Style Manager provides a central location in AutoCAD Architecture, where you can work with definitions and styles from multiple drawings and templates. For more information, see [Style Manager](#) on page 589.

Creating a Mask Block Definition from a Polyline

Use this procedure to create a mask block definition from one or more closed polylines. If you use more than one polyline to create your mask block definition, the polylines must be completely within or completely outside each other: they cannot overlap or touch. Polylines that are within each other can be specified as void areas that become holes when the mask block is created. After you create the definition, edit the definition properties to customize the characteristics of the definition.

- 1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view.

- 2 Expand Multi-Purpose Objects, right-click Mask Block Definitions, and click New.

- 3 Enter a name for the new mask block definition, and press *ENTER*.

- 4 Right-click the new mask block definition name, and click Set From.

- 5 Select the closed polyline to use to create the mask block definition.

- 6 Do one of the following to complete the mask block definition:

- Press *ENTER* to create the mask block definition from a single polyline.
- Enter *y* (Yes) to select additional polylines to add to the mask block definition. These polylines must be entirely within or outside each other; they cannot overlap or touch. Polylines that are within other rings can be specified as void areas that become holes in the mask block.

- 7 Specify an insertion base point for the mask block.

- 8 Select additional graphics to include in the mask block definition, or press *ENTER* if you do not want to include additional graphics.

NOTE You can select text or symbols to include in the mask block definition.

- 9 Click OK.

A mask block definition is created from the polyline or polylines that you selected. The new mask block definition is listed in the mask block definition tree and can be viewed in the graphics screen of Style Manager. The original polylines remain in the drawing.

Creating a Mask Block Definition from an Existing Mask Block Definition

Use this procedure to create a mask block definition from a mask block definition that already exists in a drawing. After you create the new definition, you edit the definition properties to customize the characteristics of the definition.

1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view.

2 Expand Multi-Purpose Objects, and expand Mask Block Definitions.

3 Right-click the mask block definition to copy, and click Copy.

4 Right-click, and click Paste.

5 Right-click the new mask block definition, and click Rename.

6 Enter a name, and press *ENTER*.

7 Click OK.

Importing Mask Block Definitions

Use this procedure to import a mask block definition from another drawing. After you create the definition, you edit the definition properties to customize the characteristics of the definition.

1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view.

2 On the File menu, click Open drawing to browse for the drawing that contains the definition that you want to copy to your current drawing.

3 Select the drawing with the definition to copy, and click Open.

4 Expand Multi-Purpose Objects, and expand Mask Block Definitions.

5 Right-click the mask block definition to copy, and click Copy.

6 Select the current drawing, and expand Multi-Purpose Objects.

7 Right-click Mask Block Definitions, and click Paste.

The definition is copied into the current drawing. If the current drawing already contains a definition with the same name, the duplicate names are displayed in the Import/Export - Duplicate Names Found dialog box.

8 To resolve duplicate names, select one of the following options:

- To *not* replace the existing definition in the drawing with the new definition of the same name, select Leave Existing, and click OK.
- To replace the existing definition in the drawing with the new definition, select Overwrite Existing, and click OK.
- To rename the new definition so both definitions exist in the drawing, select Rename to Unique, and click OK. New definition names are appended with a numeral in the Style Manager.

9 Click OK.

Exporting Mask Block Definitions to a New Drawing

Use this procedure to copy mask block definitions from your current drawing to a new drawing. After you create the definition, you edit the definition properties to customize the characteristics of the definition.

1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view.

2 On the File menu, click New drawing to create the drawing to which you want to copy the definition.

- 3 Enter a name for the new drawing, and click Save.
The new drawing opens in the Style Manager.
- 4 In the current drawing, Expand Multi-Purpose Objects, and expand Mask Block Definitions.
- 5 Right-click the mask block definition to copy to the new drawing, and click Copy.
- 6 Select the new drawing, and expand Multi-Purpose Objects.
- 7 Right click Mask Block Definitions, and click Paste.
- 8 Click OK.

Exporting Mask Block Definitions to an Existing Drawing

Use this procedure to copy mask block definitions from your current drawing to another drawing. After you create the definition, you edit the definition properties to customize the characteristics of the definition.

- 1 Click Format menu ► Style Manager.
The Style Manager is displayed, with the current drawing expanded in the tree view.
- 2 On the File menu, click Open drawing to browse for the drawing to which you want to copy the definition.
- 3 Select the drawing that you want to copy the definition to, and click Open.
The drawing opens in the Style Manager.
- 4 In the current drawing, Expand Multi-Purpose Objects, and expand Mask Block Definitions.
- 5 Right-click the mask block definition to copy to the second drawing, and click Copy.
- 6 Select the second drawing, and expand Multi-Purpose Objects.
- 7 Right-click Mask Block Definitions, and click Paste.
- 8 The definition is copied into the second drawing. If the drawing already contains a definition with the same name, the duplicate names are displayed in the Import/Export - Duplicate Names Found dialog box.
- 9 To resolve duplicate names, select one of the following options:
 - To *not* replace the existing definition in the drawing with the new definition of the same name, click Leave Existing, and click OK.
 - To replace the existing definition in the drawing with the new definition, click Overwrite Existing, and click OK.
 - To rename the new definition so both definitions exist in the drawing, click Rename to Unique, and click OK. New definition names are appended with a numeral in the Style Manager.
- 10 Click OK.

Editing a Mask Block Definition

Use this procedure to make any of the following types of modifications to a mask block definition:

- Change the objects or styles to which the mask block can be attached.
- Add and remove properties.
- Change the name, description, type, and format of properties.

Changes that you make to a mask block definition are immediately applied to any objects or styles to which the mask block created from the definition is attached.

1 Click Format menu ► Style Manager.

The Style Manager is displayed, with the current drawing expanded in the tree view.

2 Expand Multi-Purpose Objects, and expand Mask Block Definitions.

3 Select the mask block definition.

4 Click the Classification tab.

5 Select a classification for the classification definition.

For more information, see [Classification Definitions](#) on page 2574.

6 Click the Display Properties tab.

7 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

8 If necessary, click .

9 Click the Layer/Color/Linetype tab.

10 Select the component to change, and select a different setting.

11 Click OK.

12 Click the General tab.

13 Enter text for Description.

14 Click Notes.

15 Click the Notes tab, and enter a note.

16 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...

Then...

attach a reference file

click Add, select a file, and click OK.

edit the description of a reference file

select the file, and click Edit. Enter the description, and click OK.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click Delete.

17 To attach or edit schedule data, click Property Sets. For more information, see [Attaching Property Set Data to Objects](#) on page 2534 and [Entering Manual Properties and Fields for Objects](#) on page 2535.

18 Click OK.

Adding Classifications to a Mask Block Definition

Use this procedure to specify classifications for any classification definition applied to a mask block definition. Classifications enable you to track objects by construction status, vendor, or other criteria. For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a mask block definition tool.
- 2 Right-click a mask block definition tool, and click Mask Block Definitions.
- 3 Select the definition that you want to change.
- 4 Click the Classifications tab.
By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to mask block definitions.
- 5 For each classification definition, select the classification you want to apply to the current mask block definition.
- 6 Click OK.

Purging Mask Block Definitions

Use this procedure to purge mask block definitions from your drawing. You have the option to purge any mask block definition unless it is currently applied as a mask block in the drawing.

- 1 Click Format menu ► Style Manager.
The Style Manager is displayed, with the current drawing expanded in the tree view.
- 2 Expand Multi-Purpose Objects, and expand Mask Block Definitions.
- 3 Purge mask block definitions:

If you want to...	Then...
purge one unused mask block definition style	right-click the style you want to remove, and click Purge.
purge all unused mask block definition styles	right-click Mask Block Definitions, and click Purge. When prompted, verify that the styles you want to purge are selected, and click OK.

- 4 Click OK.

Using Mask Block Tools to Create Mask Blocks

Tools provided with AutoCAD Architecture let you quickly place mask blocks using tool with a specific mask block definition and other predefined properties. You can use the default settings of tool, or you can change any properties that are not controlled by the definition. You can also create new mask blocks by applying tool properties to existing mask blocks or to closed polylines. For more information, see [Creating a Mask Block Tool](#) on page 1886.

Mask block tools are found in the following locations:

Location	Tool
Drafting tool palette	a mask block tool for the Standard mask block definition style and default settings for other mask block properties
Drafting Tools category in the Stock Tool catalog	a mask block tool for the Standard mask block definition style and default settings for other mask block properties. For more

Location	Tool
custom tool palettes created by your CAD manager	<p>information on accessing tools in this catalog, see Understanding the Content Browser on page 121.</p> <p>Mask block tools with mask block definition styles and properties customized for your projects or office standards</p>

NOTE The Standard mask block definition style is imported if you create your drawing with a template. It will not be present if you start your drawing without using a template. For more information, see [About Templates](#) on page 155.

Adding a Mask Block

Use this procedure to add a new mask block that has the properties specified in the mask block tool that you select. To specify settings when you add a mask block, see [Adding a Mask Block with User-Specified Settings](#) on page 1885. You can add a mask block to a drawing if the drawing contains a mask block definition. For more information, see [Creating Mask Block Definitions](#) on page 1880.

TIP When you add mask blocks to your drawing, insert them on a separate layer. You can turn the layer off in 3D views, where the mask blocks no longer mask any objects.

- 1 If you have created your own mask block definition, create a tool from it as described in [Creating a Mask Block Tool](#) on page 1886.
- 2 If you are working with an existing mask block tool, open the palette it is located on.
A mask block tool is located on the Drafting tool palette and in the Drafting Tools category in the AutoCAD Architecture Stock Tool catalog. You can add this tool to any tool palette. For more information, see [Understanding the Content Browser](#) on page 121.
- 3 Select the mask block tool on the palette.
- 4 Specify the insertion point of the mask block.
You can move or hide the Properties palette to expose more of the drawing area.

NOTE If you are using a mask block to mask a wall, the mask block must be located at the baseline of the wall ($Z = 0$). Even though the wall components are at different heights, the plan display representation draws them at the height of the baseline, as they would be drawn on paper.

- 5 Continue adding mask blocks, and press *ENTER*.
The mask blocks are displayed in the drawing at the insertion point you specified. To use a mask block to clean up or correct an object in the drawing, attach the object to the mask block.

Adding a Mask Block with User-Specified Settings

Use this procedure to add a mask block with settings that you specify.

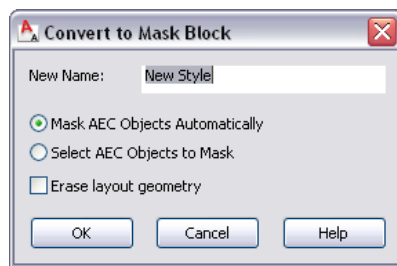

- 1 Open the tool palette that contains the mask block tool you want to use, and select the tool.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Select a definition.

- 4 Expand Scale.
- 5 Enter the X, Y, and Z scale of the mask block. The X, Y, and Z scales represent the distance from the insertion point.
- 6 Alternately, expand Location, and select Yes for Specify scale on screen. Use your pointing device to designate the scale of the mask block.
- 7 In the drawing area, specify the insertion point of the mask block.
You can move or hide the Properties palette to expose more of the drawing area.
- 8 Continue adding mask blocks, and press *ENTER*.
To use a mask block to clean up or correct an object in the drawing, attach the object to the mask block.

Creating a Mask Block from Polylines

Use this procedure to create a mask block reference from one or more closed polylines. If you use more than one polyline to create your mask block, the polylines must be completely within or completely outside each other; they cannot overlap or touch. Polygons that are within each other can be specified as void areas that become holes when the mask block is created.

- 1 Select the polylines, right-click, and click Convert To ► Mask Block.
The Convert to Mask Block worksheet is displayed.

- 2 Enter a name for the new mask block.
- 3 Clear Mask AEC Objects Automatically to avoid masking existing AEC objects overlapping the polylines being converted.
- 4 To select existing AEC objects for masking with the new mask block, make sure Select AEC Objects to Mask is selected.
- 5 Select Erase Layout Geometry to erase the original polylines, and click OK.
- 6 Edit the properties of the mask block in the Properties palette, if necessary.

Creating a Mask Block Tool

Use this procedure to create a mask block tool and add it to a tool palette. You may want to create your own mask block tools if you are placing multiple mask blocks of a specific style and they all have the same properties.

You can use any of the following methods to create a mask block tool:

- Drag a mask block that has the properties you want to a tool palette.

IMPORTANT Make sure that the mask block is in a drawing that has been saved and that will be available in the future.

- Drag a mask block definition from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Drag a copy of a tool from another palette to the current palette, and then customize the properties of the new tool.
- Copy an existing tool in the current palette, and then customize the properties of the new tool.
- Drag a tool from a tool palette in the Content Browser to a tool palette, and then customize the properties of the new tool.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a mask block in the drawing	select the mask block, and drag it to the tool palette.
create a tool from a mask block definition in the Style Manager	on the Format menu, click Style Manager. Locate the mask block definition you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool palette in the Content Browser	open the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Specify properties for the mask block created from the tool:

If you want to...	Then...
enter a description of the mask block that you can create using this tool	click Description, enter a description of the tool, and click OK.
specify a unique layer key for the object type	click Layer Key, select a layer key, and click OK.
specify a layer override for the tool	click Layer Overrides, clear Do not specify Layer Overrides, specify the override, and click OK.

If you want to...	Then...
specify a definition	click Definition, select a mask block definition, and click OK.
specify a definition location	click Definition location, select the file containing the mask block definition you want to use, click Open, and click OK.

8 Expand Scale.

9 Specify the scale for the mask block created from the tool:

If you want to...	Then...
use your pointing device to designate the scale for the mask block	click Yes for Specify scale on screen.
specify the scale of the mask block on the Properties palette	click No for Specify scale on screen, and enter the X, Y, and Z scale for the mask block.

10 Expand Location.

11 Specify the rotation for the mask block created from the tool:

If you want to...	Then...
use your pointing device to designate the angle for the mask block	click Yes for Specify rotation on screen.
specify the angle of the mask block on the Properties palette	click No for Specify rotation on screen, and enter the angle for Rotation.

12 Click OK.

Attaching Mask Blocks to Objects

Use this procedure to mask an object by attaching the mask block to the object after you have the mask block placed correctly.

- 1** Select the mask block or blocks that you want to attach to an object.
- 2** Right-click, and click Attach Objects.
- 3** Select the object that you want to mask.
- 4** Select a display representation from the list of current display representations, and click OK.

Attaching a mask block to an object

The object is now hidden by the mask block.

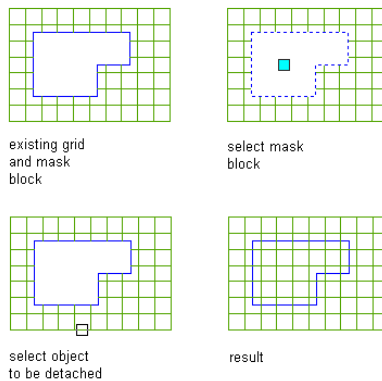

Mask blocks mask AutoCAD Architecture objects only and mask them only in plan views. Mask blocks are visible in 3D views, but they do not mask the objects that are attached to them.

Detaching Mask Blocks from Objects

Use this procedure to unmask an object in plan view by detaching the object from the mask block.

- 1 Select the mask block that you want to detach from an object, right-click, and click Detach Objects.
- 2 Select the object that you want to detach from the mask block.

Detaching an object from a mask block

The object is detached from the mask block and is no longer hidden by the mask block.

Editing Mask Blocks

AutoCAD Architecture offers several methods for editing mask blocks:

- Change the location using grips.
- Change settings on the Properties palette.
- Edit the profile.

- Select commands from the context menu.
- Change how a mask block is displayed.

Using Grips to Move Mask Blocks

Use this procedure to change the location of a mask block with grips.

- 1 Select the mask block.
- 2 Select the highlighted grip.

Viewing Mask Block Location grip

- 3 Move the grip until the door is in the desired location, and click once.

Changing the Location of a Mask Block

Use this procedure to change the rotation, elevation, and location of the mask block on the Properties palette.

You can relocate a mask block by changing the coordinate values of its insertion point. The mask block also has an orientation with respect to the WCS or the current UCS. For example, if the top and bottom of the mask block are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the mask block by aligning its normal with another axis. You can also rotate the mask block on its plane by changing the rotation angle.

For information about the world coordinate system (WCS) and the user coordinate system (UCS), see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

TIP The quickest way to locate and view an AutoCAD topic referenced in AutoCAD Architecture Help is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

- 1 Double-click the mask block you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Specify the placement of the mask block:

If you want to...

Then...

change the rotation

enter a new value for Rotation Angle.

change the elevation

enter a new value for Elevation.

- 4 Click Additional information to specify location of the mask block:

If you want to...

Then...

relocate the mask block

enter new coordinate values under Insertion Point.

If you want to...	Then...
locate the mask block on the <i>XY</i> plane	make the normal of the mask block parallel to the <i>Z</i> axis: under Normal, enter 1 for <i>Z</i> , and enter 0 for <i>X</i> and <i>Y</i> .
locate the mask block on the <i>YZ</i> plane	make the normal of the mask block parallel to the <i>X</i> axis: under Normal, enter 1 for <i>X</i> and enter 0 for <i>Y</i> and <i>Z</i> .
locate the mask block on the <i>XZ</i> plane	make the normal of the mask block parallel to the <i>Y</i> axis: under Normal, enter 1 for <i>Y</i> , and enter 0 for <i>X</i> and <i>Z</i> .
change the rotation of the mask block	enter a new value for Rotation Angle.

Editing the Profile of a Mask Block

Use this procedure to edit the geometry of a mask block.

NOTE If you want to replace the geometry of the mask block with newly drawn polylines, ellipses, or circles, draw them before you start this procedure.

- 1 Select the mask block that you want to change, right-click, and click Edit Profile In Place.
- 2 If prompted that the profile is not drawn to size, click Yes.
A temporary profile is created for you to edit the geometry of the mask block.
- 3 **NOTE** After you perform an editing task from the context menu, you may need to select the profile again to perform another editing task. If you do not see the editing commands that you expect on the context menu, select the profile, and right-click to display the context menu.

Edit the profile:

If you want to...	Then...
change the shape of the perimeter of the profile or its rings	select the profile, and use edge or vertex grips to adjust the shape. The Edge grip has two edit modes: Stretch and Move. The default mode is Stretch, and the direction of the stretch depends on the orientation of edges connected to the selected edge. For example, if the edges at both ends of the selected edge are parallel, the grip edit mode is Stretch (Parallel) and the stretch direction is limited to the direction of the parallel edges. If the connected edges are not parallel, the grip edit mode is Stretch (Offset) and the stretch direction is perpendicular to the direction of the selected edge. The Move edit mode allows an unconstrained move of the selected edge.
add vertices to the profile	select the profile, right-click, and click Add Vertex. Select a point for each new vertex, and press <i>ENTER</i> .

If you want to...	Then...
remove vertices from the profile	select the profile, right-click, and click Remove Vertex. Select each vertex to remove, and press <i>ENTER</i> .
replace an existing ring of the profile with new geometry	select the profile, right-click, and click Replace Ring. Select the ring to replace, and select the new geometry. Press <i>ENTER</i> to keep the geometry, or enter n (No) to erase it.
add a ring to the profile	select the profile, right-click, and click Add Ring. Select the geometry to define the ring. Press <i>ENTER</i> to keep the geometry, or enter n (No) to erase it.
remove a ring from the profile	select the profile, right-click, and click Remove Ring. Select the ring to remove, and press <i>ENTER</i> .
4 Save or discard the changes:	
If you want to...	Then...
restore the mask block to its original shape	select the profile, and click  .
save the changes to the current mask block	select the profile, and click  . The mask block uses the edited profile to define its geometry. Any other objects or styles that use this profile are also updated with the edited geometry.

Applying Tool Properties to an Existing Mask Block Reference

Use this procedure to apply the properties of a mask block tool to one or more existing mask blocks. The properties include the mask block definition and any other settings specified in the tool you select.

- 1 Open the tool palette that you want to use.
If necessary, scroll to display the tool that you want to use.
- 2 Right-click a mask block tool, and click Apply Tool Properties to ► Mask Block Reference.
- 3 Select the mask block reference, and press *ENTER*.
- 4 Edit the properties of the mask blocks in the Properties palette, if necessary.

Changing Display Properties of Mask Blocks

In most cases, you want the appearance of objects that belong to the same style to be consistent throughout a drawing. To achieve this, you specify the display properties of the mask blocks in each mask block definition style. However, in certain instances, you may need to override a display property for an individual mask

block to achieve a specific result. All the display properties that you can specify in mask block definition styles are available for individual mask blocks:

- The visibility of mask block components
- The layer, color, and linetype of mask block components
- The lineweight, linetype scale, and plot style of mask block components

NOTE If the mask block is attached to a grid, you can change the anchor properties as well.

When you change the display properties of a mask block, the changes apply only to that mask block. Other mask blocks of the same definition style are not affected. To change the display properties of all mask blocks of a specific definition style, see [Creating Mask Block Definitions](#) on page 1880.

Changing the Display Properties of a Mask Block

Use this procedure to change any of the following properties of the display components of an individual mask block:

- Visibility (display component is on or off)
- Layer
- Color
- Linetype
- Lineweight
- Linetype scale

1 Select the mask block you want to change, right-click, and click Edit Object Display.

2 Click the Display Properties tab.

3 Select the display representation where you want the changes to appear, and select Object Override.

The display representation in bold is the current display representation.

4 If necessary, click .

5 Click the Layer/Color/Linetype tab.

6 Select the component to change, and select a different setting for the property.

7 Click OK twice.

Attaching Hyperlinks, Notes, and Files to a Mask Block

Use this procedure to attach hyperlinks, enter notes, or attach reference files to a mask block in a drawing. You can also edit notes and edit or detach reference files from a mask block.

1 Double-click the mask block to which you want to attach information.

2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click  next to Hyperlink, and specify the link.

For more information about adding hyperlinks, see “Add Hyperlinks to a Drawing” in AutoCAD Help.

4 To add or edit a note, click  next to Notes, enter text, and click OK.

5 To attach, detach, or edit a reference file, click  next to Reference documents:

If you want to...

Then...

attach a reference file

click  , select a file, and click Open.

edit the description of a reference file

enter text under Description.

edit a reference file

double-click the reference file name to start its application.

detach a reference file

select the file name, and click  .

Multi-View Blocks

35

A multi-view block is an AutoCAD Architecture object that can have different representations in different view directions. You create a multi-view block from AutoCAD blocks that represent the different views of the custom object that you are creating.

Multi-View Blocks

A multi-view block is an AutoCAD Architecture object that can have different representations in different view directions. You create a multi-view block from AutoCAD blocks that represent the different views of the custom object that you are creating.

Understanding Multi-View Blocks

Multi-view blocks can represent different types of objects in AutoCAD Architecture. They are typically used to represent the following items:

- Furniture and fixtures, such as tables and kitchen sinks
- Annotation components, such as revision clouds or fire rating signs
- Schedule tags, such as door numbers

Multi-view blocks can be displayed differently in each view direction and each display representation. For example, the top view of a multi-view block representing a kitchen sink shows the top of the sink; the bottom view shows the bottom of the sink; and there are representations for left, right, front, and back views. Additionally, you can define a different group of displays for each display representation, so that you can have one set of views for Plan view and another for Reflected view.

You can use a multi-view block as a cutout in objects such as walls, slabs, and curtain walls. You create a view block to represent the cutting body. The block forms the body that will be subtracted from objects by applying the multi-view block as interference. For example, you can create a skylight as a multi-view block and specify the block as a subtractive Boolean in a slab.

Predefined Multi-View Blocks

The content folders of AutoCAD Architecture contain predefined multi-view blocks for various design purposes, such as furniture, electrical appliances, annotation symbols, schedule tags, and other useful elements. You can access these multi-view blocks from DesignCenter™. For more information, see [AEC Content and DesignCenter](#) on page 2599.

Creating Multi-View Block Definitions

Each multi-view block in a drawing is based on a definition that specifies the display representations in which the block can be viewed, as well as the views available in each representation. From a multi-view block definition, you can create as many multi-view blocks as you need.

Multi-view blocks typically represent 3D architectural objects. For example, you can create customized cabinetry by drawing plan, elevation, and model views, and saving each view as an individual AutoCAD block. You assign each block to a view when you create the multi-view block definition. The blocks (top, bottom, front, back, left, right, and model views) are used to define the custom object as a single multi-view block. Prior to defining the block, you can add points on the Defpoints layer to identify additional insertion points for the view block. You set the display representations and view directions in the process of defining the multi-view block.

You can see the individual blocks of your custom object as one assembly in plan, elevation, and isometric views after inserting them in the drawing as a multi-view block. For more information about working with blocks, see “Overview of Blocks” in AutoCAD Help. For more information about display representations, see [Display Representations](#) on page 544.

TIP The quickest way to locate and view an AutoCAD topic referenced in AutoCAD Architecture Help is to click the Search tab in the Help window, select the Search titles only option, and then copy and paste or type in the AutoCAD topic name, and click List Topics.

Process Overview: Creating Multi-View Block Definitions

There are four general steps for creating a multi-view block:

- 1 Create a set of view blocks for each view direction in every display representation you need.
For example, if you need a multi-view block definition that displays in Model view and Reflected Plan view, create a set of views for each representation. You create views only for those view directions where you want a different result. For example, if the top and bottom views are supposed to look the same in the Reflected Plan display representation, you draw the view block only once, and assign it to both view directions.
- 2 Create a multi-view block definition in which you assign the view blocks to view directions in individual display representations.
- 3 If you want the new multi-view block definition to be available through DesignCenter™, add the definition to DesignCenter.
- 4 If you want the new multi-view block definition to be available from a tool palette, add it to a palette.

Creating View Blocks

Use this procedure to create AutoCAD blocks to represent each view of the multi-view block definition in display representations.

1 Draw the views you need for a specific display representation:

If you want to...	Then...
create views for the front and back directions	draw them on the <i>XZ</i> plane.
create views for the left and right directions	draw them on the <i>YZ</i> plane.
create views for the top and bottom directions	draw them on the <i>XY</i> plane.
create a block for an interference condition	create a block containing objects, such as mass elements, to be used as the subtractive body.

2 Specify additional insertion points on the Defpoints layer through the AutoCAD point command, if necessary.

NOTE The points added to view blocks are cumulative. For example, if you add one point to a view block used for the top view and two points to the view block used for the model view, you have a total of four points to cycle through. The fourth point is the regular base point defined during the creation of the block.

3 Select the World Coordinate System before making blocks from these individual views.

For more information about coordinate systems, see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

4 Define each view as a block, and coordinate the location of the insertion base point as you define each block.

For example, if you specify the insertion base point of the model view block as the midpoint of the bottom edge on the back side, the front and back view blocks have an insertion base point at the midpoint of the bottom edge. Then, the left and right view blocks have an insertion base point at the bottom corner on the back side, with the insertion base point for the top and bottom view blocks at the midpoint of the back edge.

For more information about blocks, see “Create and Use Blocks (Symbols)” in AutoCAD Help.

Creating individual blocks for multi-view block definition

TIP It is helpful to have a naming convention for saving views as blocks. For example, name the plan view block *desk-p*, and name the right view block *desk-r*.

Creating a New Multi-View Block Definition

Use this procedure to create a multi-view block definition from the view blocks you created to represent different views of a custom object.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects.
- 3 Right-click Multi-View Block Definitions, and click New.
- 4 Enter a name for the new multi-view block definition, and press *ENTER*.
- 5 Edit the new multi-view block definition:

If you want to...	Then...
connect view blocks to the view directions of the different display representations	see Connecting View Blocks to View Directions on page 1899.
add notes and files to the multi-view block definition	see Attaching Notes and Files to a Multi-View Block Definition on page 1900.
add classifications to a multi-view block definition	see Adding Classifications to a Multi-View Block Definition on page 1900.
specify a cut body for the multi-view block when the block is used as interference in other objects (for example, walls, curtain walls, spaces, slabs)	click Set Interference Block, select a block, and click OK.

- 6 Click OK.

Connecting View Blocks to View Directions

Use this procedure to connect view blocks to the view directions of individual display representations.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand Multi-View Block Definitions.
- 3 Select the multi-view block definition to which you want to connect view blocks.
- 4 Click the View Blocks tab.
- 5 Select the display representation to which to connect view blocks.

Six display representations are available for multi-view blocks:

Display Representation	Purpose
General	Plan views, Section views, and Sketch views
Model	Model views
Plan	Plan views
Plan High Detail	Plan High Detail views
Plan Low Detail	Plan Low Detail views
Reflected	Reflected views

- 6 Click Add, and select a view block for the display representation.
- 7 Click OK.
- 8 Select the view directions that correspond to the selected block.
For example, to connect the view block to the left side of the multi-view block definition, select Left and clear all other directions.
You can connect a view block to multiple view directions. For example, if you have a symmetrical element that looks identical from left and right, you can select Left and Right.
The Other view direction represents a view that displays the block three-dimensionally. It is used for non-orthogonal (isometric or perspective) views of the custom object.
To ensure that the multi-view block is visible in all views, assign a block to every view direction.
- 9 To specify view blocks in other display representations, continue from step 5.
- 10 Click OK.

Defining a Multi-View Block Definition as Bounding for Associative Spaces

Use this procedure to define a multi-view block definition that can bound associative spaces.

When a multi-view block definition is set as bounding, by default all multi-view blocks that have the definition assigned will be used in the selection set for an associative space. For more information about associative spaces see [Generating Associative Spaces](#) on page 1931.

You can override the bounding settings from the multi-view block definition in an individual multi-view block, if necessary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand Multi-View Block Definitions.
- 3 Select a structural member style.
- 4 Click the General tab.
- 5 Select the check mark for Objects of this style may act as a boundary for associative spaces.
- 6 Click OK.

Attaching Notes and Files to a Multi-View Block Definition

Use this procedure to enter notes and attach reference files to a multi-view block definition. You can also edit notes and edit or detach reference files from a multi-view block.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand Multi-View Block Definitions.
- 3 Select the multi-view block definition to which you want to attach notes or files.
- 4 Click the General tab.
- 5 To add a description to the multi-view block, enter the description under Description.
- 6 Click Notes.
- 7 On the Notes tab, add or edit a note, as applicable.
- 8 On the Reference Docs tab, attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Click OK when you are done editing.
detach a reference file	select the file name, click Delete, and click OK.

- 9 Click OK twice.

Adding Classifications to a Multi-View Block Definition

Use this procedure to specify classifications for any classification definition applied to a multi-view block definition. For more information, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a multi-view block definition tool.
- 2 Right-click a multi-view block definition tool, and click Multi-View Block Definitions.
- 3 Select the definition that you want to change.
- 4 Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to multi-view block definitions.
- 5 For each classification definition, select the classification you want to apply to the current multi-view block definition.

6 Click OK.

Adding a Multi-View Block Definition to DesignCenter

Use this procedure to add a multi-view block to DesignCenter™. You can then create new multi-view blocks by dragging and dropping them from DesignCenter to your drawing. To add a multi-view block definition to DesignCenter, you need to create a DWG file using the AEC Content Wizard.

For a detailed description of the AEC Content Wizard, see [Overview of AEC Content](#) on page 2599.

1 Click Format menu ► AEC Content Wizard.

2 Select Multi-View Block.

3 Under Current Drawing, select a multi-view block definition, and click Add to add it to the Content File list.

4 Click Next.

5 Select the layer key to use when the multi-view block is inserted, and specify any additional properties:

If you want to...	Then...
explode the multi-view block when it is inserted in a drawing	select Explode on Insert.
specify an elevation for the multi-view block	enter a value for Preset Elevation.
associate an anchor with the multi-view block	select an anchor type.
specify the scale for the multi-view block	under Scale, enter X, Y, and Z scale values, and select an option for Additional Scaling.
scale the multi-view block based on the drawing units specified in the Drawing Setup dialog box	select Enable AEC Unit Scaling.
specify properties for attributes associated with the multi-view block	select options for Attribute Text Style and Attribute Text Angle.

6 Click Next.

7 Specify the drawing file in which to store the multi-view block definition:

If you want to store the multi-view block...	Then...
in the current drawing	select Current Drawing.
in a different drawing	clear Current Drawing, and then either enter a file name or click Browse to specify a file.

8 Select the icon to represent the multi-view block in DesignCenter:

If you want to...	Then...
use a bitmap of the drawing as the icon	click Default Icon.

If you want to...	Then...
specify a bitmap (.bmp) file containing the image to be used as the icon	click New Icon, and select a bitmap file.

- 9 Enter a description of the multi-view block.
The description is displayed in DesignCenter, along with the icon representing the multi-view block.
- 10 Select Save Preview Graphics to enable previewing in DesignCenter, or clear Save Preview Graphics to disable previewing.
- 11 Click Finish.

Creating a Multi-View Block Tool

Use this procedure to create a multi-view block tool and add it to a tool palette. You may want to create your own multi-view block tool for customized multi-view blocks you plan to use repeatedly. For example, you might create an office floor plan in which each conference room and office contains a floor lamp. Conference rooms and executive offices get the deluxe model floor lamp, and all other rooms get the standard model. You could define a multi-view block to represent each type of floor lamp, and then create a floor lamp tool for each type. You would then select the appropriate tool to place a floor lamp in each room.

You can use any of the following methods to create a multi-view block tool:

- Drag a multi-view block that has the properties you want to a tool palette.
- Drag a multi-view block definition from the Style Manager to a tool palette, and then customize the properties of the new tool.
- Copy an existing multi-view block tool, and then customize the properties of the new tool.
- Drag a multi-view block tool from a tool catalog in the Content Browser, and then customize the properties of the tool.

1 Open the tool palette on which you want to add a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a multi-view block in the drawing	select the multi-view block and drag it to the tool palette.
create a tool from a multi-view block definition in the Style Manager	on the Format menu, click Style Manager. Locate the definition you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a multi-view block tool from a tool catalog	in the Content Browser, locate the multi-view block tool you want to copy, then click the  icon associated with the tool and drag it to the tool palette in the workspace.
copy a tool on the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.

If you want to...	Then...
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

3 Right-click the new tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

This description is used as the tool's tooltip on the tool palette, and to describe the tool if it is stored in a tool catalog.

6 Expand Basic, and expand General.

7 Enter a description of the tool.

8 If you do not want to use the default layer key for multi-view blocks, select a Layer Key.

9 If you want to override the default layer name for multi-view blocks, select a Layer Override.

10 Select a multi-view block definition.

11 For Style location, select the drawing file containing the definition used for this multi-view block, or select Browse and use a standard file selection dialog box to select the file.

12 Under Bound Spaces, define if this multi-view block tool can be used as a bounding object for associative spaces.

You can select three options here:

- Yes: this multi-view block tool can be used as bounding object for associative spaces.
- No: this multi-view block tool cannot be used as bounding object for associative spaces.
- By style: this multi-view block tool will use the bounding settings from the multi-view block definition.

NOTE For more information on associative spaces, see [Generating Associative Spaces](#) on page 1931.

13 Expand Scale.

14 Specify the scale of the multi-view block:

If you want to...	Then...
specify fixed values for the scale	select No for Specify scale on screen, and enter X, Y, and Z values for the scale.
allow users to specify the scale of the object upon insertion	select Yes for Specify scale on screen.

15 Expand Location.

16 Specify the rotation of the multi-view block:

If you want to...	Then...
specify a fixed value for the rotation	select No for Specify rotation on screen, and enter a value for Rotation.

If you want to...	Then...
allow users to specify the rotation of the object upon insertion	select Yes for Specify rotation on screen.

- 17 Expand Advanced.
- 18 Click Insertion offset, and enter X, Y, and Z offsets for each view block in the multi-view block, as necessary.
- 19 Click OK.
- 20 Click Attributes, and edit the prompt and value of each attribute, as necessary.
- 21 Click OK twice.

Adding Multi-View Blocks to a Drawing

Multi-view blocks are inserted in a drawing by referencing their definitions in one or more of the following locations:

- DesignCenter™
- Tool palettes
- Tool catalogs

Predefined multi-view blocks supplied with AutoCAD Architecture are available with DesignCenter. These blocks represent items such as furniture, electrical appliances, pipes, ducts, annotation symbols, and schedule tags.

A generic multi-view block reference tool is supplied in the AutoCAD Architecture Stock Tool catalog. This tool is in the Helper Tools category.

How you access a custom multi-view block definition—for example, blocks that you or someone else in your organization defined—depends on what you do with the block after you define it. You can use the multi-view block definition to create AEC content in DesignCenter, or to create a multi-view block tool that can be stored in a tool palette or tool catalog.

When you insert a multi-view block reference in a drawing, you are prompted to specify the insertion point for the block. Depending on how the multi-view block was defined, you may be prompted to specify rotation angle and scale values.

Inserting a Multi-View Block

Use this procedure to add a multi-view block to a drawing.

- 1 Find the multi-view block definition and begin the insertion process:

If the multi-view block is...	Then...
stored as AEC content	use DesignCenter to locate the AEC content, and double-click the content.
inserted using a tool on a tool palette	open the tool palette containing the multi-view block tool, and click the tool.

If the multi-view block is...	Then...
inserted using a tool stored in a tool catalog	use the Content Browser to locate the tool, click the  icon for the tool, and drag it to the drawing area.

2 Specify the insertion point for the block.

If you added insertion points to the view blocks, you can cycle through the points with the *CTRL* key.

3 Specify the scale, if prompted:

If you want to...	Then...
specify a scale value	enter a value at the Command prompt.
dynamically set the scale	use the pointing device, and click when you see the appropriate scale.
set the scale to match that of another multi-view block in the drawing	enter m (match) at the Command prompt, and select a multi-view block to match the scale.

4 Specify the rotation angle, if prompted:

If you want to...	Then...
specify a rotation value	enter a value at the Command prompt.
dynamically set the rotation	use the pointing device, and click when you see the appropriate rotation.
set the rotation to match that of another multi-view block in the drawing	enter m (match) at the Command prompt, and select a multi-view block to match the rotation.

5 To insert additional references to the multi-view block, continue from step 2.

6 Press *ENTER* to finish inserting blocks.

Modifying Multi-View Blocks

You can change the attributes of a multi-view block in a drawing. For example, you can change the rotation or the scaling factor.

Changing the Rotation of a Multi-View Block

Use this procedure to change the rotation of a multi-view block.

- 1 Double-click the multi-view block whose rotation you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Enter a value for Rotation.

Changing the Associated Multi-View Block Definition

Use this procedure to change the multi-view block definition associated to the multi-view block. For information about the relationship between multi-view blocks and multi-view block definitions, see [Creating Multi-View Block Definitions](#) on page 1896.

- 1 Double-click the multi-view block you want to change.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Click Definition, and select a new multi-view block definition for the multi-view block.

Changing the Scale Factor of a Multi-View Block

Use this procedure to change the scale factor of a multi-view block.

- 1 Double-click the multi-view block you want to change.
- 2 On the Properties palette, expand Basic, and expand Scale.
- 3 Change the scale factor as needed:

If you want to...	Then...
change the X scale factor	enter a new value for X.
change the Y scale factor	enter a new value for Y.
change the Z scale factor	enter a new value for Z.

Changing the Offset of a Multi-View Block Using Grips

Use this procedure to change the offset of a multi-view block using the Location grip.

When you first add a multi-view block to a drawing, the offset value is set to 0. You can change the position of the multi-view block by offsetting it from its original insertion point. You can also change the offset of a multi-view block using the Properties palette.

- 1 Select the multi-view block you want to change.
- 2 Select the Location grip, right-click, and click Edit View Block Offsets.
- 3 Select the view block to change.

In Model view, the Location grip has three possible edit modes: Edit Along *XY* Plane, Edit Along *XZ* Plane, and Edit Along *ZX* Plane. Press *CTRL* to cycle among modes until you are in the desired mode. The default edit mode is along the *XY* plane. In Plan view, the Location grip is restricted to movement in one plane.

- 4 Offset the multi-view block to the desired location and click once, or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the multi-view block along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the multi-view block is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the multi-view block is constrained to the *Y* dimension direction.

- 5 Right-click, and click Exit Edit View Block Offsets.

The selected view block is offset from the original insertion point.

Changing the Location of a Multi-View Block Using Grips

Use this procedure to relocate an existing multi-view block using the Location grip. In Model view, the Location grip has three possible edit modes: Edit Along Object's *XY* Plane, Edit Along Object's *YZ* Plane, and Edit Along Object's *XZ* Plane. Press *CTRL* to cycle among modes until you are in the desired mode. The default edit mode is along the *XY* plane. In Plan view, the Location grip is restricted to movement in one plane.

You can also change the location of a multi-view block using the Properties palette.

- 1 Select the multi-view block you want to relocate.
- 2 Select the Location grip.

3 Move the multi-view block to the desired location and click once, or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the *Y* direction when editing along the *XY* plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the multi-view block along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the multi-view block is constrained to the second dimension direction. When editing along the *XY* plane, for example, you can enter a value for *X* dimension, and then press *TAB*. The *X* dimension is locked at that value, and movement of the multi-view block is constrained to the *Y* dimension direction.

4 Right-click, and click Deselect All to turn off grips.

Attaching Hyperlinks, Notes, or Files to a Multi-View Block

Use this procedure to attach hyperlinks, enter notes, or attach reference files to a multi-view block in a drawing. You can also edit notes and edit or detach reference files from a multi-view block.

1 Double-click the multi-view block to which you want to attach information.

2 On the Properties palette, click the Extended Data tab.

3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

For more information about adding hyperlinks, see “Add Hyperlinks to a Drawing” in AutoCAD Help.

4 To add or edit a note, click  next to Notes, enter text, and click OK.

5 To attach, detach, or edit a reference file, Click  next to Reference documents:

If you want to...

Then...

attach a reference file

click , select a file, and click Open.

edit the description of a reference file

enter text under Description.

edit a reference file

double-click the reference file name to start its application.

If you want to...

Then...

detach a reference file

select the file name, and click

Editing the Location and Rotation of Attributes in a Multi-View Block

Use this procedure to change the location and rotation of attributes within a multi-view block.

NOTE The location and rotation of an attribute in a multi-view block can only be modified if the attributes have not been inserted with the Lock position in block option selected during attribute creation. For more information, see “Attribute Definition Dialog Box” in AutoCAD Help.

Rotating a tag attribute in Plan view

1 Select the multi-view block whose attributes you want to edit.

2 Right-click, and click Edit Attribute Orientations.

Each attribute has a grip for location and for rotation.

In Model view, the Location grip has three possible edit modes: Edit Along Object’s XY Plane, Edit Along Object’s YZ Plane, and Edit Along Object’s XZ Plane. Press *CTRL* to cycle among modes until you are in the desired mode. The default edit mode is along the XY plane. In Plan view, the Location grip is restricted to movement in one plane.

If there is more than one attribute with the same offset value, the attribute location grips reposition themselves according to their priority over other offset grips.

3 To change the location of an attribute relative to the multi-view block, select the Location grip, move the block attribute to the desired location and click once, or enter a value and press *ENTER*.

If you want to enter a specific value for the second direction in any edit mode (for example, in the Y direction when editing along the XY plane), press *TAB* to cycle to the second direction.

You can also lock the movement of the block attribute along a specific direction. If you enter a value for either dimension direction in the current edit mode, and then press *TAB*, the movement of the block attribute is constrained to the second dimension direction. When editing along the XY plane, for example, you can enter a value for X dimension, and then press *TAB*. The X dimension is locked at that value, and movement of the block attribute is constrained to the Y dimension direction.

4 To change the rotation of an attribute relative to the multi-view block, select the Rotation grip, rotate the block attribute to the desired angle and click once, or enter a value and press *ENTER*.

5 To exit the attribute editing mode, right-click, and click Exit Edit Attribute Orientations.

Alternatively, you can deselect the multi-view block.

Updating Multi-View Block Attributes

Use this procedure to update the attributes of blocks in your drawing, using the current attributes defined for the view blocks upon which each multi-view block is based. You need to do this if you change attribute definitions in one or more of the block definitions on which the multi-view block is based.

- 1 On the Format Menu, click Multi-View Block, and click Multi-View Block Update.
- 2 Select the multi-view blocks to be updated.
- 3 Press *ENTER*.
- 4 Enter **y** (Yes) to include text style properties (for example, width factor, oblique, mirroring) when updating attributes, or **n** (No) to update all attributes properties except those relating to text style.
- 5 Press *ENTER* to end the update process.

Documentation

Spaces are 2-dimensional or 3-dimensional style-based architectural objects that contain spatial information about a building, including floor area, wall area, volume, surface information, and more. Spaces can be used for organizing reports such as statements of probable construction cost, energy requirements and analysis, leasing documents, operating costs and fixtures, and lists of furniture and equipment.

New Features in Spaces for AutoCAD Architecture 2009

There are a number of enhancements to the Spaces feature in AutoCAD Architecture 2009:

Improved Workflow for Associative Spaces

In AutoCAD Architecture 2009, the selection of objects that can serve as boundaries for associative spaces has been simplified and enhanced.

- The Bound Spaces property can be set on all boundary objects in the Properties palette.
- Objects on frozen and hidden layers participate in the generation of spaces.
- A visual filter allows you to quickly display all boundary objects in the drawing area, making space generation more transparent.
- The following boundary objects have been enhanced: Ellipse, Spline, 3D polylines.
- Blocks and MV-blocks now have their own Bound Spaces property.

For more information, see [Generating Associative Spaces](#) on page 1931.

Surface Openings on Curved Surfaces

In previous versions, openings on curved surfaces were segmented according to the selected facet resolution. Now, you can create unsegmented openings on curved space surfaces. For more information, see [Adding Openings to 3D Freeform Space Surfaces](#) on page 2023.

Performance Improvements for Associative Spaces

The performance for generating and updating associative spaces has been improved.

NOTE When you are converting drawings with xrefs and associative spaces from a previous version, the first time the host drawing is opened will be accompanied by a noticeable performance hit. This is however only a one-time effect; once the host drawing and its associated xref drawings have been and opened and saved with the current version, the performance will be improved for all future sessions.

Automatic Update of Associative Spaces through External References

Associative spaces that are bounded by objects in external references are now included in the automatic update of associative spaces. No manual updates are necessary anymore. For more information about working with xrefs and blocks, see [Generating Associative Spaces from Xrefs and Blocks](#) on page 1941.

Space Types

The following types of spaces can be modeled in AutoCAD Architecture:

Associative and Non-Associative Spaces

Associative spaces are generated from boundary objects. When the boundary objects change, the space updates accordingly.

In addition to associative spaces you can also create non-associative spaces with user-defined geometry. A non-associative space can stand alone in the drawing, but you can use it to generate calculations just like you would use an associative space.

Non-associative spaces can be connected to boundary objects after their creation; similarly, associative spaces can be disconnected from their boundary objects.

2D Spaces

2D spaces display spatial information in 2 plan dimensions.

2D spaces in Plan view

The Z direction is by default set to 0 and ignored during creating, editing, and scheduling the space. 2D spaces can be rectangular or polygonal. 2D spaces can either be non-associative or associative. A 2D space can be bounded by 3D objects and linework. 2D spaces are typically used for Plan views, where 3D information is not needed.

Extruded 3D Spaces

An extruded 3D space is similar to a 2D space, but has a user-defined extrusion height. Extruded spaces are useful for regularly shaped 3D spaces like uniform-height rooms in a building. Extruded spaces can have floor and ceiling components and space above the ceiling and below the floor. The space above the ceiling is often used to place ductwork, cables and electrical installations in a room.

Space height components

Space ceiling and floor components

Extruded 3D spaces can be associative to 3D objects and linework, but they are bounded only in the X and Y directions. The Z direction is defined by the extrusion height. If you need a space that is fully bounded by objects in all 3 spatial dimensions, you need to generate a 3D freeform space.

Additional space dimension components

3D Freeform Spaces

3D freeform spaces are generated from boundary objects, like walls and slabs, and are associative to them. Associative 3D freeform spaces must be bounded in all directions to form a valid boundary shape. A 3D freeform space is a complex 3D geometry with any number of surfaces needed to generate the space shape.

Some examples for 3D freeform spaces

Space Workflows

Spaces are a powerful tool to create any type of room-based object, schedule it and create calculations for it. The following sections outline some main features associated with spaces in AutoCAD Architecture.

Working with Associative Spaces - Overview

Associative spaces are generated from boundary objects in the drawing and are updated as the building geometry changes. Updates can be triggered automatically or manually.

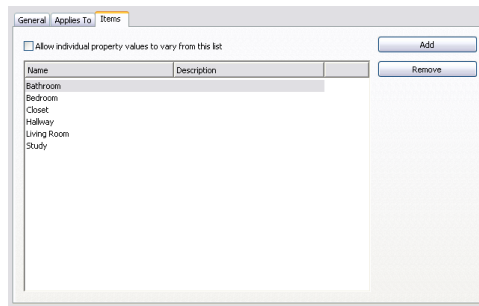

- 1 Define if spaces should update automatically when changes in the bounding objects occur, or manually by user interaction. For more information, see [Activating and Deactivating Automatic Updates](#) on page 1946.
- 2 Create the building geometry from which you want to generate associative spaces.
- 3 Start a Spaces tool, as described in [Generating an Associative Space](#) on page 1938.
- 4 Select the geometry from which the space is to be generated.
The generated space is associative to its boundary objects.

Working with List Definitions - Overview

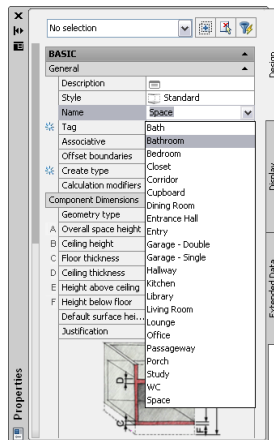

List definitions are name lists for spaces and zones. You can attach a list definition to a space style or to a zone style to ensure that all spaces or zones inserted with that style use names from the list. List definitions can be created for a number of purposes, for example to enforce consistent naming of spaces according to a building standard.

- 1 Create a list definition in Style Manager, as described in [List Definitions](#) on page 2051.

2 Attach the list definition to a space or zone style, as described in [Attaching a List Definition to a Space Style](#) on page 2042 and [Attaching a List Definition to a Zone Style](#) on page 2072.

3 Add a space or zone to the drawing, and select a name from the list.

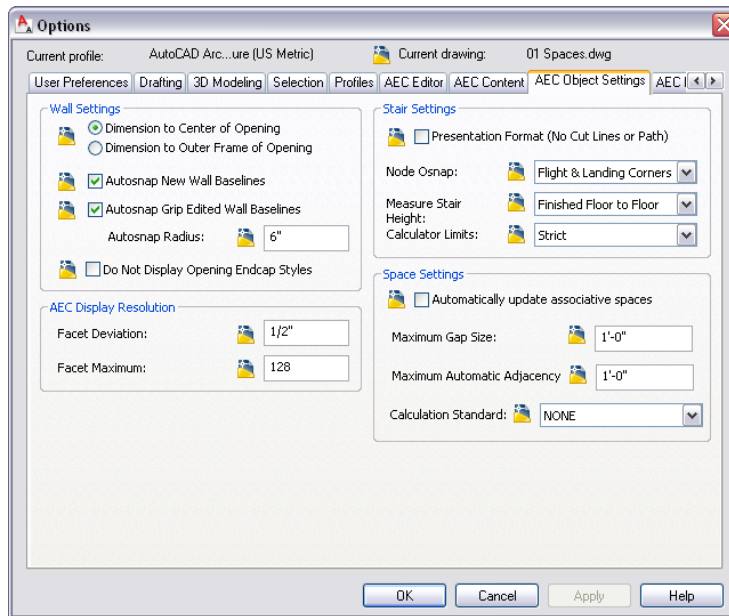

Working with Space Boundaries - Overview

Spaces can have 4 separate boundaries for the base area, net area, usable area, and gross area of the space. You can define the calculation of space boundaries with a predefined area calculation standard, with a space style, or manually. AutoCAD Architecture includes standards based on the rules of DIN 277 (Germany), BOMA (United States), and SIS (Sweden).

A typical workflow for using spaces is to create a floor plan and then generate spaces from walls and other building objects, with boundaries generated and calculated according to an area calculation standard.

1 Select the desired area calculation standard for the drawing.

For more information, see [Specifying an Area Calculation Standard for a Drawing](#) on page 1977.

2 Create the floor plan.

TIP You can reference walls and other building objects from external references. Spaces can be detected from objects in external references.

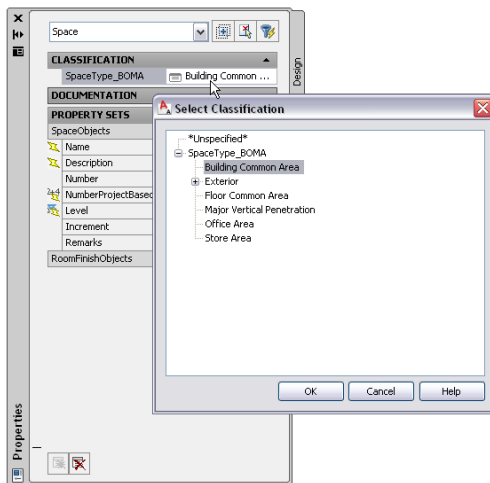

3 Generate associative spaces from the floor plan, and verify that the boundary calculation is set to By Standard <Standard Name>.

For detailed information, see [Generating an Associative Space](#) on page 1938.

4 Classify the generated spaces if required by the selected area calculation standard, as described in [Classifying a Space According to an Area Calculation Standard](#) on page 1978.

The space boundaries are offset from each other according to the rules of the selected standard.

Working with Zones - Overview

Zones are objects that can be used to group spaces. Zones can have spaces attached to them and can contain other zones in an hierarchical structure. For example, you can create a zone called Office Building with sub-zones for the individual offices in the building. Each workplace within an office can be represented by a space.

Zones in a building

- 1 Create a zone style in Style Manager, as described in [Creating a Zone Style](#) on page 2071.
- 2 If you have a zone structure that you want to use again because it represents a standard, create a zone template, as described in [Creating a Zone Template](#) on page 2080.

Zones based on DIN277 template

3 Add a zone or zone template to the drawing.

4 If necessary, attach calculation modifiers to the zone. A calculation modifier attached to a zone is used for all spaces and zones attached to the zone.

5 Attach spaces or other zones to the zone, as described in [Attaching Spaces and Zones to Zones](#) on page 2063.

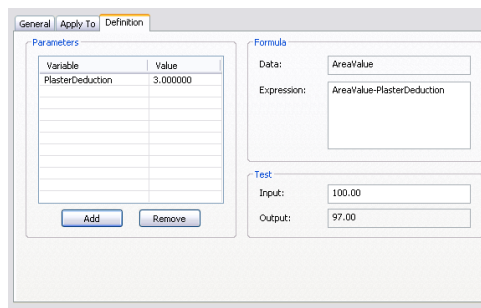

Zone with attached subzones and spaces

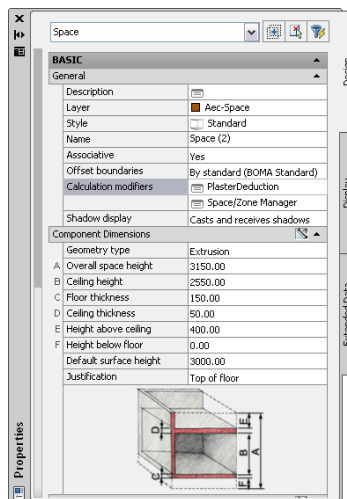

Working with Calculation Modifiers - Overview

A calculation modifier is a value or formula you can add to the area and perimeter values of each boundary of a space to modify values for certain calculations. For example, you can specify a 3% plaster deduction for all interior walls, or calculate a balcony at only 50% of its square meters for renting.

- 1 In Style Manager, create a new calculation modifier style, as described in [Creating a Calculation Modifier Style](#) on page 2089.
- 2 Define a formula with which to calculate the value of the base area or base perimeter of the space.

3 Add the calculation modifier to a space or to a zone, as described in [Adding and Removing Calculation Modifiers for Spaces](#) on page 2088 and [Changing Calculation Modifiers for a Zone](#) on page 2067.

4 To apply the modifier to the net, usable, and gross boundaries of a space, create and apply a property set definition that contains properties for the calculated area and perimeter values of the net, usable and gross boundaries. For more information, see [Property Set Definitions](#) on page 2542.

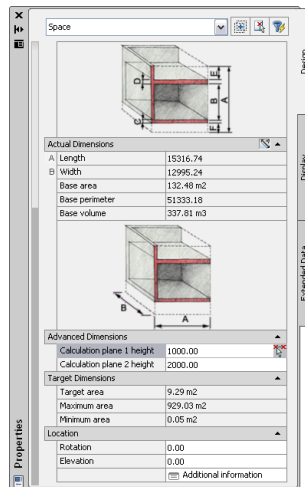

5 Use the modified values in a schedule table or in a space evaluation. For more information, see [Basic Schedules](#) on page 2491 and [Space Evaluation](#) on page 2097.

Working with Calculation Cut Planes - Overview

If you are working with 3D freeform spaces, you can calculate their area at 2 different cut plane heights. This is useful for attics, where different heights are calculated differently.

- 1 Create a 3D freeform space, as described in [Generating an Associative Space](#) on page 1938 or [Converting Mass Elements to Spaces](#) on page 1961.
- 2 Define the calculation cut planes of the space, as described in [Setting Calculation Cut Planes for 3D Freeform Spaces](#) on page 2092.

- 3 Define the display properties for the 2 calculation cut planes and the cut plane hatches, as described in [Specifying the Display Properties of a Space Style](#) on page 2045.
- 4 Generate and apply a property set definition with automatic properties for calculation cut planes. Then create a schedule table with the calculated cut plane values. For more information, see [Basic Schedules](#) on page 2491.

Working with Space Evaluations - Overview

After creating spaces and zones in your floor plan, you can generate a space evaluation report.

AutoCAD® Architecture
Space Evaluation

Illustration	Property	Value	Expression	Unit of Value
Space				
	Base Area	233.322		
	Calculate of Area	233.322		
	1 (0)	36.889	$S = 12374.091 * 6962.371$	
	2 (0)	81.782	$S = 18621 * 8549$	
	3 (0)	34.81	$S = 119168.389 * 1.864.653$	
	4 (0)	79.772	$S = 179.13 * 8110$	
	Base Perimeter	69228.00		
Space (2)				
	Base Area	72.26		
	Calculate of Area	72.26		
	1 (0)	36.13	$S = 12379.216 * 6962.211$	
	2 (0)	36.13	$S = 12379.216 * 6962.211$	
	Base Perimeter	34053.914		

- 1 Generate the spaces and zones you need for the space evaluation.
- 2 Attach calculation modifiers as necessary, as described in [Adding and Removing Calculation Modifiers for Spaces](#) on page 2088.
- 3 Select an evaluation template and the values and preview graphics you want to display in the evaluation file.

For more information, see [Preparing the Space Evaluation](#) on page 2098.

4 Generate the evaluation file either as an MS Excel document or a TXT text document. For more information, see [Creating the Space Evaluation Document](#) on page 2103.

Moving Forward to AutoCAD Architecture 2009 from Autodesk Architectural Desktop 2006 and Earlier

If you are transitioning from Autodesk Architectural Desktop 2006 or earlier to AutoCAD Architecture, you will see a number of changes in the space planning features. In AutoCAD Architecture, spaces, areas, and space boundaries have been unified into one space object which contains the properties formerly associated with these other objects, as well as new and enhanced features designed to provide a comprehensive solution for spatial design within the building model.

The table below maps objects from earlier releases to their newer counterparts.

Prior Releases	AutoCAD Architecture 2009
Spaces	Spaces
Space boundaries	Spaces
Areas	Spaces
Area groups	Zones
Area name definitions	List definitions
Area group templates	Zone templates
Area evaluation	Space evaluation

Spaces

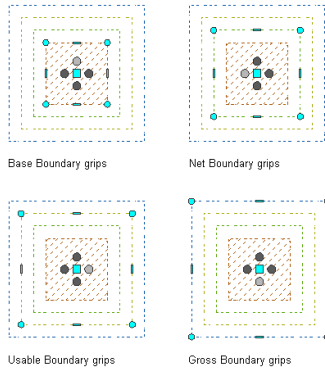

Spaces now contain the properties associated with spaces and areas prior to AutoCAD Architecture 2009, as well as engineering properties for working in AutoCAD MEP. Spaces can be associatively generated as 3D freeform objects, as extruded 3D spaces, or as 2D spaces. A space can have different boundaries for base area, net area, usable area, and gross area. Spaces can be grouped into zones and processed in space evaluations.

Space Boundaries

Space boundaries are now part of the space object, and not separate objects as they were prior to AutoCAD Architecture 2009. A space has a base boundary, net boundary, usable boundary, and a gross boundary. Space boundaries created in previous versions will be converted to walls when the drawing that contains them is opened in the current version of the software. Managed spaces will be converted to associative spaces. Space boundaries include a number of scheduling properties.

For information about converting space boundaries to walls and spaces, see [Conversion of Space Boundaries to Walls and Spaces](#) on page 2110.

Space boundaries

Areas

Areas have been integrated into spaces, which now include the properties formerly specific to areas. Among the area-specific features are the decomposition view, name definitions, calculation modifiers, and space evaluation. When you open a drawing that contains areas, the areas are automatically converted to spaces, with all area properties being converted to the corresponding space properties. For new properties, default values are used. Area tools are no longer needed and are omitted.

For information about converting areas to spaces, see [Auto-Converting Legacy Areas to Spaces](#) on page 1925.

Area Groups and Zones

Area groups have been converted to zones. When you open a drawing that contains area groups, the area groups are automatically converted to zones, with all area group properties being converted to the corresponding zone properties. For new properties, default values are used. Area group tools are no longer needed and are omitted.

Zones are a new object and serve as a grouping mechanism for spaces. Zones can be created to group spaces according to function, location, or any user-defined system. You can attach specific calculation modifiers and schedule properties to a zone. You can also build hierarchical zone structures that represent the structure of your building, a space categorization standard, or any user-defined grouping structure.

For information about converting area groups to zones, see [Converting Area Groups to Zones](#) on page 2061.

Area Name Definitions and List Definitions

Area name definitions have been converted to list definitions. A list definition is a list of names that can be assigned to a space or zone style to ensure consistent naming of spaces and zones across a project. For example, a list definition could contain entries for bedroom, living room, bathroom, and so on. When you open a drawing that contains area name definitions associated with an area or area group, the area name definition is automatically converted to a list definition. You can assign the list definition to the converted space or zone through its style.

Area Group Templates and Zone Templates

Area group templates have been converted to zone templates, which provide structure definitions for zone hierarchies. You define a zone template with a set of subzones and content restrictions, and use it to create the zone structure in the drawing. When you open a drawing that contains area group templates, the area group templates are automatically converted to zone templates.

Area Evaluation and Space Evaluation

The area evaluation feature has been converted to the space evaluation feature. Space evaluation is a documentation feature that calculates the area and perimeter information for your finished floor plan. This information is displayed in a separate file that you export from AutoCAD Architecture to a spreadsheet or text processing application. Evaluation templates ensure that the information is displayed in a consistent, structured way. Architects need the space evaluation feature for submitting floor plans to the building authorities and customers. Space evaluation can also be used for performing cost estimates, assigning jobs to contractors, or organizing the facility management of buildings.

Auto-Converting Legacy Areas to Spaces

If you have legacy drawings created in previous versions, and they contain area objects, these areas will automatically be converted to spaces when you open the drawing with the current software. The following table maps area properties to space properties.

Area property	Space property	Value/Default value
Name	Name	Existing value
Description	Description	Existing value
Layer	Layer	Existing layer (A-Area-G)
Style	Style	Area style is converted to space style. Properties are matched where possible; new properties have default values. For more information, see Converting Area Styles to Space Styles on page 2049.
Calculation modifiers	Calculation modifiers	Existing modifiers NOTE By default, converted calculation modifiers are applied only to the base area and base perimeter of the space.
N/A	Geometry	2D
Base Area	Base Area	Existing value
Calculated Area	Calculated Area	Existing value
Base Perimeter	Base Perimeter	Existing value
Calculated Perimeter	Calculated perimeter	Existing value
Rotation	Rotation	Existing value
Elevation	Elevation	Existing value

Area property	Space property	Value/Default value
Additional Information (Location)	Additional Information (Location)	Existing values
N/A	Length	Existing value
N/A	Width	Existing value

NOTE Subtracted areas and hatches will be ignored when converting a legacy area from Autodesk Architectural Desktop 2006 or earlier to a space in AutoCAD Architecture. If necessary, you can re-subtract any void portions, as described in [Creating Holes in Extruded 3D Spaces](#) on page 2000.

If the legacy area has no override for display properties at the style level, then one will be created on the migrated space to mimic the drawing default display properties of the legacy areas. This is intended to preserve visual fidelity for legacy areas that do not have display property overrides. Existing style or object display property overrides on legacy areas will carry forward to the migrated spaces.

Previous versions of the software allowed users to create areas that self-intersect. Spaces cannot self-intersect. During migration, a self-intersecting area is converted into a self-intersecting space, and a solution tip displays, advising you to grip-edit the base boundary to remove the self-intersection. For more information on grip-editing, see [Grip-Editing Space Boundaries](#) on page 1982.

Space Properties

The properties of space objects are illustrated and described below. Note that some properties are limited to specific space types. For example, a 2D space does not have any height properties.

Property	Space Type	Description
General Category		
Description	All	User-defined description of the space.
Layer	All	Specifies the layer on which the space is placed. By default the layer assignment is defined in the space style.
Style	All	Specifies the space style. The style defined in the space tool is the default.
Name	All	The name of the space. If a list definition has been specified in the space style, the defined list of names is available as a drop-down list. For more information, see Attaching a List Definition to a Space Style on page 2042.
Tag	All (only available during space add and in tool properties)	Specifies a space tag to be inserted when adding the space. Space tags are available in the sample drawings shipped with the software. You can also create your own space tags.

Property	Space Type	Description
Associative	All	<p>Indicates whether the space is associative. The geometry of an associative space is dependent on its boundary objects. You can disconnect the associativity of a space after adding it.</p> <hr/> <p>NOTE If you insert a non-associative space, the Associative field reads No and is read-only. To change the space associativity, see Making a Space Associative or Non-Associative on page 1952.</p>
Offset Boundaries	All	<p>Specifies the calculation type by which the 4 space boundaries (base boundary, net boundary, usable boundary, and gross boundary) are calculated.</p> <ul style="list-style-type: none"> ■ Manual: you use the grips on the individual boundaries to generate offsets between the individual boundaries. ■ By Style: you define the boundaries by defining offsets between them in the space style. ■ By Standard <Standard Name>: the space boundaries and their offsets from each other are determined by the area calculation standard listed. For more information, see Specify- ing an Area Calculation Standard for a Drawing on page 1977.
Calculation Modifiers	All	<p>Identifies any calculation modifiers for the space. A calculation modifier is a formula that modifies area and perimeter values of the boundaries of the space.</p> <hr/> <p>NOTE To apply the modifier to the net, usable, and gross boundaries of a space, you need to create and apply a property set definition that contains properties for the calculated area and perimeter values for those 3 boundaries. For more information, see Schedule Properties of Spaces on page 2084.</p>
Space/Zone Manager	All	<p>Accesses the Space/Zone Manager worksheet, in which you enter information used to process spaces in engineering applications. For more information, see Editing Space Surface Properties on page 2014.</p>
Create Type	Non-Associative Spaces (only available during adding a space and in tool properties)	<p>Specifies the type of space to be created:</p> <ul style="list-style-type: none"> ■ Insert: inserts a space according to the target dimension settings in the space style. For information on setting target dimensions of a space in the space style, see Specifying Target Dimensions for the Space on page 2040. ■ Rectangle: lets you create a rectangular space with user-defined dimensions. ■ Polygon: lets you create a space composed of user-defined line and arc segments. ■ Generate: lets you generate a space from boundary objects. The space is associative to the boundary objects.
Segment type	Non-associative polygonal spaces	<p>Specifies whether the individual segments of a polygonal space are lines or arcs.</p>

Property	Space Type	Description
	(only available during adding a space and in tool properties)	
Generate Space Category	Associative spaces (only available during adding a space and in tool properties)	
Allow overlapping spaces		Specifies whether you can generate spaces from boundary objects that already contain a space. By default, this setting is set to No.
Component Dimensions Category		
Geometry Type	All	Specifies the geometry type of the space to be created: <ul style="list-style-type: none"> ■ 2D: creates a 2D space. ■ Extrusion: creates a 3D space with a height extruded from the 2D geometry. Extruded 3D spaces have floor and ceiling components and can have room above the ceiling and below the floor. ■ Freeform: creates a 3D freeform space. A 3D freeform space can be generated from boundary objects or be converted from a mass element shape.
Overall Space Height	3D spaces	Specifies the overall height of the space, including floor to ceiling height, floor thickness, ceiling thickness, space above ceiling, and space below floor. <p>NOTE This value is read-only for 3D freeform spaces.</p>
Ceiling height	3D spaces	Specifies the ceiling height of the space. <p>NOTE This height is calculated from the top of the floor to the bottom of the ceiling. You can define additional floor and ceiling thickness.</p>
Floor thickness	3D spaces	Specifies the thickness of the floor. If the floor thickness is set to 0, no floor is displayed.
Ceiling thickness	3D spaces	Specifies the thickness of the ceiling. If the ceiling thickness is set to 0, no ceiling is displayed.
Height above ceiling	3D spaces	Specifies the distance between the top of the space ceiling to the top of the space.

Property	Space Type	Description
Height below floor	3D spaces	Specifies the distance between the bottom of the space floor and the bottom of the space.
Default surface height	3D spaces	Specifies the combined height of ceiling height, ceiling thickness, and height above ceiling.
Justification	Extruded 3D spaces	<p>Specifies the relative vertical position of the space insertion point on the space as one of the following:</p> <ul style="list-style-type: none"> ■ Top of floor ■ Bottom of floor ■ Bottom of space below floor (available only if the height of the space below the floor is greater than 0.) <p>3D freeform spaces are always justified to the top of floor.</p>
Actual Dimensions Category		
Length	All	Specifies the length of the space.
Width	All	Specifies the width of the space.
Base area	All	Displays the base area of the space. When inserting a space based on target dimensions, you can enter a base area value if you have not chosen to constrain the area.
Base Perimeter	All	Displays the base perimeter of the space.
Base Volume	3D spaces	Displays the base volume of the space.
Advanced Dimensions		
Calculation Plane 1 + 2 Height	3D freeform spaces	Specifies the height for calculating the areas of a 3D freeform space on 2 different calculation planes. This would be useful to calculate the rentable area of a room directly under the roof at 2 different room heights.
Target Dimensions		
Target area	Non-associative spaces based on target dimensions	Displays the target area defined in the space style.
Maximum area	Non-associative spaces based on target dimensions	Displays the maximum area defined in the space style.

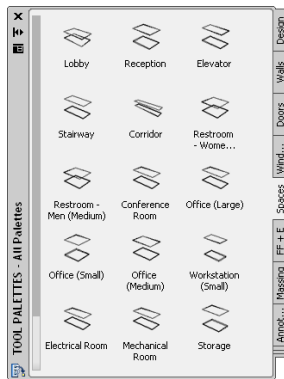

Property	Space Type	Description
Minimum area	Non-associative spaces based on target dimensions	Displays the minimum area defined in the space style.
Location		
Rotation	Non-associative spaces	Specifies the rotation of the space.
Elevation	Non-associative spaces	Specifies the elevation of the space.
Additional Information	Non-associative spaces	Specifies the location and coordinate system of the space.

In addition to these object properties there are a number of schedule properties that can be attached and calculated for a space. For a full list, see [Schedule Properties of Spaces](#) on page 2084.

Using Space Tools to Create Spaces

Tools provided with AutoCAD Architecture let you quickly place spaces by selecting a space tool with a specific space style and other predefined properties. You can use the tool with its default settings, or you can change any properties that are not controlled by the style. You can also use space tools to create new spaces by applying tool properties to existing objects.

Tool palette containing space tools

The default tool palettes in the workspace contain space tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain space tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog
- Design Tool catalog

For more information on accessing tools in these catalogs, see [Content Browser](#) on page 121.

Custom palettes created by your CAD manager or other users may also contain space tools with space styles and properties that are customized for your projects or office standards.

Generating Associative Spaces

Associative spaces are bounded by objects that define the space area. If the boundary objects change, the space inside them is updated, too. You will typically work with associative spaces when entering the documentation phase of the project.

Geometry Types of Associative Spaces

Associative spaces can be 2D spaces, extruded 3D spaces, or 3D freeform spaces. An associative 2D or extruded 3D space is associative only to the objects in the X and Y direction of the floor plan. The height is either 0 or a user-defined extrusion height. A 3D freeform space is associative to the objects bounding it in all 3 spatial dimensions.

Spaces can be associative to many 3D and linework objects. For a listing of valid boundary objects, see [Valid Boundary Objects for Associative Spaces](#) on page 1931.

External References

A space can be associative to boundary objects in external references. If the boundary objects in the external reference change, the space in the host drawing changes, too. However, spaces that have been generated in an external reference do not interact with boundary objects in the host drawing.

Boundary Objects for Associative Spaces

Associative spaces are bounded by objects. An object must fulfill a number of conditions to bound a space:

- The object must be a valid boundary object for associative spaces. For a complete list, see [Valid Boundary Objects for Associative Spaces](#) on page 1931.
- The Bound Spaces property of the object must be set to Yes. For more information, see [Setting the Bound Spaces Property for Boundary Objects](#) on page 1934.

Valid Boundary Objects for Associative Spaces

The following table lists all objects that are valid as boundary objects for associative spaces. There are different valid boundary objects for 2D/extruded 3D spaces and 3D freeform spaces. 3D freeform spaces must be bounded by objects that have a 3D geometry; 2D and extruded 3D spaces can be bounded by 2D linework, too.

All valid boundary objects must have their Bound Spaces property set to Yes in order for associative spaces to be generated from them. The Bound Spaces property for an object is located on the Properties palette. For objects that use styles, the Bound Spaces property can also be set in the style. The default value of the setting varies depending on the object type. Objects like walls and curtain walls have a default Bound Spaces value of Yes. Others, like structural members or linework have a default Bound Spaces value of No. Change the Bound Spaces properties of objects as needed to generate your spaces (as described in [Setting the Bound Spaces Property for Boundary Objects](#) on page 1934).

IMPORTANT Objects that are set as boundary objects for associative spaces and then are placed on a frozen or hidden layer still participate in the generation of associative spaces. It is possible to generate spaces from invisible boundary objects. If this is the case, review your layer settings, and unhide or unfreeze those layers as necessary.

The following table lists all valid boundary objects for both 2D/Extruded 3D spaces and 3D freeform spaces, as well as the default value of their Bound Spaces property when inserted in a drawing:

Object	Boundary object for 3D freeform spaces	Boundary object for 2D/Extruded 3D spaces	Default Bound Spaces value
Wall	<p>Yes</p> <p>The 3D freeform space is generated at the near face of the wall body (at base curve)</p> <hr/> <p>NOTE If a modifier creates a hole or gap through the wall, then the gap might be ignored in the space generation if the maximum gap size value (see Defining a Maximum Gap Size for Associative Spaces on page 1944) is greater than the width of the hole.</p> <hr/> <p>Plan modifiers, body modifiers, interferences, sweeps, end caps, and opening end caps are included in the geometry of the generated space.</p>	Yes	Yes (by Style)
Curtain wall/Curtain wall unit	<p>Yes</p> <p>The 3D freeform space is generated at the curtain wall body. Interferences, roof line, floor line, and frame profiles are included in the geometry of the generated space.</p> <hr/> <p>NOTE Empty cells or holes created by a curtain wall modifier do not impact the space generation. They are ignored and the space is generated as if the curtain wall was closed.</p>	Yes	Yes (by Style)
Door and window assembly	<p>Yes</p> <p>The 3D freeform space is generated at the near face of the frame (at base curve). Interferences and frame profiles are included in the geometry of the generated space boundary.</p> <hr/> <p>NOTE Empty cells or holes created by a door and window assembly modifier do not impact the space generation. They are ignored and the space is generated as if the assembly was closed.</p>	Yes	Yes (by Style)
Door/Window/Opening	<p>Yes</p> <hr/> <p>NOTE If a door, window, or opening is anchored in a wall, the Bound Spaces setting of the wall is used for the opening, too.</p> <hr/> <p>The opening shape also defines openings in generated freeform space surfaces.</p>	Yes	Door/Window: Yes (by Style) Opening: Yes
Mass element	<p>Yes</p> <p>The 3D freeform space is generated on the near face of the mass element body.</p>	<p>Yes</p> <p>The 2D/Extruded 3D space is generated at the near face of the mass element</p>	No (by Style)

Object	Boundary object for 3D freeform spaces	Boundary object for 2D/Extruded 3D spaces	Default Bound Spaces value
		body at the mass element bottom.	
Roof	Yes The 3D freeform space is generated at the near face of the roof body.	No	Yes
Roof slab	Yes The 3D freeform space is generated at the near face of the roof slab body (at cut plane). Body modifiers, fascia, and soffit bodies are included in the geometry of the generated space boundary. <hr/> NOTE Interferences and holes in the roof slab will be ignored when the space is generated.	No	Yes (by Style)
Slab	Yes The 3D freeform space is generated at the near face of the slab body (at cut plane). Body modifiers, fascia, and soffit bodies are included in the geometry of the generated space boundary. <hr/> NOTE Interferences and holes in the slab will be ignored when the space is generated.	No	Yes (by Style)
Structural member	Yes The freeform space is generated at the near face of the member body (at base curve). Holes or gaps in the structural member are ignored when the placement of the space boundary is determined.	Yes	No (by Style)
Multi-view block	Yes In order to bound 3D freeform spaces, a multi-view block must contain objects that have a 3D geometry and are valid boundary objects for spaces. The geometry stored in the model view block is used to generate the space. The space is generated from the model geometry (at bottom).	Yes	No (by Style)
Custom display blocks	Yes	No	Yes (by Style)
Block	Yes In order to bound 3D freeform spaces, a block must contain objects that have a 3D geometry and are valid boundary objects for spaces.	Yes	Dependent on the objects contained in the block
External Reference	Yes In order to bound 3D freeform spaces, an external reference must contain objects that have a 3D geometry and are valid boundary objects for spaces.	Yes	Yes

Object	Boundary object for 3D freeform spaces	Boundary object for 2D/Extruded 3D spaces	Default Bound Spaces value
Line	No	Yes	No
Circle	No	Yes	No
Polyline	No	Yes	No
3D Polyline	No	Yes	No
Ellipse	No	Yes	No
Spline	No	Yes	No
Arc	No	Yes	No

TIP AutoCAD 3D solids are not valid boundary objects for spaces. In order to use a 3D solid to generate a space, use one of the following methods:

- Convert the 3D solid to a mass element, as described in [Creating a Mass Element from a 3D Solid](#) on page 695, and use the mass element to generate the space.
- Wrap a polyline around the solid and use the polyline to generate the space.

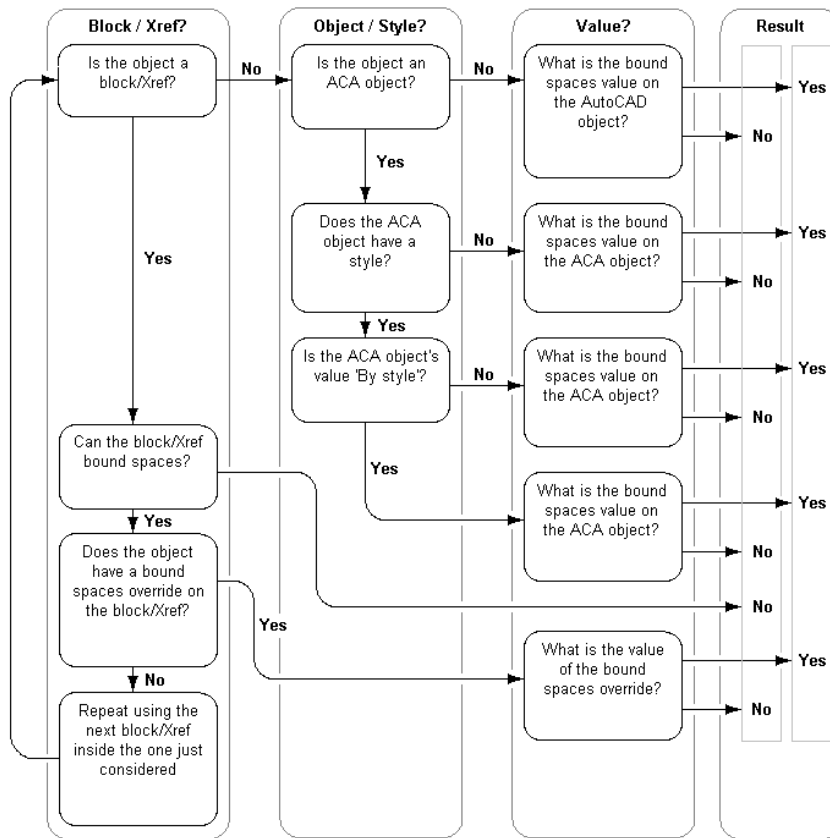

Setting the Bound Spaces Property for Boundary Objects

The objects designed to form the boundary of an associative space must have their Bound Spaces property set to Yes before generating the space. You can set the Bound Spaces property on the object, or, for objects that use styles, you can set it in the object style.

TIP Before setting the Bound Spaces property of a boundary object to Yes, verify that this type of object is a valid boundary object for the space you want to generate. For example, a roof or roof slab is a valid boundary object only for 3D freeform spaces; you cannot use it to generate an extruded 3D space or a 2D space, even if the slab's Bound Spaces property is set to Yes.

The following overview graphic shows how the setting of the Bound Spaces property on the boundary object affects the generation of associative spaces. For detailed information on how to set the Bound Spaces property for a boundary object, consult the sections following below.

Note that the term “AutoCAD object” in the graphic below refers to AutoCAD linework (lines, arcs, circles, and polylines etc.)

Migrating Profiles from Previous Versions of the Software

Beginning with AutoCAD Architecture 2009, the mechanism by which objects are defined as boundary objects for spaces has changed. In previous versions, objects were selected by applying an object filter during the space generation. In AutoCAD Architecture 2009, each object has its own Bound Spaces property on the Properties palette or in the object style and is there defined as a boundary object.

When you import a profile (ARG file) from a previous release, the Bound spaces property in the Properties palette is not displayed for AutoCAD linework (lines, arcs, circles, polylines) in the imported profile. In order to display that property for AutoCAD linework, run the **AecSpaceDisplayBoundSpacesProperty** command on the command line. This will enable the display of the Bound Spaces property for AutoCAD linework in the Properties palette.

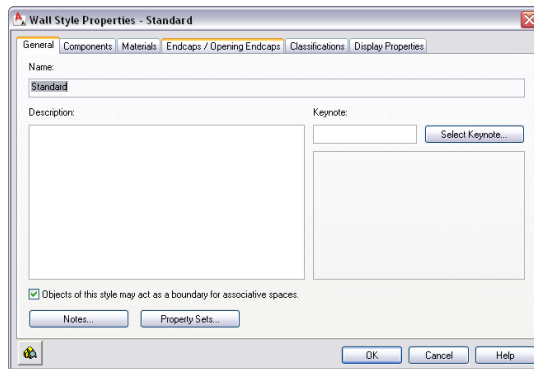

Setting the Bound Spaces Property in the Object Style

Use this procedure to set the Bound Spaces property of objects designed to bound associative spaces in the object style. You can use this method for all boundary objects that use styles. When an object style is set to bound spaces, all objects of that style will bound associative spaces. You can however override the Bound Spaces property for an individual object of that style in the Properties palette.

For example, if walls of a specific style - such as toilet stall walls or half-height kitchen counter walls - should normally not be used as boundary objects, you can set the Bound Spaces property of the wall style to No, so that any walls of that style are ignored when you generate a space.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects.

- 3 Expand the desired object category, and select the style for which you want to set the Bound Spaces property.
- 4 Click the General tab.
- 5 Select the checkbox for Objects of this style may act as a boundary for associative spaces.

- 6 Click OK.

Setting the Bound Spaces Property in the Properties Palette

Use this procedure to set the Bound Spaces property of objects designed to bound associative spaces in the Properties palette. You can use this method for all boundary objects, regardless of whether they use styles. If you set a different value for the Bound Spaces property in the Properties palette than in the object style, the settings from the Properties palette override the settings from the style.

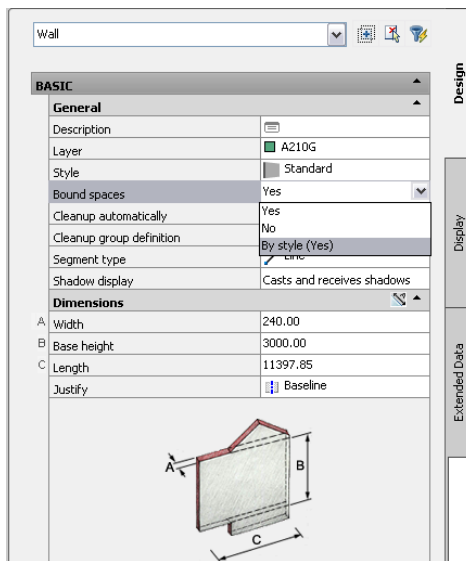

TIP If you want to define walls that do not act as boundary objects for spaces you must place these walls in a different cleanup group than those walls that do act as space boundaries. Otherwise the cleanup will result in unexpected results.

- 1 Select the object for which you want to set the Bound Spaces property, and double-click.
- 2 In the Properties palette, display the Bound Spaces setting in one of the following locations:

Object Type	Location of Bound Spaces property
Architectural objects:	Expand the General category.
Linework objects:	Expand the Advanced category.

NOTE The Bound Spaces property will not be displayed when opening the drawing in an AutoCAD Architecture Object Enabler environment such as AutoCAD, Civil 3D, or Land Desktop, or when you run AutoCAD Architecture as AutoCAD. It will only be displayed in full installations of AutoCAD Architecture or AutoCAD MEP.

- 3 For Bound Spaces, select one of the following options:
 - **By Style (Yes/No):** This object uses the Bound Spaces setting defined in the object's style. This is the default setting for objects that have styles.
 - **Yes:** this object can bound associative spaces.
 - **No:** this object cannot bound associative spaces.

NOTE You can also set the Bound Spaces property of objects by clicking Design ► Spaces ► Set Bound Spaces Property. Note that if you apply that command to objects in an xref or block, an override to the object's native Bound Spaces setting is added to the host drawing.

Displaying all Boundary Objects in the Drawing Area

In large drawings it can sometimes be difficult to determine which objects can act as boundary objects for spaces. If you are trying to generate associative spaces, and you get unexpected results or error messages, this is frequently due to wrong boundary objects. Use the **AecSpaceShowBoundingObjects** command to display only the objects in the drawing area that are currently defined as boundary objects. If one of the objects you need for a space boundary is not displayed, the object is either not a valid boundary object or its Bound Spaces property has been set to No.

You can use objects on frozen or hidden layers as boundary objects for associative spaces. When you choose to display all boundary objects in the drawing area, frozen and hidden objects are displayed, too. When you end the boundary objects-only view mode, these objects will be hidden or frozen again, and not displayed anymore. If you choose to remain in the boundary objects-only view, these objects will remain visible until you return to the normal view.

In the following example, you want to generate two spaces from the geometry below, for two different functional areas in a lobby. However, only one space is generated:

To find out if there is a problem with your boundary objects, you display only boundary objects, and get the following result:

From this result, you can deduce that the line that should separate the two functional areas has its Bound Spaces property currently set to No. After you have ended the **AecSpaceShowBoundingObjects** command, change the property accordingly ([Setting the Bound Spaces Property in the Properties Palette](#) on page 1936) in order to get the correct result:

- 1 Zoom in the drawing area until all desired spaces are visible.
- 2 On the command line, enter **AecSpaceShowBoundingObjects**.
- 3 Select one of the following options:

If you want to	Then
see boundary objects and associative spaces	press ENTER. NOTE The view includes boundary objects on frozen and hidden layers.
see only boundary objects but no associative spaces	enter S (hide associative Spaces).
exit the command and restore the original visibility settings	enter X (eXit). NOTE Any boundary objects on frozen or hidden layers will not be displayed anymore.

Generating an Associative Space

Use this procedure to generate an associative space. Associative spaces are generated from boundary objects, and are updated when the boundary objects change.

Associative 3D Freeform Spaces

To create an associative 3D freeform space, the space must be fully bounded by objects on all surfaces.

Generating a 3D freeform space

Associative 2D and Extruded 3D Spaces

When you generate an associative 2D or extruded 3D space from boundary objects, the boundary objects determine the extents of the space in the X and Y directions, and the space is associative to these. The Z-direction is either 0 (for a 2D space) or it is a user-defined extrusion height (in extruded 3D spaces).

For an associative 2D or extruded 3D space, you can define the gap allowed between colinear boundary objects. This would be useful for example if you have created a plan of a building with lines, and represented doors and windows as gaps between the lines. You can set a gap tolerance for these gaps, and the software will calculate the missing geometry from the existing colinear line segments. (AEC windows, doors, and openings in walls are not considered as gaps.)

NOTE Gaps are allowed only between colinear segments that do not contain other boundary objects, not between objects that are at other angles to each other or between colinear segments when the gap contains other boundary objects.

Generating an extruded 3D space from walls

existing walls, door, and window

select internal point

result

As a special case, you can generate an associative 2D or extruded 3D space from the outline of an object in a drawing. In this case, the object outline will be used as the boundary of the new space. For example, if you generate spaces from wall outlines, spaces will be generated from the wall outline.

Walls (left) and space generated from wall outlines (right)

IMPORTANT In previous versions of the software, objects that were invisible due to a frozen or hidden layer were never included in the generation or update of associative spaces. Beginning with this version, frozen and hidden objects are included in the space generation and update if they are set as boundary objects.

Generating an associative space

1 Verify that all necessary boundary objects have their Bound Spaces property set to Yes.

TIP On the command line of the SpaceAdd command you can find the command option Show Space Bounding Objects. Use this option to display all objects that currently have their Bound Spaces property set to Yes (including objects on frozen and hidden layers.) If the selection does not meet your needs, cancel the space generation, and first change the Bound Spaces property on all necessary objects, as described in [Setting the Bound Spaces Property for Boundary Objects](#) on page 1934.

2 Open the tool palette that contains the Space tool you want to use, and select it.

3 For Offset boundaries, select how the 4 space boundaries (base, net, usable, and gross boundary) are calculated. For information about space boundaries, see [Working with Space Boundaries](#) on page 1973.

- Manual: The net, usable, and gross boundaries can be manually edited with grips.
- By style: The net, usable, and gross boundaries are offset from the base boundary by a value defined in the space style. For more information, see [Specifying Space Boundary Offsets in a Space Style](#) on page 2041.
- By standard <Standard Name>: The net, usable, and gross boundaries are defined by the area calculation standard listed. For more information, see [Specifying an Area Calculation Standard for a Drawing](#) on page 1977.

4 For Create type, select Generate.

NOTE The Associative property is interlinked with the Create type. If the Create type is Generate, the Associative setting defaults to Yes. If the Create type is Insert, Rectangle, or Polygon, the Associative setting defaults to No and becomes read-only.

5 Select Yes for Allow Overlapping Spaces if you want to be able to generate spaces from boundaries that already contain a space.

This could be useful if you want to generate spaces from an xref drawing that already contains spaces, but you need to generate spaces with different settings (for example, with a different area calculation standard).

6 For Geometry type, select one of the following:

- 2D: generates an associative 2D space.
- Extrusion: generates an associative extruded 3D space. For an extruded 3D space, the height (Z) is defined by the user and is applied uniformly to the space.

- Freeform: generates an associative 3D freeform space.

IMPORTANT For descriptions of other Spaces settings on the Properties palette, see [Space Properties](#) on page 1926.

7 Before creating the spaces, you can perform these two optional steps to help with successfully creating spaces:

- Verify that all necessary boundary objects have their Bound Spaces property set to Yes. In order to do this, enter **sh** (SHow Bounding Objects). This option displays all objects that have their Bound Spaces property set to Yes. If an object you need for your space is not displayed, you can cancel the space generation and first change the Bound Spaces property on the object to Yes.
- Verify that all boundary objects are visible in the drawing area. If necessary, zoom in or out to display the desired objects, and then enter **v** (reset Visible boundaries) to update the drawing area.

8 In the drawing, generate the spaces:

If you want to...	Then...
generate a 3D freeform space	Enter G (Generate all).
generate a 2D or extruded 3D space	use one of the following options: <ul style="list-style-type: none"> ■ Enter G (Generate all) to generate spaces for all visible boundaries. ■ Pick inside closed boundaries in order to generate spaces for them.

Generating Associative Spaces from Xrefs and Blocks

You can generate associative spaces from objects in xrefs and blocks. The workflow for this has changed between the previous version of AutoCAD Architecture and the current version. The following sections describe the changes, as well as the workflows recommended for using xrefs and blocks for generating spaces.

Automatic Update of Associative Spaces through External References

Associative spaces that are bounded by objects in external references are now included in the automatic update of associative spaces. No manual updates are necessary anymore.

Migrating Xref Spaces from previous Versions of AutoCAD Architecture

Beginning with AutoCAD Architecture 2009, the mechanism by which linework objects (line, arc, circle, polyline) are defined as boundary objects for spaces has changed. In previous versions, linework boundaries were selected by applying an object filter during space generation. In AutoCAD Architecture 2009, each linework object has its own Bound Spaces property on the Properties palette and can be defined as a boundary object there. Additionally, xrefs and blocks now have a Bound Spaces property as well.

When you migrate a drawing with associative spaces that use linework from an xref as boundary objects you'll see the following behavior:

- All lines, arcs, circles, and polylines (as well as object outlines selected via the All Linework filter) that were defined as boundary objects in the host drawing will have their Bound Spaces setting correctly translated to the new mechanism and will continue to bound spaces.
- All lines, arcs, circles, and polylines from not-yet migrated xrefs however will not act as boundary objects for spaces in the host drawing anymore, so that if the spaces in the host drawing are updated (or new spaces are generated), the generation or update fails for these xref linework objects.

In order to update your spaces correctly, you can use an xref override on the affected linework objects (see [Changing the Display Configuration Used in Xref Drawings](#) on page 569). Alternatively, you can open the xref drawing, set the Bound spaces property on the desired linework objects to Yes, re-load the xref, and regenerate the spaces.

NOTE When you are converting drawings with xrefs and associative spaces from a previous version, the first time the host drawing is opened, will be accompanied by a noticeable performance delay. This is however only a one-time effect; once the host drawing and its associated xref drawings have been opened and saved with the current version, the performance will be improved in all future sessions.

Generating Spaces from Xrefs or Blocks Using the Xref or Block Settings

Within an xref or block you can define objects as boundary objects for spaces. These objects can be used to generate spaces in a host drawing.

In order to use boundary objects from an xref in a host drawing, the xref must have its Bound Spaces property set to Yes. (This is the default setting when inserting an xref.) If the xref's Bound Spaces property is set to Yes, objects in it that have their Bound Spaces property set to Yes, too, will be used to generate spaces in the host drawing. If the Bound Spaces property of the xref has been set to No, any objects in the xref are ignored when generating spaces in the host drawing, regardless of whether they have their Bound Spaces property set to Yes.

Perform these steps to use boundary objects from an xref to generate spaces in a host drawing:

- 1 Set the Bound Spaces property of the desired objects in the xref drawing to Yes. For instructions, see [Setting the Bound Spaces Property for Boundary Objects](#) on page 1934.
- 2 Reference the drawing into the host drawing where you want to generate spaces.
- 3 Select the xref.
- 4 In the Properties palette, expand the Advanced category.
- 5 Verify that the Bound Spaces property is set to Yes.
- 6 Generate spaces as described in [Generating an Associative Space](#) on page 1938.

This mechanism allows you to generate different spaces from multiple instances of the same xref, because the same referenced geometry can be used as boundary for spaces in one instance but not in another.

NOTE External references in Project Navigator have different default settings for the Bound Spaces property: By default, external references attached to elements, constructs and views from Project Navigator have their Bound Spaces property set to Yes; external references attached to sheets from Project Navigator have their Bound Spaces property set to No.

Blocks work according to the same principle, except that the default setting for the Bound Spaces property of a block is dependent on the Bound Spaces properties of the objects inside the block. If none the objects inside the block has its Bound Spaces property set to Yes, then the block's Bound Spaces property will be No. If there is at least one object inside the block that has its Bound Spaces property set to Yes, then the block's Bound Spaces property will be set to Yes, too.

IMPORTANT When you change the Bound Spaces properties of objects inside a block via the Block Editor, these changes are not automatically updated in the host drawing upon saving and closing the Block Editor. In order to verify that all spaces are updated correctly, you must perform a manual update of all affected spaces, as described in [Manually Updating Associative Spaces](#) on page 1947.

When blocks or external references are nested, and a block or external reference in the hierarchy has its Bound Spaces property set to No, then all blocks and external references nested in it are not used to bound spaces, even if some of the nested blocks or external references contain objects that have their Bound Spaces property set to Yes. In order to use boundary objects from nested blocks and xrefs, the containing level must have its Bound Spaces property set to Yes.

If a legacy drawing is opened in AutoCAD Architecture 2009, all blocks and external references that contain boundary objects will by default have their Bound Spaces property set to Yes.

Generating Spaces from Xrefs Using Overrides in the Host Drawing

If you do not want to make changes to the Bound Spaces property of objects in the xref drawing, you can use an override in the host drawing to change the boundary objects in xrefs without making a change to the xref drawing. For example, if you are a building engineer and receive an architectural drawing from which you want to generate spaces, but you do not want to change any boundary objects in the original drawing, you can xref the drawing into a new host drawing, and override the Bound Spaces property of xref objects in the new host drawing. The source drawing remains unchanged, but you can still generate spaces in the new drawing that are different from those generated in the xref drawing.

Override the Bound Spaces properties of xref objects in a host drawing

- 1 Xref the drawing from which you want to generate spaces into the host drawing.
- 2 Select the xref.
- 3 In the Properties palette, expand the Advanced category.
- 4 Verify that the Bound Spaces setting is set to Yes.
- 5 Display all boundary objects in the drawing (both host and xref) by entering `AecSpaceShowBoundingObjects`. (Alternatively, you can click Design menu ► Spaces ► Show Objects that Bound Spaces.)
If the objects displayed by that command do not meet your needs, you need cancel space generation, and first apply overrides to the Bound Spaces properties of the desired xref objects.
- 6 Click Design ► Spaces ► Set Bound Spaces Property.
- 7 Select the desired boundary objects in the xref, and press ENTER.
- 8 On the command line, enter Y (Yes) to generate the override, and press ENTER.

NOTE An xref override is only valid for the selected instance of the xref in the host drawing where it is set. If the same xref drawing is referenced into a different host drawing, or as another instance into the same host drawing, no overrides exist.

If you now generate the spaces, all overridden objects in the xref will now be used to generate spaces.

- 9 If you have not applied any overrides yet, and no valid space boundaries can be found because none of the objects in the xref drawing have their Bound Spaces property set to Yes or the objects that do not enclose a valid space, a task dialog will appear and prompt you to select objects that should bound spaces.
- 10 In this case either select all visible objects as boundary objects, or select individual objects, and press ENTER. This will automatically set the Bound Spaces properties of all selected objects to Yes, and if those objects are in an xref will add an override to them in the current drawing.

You can remove space boundary overrides from objects in xrefs. When the override is removed, the Bound Spaces settings of the xref objects are used again.

To remove a space boundary override from an object in an xref

- 1 Click Design ► Spaces ► Set Bound Spaces Property.
- 2 Select the boundary objects in the xref from which you want to remove the override, and press ENTER.
- 3 On the command line, enter R (Remove Override), and press ENTER.
- 4 If necessary, update the spaces in your drawing.

Generating Spaces from an Xref Drawing Containing Spaces

If you receive a drawing with spaces, but want to generate a different set of spaces, verify that the Allow Overlapping Spaces setting in the Properties palette is set to Yes before you pick your spaces. Otherwise, spaces can only be generated in areas that do not contain a space from the xref.

Defining a Maximum Gap Size for Associative Spaces

When you are generating 2D or extruded 3D spaces, it is possible to define an allowed gap size between colinear boundary objects. The software will calculate the missing segments and create the space profile from that. You cannot define a gap size for 3D freeform spaces.

- 1 Click Format menu ► Options.
- 2 Click the AEC Object Settings tab.

3 Under Maximum Gap Size, select the largest gap you want to allow between the boundary objects of an associative space.

4 Click OK.

TIP Alternatively, you can set the maximum allowed gap size between boundary objects on the command line by entering **AecSpaceMaxGapSize**.

Updating Associative Spaces

Associative spaces are defined by their boundary objects and are updated when the boundary objects change. You can choose to have associative spaces update automatically whenever there is a relevant change to boundary objects, or you can choose to perform the space update manually.

Updating Associative Spaces Bounded by External References

Objects in external references can serve as boundary objects for associative spaces in the host drawing. When the objects in the external reference change, the space is updated too. In previous versions, a manual update

was necessary to propagate changes in the external reference's boundary objects to the spaces in the host drawing; now changes from external references are automatically updated when reloading the external reference, if the automatic update of associative spaces is activated (see [Activating and Deactivating Automatic Updates](#) on page 1946).

Roundtripping Associative Spaces between AutoCAD Architecture 2009 and previous Versions

In previous versions of the software, boundary linework objects were defined by a filter selection during space generation. In the current version, each object has its own Bound Spaces property in the Properties palette. This includes blocks and xrefs. These changes can cause discrepancies when roundtripping drawings that contain 2D linework, blocks, and external references. For example, when a line in the current version of the software has its Bound Spaces property set to Yes, and is opened in a previous version, it will still be a boundary object for spaces, but it will be selected via the boundary filter of the space. When the filter is removed from the space in the previous version, and the drawing is re-opened in AutoCAD Architecture 2009, the change in the filter setting will be ignored. It is recommended that you carefully examine your spaces after roundtripping them between different versions of AutoCAD Architecture in order to avoid space errors.

Activating and Deactivating Automatic Updates

Use this procedure to activate or deactivate the automatic update of associative spaces.

Updating each temporary change to the space geometry might not be necessary or desirable. For example, if you delete a wall only to replace it with a different one in the same position, you only need the space to update after the new wall is in place, rather than once when the old wall is removed and again when the new one is inserted.

Manual updates offer better performance, but mean that the geometry of spaces and their boundary objects might be out-of-synch at a given time during the drawing session.

When the automatic update of associative spaces is deactivated, and an area calculation standard has been selected to calculate boundary offsets, the rules of the standard will only be applied to changed spaces when either the automatic update has been activated again or the spaces are updated manually, as described in [Manually Updating Associative Spaces](#) on page 1947.

IMPORTANT When you re-activate the automatic update of spaces, only those spaces will be updated that had no boundary objects added while the update was off. For example, if you added a dividing wall to a space while the automatic update was off, and then turn the automatic update on, the space will not be divided by the wall. Update the space manually to reflect the new geometry.

- 1 Click Format menu ► Options.
- 2 Click the AEC Object Settings tab.

3 Under Space Settings, specify whether associative spaces will be updated automatically:

If you want to...

Then...

update associative spaces automatically each time you make a change to the boundary objects

select Automatically update associative spaces.

update associative spaces manually

clear Automatically update associative spaces.

4 Click OK.

TIP The automatic update of spaces can also be turned on or off via the **AecSpaceAutoUpdate** command.

Manually Updating Associative Spaces

Use this procedure to manually update an associative space after its boundary objects have changed. A manual update can be necessary in these cases:

- The automatic update of associative spaces has been deactivated, as described in [Activating and Deactivating Automatic Updates](#) on page 1946, and the boundary objects of an associative space have been modified.
- A new boundary object has been added while the automatic update of spaces was deactivated.
- The automatic update cannot be performed due to any of the conditions described in [Troubleshooting Associative Spaces](#) on page 1953.

You can choose to either update only selected spaces, or all associative spaces in the drawing.

IMPORTANT Previously, objects that were on a frozen or hidden layer were not included in any space updates. Now, frozen or hidden objects are included in the space update if their Bound Spaces property is set to Yes.

When the automatic update of associative spaces is deactivated, and an area calculation standard has been selected to calculate boundary offsets, the rules of the standard will only be applied to changed spaces when either the automatic update has been activated again or the spaces are updated manually.

Manually updating selected spaces

- 1 Select the associative space you want to update.
- 2 Right-click, and click Update Space Geometry ► Selected Spaces.

Manually updating all associative spaces in the drawing

- 1 Select any associative space in the drawing.
- 2 Right-click, and click Update Space Geometry ► All Associative Spaces.

Merging Associative Spaces

Associative spaces can be merged by removing boundary objects that separate them. If you activated the automatic update of associative spaces (as described in [Activating and Deactivating Automatic Updates](#) on page 1946), the update is run automatically.

The following rules determine in descending order the precedence of property inheritance in the merged space:

- 1 If only one of the spaces to be merged has object property set data, the properties of that space are applied to the merged space.

- 2 If only one of the spaces to be merged has classification data, the properties of that space are applied to the merged space.
 - 3 If both of the spaces have object property set data or classification data, the properties of the larger space are applied to the resulting space.
 - 4 If only one of the spaces to be merged has style-defined property set data, the properties of that space are applied to the merged space.
 - 5 If all of the above criteria apply to none or both of the spaces to be merged, the properties of the older spaces are applied to the merged space.
- This can result in unexpected property assignments, so it is recommended that you check the merged space's properties.

If the automatic update of associative spaces is not activated, you need to merge spaces between deleted boundary objects manually. This process involves more steps than the automatic update, but allows you more control over which space's properties are retained in the resulting space.

Manually merging associative spaces

- 1 Verify that the automatic update of associative spaces is deactivated, as described in [Activating and Deactivating Automatic Updates](#) on page 1946.
- 2 Select the boundary object that separates the spaces you want to merge, and delete it.
You now have 2 separate spaces within the same boundary objects.
- 3 Select and delete the space whose properties you do not want to keep.
If you have no preference, you can delete either space.
- 4 Right-click the remaining space, and click Update Space Geometry ► Selected Spaces.
The space is updated to the new boundaries.

Dividing an Associative Space

Associative spaces can be divided by adding new boundary objects. If you activated the automatic update of associative spaces (as described in [Activating and Deactivating Automatic Updates](#) on page 1946), the update is run automatically.

NOTE Verify that the new boundary object has its Bound Spaces property set to Yes before the space will be divided. For more information, see [Setting the Bound Spaces Property in the Properties Palette](#) on page 1936.

Manually dividing associative spaces

- 1 Verify that the automatic update of associative spaces is deactivated, as described in [Activating and Deactivating Automatic Updates](#) on page 1946.
- 2 Create a new boundary object to divide the existing space.
The space object now spans 2 sets of boundary objects.
- 3 Select the space, right-click, and click Update Space Geometry ► Selected Spaces.
The existing space is updated to fit into one of the 2 sets.
- 4 Create a new associative space in the empty set, as described in [Generating an Associative Space](#) on page 1938.

Deducting Spaces from an Associative Space

You can deduct objects enclosed in an associative space from the overall space area. This would be useful for deducting areas filled by columns or shafts.

Enclosed objects included in space area

Enclosed objects deducted from space area

- 1 Before generating the space, verify that the enclosed objects you want to deduct from the overall space volume are both valid boundary objects (see [Valid Boundary Objects for Associative Spaces](#) on page 1931) and have their Bound Spaces property set to Yes (see [Setting the Bound Spaces Property for Boundary Objects](#) on page 1934).
- 2 Generate the space by one of the methods described in [Generating an Associative Space](#) on page 1938.
Objects that are fully enclosed in the generated space are automatically deducted.

Making a Space Associative or Non-Associative

When you make a space associative, you connect it to a set of boundary objects that define the space's geometry. To make it non-associative you disconnect it from its boundary objects, so that it is not affected by future modifications to those objects.

If you make a non-associative space associative, the software checks if a valid set of enclosing boundary objects can be found. If this is so, the space is made associative to them and the geometry is updated accordingly.

Making a space associative to boundary walls

If you make an associative space non-associative, the space is disconnected from its boundary objects. The space geometry retains its current shape after the associativity is deactivated, but is grip-editable.

Removing the associativity of a space to the boundary walls

Making an associative space non-associative

- 1 Double-click the space you want to make non-associative.
- 2 On the Properties palette, for Associative select No.
Edit the space as desired.

Making a non-associative space associative

- 1 Select the space you want to make associative to boundary objects.
- 2 Right-click, and click Make Associative.

If a valid set of boundary objects is detected, the space geometry is updated to the boundary of these objects, and the Associative property on the Properties palette is set to Yes.

If no valid set of boundary objects is detected, the space geometry remains unchanged and the Associative property on the Properties palette remains read-only and set to No.

TIP When a non-associative space is made associative, and its Offset boundaries property is set to Manual, then making the space associative will align only the base boundary of the space to the new boundary objects. The net, usable, and gross boundaries will stay in their previous shape. You can fix this by changing the Offset boundaries property to either By style or By standard.

Troubleshooting Associative Spaces

In this section, frequently asked questions about associative spaces are addressed.

When I use the Generate all option to generate spaces from my drawing, the process takes a very long time. How can I speed it up?

Before starting the space generation, zoom in on the model to decrease the current drawing area. The space generation processes all objects in the current drawing area, so the larger the drawing area, the longer the processing will take.

I have noticed a decrease in performance between space drawings in previous versions of AutoCAD Architecture and in the current version. There have been no changes to the drawings, so what can be the reason?

Check if your drawing contains spaces bounded by objects in external references. In previous versions of the software, a manual update was necessary to propagate changes in the external reference's boundary objects to associative spaces in the current drawing; now changes from external references are automatically updated, if the automatic update of associative spaces is activated. This can result in a noticeable performance lag. Deactivate the automatic update, as described in [Activating and Deactivating Automatic Updates](#) on page 1946.

Another possibility can be that when you are converting drawings with xrefs and associative spaces from a previous version, the first time the host drawing is opened will be accompanied by a noticeable performance hit. This is however only a one-time effect; once the host drawing and its associated xref drawings have been and opened and saved with the current version, the performance will be improved for all future sessions.

When I try to generate a 3D freeform space from my model, why do I get an error message: Valid boundary not found?

The space generation mechanism may not be able to detect a valid space boundary for any of the following reasons:

1. The boundary objects are not 100% closed

Double-check your model to verify that the objects are really enclosing the space. There may be tiny, barely visible gaps between the designated boundary objects in the building model.

For example, if an interior wall is auto-projected to a roof slab without ceiling, and the interior wall extends only to the baseline and not to the outside of the outside wall, the 3D freeform space cannot be generated. In such a case you could create a ceiling under the roof slab, so that walls are projected to the ceiling instead of the actual roof. Or you could extend the interior wall all the way to the outside of the exterior wall. You could also place a sweep on the wall to make the top of the wall flush with the sloping roof slab.

2. Objects intended as boundary objects are not valid for the 3D freeform space generation

The boundary objects for an associative 3D freeform space must belong to the objects listed under [Valid Boundary Objects for Associative Spaces](#) on page 1931. Any other AutoCAD Architecture objects, such as railings or 2D linework, will not be recognized by the space generation. If your selection set includes one of these

objects, it will be filtered out, and the boundary set will be considered not closed. To create a valid bounded space, substitute a valid boundary object for the invalid one.

3. Edges of boundary objects touch, but do not overlap

When boundary objects like walls, slabs, and other 3D geometry just touch each other but do not have any overlap, or when objects intersect only along an edge (to form a line rather than a surface intersection), they are considered open even though the corresponding real-world components would be closed. In such cases, no 3D freeform space can be created. To fix this problem, extend one of the objects just far enough to create an overlap.

When I try to generate a 2D or extruded 3D space from my model, why do I get an error message: Valid boundary not found?

The space generation mechanism may not be able to detect a valid space boundary for any of the following reasons:

1. Some objects are not boundary objects

Some objects that are needed to create a closed boundary for the space are either not valid boundary objects for spaces or their Bound Spaces property is set to No. To see all objects that are currently boundary objects for spaces, run the **AecSpaceShowBoundingObjects** command. If an object that is needed for the boundary does not display, it is either not a valid boundary object or its Bound Spaces property is set to No. For more information see [Valid Boundary Objects for Associative Spaces](#) on page 1931 and [Setting the Bound Spaces Property for Boundary Objects](#) on page 1934.

2. The Maximum gap size is smaller than some colinear gaps in your model

When you generate a 2D or extruded 3D space, you can define an allowed gap size between colinear boundary objects. If the colinear gaps in your model are larger than the allowed gap size, the model is considered not closed, and a space cannot be generated or might flow into an adjacent area. In that case, change the maximum gap size to a value greater than your largest colinear gaps, as described in [Defining a Maximum Gap Size for Associative Spaces](#) on page 1944.

Are there other factors I should check if my associative spaces are not generated correctly?

There are a number of general possibilities to check when your spaces are not generated:

Boundary walls have been placed in the same cleanup group as walls that are no boundary objects

If a wall that is no boundary object intersects with a wall that is a boundary object, and they are in the same cleanup group, the wall that is a boundary object is considered to be not a boundary object because of its cleanup with the other wall. As a result, no space can be generated even if the geometry would otherwise be closed. In that case, you need to create a new cleanup group and place only the walls that are no boundary objects in that group.

The visible drawing area was changed by zooming or panning in between starting the Space tool and selecting the boundary objects

When you generate associative spaces, only boundary objects visible in the drawing area at the time you start the space generation tool are included in the selection set. If you have zoomed or panned before generating spaces, the space detection is not automatically updated to the new drawing area. To update the selection set, use the **v** (reset Visible boundaries) option on the command line. This option will update the drawing area to its current extents. Then, generate the space again.

When I generate spaces by using the Generate all option, the spaces are generated but not according to the boundary objects visible in the drawing area. The same happens when I try to update some existing spaces. What is the reason?

Some boundary objects for these spaces might be on a frozen or hidden layer. In previous versions of AutoCAD Architecture, objects that were invisible due to a frozen or hidden layer were not included in associative spaces. Now, frozen or hidden objects are included in the space generation if they are set as boundary objects and are located in the current drawing area. To verify if this is the case, display all boundary objects in the drawing area, as described in [Displaying all Boundary Objects in the Drawing Area](#) on page 1937. If you now see previously invisible objects, these objects are on a frozen or hidden layer. To exclude objects on a frozen or hidden layer from the boundary set, unfreeze or unhide the layer, and change the Bound Spaces property of the objects from Yes to No.

When I try to generate a space from the outlines of walls, I get unexpected space boundaries. How can I fix this?

Generating spaces from object outlines can be useful for generating spaces that are deducted from other spaces, like a mass element representing a shaft, or walls that represent a construction space. A space generated from wall outlines should look like this:

In some cases, the space generation may result in different and segmented boundaries like this:

If this is the case, the maximum allowed gap size between boundary objects is too big, and the end wall conditions between walls are not calculated correctly. Recreate the space with a very small maximum gap size. For more information, see [Defining a Maximum Gap Size for Associative Spaces](#) on page 1944.

When I update the boundary objects for associative spaces (like for example, I move a wall to a different position) the space does not update. In some cases, it displays a solution tip icon, but in other cases just does not update. How can I get the space to update?

The following factors can be responsible for spaces not updating:

1. The space is no longer associative

Verify that the Associative setting on the Properties palette is still set to Yes. If it has been accidentally set to No, the space loses its associativity to the boundary objects. The space no longer updates, but displays no solution tip icon.

2. In the AEC Options, the Automatic update of associative spaces has been disabled

You can choose to not automatically update associative spaces each time a change in geometry occurs. This can be useful to improve performance. If the Automatically update associative spaces option on the AEC Object Settings tab of the Options dialog has been cleared, then a space will not automatically react to changes in the boundary objects. You can either reselect the automatic update option, or, if you do not want to have automatic updates, you can select the space, right-click, and click Update Space Geometry ► Selected Spaces.

NOTE When you activate the automatic update of spaces, only those spaces will be updated that had no boundary objects added while the update was off. For example, if you add a dividing wall to a space while the automatic update is off, and then turn the automatic update on, the space will not be divided by the wall. You should then manually update the space.

3. Grip-editing the boundary objects has introduced a new boundary object for the space

If a grip-edit operation on the boundary objects has resulted in additional boundary objects, the space will not automatically update to reflect this change, but will display a solution tip icon. In that case, select the space, right-click, and click Update Space Geometry ► Selected Spaces.

4. The change in the boundary objects has invalidated the closed boundary

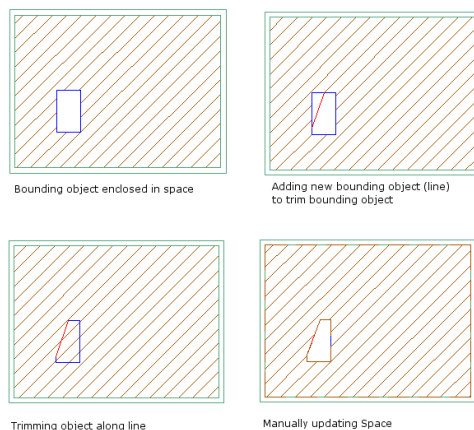

Verify that the change in the geometry has not accidentally opened up a gap in the boundary objects. This could happen if you move a wall so that it no longer intersects neighboring walls. It could also happen if a wall is moved so that it intersects with another wall that is not defined as a boundary object and is in the same cleanup group.

5. The visible drawing area has changed between creating and updating the space

The Update Space Geometry command uses the current viewport's zoom value. This might lead to unexpected results, if you have zoomed in on the drawing area between generating and updating the space. Zoom out so that the space and its boundary objects are entirely visible, and try to update again.

After trimming a part of a boundary object enclosed in a space (for example, if you trim a part of a shaft,) the enclosed object is not recognized as a boundary object anymore, and the surrounding space flows into it. What is the reason and how can I fix this?

When trimming a boundary object by substituting a new boundary object in the trimming position, the new object will not be recognized automatically as boundary object for the space, because it did not bound the space previously. In this case, you need to update the space manually to recognize the new bounding object. See the following example:

I have updated an associative space. The base boundary updates correctly, but the net, usable, and gross boundaries stay as they were before the update. What causes that behavior?

If the net, usable, and gross boundaries of an associative space do not get updated when the base boundary is updated after a change in the boundary objects, the space uses manual boundary offsets.

Net, usable, and gross boundaries not updating

Manual net, usable, and gross boundaries do not automatically react to changes in the base boundary. To make the net, usable and gross boundaries update automatically when the base boundary is updated, you need to define the boundary offset of the space as By Style or By Standard on the Properties palette.

I am using an area calculation standard to generate associative spaces. Sometimes when generating or updating my spaces, I see solution tip icons for which I cannot find a valid reason in the boundary objects. What is the reason for this and how can I work around it?

A solution tip icon can appear when the area calculation standard is for some reason unable to generate or update the space boundaries correctly. Install the standard or support file as advised in the solution tip, or correct the boundary offsets, by deactivating the area calculation standard and working with manual offsets, as described in [Defining the Boundary Offset Type of a Space](#) on page 1976. Then, grip-edit the incorrect boundaries so that they are correct again. Note that you have to do this only for those spaces that display that solution tip icon, not for all associative spaces based on the area calculation standard. It is not recommended to switch back to the offset boundary type By Standard after making the change, because as soon as the space is updated again, the corrected boundaries will be overwritten with the incorrect standard-based ones.

I have problems with incorrect offsets of the net, usable, and gross boundaries of associative spaces when I use an area calculation standard to generate them. What can be the reason?

There are a number of conditions under which the correct calculation of boundary offsets for associative spaces does not work when using an area calculation standard:

- The space and its boundary objects have been mirrored. When associative spaces are mirrored, they need to be updated manually to recalculate the net, usable, and gross boundaries correctly. For instructions, see [Manually Updating Associative Spaces](#) on page 1947.
- Some boundary objects are arc walls. In some cases, the net, usable, and gross boundaries of associative spaces are not calculated correctly when the boundary objects include arc walls. If this happens, deactivate the rule based offset calculation and set manual offsets, as described in [Defining the Boundary Offset Type of a Space](#) on page 1976. Then, grip-edit the incorrect boundaries so that they are correct again. It is not recommended to switch back to the offset boundary type By Standard after making the change, because as soon as the space is updated again, the corrected boundaries will be overwritten with the incorrect standard-based ones.

Some of my walls have sweeps and modifiers attached to them. When I try to generate spaces from them, the space boundary ignores the sweeps and modifiers and generates the space from the wall profiles. How can I get the space generation to observe sweeps and modifiers?

To make the space generation include wall sweeps and wall modifiers into the boundary of an associative space, the cut plane height of the wall with the sweep or modifier must be set to 0. For more information, see [Specifying the Cut Plane Display of a Wall Style](#) on page 891.

When I turn on the automatic update of associative spaces, as described in [Activating and Deactivating Automatic Updates](#) on page 1946, some of my existing spaces suddenly display solution tip icons. How can I fix this?

When a solution tip icon appears after you have activated the automatic update of associative spaces, the space and its boundary objects are out-of-synch. Select the space with the solution tip icon showing, right-click, and click Update Space Geometry ► Selected Spaces.

When I deselect the automatic update of associative spaces, and divide an associative space with a new boundary object, as described in [Dividing an Associative Space](#) on page 1950, the space will not be divided immediately. This is according to my expectations. However, if I then activate the automatic update of associative spaces, my space is not divided either. Is this correct?

Boundary objects added while the automatic space update is turned off will not be used to update spaces later when the setting is turned on again. Only objects added or modified while the automatic update is turned on will be used to update the spaces. If you encounter the situation above, delete the wall and re-insert it with the automatic update turned on.

When I insert a scaled external reference with boundary objects into a drawing, any associative spaces generated from the objects in the external reference will not be correctly calculated when using an area calculation standard. What can I do to fix this?

Currently, when an external reference is scaled during insertion, the boundary offset calculation will never be correct if the boundary offsets are calculated by an area calculation standard. You can either re-insert the external reference without scaling, or you can change the boundary offsets from By Standard to By Style or Manual and try to emulate the rules of the area calculation standard in the style of by manually offsetting the boundaries.

Creating Non-Associative Spaces

Non-associative spaces are freestanding spaces with user-defined geometry. You can either draw a space or convert linework, object outlines, mass elements, or slabs to spaces, which you can then modify according to your needs.

Drawing a Non-Associative 2D or Extruded 3D Space

When you draw a non-associative 2D or extruded 3D space, you can either base it on target dimensions taken from the space style, or you can draw rectangular or polygonal spaces with dimensions that you define.

Inserting a Space with Style-Defined Target Dimensions

Use this procedure to insert a non-associative space based on target dimensions set in the space style. For information about setting target dimensions in the space style, see [Specifying Target Dimensions for the Space](#) on page 2040.

- 1 Open the tool palette that contains the Space tool you want to use, and select it.
- 2 For Create type, select Insert.

NOTE For spaces with the Create type of Insert, Rectangle, or Polygon, the Associative setting is always No.

3 Expand Component Dimensions.

4 Specify the geometry type of the new space:

If you want to...

Then...

create a 2D space

select 2D from the list.

create an extruded 3D space

select Extrusion from the list.

5 Expand Actual Dimensions.

6 To specify the geometry of the space within the boundaries of the target dimensions on screen, select Yes for Specify on screen.

To specify the geometry of the space by entering values in the Properties palette, select No for Specify on Screen.

7 Specify which dimension of the space is to be constrained during insertion:

If you want to...

Then...

fix the space area value during insertion

select Area for Constrain. This lets you change the length and width of the space, but only within the range of the target dimensions. For example, if you constrain the area to 9m², you can still choose to make both length and width 3m, or to make the length 4m, and the width 2.25 meters, as both combinations result in an area of 9 m².

fix the space length during insertion

select Length for Constrain. If you constrain the length of a space, then any change to the space area will only change the width dimension of the space, and vice versa.

fix the space width during insertion

select Width for Constrain. If you constrain the width of a space, then any change to the space area will only change the length dimension of the space, and vice versa.

do not fix a specific dimension during insertion

select *NONE* for Constrain. In this case no individual dimension is constrained, and you can specify any geometry as long as it is within the target dimensions.

8 If you have selected to not specify the space on screen, enter values for the non-constrained dimensions for Base Area, Length, and Width.

9 Insert spaces in the drawing:

If...

Then...

you have selected to specify the space on screen,

click in the drawing to define the insertion point of the space. Then drag and click to define the space dimension, and specify a rotation.

you have entered values for the space geometry in the Properties palette

click in the drawing to define the insertion point of the space, and then specify a rotation.

10 Continue adding spaces, and press *ENTER*.

IMPORTANT For descriptions of other Spaces settings on the Properties palette, see [Space Properties](#) on page 1926.

Drawing a Rectangular Space

Use this procedure to draw a non-associative rectangular 2D or extruded 3D space.

- 1 Open the tool palette that contains the Space tool you want to use, and select it.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 For Create type, select Rectangle.

NOTE For spaces with the Create type of Insert, Rectangle, or Polygon, the Associative setting is always No.

- 4 Expand Component Dimensions.
- 5 Specify the geometry type of the new space:

If you want to...	Then...
create a 2D space	select 2D from the list.
create an extruded 3D space	select Extrusion from the list.

- 6 In the drawing area, specify the start point of the space, and drag and click to define the opposite corner.
- 7 Continue adding spaces, and press *ENTER*.

IMPORTANT For descriptions of other Spaces settings on the Properties palette, see [Space Properties](#) on page 1926.

Drawing a Polygonal Space

Use this procedure to draw a non-associative polygonal 2D or extruded 3D space. A polygonal space is composed of line and arc segments and can be used to represent non-rectangular rooms.

- 1 Open the tool palette that contains the Space tool you want to use, and select it.
- 2 For Create type, select Polygon.

NOTE For spaces with the Create type of Insert, Rectangle, or Polygon, the Associative setting is always No.

- 3 For Segment type, select if the first space segment should be a line or an arc.
- 4 Expand Component Dimensions.
- 5 Specify the geometry type of the new space:

If you want to...	Then...
create a 2D space	select 2D from the list.

If you want to...	Then...
create an extruded 3D space	select Extrusion from the list.

- 6 If you have selected Line for Segment type, specify the start and end point of the first linear segment on screen.
- 7 If you have selected Arc for Segment type, specify the start point, a point on the arc, and the endpoint of the segment on screen.
- 8 Proceed with adding segments for the space.
By default, for each new segment the segment type of the previous segment is used. If necessary, you can change the segment type in the Properties palette.
- 9 Close the space and press ENTER.

IMPORTANT For descriptions of other Spaces settings on the Properties palette, see [Space Properties](#) on page 1926.

Converting Objects, Profiles, and Polylines to Non-Associative Spaces

Various objects can be converted to non-associative spaces. If you are converting a non-extruded mass element, you can convert its geometry to a 3D freeform space. If you are converting other AEC objects or polylines, the 2D profile of the object or polyline is converted to a 2D space or an extruded 3D space.

Converting Mass Elements to Spaces

Use this procedure to convert a mass element to a space.

Converting a Mass Element to a 3D Freeform Space

When you convert a non-extrusion type mass element to a space, it is created as a 3D freeform space, unless the space tool you use has its geometry type set expressly to Extrusion. Non-extrusion type mass elements include:

- Arch
- Barrel Vault
- Isosceles Triangle
- Right Triangle
- Pyramid
- Cone
- Dome
- Sphere
- Gable

■ Freeform

Converting a Mass Element to an Extruded 3D Space

When you convert an extrusion type mass element to a space, it is created as an extruded 3D space. Non-extrusion type mass elements include:

Mass elements that can be converted to an extruded 3D space include:

- Box
- Cylinder
- Extrusion

NOTE To make sure that the converted space uses the mass element geometry, verify that the space tool used has its geometry type set to Undefined (--). If it is set to Extrusion, a mass element is converted based on its profile shape and extruded from that. A non-extruded mass element shape, like for example a pyramid, will be converted to an extruded box shape with the pyramid profile.

- 1 Open the tool palette that contains the Space tool you want to use, and select it.
(You may have to scroll to display the desired tool.)
- 2 Right-click the space tool, and click Apply Tool Properties to ► Mass Element.
- 3 Select the mass element that you want to convert to a space, and press *ENTER*.
- 4 When prompted to erase the original geometry, press *ENTER* to keep the mass element or enter *y* (Yes) to erase it.
- 5 Edit the properties of the space in the Properties palette as needed.

Converting Mass Groups to Spaces

Use this procedure to convert a mass group to a space.

IMPORTANT If the mass group contains multiple mass elements that do not intersect, one space with multiple profiles will be created. In most cases, this is not the desired result, so it is recommended that you disconnect each mass element from the mass group first, and convert it individually.

- 1 On the command line, enter **SpaceConvertMassElement**.
- 2 Select the mass group you want to convert to a space, and press *ENTER*.

- 3 When prompted to erase the original geometry, press *ENTER* to keep the mass group or enter *y* (Yes) to erase it.

Converting Polylines, Profiles, and Object Outlines to Spaces

Use this procedure to convert polylines or 2D profiles of objects to spaces. This can be useful for defining construction spaces that usually consist of the outlines of walls, columns, stairs, and other building objects.

The new space generated from the profile of the object will be created with the properties defined in the space tool. If a specific setting has been set to Undefined (--) in the space tool properties or cannot be set in the tool properties, the last used setting on the Properties palette will be used.

You can use the following object outlines as space boundaries:

- Walls/Curtain walls
- Columns/Braces/Beams/Slabs
- Doors/Windows/Window assemblies
- Roofs/Roof slabs/Slabs
- Stairs/Railings
- Mass elements/Mass groups
- AEC polygons
- Profiles
- Closed polylines

Column objects (left), converted to spaces (right)

- 1 Open the tool palette that contains the Space tool you want to use, and select it.
(You may have to scroll to display the desired tool.)
- 2 Right-click a space tool, and click Apply Tool Properties to ► Linework and AEC objects.
- 3 Select the objects and closed polylines to convert, and press *ENTER*.
- 4 In the Convert to Space worksheet, under Cut Plane Height, the height at which the object should be cut to generate the profile of the new space.
- 5 If you want to erase the underlying object, select Erase Layout Geometry. To keep the object in the drawing, verify that the option is cleared.
- 6 If you want to define the cut plane height on screen, select Specify on Screen.
- 7 Click OK.
- 8 If necessary, select the cut plane height in the drawing.

Creating a Space Tool

Use this procedure to create a space tool add it to a tool palette. You may want to create your own tools if you frequently place multiple spaces of specific styles that have the same properties.

For example, you might create an office plan with spaces for cubicles. Although all cubicles use the same space style in your floor plan, the cubicle walls in administrative areas are lower than the walls in office areas. To work efficiently, you can create a space tool for each space height. You can then select the appropriate tool to place the cubicles with the correct height in each area of the floor plan.

TIP Space tools can be created for associative and non-associative spaces. When a tool for associative spaces is started, the initial processing of valid boundaries in the drawing can be a lengthy process, depending on the size of the model. Therefore, it is recommended to clearly name your space tools regards to their associativity.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to...	Then...
create a tool from a space in the drawing	select the space, and drag it to the tool palette.
create a tool from a space style in the Style Manager	click Format menu ► Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.
copy a tool in the current tool palette	right-click the tool, and click Copy. Right-click, and click Paste.
copy a tool from another tool palette	open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.
copy a tool from a tool catalog	open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new tool, and click Properties.

Defining general tool properties

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

6 To add keywords to the tool, click More Info.

7 Expand Basic, and expand General.

8 Click the setting for Description, enter a description displayed for all spaces created from this tool, and click OK.

9 If you do not want to use the layer assignments specified in the layer key style used in the drawing, specify a layer key and any layer key overrides.

10 Select a space style.

11 Select the drawing file containing the style used for this space tool.

12 Enter a name for spaces inserted with the tool.

13 Select a space tag.

14 Select the drawing file containing the tag used for this space tool.

NOTE The Associative property is interlinked with the Create type. If the Create type is Generate, the Associative setting can be edited. You can use the default setting of Undefined (--). If the Create type is Insert, Rectangle, or Polygon, the Associative setting defaults to Undefined (--) and becomes read-only.

15 For Offset boundaries, select how the 4 space boundaries (base, net, usable, and gross boundary) are calculated. For information about space boundaries, see [Working with Space Boundaries](#) on page 1973.

- Manual: The net, usable, and gross boundaries can be manually edited with grips.
- By style: The net, usable, and gross boundaries are offset from the base boundary by a value defined in the space style. For more information, see [Specifying Space Boundary Offsets in a Space Style](#) on page 2041.
- By standard <Standard Name> (associative spaces only): The net, usable, and gross boundaries are defined by the area calculation standard listed. For more information, see [Specifying an Area Calculation Standard for a Drawing](#) on page 1977.

16 Select the Create type of the space. You can choose one of these options:

- Insert: Inserts a space according to the target dimensions in the space style.
- Rectangle: Inserts a rectangular space with user-defined length and width.
- Polygon: Inserts a polygonal space with user-defined segments.
- Generate: Inserts a space associative to boundary objects.

17 If you selected Polygon for Create type, define the shape of the first space segment for Segment Type.

You can select a line or an arc segment.

Defining settings for associative spaces

18 If you need to generate spaces within boundaries that already contain a space, select Yes for Allow overlapping spaces.

By default, you cannot generate a new space in a boundary that already contains an existing space. However, a situation can arise where you want to establish an interference between 2 spaces and therefore need to generate a space within a boundary that already contains a space.

Defining the geometry type of the space

19 Expand Component Dimensions.

20 Specify the geometry type of the space tool:

If you want to...	Then...
create a 2D space tool	select 2D from the list.
create an extruded 3D space tool	select Extrusion from the list.
create an associative 3D freeform space tool (associative spaces only)	select Freeform from the list.

If you want to...	Then...
create multiple space types with the tool	select Undefined (--) from the list.

Defining the space height in the space tool

21 If you are creating a space tool for a 3D space, you can enter parameters for the space height.

NOTE If you want to create spaces of different heights with this tool, you can leave all the settings as Undefined (--).

If you want to...	Then...
specify the overall height of the space, including floor to ceiling height, ceiling and floor thickness, and space above ceiling and below floor	enter a value for Overall space height.
specify the ceiling height of the space	enter a height value.
specify a floor thickness	enter a value for Floor thickness.
specify a ceiling thickness	enter a value for Ceiling thickness.
specify the distance between the top of the space ceiling to the top of the space	enter the appropriate value for Height above ceiling.
specify the distance between the bottom of the space floor and the bottom of the space	enter the appropriate value for Height below floor.
specify the combined height of ceiling height, ceiling thickness, and height above ceiling	enter a value for Default surface height.

22 Select one of the following options for Justification to specify the vertical position of the space insertion point relative to the space:

- Top of floor
- Bottom of floor
- Bottom of space below floor (available only if the height of the space below the floor is bigger than 0.)

Defining target dimensions in the space tool

23 Expand Actual Dimensions.

NOTE The settings for target dimensions of a space are visible only if you have selected Insert as the Create type. Rectangular and polygonal spaces do not observe target dimensions. The range of values allowed here depends on the target dimensions defined in the space style.

24 To specify the geometry of the space within the boundaries of the target dimensions on screen, select Yes for Specify on Screen.

To specify the geometry of the space by entering values in the Properties palette, select No for Specify on Screen.

25 Specify which dimension of the space should be constrained during insertion:

If you want to...	Then...
fix the area value during insertion	select Area for Constrain. This lets you change the length and width of the space, but only within the range of the target dimensions. For example, if you constrain the area to 9m ² , you can still choose to make both length and width 3m, or to make the length 4m, and the width 2.25 meters, as both combinations result in an area of 9 m ² .
fix the length during insertion	select Length for Constrain. If you constrain the length of a space, then any change to the space area will only change the width dimension of the space, and vice versa.
fix the width during insertion	select Width for Constrain. If you constrain the width of a space, then any change to the space area will only change the length dimension of the space, and vice versa.
do not fix a specific dimension during insertion	select *NONE* for Constrain. In this case no individual dimension is constrained, and you can specify any geometry as long as it is within the target dimensions.

26 If you selected No for Specify on screen, enter values for the non-constrained dimensions for Base Area, Length, and Width.

27 If you have selected to generate a 3D freeform space, define the 2 calculation cut planes under Advanced Dimensions.

28 Click OK.

Editing General Space Properties

These general properties of a space can be edited for all space types:

Renaming a Space

Use this procedure to rename a space.

- 1** Double-click the space you want to rename.
- 2** On the Properties palette, expand Basic, and expand General.
- 3** For Name, do one of the following:
 - If a list definition has been attached to the space style, select a name from the list.
 - If no list definition has been attached to the space style, enter a name in the Name field. For more information, see [List Definitions](#) on page 2051.

Changing the Style of a Space

Use this procedure to assign a different space style to a space. The space style defines the list definition used, boundary offsets, and the display properties of the space. For more information, see [Space Styles](#) on page 2039.

- 1 Double-click the space you want to change.
- 2 On the Properties palette, select a new style for Style.

When you change the space style, and the new space style has a different list definition in which the existing space name is not contained, it is possible that the existing space name is deleted and the space name defaults to the first name in the new list definition.

For more information, see [List Definitions](#) on page 2051.

Changing the Location of a Space

Use this procedure to relocate a space by changing the coordinate values of its insertion point. The space also has an orientation with respect to the world coordinate system (WCS) or the current user coordinate system (UCS). For example, if the top and bottom of the space are parallel to the *XY* plane, its normal is parallel to the *Z* axis. You can change the orientation of the space by aligning its normal with another axis. You can also rotate the space on its plane by changing the rotation angle.

NOTE This procedure is valid only for non-associative spaces. The location of an associative space is determined by its boundary objects.

For information about moving individual space boundaries, see [Changing the Location of a Space Boundary](#) on page 1988.

For more information about the WCS and the UCS, see “Use Coordinates and Coordinate Systems” in AutoCAD Help.

- 1 Double-click the space you want to change.
- 2 On the Properties palette, expand Basic, and expand Location.
- 3 Click Additional information.
- 4 On the Location worksheet, specify the location of the space:

If you want to...

Then...

relocate the space

enter new coordinate values for Insertion Point.

locate the space on the *XY* plane

make the normal of the space parallel to the *Z* axis:
for Normal, enter **1** for *Z*, and enter **0** for *X* and *Y*.

locate the space on the *YZ* plane

make the normal of the space parallel to the *X* axis:
for Normal, enter **1** for *X* and enter **0** for *Y* and *Z*.

locate the space on the *XZ* plane

make the normal of the space parallel to the *Y* axis:
for Normal, enter **1** for *Y*, and enter **0** for *X* and *Z*.

change the rotation of the space

enter a new value for Rotation Angle.

- 5 Click OK.

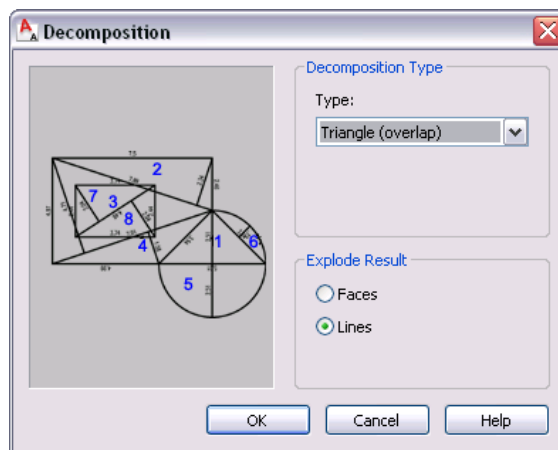

Specifying the Decomposition Type for a Space

Use this procedure to specify the type of subtentities into which a space is decomposed and the type of AutoCAD entities into which the decomposed space is converted when exploded.

- 1 Double-click the decomposed space.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all space decompositions in the drawing, select Drawing default setting. To apply changes to all space decompositions of this style, select Space Style:<style name>. For more information on styles, see [Space Styles](#) on page 2039.

- 5 For Display representation, verify that Decomposed is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.
- 7 Click  Decomposition.

- 8 Under Decomposition Type, select an option for Type:

If you want to...	Then...
display a trapezoid decomposition	select Trapezoid.
display a triangular decomposition without overlapping triangles	select Triangle.
display a triangular decomposition with overlapping triangles	select Triangle (overlap).

- 9 Under Explode Result, select an option:

If you want to...	Then...
change the decomposed space into single lines after exploding	select Lines.

If you want to...	Then...
change the decomposed space into closed polylines for each decomposed part	select Faces.

10 Click OK.

You can also access these option through the decomposed space's context menu, as follows:

- 1 Select the decomposition, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Decomposition tab, and then specify the options that you want.
- 5 Click OK twice.

Specifying the Decomposition Text Properties for a Space

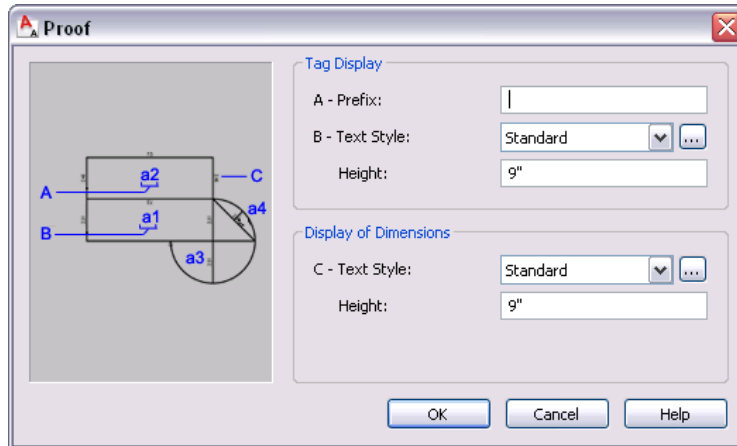

Use this procedure to specify the text properties for the tags and edge dimensions displayed for subentities in a space decomposition.

- 1 Double-click the decomposed space.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all space decompositions in the drawing, select Drawing default setting. To apply changes to all space decompositions of this style, select Space Style:<style name>. For more information on styles, see [Space Styles](#) on page 2039.

- 5 For Display representation, verify that Decomposed is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.

7 Click  Proof.

8 Under Tag Display, define the prefix settings:

If you want to...	Then...
display a prefix for the numbers of the space subdivisions	enter a prefix.
change the style of the numbers of the space subdivisions	either select a text style from the list or click the Browse button and create a new text style. For more information, see "Text Style Dialog Box" in AutoCAD Help.
change the height of the numbers in the space subdivisions	enter a value for Height.

9 Under Display of Dimensions, define the edge dimension settings:

If you want to...	Then...
change the style of the edge dimensions	either select a text style from the list or click the Browse button and create a new text style. For more information, see "Text Style Dialog Box" in AutoCAD Help.
change the height of the edge dimensions	enter a value for Height.

10 Click OK.

You can also access these option through the decomposed space's context menu, as follows:

- 1 Select the decomposition, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.

- 4 In the Display Properties dialog, click the Proof tab, and then specify these options as desired.
- 5 Click OK twice.

Specifying the Cut Plane Display of a Space

Use this procedure to specify the properties of one or more cut planes for an individual space. Cut plane display properties apply only to display representations, such as Plan, that are used in the Top view (plan view) of a drawing.

- 1 Double-click the space you want to change.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that *NONE* is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all spaces in the drawing, select Drawing default setting. To apply changes to all spaces of this style, select Space Style:<style name>. For more information on styles, see [Space Styles](#) on page 2039.

- 5 If necessary, expand Object Display Properties ► Cut Plane.
- 6 For Override cut plane, specify whether you want to override the global cut plane defined for the current display configuration.
- 7 If you selected Yes for Override cut plane, enter a value for Height to define the cut plane for this object. (Alternatively, you can click the value, click , and specify 2 points in the drawing area to define the new height.)

You can also access and modify these same cut plane settings through the space's context menu, as follows:

- 1 Select the space you want to change, right-click, and click Edit Object Display.
- 2 In the Object Display dialog, click the Display Properties tab.
The current display representation is displayed in bold.
- 3 Select the display representation where you want the changes to appear, and select Object Override. If Object Override is already selected, click  at the upper-right corner of the tab.
- 4 In the Display Properties dialog, click the Cut Plane tab, and then change the settings as needed.
- 5 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Space

Use this procedure to attach hyperlinks, notes, or files to a space. You can also edit hyperlinks and notes, and edit or detach reference files from a space.

- 1 Double-click the space to which you want to attach information.
- 2 On the Properties palette, click the Extended Data tab.
- 3 To add a hyperlink, click the setting for Hyperlink, and specify the link.
- 4 Click OK.
- 5 To add a note, click the setting for Notes, and enter the note.
- 6 Click OK.

7 To add a reference file, click the setting for Reference documents, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

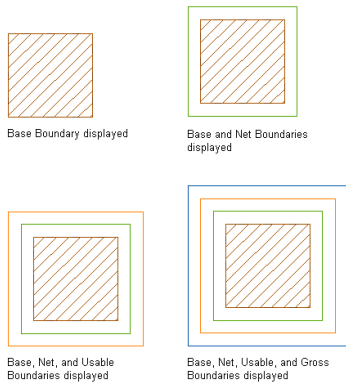

8 Click OK twice.

Working with Space Boundaries

Spaces have 4 different boundaries. You can use them to display, edit, and schedule different aspects of the space. You can choose that these boundaries are not offset from each other, and lie on top of each other. If you do not need different boundaries, you can even turn off the display components for the additional boundaries. Here are some typical use cases for using individual boundaries:

- **Base boundary:** Normally representing the inner area of a room covered by a space. This is the area generated by boundary objects in an associative space. In most cases, the base boundary is identical to the net boundary, except in some area calculation standards like the Swedish SIS standard.
- **Net boundary:** This boundary can be used for planning and detailed design. For example, if you need to determine the hiring of cleaning personnel for an office, you would use the net area as the calculation basis. The net boundary can also be used for special applications when the calculated area of a space is smaller than the base boundary.
- **Usable boundary:** This boundary is in many area calculation standards used for planning and detailed design, renting calculations, tax and other duty calculations, statistical calculations, maintenance, pricing, and more. The usable boundaries typically extend from the inside of the exterior walls to the middle of the interior walls (or a specified distance into the interior walls).

- **Gross boundary:** the gross boundary can be used in connection with cost calculation, price estimation, calculation of tax and other duties, key numbers for the building or a specific floor, and more. Normally, the gross boundary is measured from the outside of the exterior walls to the middle of the interior walls.

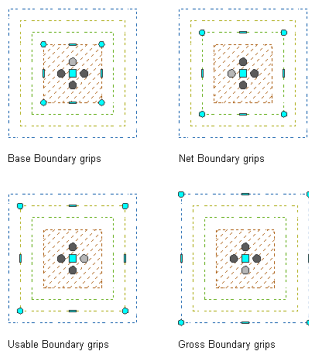

There are different ways to determine how the boundaries should be offset from each other and calculated:

- Manual
- By style
- By area calculation standard

Working with Manual Boundaries

You can define the boundaries of a space manually. Manual boundaries have grips to edit the boundary shape of each boundary. If you insert a new space with manual boundaries, by default the offsets between the boundaries are 0. To grip-edit manual boundaries, you first must activate the boundaries ([Activating Manual Space Boundaries](#) on page 1981) and then grip edit them ([Grip-Editing Space Boundaries](#) on page 1982).

Grip-editable manual boundaries

In a non-associative space with manual boundaries all 4 boundaries are grip-editable. In an associative space with manual boundaries, the net, usable, and gross boundaries are editable. The base boundary of an associative space is controlled by the boundary objects.

Working with Style-Based Boundaries

You can define the offsets between space boundaries in the space style ([Specifying Space Boundary Offsets in a Space Style](#) on page 2041.) In a non-associative space with style-based boundary offsets, you can grip-edit the base boundary only; the net, usable, and gross boundary are controlled by the style. In an associative space with style-based offsets, you cannot grip-edit any boundary. The base boundary is controlled by the boundary objects of the space, and the net, usable, and gross boundaries are controlled by the style.

Working with Boundaries Based on an Area Calculation Standard

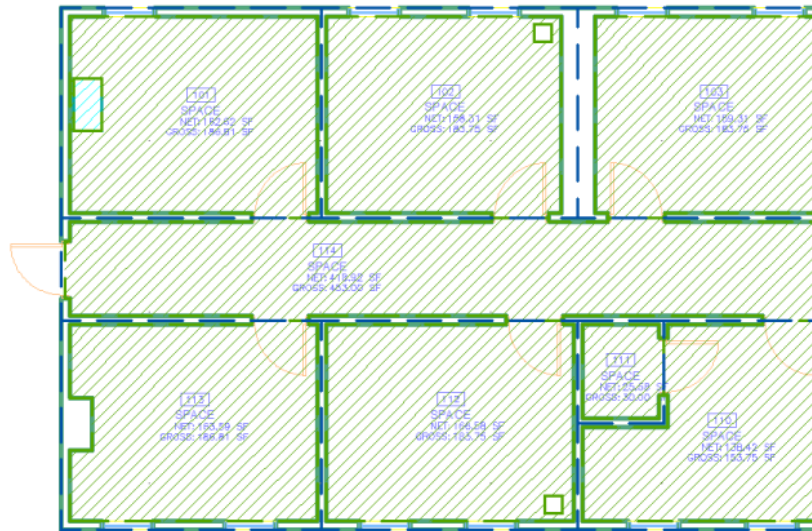

You can define the boundaries of a space by an area calculation standard specified in the drawing. The area calculation standard may consider the space's type, classification, location, and relation to other spaces when calculating the space's boundaries. For example if a room is bounded by an exterior wall, the area calculation standard may place the gross boundary of the space at the outside of the exterior wall. If a room is bounded by an interior wall, the area calculation standard may place the net boundary at the middle of the interior wall. In many cases, spaces need to be classified to have their offsets calculated correctly. For example, if a space is classified as Office Area using the BOMA area calculation standard, then its usable boundary is measured to the inside face of the wall if the adjacent space is classified as Common Floor Area. If the adjacent space is also classified as Office Area, the usable boundary is measured to the centerline of the wall.

To use an area calculation standard, you need to define it for your drawing, as described in [Specifying an Area Calculation Standard for a Drawing](#) on page 1977. For some standards you also need to classify spaces, as described in [Classifying a Space According to an Area Calculation Standard](#) on page 1978.

Standards shipped with AutoCAD Architecture include a general Basic standard, DIN-277, BOMA, and SIS. For more information, see [Appendix 2: Predefined Area Calculation Standards](#) on page 2114.

Only associative spaces may have their boundaries calculated by an area calculation standard. In a space with standard-based offsets, you cannot grip-edit any boundary. The base boundary is controlled by the

boundary objects of the space, and the net, usable, and gross boundaries are controlled by the area calculation standard.

Defining the Boundary Offset Type of a Space

Use this procedure to define how the boundaries of a space are offset. You can set the boundary offset type while creating a space or you can select an existing space and change the existing offset type.

For non-associative spaces, you can select manual and style-based offsets. For associative spaces, you can select manual, style-based, and calculation standard-based offsets.

Defining the boundary offset type of a new space

- 1 Select a space tool to create a space.
- 2 In the Properties palette, under Offset boundaries, select one of these boundary offset types:
 - Manual
 - By Style
 - By Standard
- 3 Proceed with creating the space as described in [Creating Non-Associative Spaces](#) on page 1958.

Changing the boundary offset type of an existing space

- 1 Select the space where you want to change the boundary calculation.
- 2 In the Properties palette, under Offset boundaries, select the desired boundary offset type. Depending on which type you choose, the boundaries can react in different ways:

Associativity	Switch from	Switch to	Effect
Non-associative	Manual	By Style	The net, usable, and gross boundaries are re-calculated according to the style offsets, and become non-editable. The base boundary remains unchanged and editable.

Associativity	Switch from	Switch to	Effect
Non-associative	By Style	Manual	The net, usable, and gross boundaries keep their offsets but become editable. The base boundary remains unchanged and editable.
Associative	Manual	By Style	The boundaries are re-calculated according to the style offsets, and become non-editable. The base boundary remains unchanged and non-editable.
Associative	Manual	By Standard	The boundaries are re-calculated according to the rules in the area calculation standard, and become non-editable. The base boundary remains unchanged and non-editable.
Associative	By Style	Manual	The net, usable, and gross boundaries keep their offsets but become editable. The base boundary remains unchanged and non-editable.
Associative	By Style	By Standard	The net, usable, and gross boundaries are re-calculated according to the rules in the area calculation standard. All boundaries remain non-editable.
Associative	By Standard	Manual	The net, usable, and gross boundaries keep their offsets but become editable. The base boundary remains unchanged and non-editable.
Associative	By Standard	By Style	The net, usable, and gross boundaries are re-calculated according to the offsets defined in the space style. All boundaries remain non-editable.

Specifying an Area Calculation Standard for a Drawing

Use this procedure to specify an area calculation standard for a drawing. The standard defines the calculation of the individual boundaries according to the rules of the chosen standard.

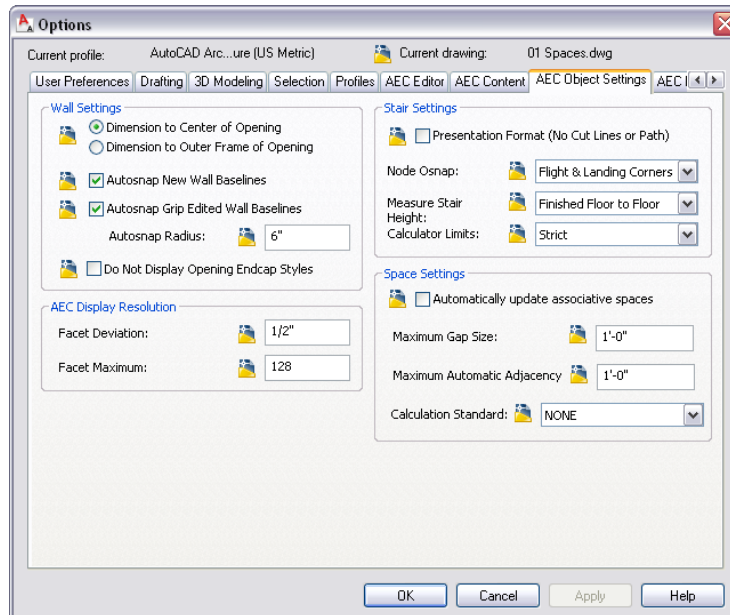

AutoCAD Architecture ships with a number of predefined area calculation standards based on the rules of these country-specific standards:

- BOMA standard (USA)
- DIN-277 standard (Germany)
- SIS standard (Sweden)

- Basic standard (Generic standard)

NOTE An area calculation standard can be used only for associative spaces. The boundaries of non-associative spaces can only be calculated in the space style or modified manually.

- 1 Click Format menu ► Options.
- 2 Click the AEC Object Settings tab.

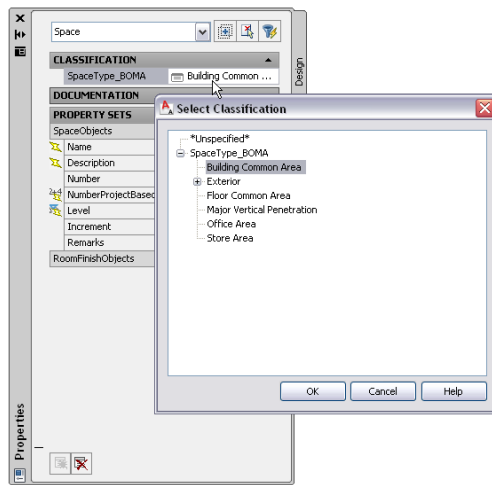

- 3 For Calculation Standard, select the area calculation standard you want to use when generating spaces from your floor plan.
- 4 Click OK.

TIP Alternatively, you can set the area calculation standard on the command line by entering **AecSpaceCalculationStandard**.

Classifying a Space According to an Area Calculation Standard

If you have generated a space that has its boundaries calculated by an area calculation standard, you may need to classify the space according to the selected standard, in order to provide the standard with the necessary information to calculate the boundaries. For example, the BOMA standard requires classifying spaces according to their space type, as the space type is relevant for determining boundary offsets.

- 1 Select a space that has its boundary calculation defined by an area calculation standard.
- 2 On the Properties palette, click the Extended Data tab.
- 3 For Classification, the classification definition belonging to the area calculation standard defined for this drawing is displayed.
For example, if you have selected the BOMA area calculation standard for your drawing, the BOMA classification definition is displayed.
- 4 Click the setting for the required classification type, and select a classification in the Select Classification worksheet.

5 Click OK.

Changing the Area Calculation Standard for Existing Spaces

If you have created a number of spaces in your drawing with an area calculation standard, and then change the area calculation standard for the drawing, the spaces get recalculated according to the rules of the new standard. The classification definition for the new area calculation standard is inserted in the drawing, but the space might need to get re-classified according to the new standard. For example, if you calculate your spaces according to the SIS standard, and classify a space as “Shaft”, and then re-calculate the spaces according to the BOMA standard, then the initial BOMA classification is set to “Unspecified.” You need to select a corresponding BOMA classification, like for example “Major Vertical Penetration.”

For more information, see [Specifying an Area Calculation Standard for a Drawing](#) on page 1977 and [Classifying a Space According to an Area Calculation Standard](#) on page 1978.

When a new area calculation standard is selected for the drawing, the classification definition for the previously used standard is not removed, but remains in the drawing. This can be helpful if you need to switch back and forth between different standards, and do not want to lose the classifications of the currently not active standard every time you switch.

If you know that you will not be using a certain standard anymore, you can delete its classification definition from Style Manager. To delete a classification definition, it must not be referenced by any objects. To remove the references to the classification standard, change all spaces that use a classification from this definition to *Unspecified*.

Working with Drawings with Different Area Calculation Standards

When you exchange drawings that contain spaces with boundary offsets calculated by an area calculation standard, the recipient of the drawing must have the same area calculation standard available in their version of AutoCAD Architecture. If you try to open the drawing in a version of AutoCAD Architecture where you cannot select that standard in the AEC Options page - meaning that this standard is not installed - all spaces will be drawn with a solution tip icon. To remedy this, copy the DLL for the necessary standard into \\Autodesk AutoCAD Architecture 2009\Space Calculation Standards\ folder. In AutoCAD Architecture DLLs for these 4 standards are included: Basic, BOMA, SIS, and DIN-277. The Basic standard is located directly in the application folder and should not be moved or deleted.

If you are working with spaces in external references, each space will use the boundary offsets and area calculation standard defined in its containing drawing. This can cause different boundary offsets to be used across a project, so you should verify that each drawing uses the same boundary offsets and area calculation standard.

User-Defined Area Calculation Standards

Each area calculation standard is written in a separate module using .NET. Each .NET module includes the space calculation method as well as generating the space classification. In AutoCAD Architecture there are 4 standards included: Basic, BOMA, SIS, and DIN-277. The .NET modules for BOMA, SIS, and SIN are in the folder `\\AutoCAD Architecture 2009\Space Calculation Standards\`. The Basic standard .NET module is located directly in the application folder and should not be moved or deleted. Users can create and use their own standards. For more information, see [Appendix 3: Implementing an Area Calculation Standard Plug-in with the AutoCAD Architecture .NET API](#) on page 2126.

Editing Space Boundaries

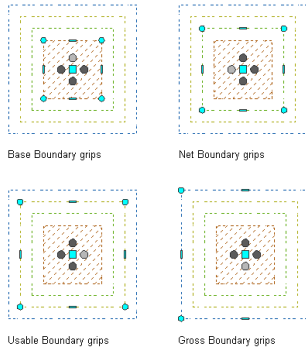

Spaces have 4 boundaries.

Depending on which type of space you have created and which boundary offset type you use, different boundaries can be edited with grips:

Space Type	Boundary Offset Type	Editable Boundaries
Associative	Manual	Net, Usable, Gross
Associative	By Style	None
Non-Associative 2D or extruded 3D	Manual	Base, Net, Usable, Gross
Non-Associative 2D or extruded 3D	By Style	Base
Non-Associative 3D Freeform	Manual	Net, Usable, Gross
Non-Associative 3D Freeform	By Style	None

IMPORTANT The net, usable, and gross boundaries of a space can only be displayed in plan views. In model views, only the base boundary and the base body of the space are displayed.

Editable boundaries of a space with manual offsets

Displaying Space Boundaries

By default, only the base boundary of a space is displayed. If you want to display or edit the net, usable, and gross boundaries, you need to make their display components visible.

For instructions on how to display the additional space boundaries in the space style, see [Specifying the Display Properties of a Space Style](#) on page 2045.

Activating Manual Space Boundaries

After making the net, usable, and gross boundaries visible, you need to activate them in order to be able to grip-edit them.

NOTE Activating a boundary is a precondition for any operation you want to perform on the boundary, like grip-editing or boolean operations.

1 If necessary, switch to a Plan view.

The net, usable, and gross boundaries of a space can only be activated and displayed in Plan views.

2 Select a space for which you want to display a boundary.

Activated boundary grips

3 Verify that Offset Boundaries in the Properties palette is set to Manual.

4 Use the trigger grip for the appropriate boundary to activate and deactivate the grip set.

Alternatively, you can right-click a space, click Edit Boundaries on the context menu, and then select a boundary from the submenu to activate or deactivate.

Grip-Editing Space Boundaries

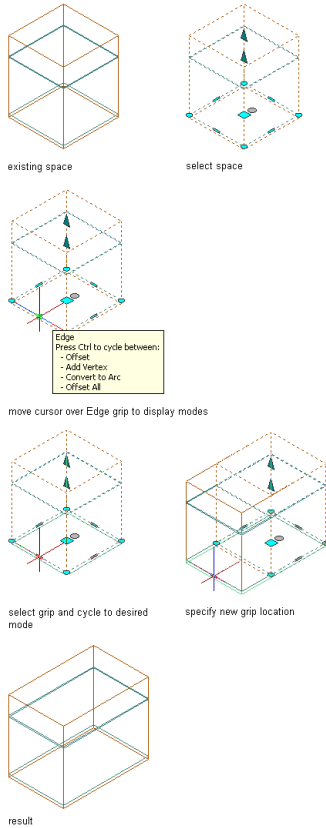

Use this procedure to edit a space using grips.

The Edge grip has 4 edit modes:

- **Offset:** This is the default. Use it to offset the selected edge in a direction perpendicular to the midpoint of the edge. Depending on the shape of the boundary and the edge, neighboring lines are extended or trimmed, and new lines are added as necessary.

Offsetting the edge of a space boundary using the Edge grip

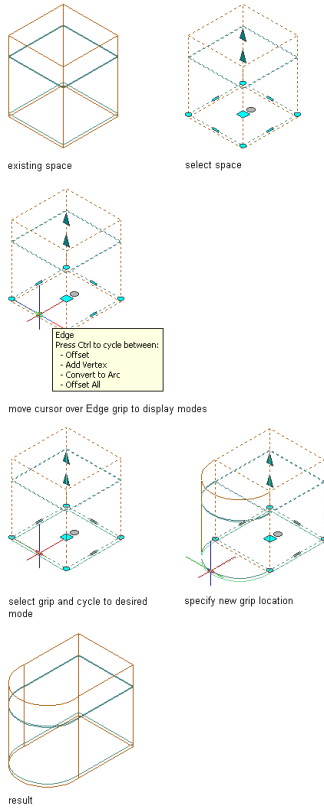

- **Add Vertex:** Use this edit mode to add a vertex to the selected edge, and create a new edge. If the selected edge is an arc, the new edge is also an arc.

Adding a vertex to the edge of a space boundary using the Edge grip

- **Convert to Arc:** Use this edit mode to convert the selected edge to an arc and stretch the midpoint of the arc. The edge grip for an arc also has a Stretch mode. You can use it to stretch the midpoint of the arc, thus increasing the size of the arc.

Converting the edge of a space boundary to an arc using the Edge grip

- **Offset all:** Use this option to move all edges of a space boundary an identical distance. When you drag one edge, all other edges are repositioned accordingly. This option is very useful for regular resizing operations, like scaling a space boundary.

Offsetting all edges of a space boundary using the Edge grip

Changing the edge of a space boundary

- 1 Activate the boundary where you want to change an edge.
- 2 Select the Edge grip for the edge you want to change.
- 3 Specify the new edge location:

If you want to...

Then...

offset the edge

move the edge to the desired location and click, or enter a value and press *ENTER*.

add a vertex and create an edge

press *CTRL* to switch to the Add Vertex edit mode. Move the edge to the desired location and click, or enter a value and press *ENTER*.

change a selected edge to an arc/change a selected arc to a line

press *CTRL* twice to switch to the Convert to Arc/Convert to Line edit mode. Stretch the midpoint to the desired location and click, or enter a value and press *ENTER*.

offset all edges at an identical distance

press *CTRL* 3 times to switch to the Offset All edit mode. Move the selected edge to the desired location for all edges and click, or enter a value and press *ENTER*.

4 Right-click, and click Deselect All to turn off grips.

Changing the vertex of a space boundary

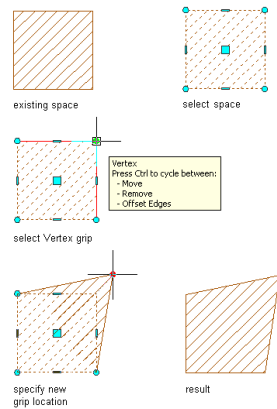

1 Activate the boundary where you want to change a vertex.

2 Select the Vertex grip for the vertex you want to change.

The Vertex grip has 3 edit modes:

- **Move:** This is the default. Use it to move the selected vertex in any direction. The neighboring segments are stretched if necessary.

Moving the vertex of a space boundary using the Vertex grip

- **Remove:** Use this edit mode to remove a vertex. The neighboring segments are replaced with a line.

Removing the vertex of a space boundary using the Vertex grip

- **Offset Edges:** Use this edit mode to move a vertex and the adjacent edges of the space boundary with it.

Offsetting edges of a space boundary using the Vertex grip

3 Edit the vertex as necessary:

If you want to...	Then...
move the vertex	move the vertex to the desired location and click; or enter a value, and press <i>ENTER</i> .
remove the vertex	press <i>CTRL</i> to switch to the Remove Vertex edit mode, and click to confirm the removal.
move the vertex and the adjacent edges	press <i>CTRL</i> twice to switch to the Offset Edges edit mode. Move the vertex to the desired location, and click; or enter a value, and press <i>ENTER</i> .

4 Right-click, and click Deselect All to turn off grips.

Resetting Manual Space Boundaries

Use this procedure to cancel all changes made by grip-editing the net, usable, or gross boundaries of a space. The boundaries will revert back to the geometry of the base boundary.

- 1 Select the space the boundaries of which you want to reset.
- 2 Right-click, and click Edit Boundary ► Reset.

Changing the Location of a Space Boundary

Use this procedure to move an individual space boundary to a different location with grips. You can move individual boundaries only if you have selected Manual for Offset boundaries.

For associative spaces, only the net, usable, and gross boundaries can be moved. The base boundary is tied to the boundary objects.

For information about moving a space with the location worksheet, see [Changing the Location of a Space](#) on page 1968.

- 1 Select the space for which you want to move an individual boundary.
- 2 Move a boundary as necessary:

If you want to...	Then...
move the entire space	move space to the desired location and click to release it.
move the base boundary of the space	click and hold the location grip, and press CTRL to switch to Move base boundary mode. Then move the base boundary to the desired location, and click to release it.
move the net boundary of the space	click and hold the location grip, and press CTRL twice to switch to Move net boundary mode. Then move the net boundary to the desired location, and click to release it.
move the usable boundary of the space	click and hold the location grip, and press CTRL 3 times to switch to Move usable boundary mode. Then move the usable boundary to the desired location, and click to release it.
move the gross boundary of the space	click and hold the location grip, and press CTRL 4 times to switch to Move gross boundary mode. Then move the gross boundary to the desired location, and click to release it.

Changing the Type of a Space

You can change an extruded 3D space to a 2D space, or to a 3D freeform space, and vice versa. You can also make a non-associative space associative to boundary objects or disconnect an associative space from its boundary objects. Each of these operations will change editable properties of the space and the user interaction. The following table shows the results of changing a space from one geometry type to another.

Original Geometry Type	New Geometry Type	Result
Non-associative 2D	Non-associative extruded 3D	<ul style="list-style-type: none"> ■ Editable properties for the space height and space justification are added. The insertion point and justification of the space will be set to the top of the floor.

Original Geometry Type	New Geometry Type	Result
		<ul style="list-style-type: none"> ■ Surface editing is enabled.
Non-associative 2D	Non-associative 3D freeform	<ul style="list-style-type: none"> ■ Editable properties for a subset of the space height are added. ■ Editable properties for calculation cut planes are added. ■ Surface editing is enabled. ■ Length and width properties become non-editable.
Non-associative 2D	Associative 2D	<ul style="list-style-type: none"> ■ Length, width, rotation, and elevation become dependent on the boundary objects and are not editable anymore. ■ Base boundary becomes dependent on boundary objects and is not grip-editable anymore.
Non-associative 2D	Associative extruded 3D	<ul style="list-style-type: none"> ■ Length, width, rotation, and elevation become dependent on the boundary objects and are not editable anymore. ■ The insertion point and justification of the space will be set to the top of the floor. ■ Editable properties for the space height and space justification are added. ■ Base boundary becomes dependent on boundary objects and is not grip-editable anymore.
Non-associative 2D	Associative 3D freeform	<ul style="list-style-type: none"> ■ Length, width, rotation, and elevation become dependent on the boundary objects and are not editable anymore. ■ Editable properties for a subset of the space height are added. ■ Editable properties for calculation cut planes are added. ■ Base boundary becomes dependent on boundary objects and is not grip-editable anymore.
Non-Associative Extruded 3D	Non-Associative 3D Freeform	<ul style="list-style-type: none"> ■ Overall space height property can only be edited by in-place editing the space geometry. Properties for Default surface height and space justification are not available. ■ Length and width properties can only be edited by in-place editing of space geometry. ■ Editable properties for calculation cut planes are added.
Non-Associative Extruded 3D	Associative extruded 3D	<ul style="list-style-type: none"> ■ Length, width, rotation, and elevation become dependent on boundary objects and are not editable anymore. ■ Surface editing is disabled.

Original Geometry Type	New Geometry Type	Result
		<ul style="list-style-type: none"> ■ Base boundary becomes dependent on boundary objects and is not grip-editable anymore.
Non-Associative Extruded 3D	Associative 3D Freeform	<ul style="list-style-type: none"> ■ Overall space height, length, width, rotation, and elevation become dependent on boundary objects and are not editable anymore. Properties for Default surface height and space justification are not available. ■ Editable properties for calculation cut planes are added. ■ Surface editing is disabled. ■ Base boundary becomes dependent on boundary objects and is not grip-editable anymore.
Non-Associative 3D freeform	Associative 3D Freeform	<ul style="list-style-type: none"> ■ Rotation and elevation become dependent on boundary objects and are not editable anymore. ■ Surface editing is disabled.

Space types with grips

Use this procedure to change the type of a space.

- 1 Select the space for which you want to change the geometry type, and double-click to display the Properties palette.
- 2 Expand Basic, and expand Component Dimensions.
- 3 For Geometry type, select the desired geometry.
- 4 For information on changing the associativity of a space, see [Making a Space Associative or Non-Associative](#) on page 1952.

Changing the Space Height

Depending on the geometry type of a space various of its height properties can be edited.

Changing the Height of Extruded 3D Spaces

Use this procedure to change the height of an extruded 3D space. An extruded space is not constrained in the z-direction, and all height components are user-definable. The sum of all components' heights is the overall space height.

NOTE This procedure is valid for associative and non-associative spaces.

- 1 Double-click the space for which you want to change a height component.
- 2 On the Properties palette, expand Basic, and expand Component Dimensions.
- 3 Modify the height of the space:

If you want to...

Then...

specify the overall height of the space, including floor to ceiling height, ceiling and floor thickness, and space above ceiling and below floor

enter a value for Overall space height.

specify the ceiling height of the space

enter a height value. The value you enter here is applied uniformly to the space.

specify a floor thickness

enter a value for Floor thickness.

specify a ceiling thickness

enter a value for Ceiling thickness.

specify the distance between the top of the space ceiling to the top of the space

enter the appropriate value for Height above ceiling.

specify the distance between the bottom of the space floor and the bottom of the space

enter the appropriate value for Height below floor.

specify the combined height of ceiling height, ceiling thickness, and height above ceiling

enter a value for Default surface height.

Changing the Height of 3D Freeform Spaces

In a 3D freeform space, the overall space height is determined either by the boundary objects in an associative space, or by the height of the 3D geometry in a non-associative space. Within the overall space height, you can change the height of individual components, but they will not add or subtract from the overall space height. For example, if you increase the height above the ceiling, then the ceiling height is lowered in return.

These additional restrictions apply to changing the height of a 3D freeform space:

- You can change the ceiling thickness and the height above the ceiling. However, if the ceiling thickness is set to 0, the height above ceiling is 0 and read-only.
- You can change the floor thickness and the height below the floor. However, if the floor thickness is set to 0, the height below floor is 0 and read-only.
- If both ceiling thickness and floor thickness are 0, the ceiling height is read-only.
- The justification of a 3D freeform space is always set to Top of Floor.
- If you put the bottom of the ceiling to the same height as the top of the space, then the ceiling is situated above the actual bounded volume, and will not be drawn. You cannot, however put the bottom of the ceiling above the top of the space.
- If you put the top of the floor to the same height as the bottom of the space, then the floor is situated below the actual bounded volume, and will not be drawn. You cannot, however put the top of the floor below the bottom of the space.
- The ceiling height of a 3D freeform space ranges from the bottom of the ceiling to the top of the floor. In cases where the ceiling and floor are set to 0, the ceiling height ranges from the top of the space to the bottom of the space.

Changing the overall height of a 3D freeform space

This procedure is valid only for non-associative spaces.

- 1 Select a 3D freeform space for which you want to change the overall height, right-click, and click Edit in Place.
- 2 Select the surface grip for the top surface, and drag it to the desired height.
- 3 Changing the height of a 3D freeform space

- 4 To save the changes to the space height, click  on the In-Place Edit toolbar.

Changing the height of individual components of a 3D space

This procedure is valid for associative and non-associative spaces.

- 1 Select the 3D freeform space for which you want to change individual height components.
- 2 On the Properties palette, expand Basic, and expand Component Dimensions.
- 3 Modify the height components of the space:

If you want to...	Then...
specify the ceiling height of the space	enter a height value. The value you enter here is applied uniformly to the space.
specify a floor thickness	enter a value for Floor thickness.
specify a ceiling thickness	enter a value for Ceiling thickness.
specify the distance between the top of the space ceiling to the top of the space	enter the appropriate value for Height above ceiling.
specify the distance between the bottom of the space floor and the bottom of the space	enter the appropriate value for Height below floor.

Changing the Height of Space Surfaces (Extruded 3D Spaces)

Use this procedure to grip-edit the height of an individual surface of an extruded 3D space.

NOTE This procedure is valid for associative and non-associative spaces.

- 1 Verify that you are working in a 3D isometric view.
- 2 Select the extruded 3D space for which you want to change the height of a surface, and click the Edit Surfaces grip.
- 3 Select the Surface Height grip for the surface you want to edit, and drag it to the desired height or enter a value for the height.

TIP If you can move the height grip for a surface, but do not see the resulting changed surface, the Surfaces display component might have been turned off either in the space style or in the object display properties. For information about making the component visible, see [Specifying the Display Properties of a Space Style](#) on page 2045.

Boolean Operations for Extruded 3D Spaces

There are a number of boolean operations to change the geometry of an extruded 3D space.

Creating Interference Conditions for Spaces

Use this procedure to place objects such as mass elements in a space in order to create custom openings or cutouts. For example, a column grid structure might have columns within the space. Once defined as interference conditions, the columns cut out an area at the floor and ceiling of the space.

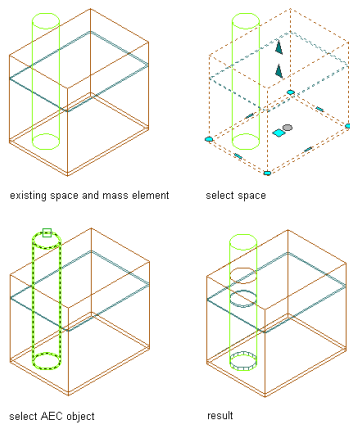

NOTE This procedure is valid for associative and non-associative spaces.

Any AEC object that has a 3D geometry can be used as an interference condition, as can AutoCAD polylines.

NOTE Interference conditions are deducted from the base volume of a space. You can add the automatic property Base Area Minus Interference to schedule the value of the area with without the interference condition.

When another object, such as a ceiling grid, is attached to a space object, it recognizes the interference condition. For example, if you add a column to the space as an interference condition, as long as the ceiling

grid is anchored to the space object, the ceiling grid is cut. If you move the column, the ceiling grid is updated with the new column location.

Adding an interference condition to a space

- 1 Place the object you want to use as the interference condition in a location intersecting the space as needed.
- 2 Select the space to which you want to add the interference condition, right-click, and click Interference Condition ► Add.
- 3 Select the objects intersecting the space as the interference condition, and press *ENTER*.

Removing Interference Conditions from Spaces

Use this procedure to remove interference conditions from spaces.

NOTE This procedure is valid for associative and non-associative spaces.

- 1 Select the space with the interference condition, right-click, and click Interference Condition ► Remove.
- 2 Select the object(s) functioning as the interference condition, and press *ENTER*.

Merging Extruded 3D Spaces

Use this procedure to merge 2 or more 3D spaces in a drawing. When you merge spaces that overlap each other, their boundaries are combined to form the boundaries of the merged space.

NOTE This procedure is valid for non-associative spaces.

You can merge a non-associative 3D freeform space into a 2D space or extruded 3D space. In that case, the base profile of the 3D freeform space is used for the merge. You cannot merge a 2D or extruded 3D space into a 3D freeform space.

The following properties of the first selected space are applied to subsequent spaces merged into it:

- Name
- Description
- Layer

- Style
- Tag
- Calculation modifiers
- Zone attachments
- Space height
- Floor thickness
- Ceiling thickness
- Height above ceiling
- Height below floor
- Default Surface height
- Justification
- Boundary offset type
- Rotation
- Display properties
- Schedule properties

Merging Spaces with Manual Boundary Offsets

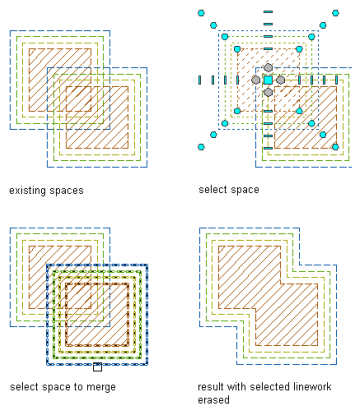

If you merge spaces that have manual boundary offsets, each activated boundary on the first space is merged with the corresponding boundary on the other space (base with base, net with net, and so on).

If a manual space boundary on the first space is not activated (displaying its grips), it is not included in the merge operation. Whether the boundaries on the second space are activated is not relevant for the merge. They are merged if their corresponding boundary on the first space is activated. If a boundary on the first space is not activated, the existing boundary on the first space will remain as it is, and the corresponding boundary on the second space will be deleted. This can result in irregular space boundaries. To avoid this, make sure that on the first space all relevant boundaries are activated, and can be merged.

For information on activating manual space boundaries, see [Activating Manual Space Boundaries](#) on page 1981.

The display properties of the boundaries of the first selected space are applied to the resulting merged boundary. For example, if the net boundary of the first space is red with a lineweight of 0.18 mm, the net boundary of the resulting merged space will be red with a lineweight of 0.18 mm.

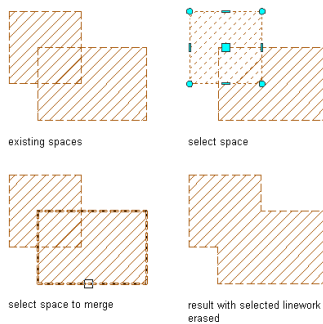

Merging spaces with manual boundaries

Merging Spaces with Style-Defined Boundary Offsets

If you merge spaces with style-defined boundary offsets, the base boundaries of both spaces are merged, and the boundary offsets defined in the style of the first space are applied to the resulting merged space.

Merging spaces with style-defined boundaries

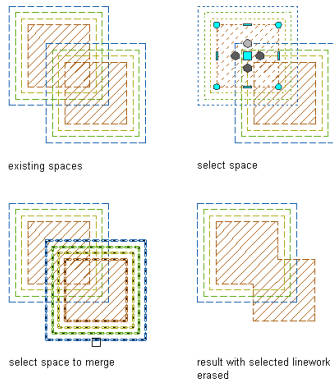

Merging Spaces with Different Boundary Offsets

If the space boundaries of the merging spaces are determined by different methods, the method used for the first selected space is used for the resulting space.

Example 1: The boundaries of the first space are offset by style, and the style defines an offset between boundaries of 0.25 m. The boundaries of the second space are offset manually, and have 0 offset between the individual boundaries. If the first space is merged with the second space, the boundaries previously belonging to the second space are recalculated by the style of the first space, and offset from each other by 0.25 m.

Merging spaces with different boundary offset types

Example 2: The boundaries of space 1 are offset manually, and have 0.3 offset between the individual boundaries. The boundaries of space 2 are offset by style, and the style defines an offset between boundaries of 0.25 m. If space 1 is merged with space 2, the value of the Offset boundaries property for the resulting space will be Manual. Since the net, usable, and gross boundaries of a space with style-based offsets are not grip-editable, only the base boundaries of both spaces will be merged. The boundaries of the second space are deleted from the drawing.

- 1 Select one of the spaces to be merged, right-click, and click AEC Modify Tools ► Merge.
- 2 Select the space to merge with the first space.

NOTE You can merge only those spaces that lie on the same Z-plane. Spaces with different Z-positions in the same coordinate system cannot be merged.

- 3 Enter **y** (Yes) to erase the second space or **n** (No) to leave the space in the drawing.

Dividing Extruded 3D Spaces

Use this procedure to divide an extruded 3D space into smaller spaces by using a divide line. The space is split at the line.

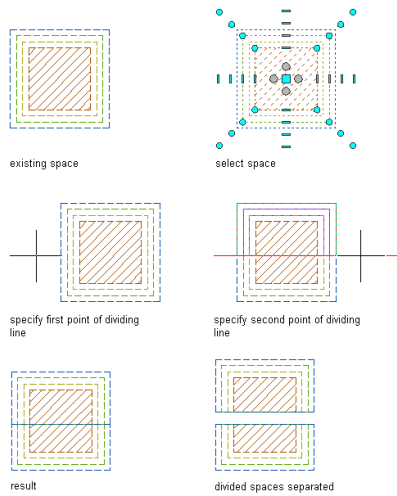

NOTE This procedure is valid for non-associative spaces only.

All properties - like for example property data, calculation modifiers, or boundary offset types - will be applied to both resulting spaces.

IMPORTANT If you are dividing a space with manual boundary offsets, verify that the all boundaries are activated. Boundaries that are not activated are not divided. For information about activating manual boundaries, see [Activating Manual Space Boundaries](#) on page 1981.

- 1 Select a space to divide, right-click, and click AEC Modify Tools ► Divide.
- 2 Specify the divide line start point.
- 3 Specify the divide line endpoint.

Depending on the boundary offset type, the divide line will create different results for the net, usable, and gross, boundaries.

Creating Holes in Extruded 3D Spaces

Use this procedure to subtract extruded 3D spaces from one another in order to create a hole in a space.

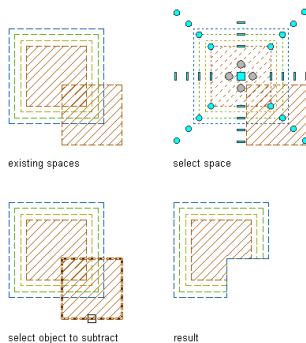

NOTE This procedure is valid for non-associative spaces only.

To create a hole, you need to select spaces that intersect one another. Alternatively, you can select a closed polyline as the shape to subtract. You can choose whether to keep the subtracted space or polyline in the drawing as a separate unit. For example, you may want to keep the space if you need to subtract the same shape from other spaces.

When you subtract one space from another, the base boundary of the subtracted space is subtracted from all boundaries of the first space. The other boundaries of the subtracted space are just deleted without interacting with the first space. Depending on whether the first space has style-defined offsets or manual offsets, the boundaries around the hole are either re-calculated according to the style offsets or cut off at the intersection.

IMPORTANT Before subtracting a space from another space with manual boundary offsets, verify that all boundaries you want to be cut are activated. If a boundary is not activated, the hole will not cut through it. For information about activating manual boundaries, see [Activating Manual Space Boundaries](#) on page 1981.

Subtracting spaces with style-defined boundary offsets

Subtracting spaces with manual boundary offsets

- 1 Create a space in which to create a hole.
- 2 Create a second, smaller space to be subtracted from the larger space.
You can draw the second space within or overlapping the first space, or you can draw it in another location and then move it onto the larger space.
Alternatively, you can select a closed polyline to subtract from the space.
- 3 Select the larger space, right-click, and click AEC Modify Tools ► Subtract.
- 4 Select the smaller space to subtract from the larger space.
- 5 Enter **y** (Yes) to erase the subtracted space, or **n** (No) to leave the space in the drawing.

Creating Spaces from the Intersection of Other Spaces

Use this procedure to create a new extruded 3D space from the overlapping portion of 2 intersecting extruded 3D spaces. You can choose whether to retain the original geometry after creating the new intersection space.

NOTE This procedure is valid for non-associative spaces only.

When a space is created from 2 intersecting spaces, the following properties of the first selected space are applied to the resulting intersection space:

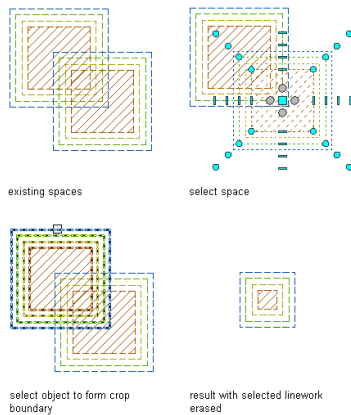

- Name
- Description
- Layer
- Style
- Tag
- Calculation Modifiers
- Zone attachments
- Space height
- Floor thickness
- Ceiling thickness
- Height above ceiling

- Height below floor
- Default surface height
- Justification
- Boundary offset type
- Rotation
- Display properties
- Schedule properties

Intersecting Spaces with Manual Boundary Offsets

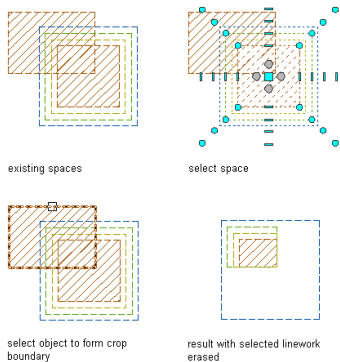

If you intersect spaces with manual boundary offsets, each activated space boundary is intersected with the corresponding space boundary on the other space (base to base, net to net, and so on.)

Intersecting spaces with all boundaries activated

If a manual space boundary on the first space is not activated (displaying its grips), it is not included in the intersecting operation. This will effect the existing boundary on the first space to remain as it is, and the corresponding boundary on the second space to be deleted. This can result in irregular space boundaries. To avoid this, make sure that all relevant boundaries on the first space are activated.

Intersecting spaces with only base boundary activated

For information on activating manual space boundaries, see [Activating Manual Space Boundaries](#) on page 1981.

The display properties of the boundaries of the first selected space are applied to the resulting intersection boundary. For example, if the net boundary of space 1 is red with a lineweight of 0.18 mm, the net boundary of the resulting space will be red with a lineweight of 0.18 mm.

Intersecting Spaces with Style-Defined Boundary Offsets

If you intersect spaces with style-defined boundary offsets, the base boundaries of both spaces are intersected with each other, and the boundary offsets defined in the style of the first space are applied to the resulting intersection space.

Intersecting spaces with style-defined boundary offsets

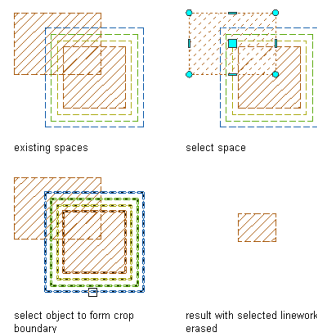

Intersecting Spaces with Different Boundary Offsets

If the space boundaries of the 2 spaces are calculated with different offset types, the method used by the first selected space is also used for the resulting space.

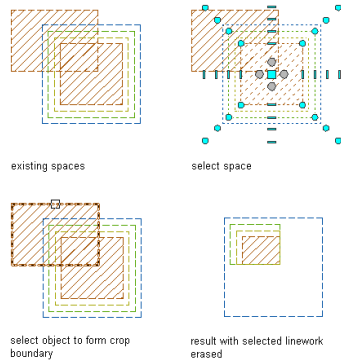

Example 1: The boundaries of space 1 are offset by style, and the style defines an offset between boundaries of 0.25 m. The boundaries of space 2 are offset manually, and have 0 offset between the individual boundaries. If space 1 is intersected with space 2, the base boundaries of the 2 spaces are intersected with each other, and the remaining boundaries are recalculated by the offsets of the style of space 1, and offset from each other by 0.25 m.

Intersecting style-based boundaries (left) with manual boundaries (right)

Example 2: The boundaries of space 1 are offset manually, and have 0.3 offset between the individual boundaries. The boundaries of space 2 are offset by style, and the style defines an offset between boundaries of 0.25 m. If space 1 is merged with space 2, the value of the Offset boundaries property for the resulting space will be Manual. Since the net, usable, and gross boundaries of a space with style-based offsets are not grip-editable, only the base boundaries of both spaces will be intersected. The boundaries of the second space are deleted from the drawing.

Intersecting manual boundaries (left) with style-based boundaries (right)

- 1 Create 2 overlapping spaces.
- 2 Select the first overlapping space, right-click, and click AEC Modify Tools ► Crop.
- 3 Select the second overlapping space.
- 4 Enter **y** (Yes) to erase the original spaces, or **n** (No) to leave the spaces in the drawing.

Trimming an Extruded 3D Space

Use this procedure to trim an extruded 3D space with a trim line.

NOTE This procedure is valid for non-associative spaces only.

IMPORTANT If you are trimming a space with manual boundary offsets, verify that the all boundaries are activated. Boundaries that are not activated are not trimmed. For information about activating manual boundaries, see [Activating Manual Space Boundaries](#) on page 1981.

Trimming spaces with different boundary offset types

- 1 Select the space to be trimmed, right-click, and click AEC Modify Tools ► Trim.
- 2 Specify a start point for the trim line.
- 3 Specify an endpoint for the trim line.
- 4 Select the side of the space to be trimmed.

Removing Voids from Spaces

Use this procedure to remove individual voids from a space with multiple rings.

NOTE This procedure is valid for non-associative 2D and extruded 3D spaces only.

Voids can be created in the following cases:

- You cut a hole in a space as described in [Creating Holes in Extruded 3D Spaces](#) on page 2000.
- You generate a space from boundary objects that have interference objects within their boundaries. For example, you can generate a space for a room with a row of columns in it. In that case, the boundaries for the room would be defined as the outer space ring and the columns would be deducted as holes from the generated room. If you deactivate the associativity of the space, you can remove the resulting space rings.

- A legacy multi-ring area is converted to a space using the current software.

- 1 Select a space with voids, right-click, and click Remove Void.
- 2 Select the void you want to remove from the space.
The void is removed.
- 3 Press *ENTER*.

Reversing Space Rings

Use this procedure to reverse the value of an individual space ring, so that a positive ring (space) can be transformed into a negative ring (hole), or a negative ring back into a positive ring.

NOTE This procedure is valid for non-associative 2D and extruded 3D spaces only.

Multi-level space rings are most likely to occur in legacy area objects that have been converted to spaces.

- 1 Select a space of which you want to reverse a ring.
- 2 On the command line, enter **SpaceReverseRing**.
- 3 Select the space ring you want to reverse.

Reversing All Rings in a Space

Use this procedure to reverse all rings of a space at once.

NOTE This procedure is valid for non-associative 2D and extruded 3D spaces only.

When you reverse the space rings, all positive rings are transformed into negative rings and all negative rings are transformed into positive rings.

Reversing the value of all space rings may be desirable for legacy area objects that have been converted to spaces.

- 1 Select the space you want to reverse.
- 2 On the command line, enter **SpaceReverseProfile**.
- 3 Select further spaces for reversing.
- 4 Press *ENTER* to end your selection.

Boolean Operations for 3D Freeform Spaces

You can change the shape of a 3D freeform space by in-place editing the surfaces of the space.

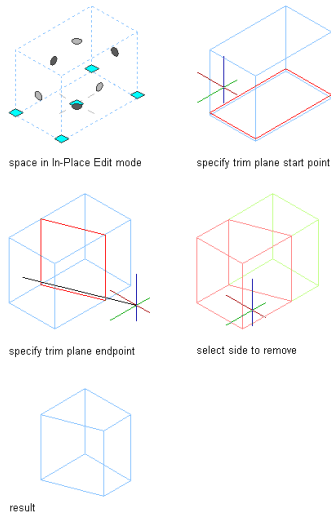

NOTE When you start an in-place edit operation on an extruded 3D space, it is automatically converted to a 3D freeform space. You can convert it back to an extruded 3D space once you have finished editing it, but you will lose any geometry changes that are not compatible with extruded 3D spaces.

Trimming 3D Freeform Spaces

You can trim a part of an existing 3D freeform space by trimming one of its surfaces.

NOTE This procedure is valid for non-associative spaces only. If you perform it on an associative space, it will lose associativity after exiting the in-place edit mode.

Trimming a 3D space

- 1 Verify that you are working in a 3D isometric view.
- 2 Select the space you want to trim along the horizontal or vertical plane, right-click, and click Edit in Place.

3D space (left) in in-place editing mode (right)

- 3 Re-select the space, right-click, and click Trim by Plane.
- 4 Specify the trim plane either on screen or by entering 3 points on the command line.

TIP Use a Front view to generate a horizontal trim plane and a Plan view to generate a vertical trim plane.

- 5 To save the changes to the space, click  on the In-Place Edit toolbar.

Splitting Surfaces of 3D Freeform Spaces

You can split a surface of a 3D freeform space. This is useful when you need to change the geometry of only one part of a space surface, as when creating a cable channel in a space ceiling.

NOTE This procedure is valid for non-associative spaces only. If you perform it on an associative space, it will lose associativity after exiting the in-place edit mode.

Splitting a surface

- 1 Select the space where you want to split a surface, right-click, and click Edit in Place.
3D space (left) in in-place editing mode (right)

- 2 Re-select the space, right-click, and click Split Face.
- 3 Select the start point of the splitting line.
- 4 Select the endpoint of the splitting line.

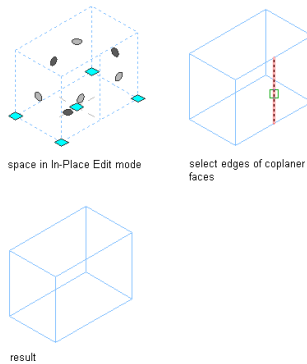

- 5 To save the changes to the space, click  on the In-Place Edit toolbar.

Joining Surfaces of 3D Freeform Spaces

Use this procedure to join 2 previously split surfaces of a 3D freeform space.

NOTE This procedure is valid for non-associative spaces only.

Joining 2 space surfaces

- 1 Verify that you are working in a 3D isometric view.

2 Select the space where you want to join 2 surfaces.

3 Right-click, and click Edit in Place.

3D space (left) in in-place editing mode (right)

4 Re-select the space, right-click, and click Join Faces.

5 Select the edge separating the 2 surfaces, and press ENTER.

6 To save the changes to the space, click  on the In-Place Edit toolbar.

Merging 3D Freeform Spaces with AEC Objects

Use this procedure to merge a 3D freeform space with a space or other AEC object. You can merge a 3D freeform space with all AEC objects that have a 3D geometry.

NOTE This procedure is valid for non-associative spaces only. If you perform it on an associative space, it will lose associativity after exiting the in-place edit mode.

1 Switch to a 3D isometric view.

2 Select the 3D freeform space you want to merge with another object, right-click, and click Edit in Place.

3 When you are in in-place editing mode, select the space again, right-click, and click Boolean ► Union.

4 Select the AEC object you want to merge with the 3D freeform space, and press Enter.

5 Enter **y** (Yes) to erase the merged-in object, or **n** (No) to leave the object in the drawing.

Merging an extruded space to a freeform space

existing extruded and freeform spaces

freeform space in in-place editing mode

select object to union

result with layout geometry erased

result with layout geometry retained

6 To save the changes to the space, click  on the In-Place Edit toolbar.

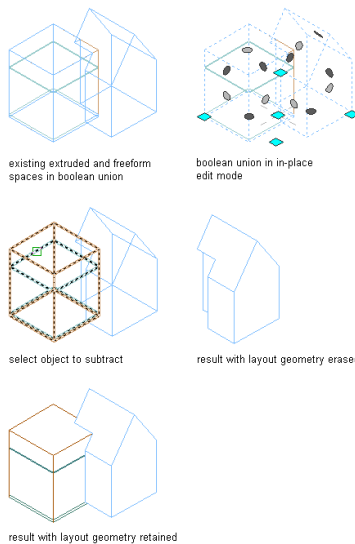

Subtracting AEC Objects from 3D Freeform Spaces

Use this procedure to subtract a space or other AEC object from a 3D freeform space. You can subtract any AEC object that has a 3D geometry from a space.

NOTE This procedure is valid for non-associative spaces only. If you perform it on an associative space, it will lose associativity after exiting the in-place edit mode.

- 1 Switch to a 3D isometric view.
- 2 Select the 3D freeform space from which you want to subtract an object, right-click, and click Edit in Place.
- 3 When you are in in-place editing mode, select the space again, right-click, and click Boolean ► Subtract.
- 4 Select the AEC object you want to subtract from the 3D freeform space, and press Enter.
- 5 Enter y (Yes) to erase the subtracted object, or n (No) to leave the object in the drawing.

Subtracting an extruded space from a freeform space

6 To save the changes to the space, click  on the In-Place Edit toolbar.

Intersecting 3D Freeform Spaces with AEC Objects

Use this procedure to intersect a 3D freeform space with a space or other AEC object. You can intersect a 3D freeform space with all AEC objects that have a 3D geometry.

NOTE This procedure is valid for non-associative spaces only. If you perform it on an associative space, it will lose associativity after exiting the in-place edit mode.

- 1 Switch to a 3D isometric view.
- 2 Select the 3D freeform space that you want to intersect with an AEC object, right-click, and click Edit in Place.
- 3 When you are in in-place editing mode, select the space again, right-click, and click Boolean ► Intersect.
- 4 Select the AEC object you want to intersect with the 3D freeform space, and press Enter.
- 5 Enter **y** (Yes) to erase the object, or **n** (No) to leave the object in the drawing.

- 6 To save the changes to the space, click  on the In-Place Edit toolbar.

Grip-Editing the Surfaces of 3D Freeform Spaces

Use this procedure to grip-edit individual surfaces of a 3D freeform space.

NOTE This procedure is valid for non-associative spaces only. If you perform it on an associative space, it will lose associativity after exiting the in-place edit mode.

You have 6 different options for grip-editing a space surface.

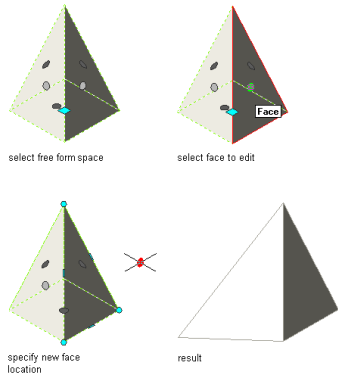

As you cycle through the options by pressing **CTRL**, the tooltip advances sequentially to indicate the current option. Pressing **CTRL** more than 5 times returns you to the first option, allowing you to continue cycling through the edit choices.

The cursor is constrained when you choose an orthogonal option and unconstrained when you choose a free option.

Moving a space surface orthogonally while stretching adjacent surfaces

Moving a space surface freely while stretching adjacent surfaces

Moving a space surface orthogonally while maintaining the planes of adjacent surfaces

Pulling a space surface orthogonally while adding adjacent surfaces

Pulling a space surface freely while adding adjacent surfaces

Pulling a space surface orthogonally while adding adjacent surfaces

Pushing a space surface orthogonally to create a hole

- 1 Verify that you are working in a 3D isometric view.
- 2 Select the space you want to edit, right-click, and click Edit in Place.
- 3 Select the surface grip to edit.
The tooltip displays the available edit operations:
- 4 Select the grip edit operation you want to perform:

If you want to...	Then...
move the space surface orthogonally while stretching adjacent surfaces	click the surface grip. Then, move it to the new position.
move the space surface freely while stretching adjacent surfaces	click and hold the surface grip, press CTRL once, and specify the new location.
move the space surface orthogonally while maintaining the planes of adjacent surfaces	click and hold the surface grip, press CTRL twice, and specify the new location.
pull the space surface orthogonally while adding adjacent surfaces	click and hold the surface grip, press CTRL 3 times, and specify the new location.
pull the space surface freely while adding adjacent surfaces	click and hold the surface grip, press CTRL 4 times, and specify the new location

NOTE The location of the current UCS is temporarily moved to coincide with the original position of the surface grip that you select when you are working with this option. Only the UCS origin is changed, not its orientation.

If you want to...**Then...**

push or pull the space surface orthogonally while either adding adjacent surfaces or creating a hole

click and hold the surface grip, press CTRL five times, and specify the new location.
Push into the space to create a hole, or pull out of the space to add adjacent faces.

NOTE You cannot pull the space surface at such an angle, either horizontally or vertically, that the adjacent surfaces become non-planar. If this distorted condition occurs, the space surface automatically returns to its original position and an error message is displayed on the command line.

5 To save the changes to the space, click  on the In-Place Edit toolbar.

Editing Space Surface Properties

You can edit the properties of 3D space surfaces with the Space/Zone Manager worksheet.

Space surfaces can be assigned a number of properties important for processing spaces in a downstream engineering or facility management application. You can define these properties in the architectural plan, and later export the plan or open it in an engineering application to perform calculations, such as determining the heating/cooling load on a building.

Use this procedure to edit any of the following surface properties for a non-associative 3D space:

- Surface name
- Surface type
- Surface style
- Surface height (extruded 3D spaces only)
- Surface openings
- Opening name
- Opening type
- Opening style
- Opening dimensions
- Opening area
- Opening reported area (3D freeform spaces only)

IMPORTANT For the surfaces of an associative space, only the surface name, the surface type, and the ceiling and floor style as can be edited. All other surface properties, including the properties for associative surface openings, are read-only.

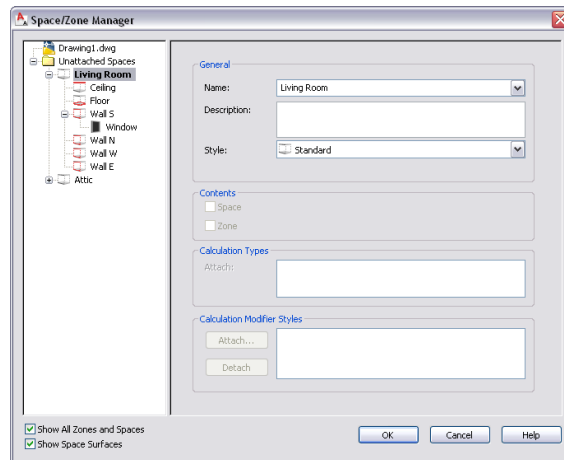

Opening the Space/Zone Manager

Use this procedure to open the Space/Zone Manager.

1 Open the Space/Zone Manager worksheet in one of these ways:

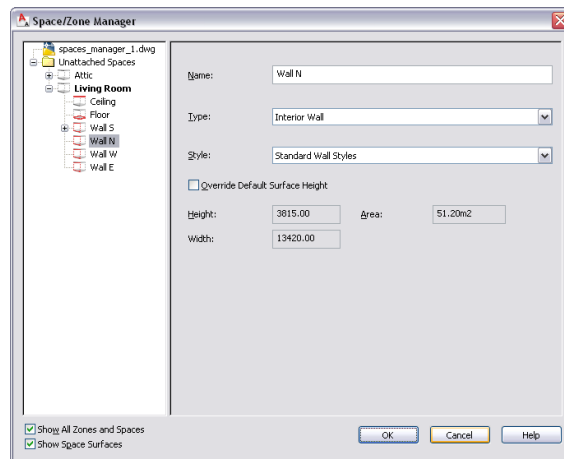

- Select a space, and on the Properties palette click the setting for Space/Zone Manager. Alternatively, you can right-click, and click Space/Zone Manager on the context menu.

To see all spaces in the drawing, as well as their surfaces and surface openings, verify that the settings for Show all Zones and Spaces and Show Space Surfaces are selected.

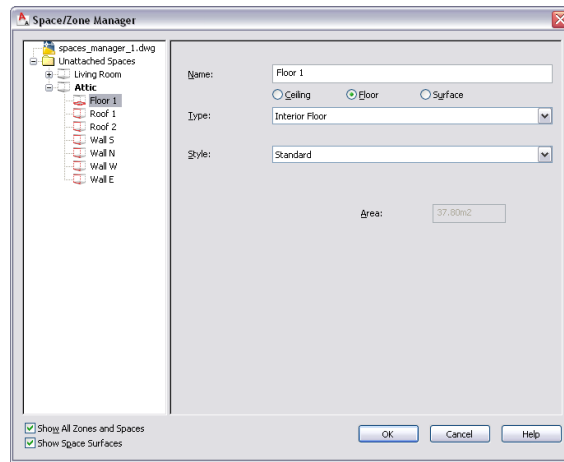

- Non-associative extruded 3D spaces only: Select a space, click the Edit Surfaces grip, and then click the Edit Surface Properties grip.

To see all spaces in the drawing, as well as their surfaces and surface openings, verify that both settings for Show all Zones and Spaces and Show Space Surfaces are selected.

- Non-associative 3D freeform spaces only: Select a space, click the Edit Surfaces grip, and then click the Edit Surface Properties grip on one surface. Then click the Edit Surface Properties grip for that surface.

To see all spaces in the drawing, as well as their surfaces and surface openings, verify that both settings for Show all Zones and Spaces and Show Space Surfaces are selected.

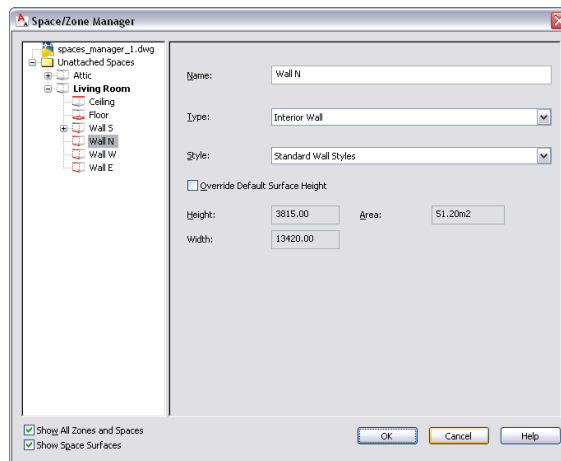

In the tree view on the left, all spaces are listed either under their containing zone or under the Unattached Spaces folder. The surfaces of a space are listed under the space. Surface openings are listed under the surface that contains them. To access a space, surface or zone, you may need to expand the tree until you reach the desired item.

Editing Surface Properties

Use this procedure to edit the properties of a space surface.

- 1 Open the Space/Zone Manager with one of the instructions described in [Opening the Space/Zone Manager](#) on page 2014.
- 2 Verify that Show Space Surfaces is selected.
- 3 If necessary expand the tree view to display the surface you want to edit.

- 4 Select the surface in the tree view and change its properties on the right:

Property	Options
Name	enter a new value for Name.
Surface type (3D freeform only)	<input type="checkbox"/> Ceiling <input checked="" type="checkbox"/> Floor

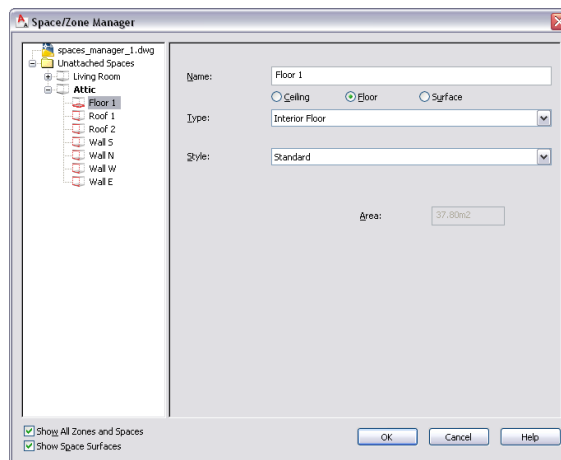

Property	Options
	<input checked="" type="checkbox"/> Surface This setting can be useful for complex freeform shapes, where the ceiling or the floor of the space can be represented by more than one surface.
Type	for Type, select one of the following: <input checked="" type="checkbox"/> Interior Wall <input checked="" type="checkbox"/> Exterior Wall <input checked="" type="checkbox"/> Shade <input checked="" type="checkbox"/> Air <input checked="" type="checkbox"/> Underground Wall
Style	all available wall and curtain wall styles in the drawing
Height/Area (extruded 3D spaces only)	select Override Default Surface Height, and enter a new value for either Height or Area. Both of these fields change only the height of the surface.

5 Click OK.

Editing Ceiling and Floor Surfaces

Use this procedure to edit the ceiling and floor surfaces of a space.

- 1 Open the Space/Zone Manager with one of the instructions described in [Opening the Space/Zone Manager](#) on page 2014.
- 2 Verify that Show Space Surfaces is selected.
- 3 If necessary expand the tree view to display the ceiling and floor surfaces you want to edit.

- 4 Select the ceiling surface of a space in the tree view, and make the necessary changes on the right:

If you want to...

Then...

change the name of the ceiling

enter a new value for Name.

If you want to...	Then...
change the ceiling type	for Type, select one of the following: <ul style="list-style-type: none"> ■ Ceiling ■ Roof ■ Underground ceiling
change the assigned roof slab style of the ceiling	for Style, select a slab or roof slab style from the drop-down list.

5 Select the floor of a space in the tree view, and make the necessary changes on the right:

If you want to...	Then...
change the name of the floor	enter a new value for Name.
change the floor type	for Type, select one of the following: <ul style="list-style-type: none"> ■ Interior Floor ■ Raised Floor ■ Slab on Grade ■ Underground Slab
change the assigned slab style of the floor	for Style, select a slab style from the drop-down list.

- 6** To add an opening to a ceiling or floor, select the ceiling or floor in the tree view, right-click, and click Add Opening.
- 7** To remove an opening from a ceiling or floor, select the opening in the tree view, right-click, and click Remove Opening.
- 8** Click OK.

Working with Surface Openings

Openings on space surfaces can be important for building systems calculations when the drawing is used in AutoCAD MEP or other building applications.

You can add openings to the surfaces of extruded 3D spaces and 3D freeform spaces. Depending on the geometry type of the space, the openings have different features. For example, on a 3D freeform space, you can edit the opening profile into any shape; however, on an extruded 3D space surface, the openings are limited to rectangular shapes.

Surface openings can have properties like opening name, opening type and opening dimensions attached to them. For more information, see [Editing Space Surface Properties](#) on page 2014.

NOTE You can add openings only to non-associative spaces. The openings in an associative space are determined by the openings in the boundary objects.

Adding Openings to Extruded 3D Space Surfaces

Use this procedure to add an opening to the surface of an extruded 3D space. Openings can be added to flat surfaces or curved surfaces (like a cylinder surface).

Openings displayed

Opening grips displayed

You can use grips or the Space/Zone Manager to add openings to a space surface. For more information about working with the Space/Zone Manager, see [Editing Space Surface Properties](#) on page 2014.

- 1 Select the space to which you want to add a surface opening, and click the Edit Surfaces grip.

2 Click the Add Window grip on the surface to which you want to add an opening. By default, a window opening is created.

To add a door, hold down CTRL while clicking the Add Window grip. Note that doors are positioned at the top of the floor surface.

3 When you are finished, click the Exit Editing Surfaces grip.

NOTE If an opening is added to the ceiling or floor surface of an extruded 3D space, it is always created on the bottom or top surface of the space geometry. The position of the opening is not affected by the justification of the space.

NOTE If the openings are not displayed after you exit the surface editing mode, then the Surface components display component in the space style or the space object display properties has not been activated. For more information, see [Specifying the Display Properties of a Space Style](#) on page 2045.

Editing Openings in Extruded 3D Space Surfaces

Use this procedure to stretch, move, or copy a surface opening in an extruded 3D space.

- 1 Select the space where you want to edit a surface opening, and click the Edit surfaces grip.
- 2 Select one of the corner grips of the surface opening.

3 Edit the opening:

If you want to...

Then...

stretch an edge of the opening

move the corner grip to the desired position.

move the opening to a new position on the surface

press CTRL, and move the opening to the desired position.

copy the opening on the surface

press CTRL twice, and copy the opening to the desired position.

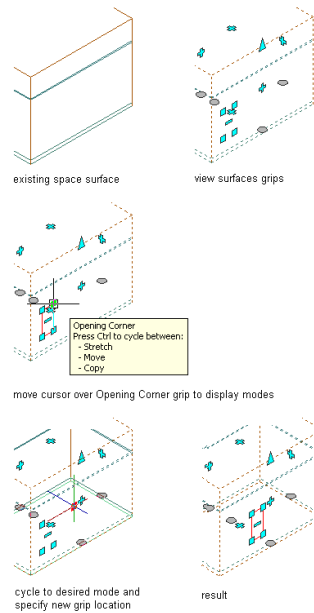

Stretching a surface opening

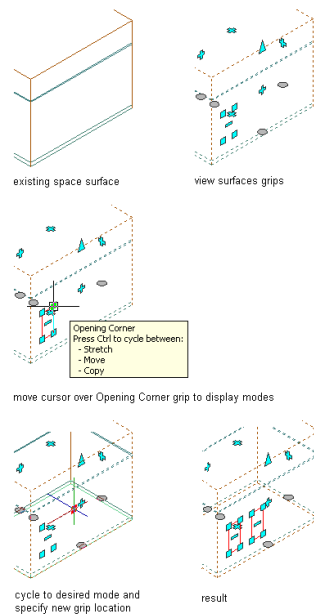

move cursor over Opening Corner grip to display modes

Moving a surface opening

Copying a surface opening

4 When you are finished, click the Exit Editing Surfaces grip.

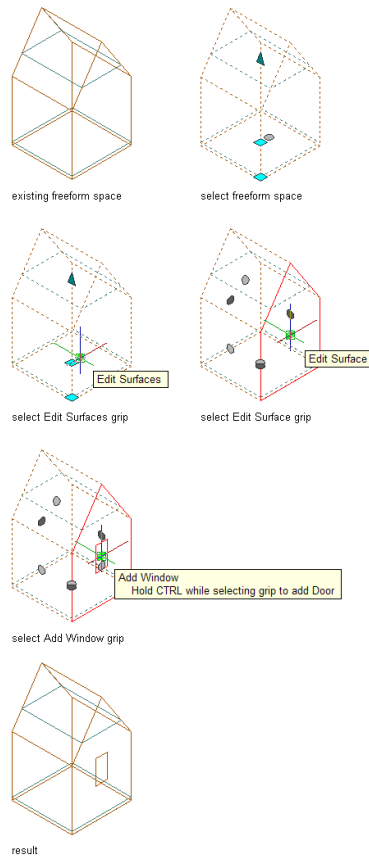

Adding Openings to 3D Freeform Space Surfaces

Use this procedure to add an opening to the surface of a 3D freeform space. Openings can be added to flat surfaces or curved surfaces (like a cylinder surface).

NOTE Openings cannot be added to dome- and sphere-shaped surfaces.

- 1 Select the space to which you want to add a surface opening, and click the Edit Surfaces grip.
- 2 Click the surface grip for the surface to which you want to add an opening.
- 3 Click the Add Window grip on the activated surface.

Adding a window opening to a freeform space surface

To add a door, hold down CTRL while clicking the Add Window grip. Note that doors are positioned at the bottom of the selected surface.

NOTE If the openings are not displayed after you exit the surface editing mode, then the Surface components display component in the space style or the space object display properties has not been activated. For more information, see [Specifying the Display Properties of a Space Style](#) on page 2045.

Moving 3D Freeform Space Openings

Use this procedure to move an opening in a 3D freeform space surface.

- 1 Select the space on which you want to move a surface opening, and click the Edit Surfaces grip.
- 2 Click the grip for the surface with the opening you want to move.
- 3 Select the Location grip for the opening you want to move, and move it to another location on the surface.

Moving a window opening on a freeform space surface

NOTE Moving the opening onto another surface or outside the space will result in the opening area being reported as zero.

4 To exit the surface editing mode, click the Exit Editing Surfaces grip.

Editing the Shape of 3D Freeform Space Openings

Use this procedure to edit the shape of a 3D freeform space opening.

3D freeform space surface openings can be edited like any profile-based boundary in AutoCAD Architecture. The opening boundary has vertex and edge grips to generate the desired shape.

Changing the edge of a space surface opening

- 1 Select the space on which you want to edit the edge of a surface opening, and click the Edit Surfaces grip.
- 2 Click the grip for the surface with the opening you want to edit.
- 3 Select the Edge grip for the edge you want to change.

Offsetting the edge of a window opening on a freeform space surface

existing freeform space with window opening

select freeform space

select Edit Surfaces grip

select Edit Surface grip

move cursor over Edge grip to display modes

Press Ctrl to cycle between:
- Offset
- Add Vertex
- Convert to Arc
- Offset All

Offset line, extending or trimming neighbors, and potentially adding or removing new lines

cycle to desired mode and specify new grip location

result

Adding a vertex to the edge of a window opening on a freeform space surface

existing freeform space with window opening

select freeform space

select Edit Surfaces grip

select Edit Surface grip

move cursor over Edge grip to display modes

cycle to desired mode and specify new grip location

result

Converting the edge of a window opening to arc on a freeform space surface

existing freeform space with window opening

select freeform space

select Edit Surfaces grip

select Edit Surface grip

move cursor over Edge grip to display modes

- Edge
- Press Ctrl to cycle between:
- Offset
- Add Vertex
- Convert to Arc
- Offset All

cycle to desired mode and specify new grip location

result

Offsetting all edges of a window opening on a freeform space surface

4 Specify the new edge location:

If you want to...

Then...

offset the edge

move the edge to the desired location, and click; or enter a value, and press *ENTER*.

add a vertex and create an edge

press *CTRL* to switch to the Add Vertex edit mode. Move the edge to the desired location, and click; or enter a value, and press *ENTER*.

change a selected edge to an arc/change a selected arc to a line

press *CTRL* twice to switch to the Convert to Arc/Convert to Line edit mode. Stretch the midpoint to the desired location, and click; or enter a value, and press *ENTER*.

If you want to...	Then...
offset all edges at an identical distance	press <i>CTRL 3</i> times to switch to the Offset All edit mode. Move the selected edge to the desired location for all edges, and click; or enter a value, and press <i>ENTER</i> .

5 To exit the surface editing mode, click the Exit Editing Surfaces grip.

Changing a vertex of a space surface opening

- 1 Select the space on which you want to edit an opening vertex, and click the Edit Surfaces grip.
- 2 Click the grip for the surface with the opening you want to edit.
- 3 Select the Vertex grip for the vertex you want to change.

The Vertex grip has 3 edit modes:

- **Move:** This is the default. Use it to move the selected vertex in any direction. The neighboring segments are stretched if necessary.
- **Remove:** Use this edit mode to remove a vertex. The neighboring segments are replaced with a line.
- **Offset Edges:** Use this edit mode to move a vertex and the adjacent edges of the space boundary with it.

Moving the vertex of a window opening on a freeform space surface

existing freeform space with window opening

select freeform space

select Edit Surfaces grip

select Edit Surface grip

move cursor over Vertex grip to display modes

- Vertex
Press Ctrl to cycle between:
- Move
 - Remove
 - Offset Edges

cycle to desired mode and specify new grip location

result

Removing the vertex of a window opening on a freeform space surface

existing freeform space with window opening

select freeform space

select Edit Surfaces grip

select Edit Surface grip

move cursor over Vertex grip to display modes

- Vertex
Press Ctrl to cycle between:
- Move
 - Remove
 - Offset Edges

cycle to desired mode and specify new grip location

result

Offsetting the edges of a window opening on a freeform space surface

4 Edit the vertex as necessary:

If you want to...

Then...

move the vertex

move the vertex to the desired location, and click; or enter a value, and press *ENTER*.

remove the vertex

press *CTRL* to switch to the Remove Vertex edit mode, and click to confirm the removal.

move the vertex and the adjacent edges

press *CTRL* twice to switch to the Offset Edges edit mode. Move the vertex to the desired location, and click; or enter a value, and press *ENTER*.

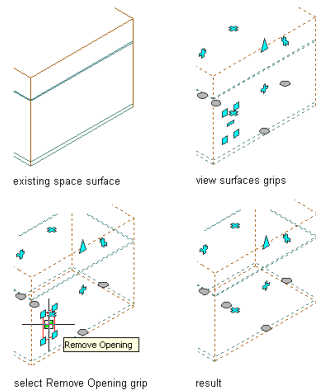

5 To exit the surface editing mode, click the Exit Editing Surfaces grip.

NOTE You cannot create non-rectangular shaped openings on extruded 3D spaces. If you need a different surface opening shape, convert the extruded 3D space to a 3D freeform space first as described in [Changing the Type of a Space](#) on page 1989.

Removing Openings from Extruded 3D and 3D Freeform Space Surfaces

Use this procedure to remove an opening from the surface of a 3D space.

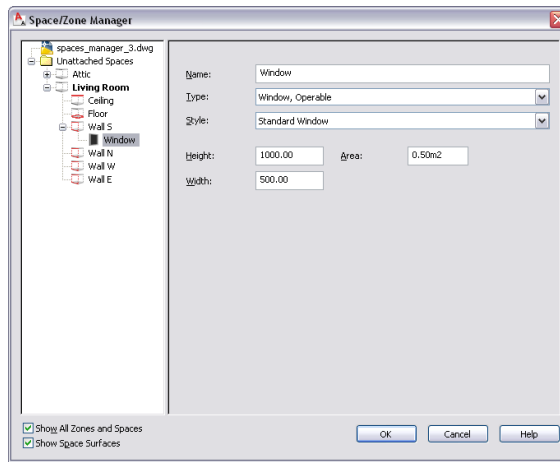

- 1 Select the space from which you want to remove a surface opening and display the grips for the surface openings in one of these ways:
 - If you have selected an extruded 3D space, click the Edit Surfaces grip. All surface opening grips on the space are displayed.
 - If you have selected a 3D freeform space, click the Edit Surfaces grip, and then select the Edit Surface grip for the surface containing the opening you want to remove. The grips for the openings on this surface are displayed.
- 2 Click the Remove Opening grip for the opening you want to remove.

Editing Surface Openings in Space/Zone Manager

Use this procedure to edit surface openings.

- 1 Open the Space/Zone Manager with one of the instructions described in [Opening the Space/Zone Manager](#) on page 2014.
- 2 Verify that Show Space Surfaces is selected.
- 3 If necessary expand the tree view to display the surface and the opening you want to edit.

4 To add a new opening to a surface, select the surface in the tree view, right-click, and click Add Opening.

The new opening is inserted with default properties.

5 To change the properties of an opening, select the opening in the tree view, and make the desired changes on the right:

If you want to...	Then...
change the opening name	enter a new value for Name.
change the opening type	for Type, select a new type from the drop-down list. Depending on whether the opening is a door or window opening, different types are available: <ul style="list-style-type: none"> ■ Fixed Window ■ Operable Window ■ Fixed Skylight ■ Operable Skylight ■ Non sliding Door ■ Sliding Door ■ Air
change the assigned window or door/window assembly style of the opening	select a window style, door style, or door/window assembly style from the list. The list contains all styles available in the drawing.
change the area of a surface opening	enter values for Area, Height, or Width of the opening.

NOTE For a 3D freeform space opening, you cannot edit the height or width on this worksheet. You can change the width and height of a 3D freeform surface opening using grips, as described in [Editing the Shape of 3D Freeform Space Openings](#) on page 2025.

For openings in 3D freeform spaces, the reported area is displayed alongside the overall area. The reported area can differ from the overall area in cases where an opening is only partly on the surface, and the rest is either on a different surface or outside the space. In this case, the reported area displays

If you want to...

Then...

the part of the opening that is on the surface. The value for reported area is read-only.

- 6 To remove an opening from a surface, select the opening, right-click, and click Remove Opening.
- 7 Click OK.

How Changing the Space Geometry Affects Surface Openings

When you change the geometry of a space, it can have different results for openings attached to the space surfaces.

Changing the Shape of a 3D Freeform Space

3D freeform spaces have a large number of possible geometries, such as a box, a pyramid, or an irregular freeform shape. Changing the geometry of the space can affect openings in space surfaces in the following ways:

- When a surface is deleted or moved so that it is no longer coplanar to an opening it contains, the opening will be deleted.
- When a surface is edited in a way that does not affect the opening, the opening is retained unchanged.
- When a surface is split and an opening crosses the split line, the opening is split into 2 openings.

NOTE If the space geometry is changed in any way that changes the total number of surfaces, then openings may be deleted or may occasionally move from one surface to another.

Changing the Geometry Type

You can convert a 3D freeform space to an extruded 3D space, and vice versa. This will affect contained openings in different ways.

To change the geometry type of a space, see [Changing the Type of a Space](#) on page 1989.

- When an extruded 3D space is converted to a 3D freeform space, all openings will be retained with the same location, shape, and area. The opening grips change to the grips of an extruded 3D space surface opening.

Viewing Extruded and Freeform space surface openings

- When a 3D freeform space is converted to an extruded 3D space, the openings on the horizontal roof or floor surfaces will be kept on the roof or floor of the extruded 3D space. The openings on the surfaces that intersect with the base profile will be retained on the respective edge surfaces. All other openings will be lost. The openings that are retained will change to rectangles, and the area of the opening will remain the same.

Viewing Freeform and Extruded space surface openings

- When an extruded 3D space or a 3D freeform space is changed to a 2D space, all surface openings are lost.

Changing the Associativity

You can convert associative spaces to non-associative spaces, and vice versa. This will affect contained openings in different ways.

To change the associativity of spaces, see [Making a Space Associative or Non-Associative](#) on page 1952.

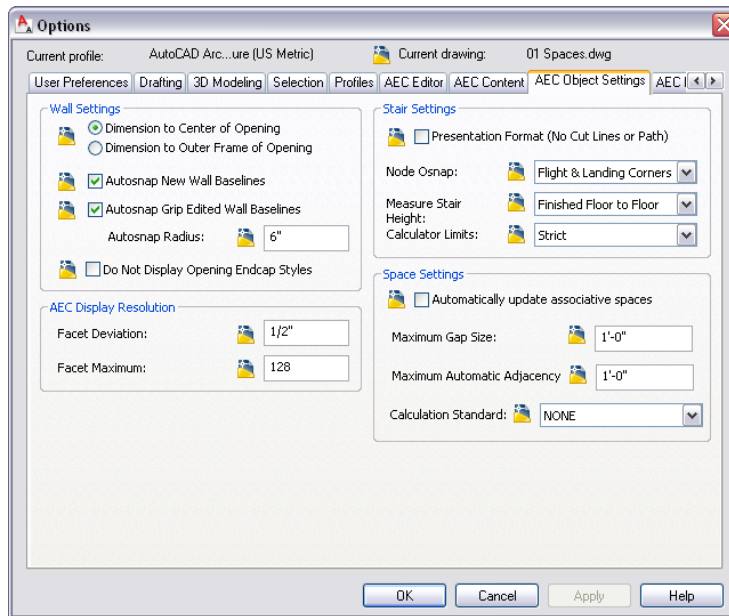

The openings in associative spaces are generated by any openings that are in the boundary walls. For example, if a boundary wall has a window and a door, openings with the shape of the window and door are inserted in the space.

- If an associative extruded 3D space is converted to a non-associative extruded 3D space, all openings will be retained in their original position, but will now have editing grips. If the shape of the original opening is not rectangular, the opening shape will change to a rectangle identical in area to the original shape.
- If an associative 3D freeform space is converted to a non-associative 3D freeform space, all openings will be retained with identical location, size, and shape, and will have editing grips.

Setting Up Adjacency Relations between Space Surfaces

Spaces can detect adjacencies between surfaces of neighboring spaces. This is important for processing a building plan in an engineering application like AutoCAD MEP. You can define the maximum allowed adjacency distance between space surfaces.

- 1 Click Format menu ► Options.
- 2 Click the AEC Object Settings tab.

3 For Maximum Automatic Adjacency select the maximum allowed distance between 2 surfaces that should be considered adjacent to each other.

4 Click OK.

TIP Alternatively, you can set the maximum automatic adjacency between space surfaces on the command line by entering **AecSpaceMaxAutoAdjacency**.

Displaying Adjacency Relations between Space Surfaces

In most cases, adjacency relations between space surfaces are important for exporting and processing building plans to an engineering application. If you need to check the status of adjacency relations within AutoCAD Architecture, you can make the adjacency relations visible in the drawing.

Displaying surface adjacencies

existing adjacent spaces

space adjacencies displayed

- 1 On the command line, enter **AecShowSpaceAdjacencies**.
- 2 Adjacent space surfaces are displayed with lines.
- 3 To hide the surface adjacency lines, press ENTER.

Space Styles

A space style is a set of parameters that determines the appearance and other characteristics of the space object to which it is assigned. Depending on the scope of the drawing, you may want to create different space styles to represent different types of spaces, such as different room types in an office building.

Within the space style you can set up the space decomposition. Decomposition geometrically divides an existing space into triangular or trapezoid subparts. In some countries, such as Germany and Japan, the visual decomposition of spaces into subdivisions is needed for the space proof that must be presented to the building administration for approval.

You can use styles for controlling the following aspects of spaces:

- **Boundary offsets:** You can specify the distance that a space's net, usable, and gross boundaries will be offset from its base boundary. Each boundary has its own display components that you can set according to your needs.
- **Name lists:** You can select a list of allowed names for spaces of a particular style. This helps you to maintain consistent naming schemes across a building project.
- **Target dimensions:** You can define a target area, length, and width for spaces inserted with a specific style. This is helpful when you have upper and lower space limits for a type of room that you want to insert.
- **Displaying different space types:** You can draw construction spaces, demolition spaces, and traffic spaces with different display properties. For example, you might draw all construction areas in green and hatched, and the traffic areas in blue with a solid fill.
- **Displaying different decomposition methods:** You can specify how spaces are decomposed (trapezoid or triangular). If you are not working with space decomposition extensively, you will probably set it up in the drawing default. For information about space decomposition, see [Space Decomposition](#) on page 2093.

Creating a Space Style

Use this procedure to create a space style. You can start by using the default style or you can copy an existing style to use as your template. You then edit the style properties to customize the characteristics of the style.

1 Click Format menu ► Style Manager.

The Style Manager is displayed with the current drawing expanded in the tree view.

2 Expand Architectural Objects, and expand Space Styles.

3 Create a space style:

If you want to...	Then...
create a style with default properties	right-click Space Styles, and click New.
create a style from an existing style	right-click the space style you want to copy, and click Copy. Right-click, and click Paste.

4 Enter a name for the new space style, and press *ENTER*.

5 Edit the new space style:

If you want to...	Then...
define target dimensions for the space base boundary	see Specifying Target Dimensions for the Space on page 2040.
specify style-based offsets for the net, usable, and gross boundaries	see Specifying Space Boundary Offsets in a Space Style on page 2041.
add a list definition to the style	see Attaching a List Definition to a Space Style on page 2042.
specify materials for space components	see Specifying the Materials of a Space Style on page 2043.
add a classification to the style	see Specifying Classifications for a Space Style on page 2042.
set the display of space boundaries and calculation cut planes	see Specifying the Display Properties of a Space Style on page 2045.
define the hatching of the space	see Specifying the Hatching for Components of a Space Style on page 2047.
define the cut plane for the space	see Setting the Object Cut Plane of a Space Style on page 2048.
attach notes and files to the style	see Attaching Notes and Files to a Space Style on page 2049.
specify a space decomposition view	see Space Decomposition on page 2093.

6 When you finish specifying properties, click OK.

Specifying Target Dimensions for the Space

Use this procedure to specify a target area for the space in the space style. Target dimensions can be useful when dimension requirements for a space are already known and cannot be exceeded. If the area, length, or width of a space you insert falls outside the sizes specified in the style, the dimension is truncated to the target size, and a solution tip icon displays.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Design Rules tab.

5 Specify the target dimensions for the space style:

If you want to...	Then...
specify a different area	enter a new value for Target Area, Min Area, or Max Area.
specify a different length	enter a new value for Target Length, Min Length, or Max Length.
specify a different width	enter a new value for Target Width, Min Width, or Max Width.

Target values must fall between the set minimum and maximum values.

6 Click OK twice.

Specifying Space Boundary Offsets in a Space Style

Use this procedure to define the offsets of the net, usable, and gross boundaries of a space from the base boundary in the space style. Space boundary offsets can also be set manually. When the net, usable, and gross boundaries of a space are determined manually, they can be grip-edited. When they are determined from the space style, they cannot be grip-edited.

For information about applying style-based offsets to a space, see [Specifying Space Boundary Offsets in a Space Style](#) on page 2041.

Space boundaries by style

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Design Rules tab.
- 5 Specify the distance to offset the net, usable, and gross boundaries from the base boundary:

If you want to...	Then...
offset the net boundary from the base boundary	enter a value for Net Offset. NOTE In many calculations, the net boundary is identical to the base boundary. If you enter 0 for the Net Offset, the net boundary is not offset from the base boundary.
offset the usable boundary from the base boundary	enter a value for Usable Offset.
offset the gross boundary from the base boundary	enter a value for Gross Offset.

6 Click OK.

Attaching a List Definition to a Space Style

Use this procedure to attach a list definition to a space style so that spaces using the style are named consistently according to a defined list of names. List definitions can be created according to government standards, company standards, or any other naming system you want to implement. For information about creating list definitions, see [List Definitions](#) on page 2051.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Design Rules tab.
- 5 For Space Names, select a list definition from the drop-down list.

NOTE The drop-down list displays only list definitions that apply to spaces. For more information, see [Specifying the Application for a List Definition](#) on page 2052.

6 Click OK.

When you change the name list in the space style, it is possible that the new space style has a different name list. In this case, the space name can interact with the new list definition in the following ways:

- The name of an existing space is also included in the new list definition. In this case, no change to the name is made.
- The name of an existing space is not included in the new list definition, but the list definition allows individual names to differ from the list. In this case, the existing name is retained as a non-standard name.
- The name of an existing space is not included in the new list definition, and the list definition does not allow individual names to differ from the list. In this case, the existing name is removed and the space name defaults to the first name in the new list definition.

Specifying Classifications for a Space Style

Use this procedure to specify classifications for any classification definition applied to a space style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to space styles.
- 5 For each classification definition, select the classification you want to apply to the current space style.
- 6 Click OK.

Specifying the Materials of a Space Style

A space consists of a number of components whose display properties can be determined by the materials assigned to each component.

When you assign materials to a space style, you assign one material to each physical component of the space. For example, you assign a wood material to the floor and a ceiling tile material to the ceiling.

If you want to use the display properties of the space style, you can turn off the material assignments in the display properties of the space style.

Material definitions consist of display components that correspond to component types of objects. For example, the Linework component of a material is used for all linework in plan view. The Surface Hatch component is used to hatch all object surfaces in 3 dimensional (3D) model views and in elevations.

Space Materials and Display Components

The following table lists space components and the material components that determine them in specific views.

Display Representation	Space Component	Material Component
Plan, Plan High Detail, Plan Low Detail, Plan Presentation, Plan Screened, Reflected, Reflected Screened	Base Boundary	Plan Linework
	Base Hatch	Plan Hatch
	Net Boundary	No material
	Net Hatch	No material
	Usable Boundary	No material
	Usable Hatch	No material
	Gross Boundary	No material
	Gross Hatch	No material
	Cut Plane	No material
	Cut Plane Hatch	No material
	Above Cut Plane	No material
	Below Cut Plane	No material

Display Representation	Space Component	Material Component
	Calculation Plane 1	No material
	Calculation Plane 1 Hatch	No material
	Calculation Plane	No material
	Calculation Plane Hatch	No material
Model		
	Floor	3D Body
	Ceiling	3D Body
	Net Volume	No material
	Surfaces	No material
	Surface Components	No material
	Usable Volume	No material
	Gross Volume	No material

Assigning Materials to a Space Style

Use this procedure to assign materials to individual components of a space style. The component may use the display properties of the material instead of the style display properties.

You can assign a material to any physical component of the space. Custom components and components that are only symbolic graphics do not use materials for their display properties. For example, the floor and ceiling are physical components. The gross boundary is a symbolic component.

NOTE If a material assignment does not determine the display properties of a space component, you can change the display properties of the space style as described in [Specifying the Display Properties of a Space Style](#) on page 2045.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Materials tab.
- 5 Select the component you want to change, and select a different material definition.

You can select any material definition in the current drawing, or click  to create a new material definition and assign it to a component.

WARNING Any changes you make to the material definition in this dialog will apply to all objects that are assigned the material.

6 Click the Display Properties tab.

7 Select the display representation where you want the changes to appear, and select Style Override.

8 If necessary, click .

9 Click the Layer/Color/Linetype tab.

10 Select By Material for any component to which you want to assign a material, and click OK.

If the setting for By Material is not available, the display of this component cannot be determined by a material.

11 Click OK.

Specifying the Display Properties of a Space Style

Use this procedure to define any of the following display components of a space in the style:

- Space boundaries (Plan views): You can set the display of the base, net, usable, and gross boundaries. If boundaries are offset from each other, it is a good idea to differentiate them by color, linetype, or lineweight. If you do not need boundary offsets, you could also hide the net, usable, and gross boundaries and their respective hatches, so as not to clutter the drawing.

- Boundary hatches (Plan views): Each space boundary has an associated hatch that you can display.

Base hatch

Usable hatch

Net hatch

Gross hatch

- Above and Below Cut Plane components (Plan views): If the space is cut by an object cut plane, you can define different visuals for the parts that lie above the cut plane and below the cut plane.

- Calculation cut planes and hatches (Plan views): For 3D freeform spaces, 2 calculation cut planes can be set. This helps to create evaluations of non-uniform space heights. For each of the calculation cut planes, you can set a boundary display and a hatch.
- Floor and ceiling components (Model views): 3D spaces can have floors and ceilings with a user-specified thickness. You can display them in a model view.

NOTE If the thickness of the ceiling or floor component is set to 0, it does not display in the drawing.

Floor and ceiling components in Model view

- Surfaces and surface components (Model views): 3D freeform spaces are composed of individual surfaces, which can have additional components like door and window openings.

Space surface with surface openings

Openings displayed

Opening grips displayed

NOTE If a material assignment determines the display properties of components in the space style, you can change the properties of the display component by clearing By Material. You can also override the material assignment with a different material. For more information, see [Specifying the Materials of a Space Style](#) on page 2043.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 Click the Layer/Color/Linetype tab.
- 7 Select the space component to change, and change the following settings:
 - Material: If you select By Material, all display settings are taken from the assigned material. Components that cannot be set by material have the check box deactivated.
 - Visibility
 - Layer
 - Color
 - Linetype/Lineweight/Linetype Scale
 - Plot Style
- 8 Click OK.

Specifying the Hatching for Components of a Space Style

Use this procedure to specify the hatching for display components of a space style. Space hatching is displayed only in display representations that represent a Plan view.

The following hatch components are available for spaces:

- Base hatch: the hatch component for the base boundary of a space.
- Net hatch: the hatch component for the net boundary of a space.
- Usable hatch: the hatch component for the usable boundary of a space.
- Gross hatch: the hatch component for the gross boundary of a space.
- Cut Plane hatch: the hatch for the object cut plane. This cut plane is different from the calculation cut planes you can set for 3D freeform spaces.
- Calculation Cut Plane Hatch (1 and 2): If you define calculation cut planes for a 3D freeform space, you can add a hatch to the calculation cut plane boundary.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and click Style Override.
The display representation in bold is the current display representation.
- 6 Click the Hatching tab.
- 7 Select a display component, and click the setting for Pattern.

8 Select the hatching for the display component:

If you want	Then...
a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
single hatching	select User-defined for Type, and clear Double Hatch.
double hatching	select User-defined for Type, and select Double Hatch.
solid fill	select Solid Fill for Type.

9 Click OK.

10 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

11 Click Angle, and enter the angle for the selected pattern.

12 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

13 Click OK.

Setting the Object Cut Plane of a Space Style

Use this procedure to set the object cut plane of a space style.

The object cut plane of a space is used to display the space in Plan views at a defined cut height. It is unrelated to the calculation cut planes you can set for 3D freeform spaces. The object cut plane cannot, for example, be used in scheduling properties or in a space calculation. In most cases the cut plane of a space is determined by the cut plane of the display configuration of the current view. You can set up a different cut plane for individual spaces, if necessary.

1 Click Format menu ► Style Manager.

2 Expand Architectural Objects, and expand Space Styles.

3 Select the space style that you want to change.

4 Click the Display Properties tab.

5 Select the display representation where you want the changes to appear, and click Style Override.
The display representation in bold is the current display representation.

6 Click the Other tab.

7 To use the cut plane defined in the display configuration, verify that Override Display Configuration Cut Plane is cleared.

- 8 To define a cut plane differing from the cut plane of the display configuration, select Override Display Configuration Cut Plane, and enter the desired height for Cut Plane Height.
- 9 Click OK.

Attaching Notes and Files to a Space Style

Use this procedure to enter notes and attach reference files to a space style. You can also edit notes and edit or detach reference files from a space style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Space Styles.
- 3 Select the space style that you want to change.
- 4 Click the General tab.
- 5 To add a description to the space style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click OK.
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click Delete.

- 9 Click OK twice.

Converting Area Styles to Space Styles

If you open a drawing from a previous version of AutoCAD Architecture that has area styles in it, the area styles will be automatically converted to space styles. The following settings will be converted:

Area style property	Space style property	Value/Default value
Name	Name	Existing value
Description	Description	Existing value
Keynote	Keynote	Existing value
Notes/Reference Docs	Notes/Reference Docs	Existing notes and attached documents

Area style property	Space style property	Value/Default value
Property Sets	Property Sets	Area property sets are converted to space property sets and attached to the converted space style
N/A	List Definition	Standard NOTE In older versions of AutoCAD Architecture, list definitions were attached to area groups or area group templates. Now, list definitions are attached either to the space style or to the zone style.
N/A	Target Area	Default
N/A	Target Length	Default
N/A	Target With	Default
N/A	Net Offset	0
N/A	Usable Offset	0
N/A	Gross Offset	0
N/A	Floor Material	Standard
N/A	Ceiling Material	Standard
Classifications	Classifications	Existing classification values. NOTE Area classification definitions from older versions of AutoCAD Architecture are converted to space classification definitions and applied to converted space styles.
Display Representations		
N/A	Model	Drawing Default
Plan	Plan	Existing settings
Plan High Detail	Plan High Detail	Existing settings
Plan Low Detail	Plan Low Detail	Existing settings
N/A	Plan Presentation	Drawing Default
N/A	Plan Screened	Drawing Default

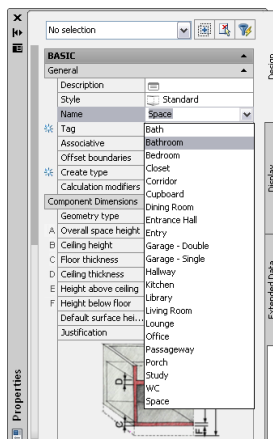

Area style property	Space style property	Value/Default value
N/A	Reflected	Drawing Default
N/A	Reflected Screened	Drawing Default
N/A	Volume	Drawing Default
Decomposed	Decomposed	Existing settings

List Definitions

A list definition is a list of names that may be used as allowed names for spaces or zones. List definitions can be attached to a space style or a zone style, so that the list of names is available on the Properties palette when you create or edit a space or zone with that style.

For more information see [Attaching a List Definition to a Space Style](#) on page 2042 and [Attaching a List Definition to a Zone Style](#) on page 2072.

List definition for a space

For a description of the typical workflow for list definitions, see [Working with List Definitions - Overview](#) on page 1916.

List definitions are useful when you create spaces according to government or company standards.

When you change the name list in a space or zone style, a space or zone name can interact with the new list definition in the following ways:

- The existing name is also included in the new list definition. In this case, no change to the space name is made.
- The existing name is not included in the new list definition, but the list definition allows individual names to differ from the list. In this case, the existing name is retained as a non-standard name.
- The existing name is not included in the new list definition, and the list definition does not allow individual names to differ from the list. In this case, the existing name is removed and the name defaults to the first name in the new list definition.

Creating a List Definition

Use this procedure to create a list definition that can be attached to a space or zone style to specify the allowable values for the name property.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand List Definitions.
- 3 Create a new list definition:

If you want to...	Then...
create a new list definition with default properties	right-click List Definitions, and click New.
create a new list definition from an existing list definition	right-click the list you want to copy, and click Copy. Right-click, and click Paste.

- 4 Enter a name for the list definition, and press *ENTER*.
- 5 Edit the properties of your new list:

If you want to...	Then...
define the objects the list definition applies to	see Specifying the Application for a List Definition on page 2052.
edit the list definition	see Editing a List Definition on page 2053.
add notes or files to the definition	see Attaching Notes and Files to a List Definition on page 2053.

- 6 Click OK.

Specifying the Application for a List Definition

You can create list definitions that apply to spaces names, to zone names, or that can be used as drop-down lists for manual scheduling properties. For information on manual scheduling properties, see [Entering Manual Properties and Fields for Objects](#) on page 2535.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand List Definitions.
- 3 Select the definition you want to edit.
- 4 Click the Applies to tab.
- 5 Select one or more of the following options:
 - Spaces: (If you want the list to be available for space names)
 - Zones: (If you want the list to be available for zone names)
 - Manual Property Definition: (If you want the list to be available for manual schedule properties)
- 6 Click OK.

Editing a List Definition

Use this procedure to edit a list definition.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand List Definitions.
- 3 Select the list you want to edit.
- 4 Click the Items tab.
- 5 Add, delete, or rename entries in the list definition:

If you want to...	Then...
add a new entry to the list	click Add, and enter the name of the entry.
delete an entry from the list	select the entry, and click Remove.
rename an entry in the list	select the entry, and enter the new name.

- 6 If you want users to have the alternative of entering a non-list name for the space or zone, select Allow individual property values to vary from this list.
- 7 Click OK.

Attaching Notes and Files to a List Definition

Use this procedure to attach text notes and files to a list definition.

- 1 Click Format menu ► Style Manager.
- 2 Expand Multi-Purpose Objects, and expand List Definitions.
- 3 Select the list definition for which you want to add a note or file.
- 4 Click the General tab.
- 5 To add a description to the list, enter the description for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click Open.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Close the application when you are done editing.
detach a reference file	select the file name, click Delete, and click OK.

- 9 Click OK.

Zones

In AutoCAD Architecture, a zone is a container in which you can group spaces and other zones. You need zones to create an evaluation of your floor plan. With zones, you structure spaces into various groups, according to different schemes. For example, you can have functional zones (construction, traffic, and so on) or zones for building units (Apartment 1 Ground Floor, Apartment 2 Ground Floor, and so on.)

Spaces can be contained in more than one zone. For example, you can attach a balcony space to both the Construction Spaces group and the Apartment 1 Ground Floor group. You can set up a restriction in the zone style, so that a space can only be attached to one zone of a specific style.

Spaces attached to zones

A zone can have list definitions and calculation modifiers attached. List definitions are attached through the zone style, whereas calculation modifiers are attached directly to the zone.

Zone Templates

Zones can be connected and nested into complex structures. A zone structure for a building, for example, may have one top-level zone named “Building.” Below that zone would be a number of zones for apartments—the apartment 1 zone, the apartment 2 zone, and so on. The individual apartment zones can contain other zones like a construction areas zone, a 50% deduction zone, or spaces like the living room, the bedroom, and so on.

When you often need a complex zone structure, you can create a zone template that defines the necessary zones and their grouping. For example, when designing a new building, you can insert a zone structure based on a Building zone template, which would contain the main building zone plus all subordinate zones. A number of predefined zone templates are provided with the software.

Zones in the Space Evaluation

When you create a space evaluation of the floor plan, you can specify which zones are included.

For example, if you wanted to create a space evaluation for a single apartment in a building to determine the area and set the rent accordingly, you would select the zone representing that apartment. Within the same drawing you might also want to create an evaluation that contains only bathrooms, to determine how many tiles to order from a supplier. To do this you would first create a bathrooms zone, add all bathrooms from all apartments to it, and then evaluate the overall area of that zone.

For information about space evaluations of the floor plan, see [Space Evaluation](#) on page 2097.

Zone Attachments Across External References

You can attach spaces or zones from an external reference to a zone in the current drawing. You cannot, however, attach spaces and zones in the current drawing to zones in an external reference. If you detach an

external reference from which spaces or zones have been attached to a zone in the current drawing, those spaces or zones are also detached. If you re-attach the external reference to the current drawing, you would need to manually re-attach the spaces and zones from the external reference, if desired.

Using Zone Tools to Create Zones

Tools provided with AutoCAD Architecture let you quickly place zones by selecting a zone tool with a specific zone style and other predefined properties. When you place zones using zone tools, you can use the default settings of the tool, or you can change settings for the zone properties. You can also use zone tools to apply the settings of a zone tool to existing zones.

Tool palettes containing zone tools

The default tool palettes in the workspace contain sample zone tools that you can use and customize as needed. In addition, the following catalogs provided with the software contain zone tools that you can add to your tool palettes:

- Stock Tool catalog
- Sample Palette catalog

Custom palettes created by your CAD manager or other users may also contain zone tools with zone styles and properties that are customized for your projects or office standards.

Zone Properties

In AutoCAD Architecture, a zone is a documentation object that is used to group and organize spaces. The following table describes the properties that are displayed for a zone in the Properties palette.

Zone Property	Description
General Category	
Description	User-specified description of the zone object
Layer	Specifies the layer on which the zone is placed. By default, the layer assignment is defined in the zone style.
Style	Specifies the zone style. The style defined in the zone tool is the default.

Zone Property	Description
Name	The name of the zone. If a list definition has been specified in the zone style, the list is available as a drop-down list. For more information, see Attaching a List Definition to a Zone Style on page 2072.
Tag	Specifies a zone tag to be inserted when adding the zone. Zone tags are available in the sample drawings shipped with the software. You can also create your own zone tags. NOTE This property is available only during adding a zone.
Calculation Modifiers	Identifies any calculation modifiers for the zone. A calculation modifier is a formula that modifies selected values of spaces attached to the zone. For more information, see Calculation Modifiers on page 2088.
Number of Spaces	Displays the number of spaces that are directly attached to the zone.
Total number of spaces	Displays the number of spaces that are directly attached to the zone plus the number of spaces that are attached indirectly through subzones of the zone.
Number of Zones	Displays the number of zones that are directly attached to the zone.
Total number of zones	Displays the number of zones that are attached directly to the zone plus the number of zones that are attached through subzones of the zone.
Space/Zone Manager	An icon providing access to the Space/Zone Manager worksheet where you can rename zones, attach spaces and zones, define the content model of the zone, and attach calculation modifiers.
Dimensions Category	
Base area	Displays the combined base area of all spaces attached to the zone.
Calculated area	Displays the base area of all spaces attached to the zone processed with any calculation modifiers attached to the zone.
Base perimeter	Displays the combined base perimeter of all spaces attached directly or indirectly to the zone.
Calculated perimeter	Displays the base perimeter of all spaces attached to the zone processed with any calculation modifiers attached to the zone.
Base volume	Displays the combined base volume of all spaces attached directly or indirectly to the zone.

Zone Property	Description
Zone Boundary Offset	Specifies the offset distance for the zone boundary that is drawn around any space attached to the zone to show the space/zones relationship.
Calculation Category	
Calculate area	Specifies whether the area of spaces that are attached to the zone will be calculated using any applicable calculation modifiers.
Calculate perimeter	Specifies whether the perimeter of spaces that are attached to the zone will be calculated using any applicable calculation modifiers.
Content	
Can contain spaces	This property defines that the zone is allowed to have spaces directly attached.
Can contain zones	This property defines that the zone is allowed to have zones attached. NOTE If you select both content options, the zone can contain spaces and zones.
Location	
Rotation	Specifies the rotation of the zone.
Elevation	Specifies the elevation of the zone.
Additional Information	Specifies the location and coordinate system of the zone.

Creating a Zone

Use this procedure to add a new a zone that has the properties specified in the zone tool that you select. To specify settings when you add a zone, see [Creating Zones with User-Specified Settings](#) on page 2058.

- 1 Open the tool palette that contains the Zone tool you want to use, and select it.
(You may have to scroll to display the desired tool.)
- 2 Specify the insertion point of the zone.
You can move or hide the Properties palette to expose more of the drawing area.
- 3 Continue adding zones as needed, and then press *ENTER*.

Creating Zones with User-Specified Settings

Use this procedure to add a zone with settings that you specify.

- 1 Open the tool palette that contains the Zone tool you want to use, and select it.
(You may have to scroll to display the desired tool.)
- 2 On the Properties palette, expand Basic, and expand General.
- 3 Enter a name for the zone.
If you have assigned a list definition to the zone style, you can select a name from the drop-down list.
- 4 Select a style.
- 5 Select a tag for the zone.

NOTE If no zone tags are contained in the list, you can drag a tag into the drawing from the Content Browser. You can also create your own tags from multi-view blocks.

- 6 To add a calculation modifier to the zone, click the setting for Calculation Modifiers, and select one or more calculation modifiers for the zone.
If you assign a calculation modifier to a zone, the area and perimeter values of spaces attached to the zone will be modified with the calculation modifier. For information about calculation modifiers, see [Calculation Modifiers](#) on page 2088.
- 7 Expand Dimensions.
- 8 For Zone boundary offset, enter a value to specify the distance you want between the zone boundary and the base boundary of any attached space.
If you select 0 offset, the zone boundary is identical to the base boundary of the space.

Zone boundary offset at 0 (left) and at an offset value (right)

TIP If you cannot see the zone boundary, the display component for the zone boundary may not be activated in the zone style. For more information, see [Specifying the Layer, Color, and Linetype Properties of a Zone Style](#) on page 2074.

9 Expand Calculation.

10 Specify which space values should be calculated in the zone:

If you want to ...	Then...
calculate the area values of attached spaces including any applicable calculation modifiers	select Yes for Calculate Area.
calculate the perimeter values of attached spaces including any applicable calculation modifiers	select Yes for Calculate Perimeter.

For information about space evaluations, see [Space Evaluation](#) on page 2097.

11 Expand Content.

12 Define the content allowed in the zone:

If you want to ...	Then...
allow spaces to be attached to the zone	select Yes for Can Contain Spaces.
allow zones to be attached to the zone	select Yes for Can Contain Zones.

13 In the drawing area, specify the insertion point of the zone.

You can move or hide the Properties palette to expose more of the drawing area.

14 Continue adding zones as needed, and then press *ENTER*.

Creating Zone Structures from a Zone Template

Use this procedure to create zone structures based on a zone template. This procedure is recommended if you use the same zone structure frequently.

When you add a zone structure, all zones that are connected in that structure are inserted in the drawing. Depending on the style settings for the zone template, you can display individual zones with different color and hatch. You can also display zone connection lines. Below is an example for a zone structure representing the DIN 277 building norm.

Zones according to DIN277 zone template

For information about creating zone templates, see [Zone Templates](#) on page 2079.

1 Open the tool palette that contains the Zone from Template tool you want to use, and select it.

(You may have to scroll to display the desired tool.)

2 On the Properties palette, expand Basic, and expand General.

3 Select the zone template you want to create a structure of zones from.

4 Define the offsets between individual zones in the structure:

If you want to...

Then...

define the offset between rows of the zone structure

enter a value for Row Offset.

define the offset between columns of the zone structure

enter a value for Column Offset.

5 In the drawing area, specify the insertion point of the zone structure.

You can move or hide the Properties palette to expose more of the drawing area.

6 Continue adding zone structures from the template as needed, and then press *ENTER*.

Creating a Zone Tool

Use this procedure to create a zone tool and add it to a tool palette. You may want to create your own zone tools if you are placing multiple zones with specific properties that you want to be the same for each instance.

For example, if you are creating an office floor plan with different calculation types for zones, you can create a zone tool for each calculation type.

1 Open the tool palette where you want to create a tool.

2 Create the tool:

If you want to...

Then...

create a tool from a zone in the drawing

select the zone, and drag it to the tool palette.

create a tool from an zone style in the Style Manager

click Format menu ► Style Manager. Locate the style you want to copy, and drag it to the tool palette. Click OK to close the Style Manager.

copy a tool in the current tool palette

right-click the tool, and click Copy. Right-click, and click Paste.

copy a tool from another tool palette

open the other tool palette, right-click the tool, and click Copy. Reopen the palette where you want to add the tool, right-click, and click Paste.

copy a tool from a tool catalog

open the catalog in the Content Browser, and locate the tool you want to copy. Position the cursor over the i-drop handle, and drag the tool to the tool palette.

3 Right-click the new zone tool, and click Properties.

4 Enter a name for the tool.

5 Click the setting for Description, enter a description of the tool, and click OK.

- 6 Expand Basic, and expand General.
- 7 Click the setting for Description, enter a description of the zone created from this tool, and click OK.
- 8 Specify a layer key and any layer key overrides if you do not want to use the layer assignments specified in the layer key style used in the drawing.
- 9 Select a zone style.
- 10 Select the drawing file containing the style used for this zone tool.
- 11 Select a tag for the zone.
- 12 Select the drawing file containing the tag used for this zone tool.
- 13 Expand Dimensions.
- 14 Enter the distance you want the zone boundary to be offset from attached spaces.
- 15 Expand Calculation.
- 16 Specify which values will be calculated for zones created from this tool:

If you want to ...	Then...
calculate the area of attached spaces	select Yes for Calculate Area.
calculate the perimeter of attached spaces	select Yes for Calculate Perimeter.

- 17 Expand Content.
- 18 Define the allowed content in the zone tool:

If you want to ...	Then...
allow spaces to be attached to zones created from this tool	select Yes for Can contain spaces.
allow zones to be attached to zones created from this tool	select Yes for Can contain zones.

For information about zone content, see [Changing the Content Rules of a Zone](#) on page 2066.

- 19 Click OK.

Converting Area Groups to Zones

Area groups in legacy drawings are automatically converted to zones when you open the drawing in the current version of AutoCAD Architecture. The following table maps area group properties to zone properties:

Legacy area group property	New zone property	Value/Default Value
Name	Name	Existing value NOTE Name lists that were attached to the area group are not re-attached to the zone. To use a converted legacy name list, you must attach it to the zone style.
Description	Description	Existing value

Legacy area group property	New zone property	Value/Default Value
Layer	Layer	Existing layer
Style	Style	Area group style is converted to zone style. Properties are matched where possible; new properties have default values. For more information, see Converting Area Group Styles to Zone Styles on page 2078.
Calculation modifiers	Calculation modifiers	Existing modifier
N/A	Number of spaces	Existing value
N/A	Total number of spaces	Existing value
N/A	Number of zones	Existing value
N/A	Total number of zones	Existing value
Net area	Base area	Existing value
Calculated area	Calculated area	Existing value
Net perimeter	Base perimeter	Existing value
Calculated perimeter	Calculated perimeter	Existing value
N/A	Base volume	0
N/A	Zone boundary offset	Default value
Calculate area	Calculate area	Existing value
Calculate perimeter	Calculate perimeter	Existing value
Can contain areas	Can contain spaces	Existing value
Can contain area groups	Can contain zones	Existing value
Rotation	Rotation	Existing value
Elevation	Elevation	Existing value
Additional information (Location)	Additional information (Location)	Existing values

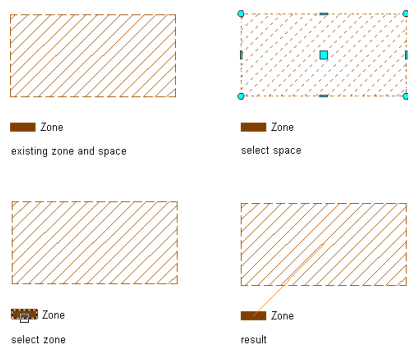

NOTE If you are converting a legacy zone structure, and connections between zones are not converted correctly, it is possible that the source drawing contained an error in the content rules for the parent zone. In cases like this, verify that the content rules of the parent zone allow attaching zones, as described in [Changing the Content Rules of a Zone](#) on page 2066, and then re-attach the lost zones as described in [Attaching Spaces and Zones to Zones](#) on page 2063.

Zones and Spaces

Zones are used to group spaces and subordinate zones.

Attaching Spaces and Zones to Zones

Use this procedure to attach spaces and zones to a selected zone.

NOTE You can attach spaces and zones to zones inside blocks, or attach spaces or zones inside a block to a zone outside the block, but if the blocks are exploded the attachments will be removed.

Connections of spaces and zones are not unique. You can attach a space or a zone to any number of different zones, unless you place restrictions on space/zone and zone/zone attachments in the zone, style:

- You can specify that a space can only be attached to one zone of the same style. That would prevent a space from being calculated multiple times, as in a case where you do not want the same room to be attached to multiple apartment zones.
- You can specify that zones of this style can only be attached to other zones of the same style. This would be useful for Building Systems applications where you want to generate HVAC and Lighting zones, but do not want to allow a zone of one kind to be attached to a zone of the other kind.

For more information, see [Restricting the Content of a Zone Based on the Zone Style](#) on page 2073.

In the properties of a zone, you can restrict the type of objects can be attached to the zone, allowing only spaces or only zones. For more information, see [Changing the Content Rules of a Zone](#) on page 2066.

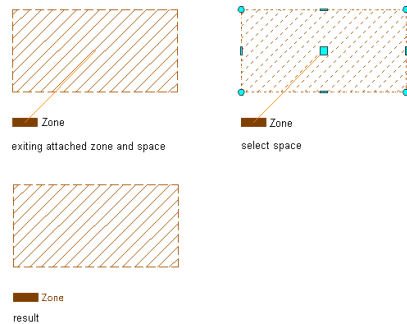

When you attach a zone to another zone, it is attached as a subzone to the first zone.

- 1 Select the zone to which you want to attach a space or zone.
- 2 Attach the space or zone to the selected zone in one of the following ways:
 - Click the Add (Plus) grip on the zone, and select spaces and zones to attach.
 - Right-click, and click Attach Spaces/Zones, and then select the spaces and zones to attach.
- 3 Press ENTER.

Detaching Spaces and Zones from Zones

Use this procedure to detach spaces and zones from a zone.

You can detach only directly attached spaces or zones.

- 1 Select the zone from which you want to detach a space or zone.
- 2 Detach the space or zone in one of the following ways:
 - Click the Detach (Minus) grip on the connection line to the attached space or zone.
 - Right-click, and click Detach Spaces/Zones. Then select the space or zone you want to detach from the zone, and press *ENTER*.

Selecting Spaces and Zones Attached to a Zone

Use this procedure to select the spaces and zones that are attached to a zone.

- 1 Select a zone that has zones or spaces attached to it.
- 2 Right-click, and click Select Attached Spaces/Zones.

The spaces and zones that are attached to the zone are selected in the drawing.

NOTE Spaces and zones that are located in an external reference will be highlighted, but not selected.

Editing Zones

You can use either of the following methods to change zone properties such as the ones that control the allowed content for the zone, the types of calculation performed, and the calculation modifiers applied:

- You can change zone settings on the Properties palette.
- You can select editing commands from the context menu for a selected zone.

Renaming a Zone

Use this procedure to rename a zone.

If a list definition has been attached to the zone style, you can choose a name from the list. A list definition can either be restrictive and allow only names selected from the list, or it can allow you to enter a name of your choice. For more information, see [List Definitions](#) on page 2051.

- 1 Double-click the zone you want to rename.
- 2 On the Properties palette, expand Basic, and expand General.
- 3 For Name, do one of the following:
 - Select a name from the list.
 - Enter a name.

Changing the Zone Style

Use this procedure to change the style associated with a zone. Zone styles contain information about the content rules of the zone and the display of the zone and its attached zones and spaces. You can also add classifications here. For information about how to define zone styles, see [Zone Styles](#) on page 2071.

- 1 Select one or more zones, and double-click one of them.
- 2 Expand Basic, and expand General.
- 3 Select a new zone style.

When you change the zone style, it is possible that the new zone style has a different name list definition. In this case, the zone name can interact with the new list definition in the following ways:

- The existing name of the zone is also included in the new list definition. In this case, no change to the zone name is made.
- The existing name of the zone is not included in the new list definition, but the list definition allows individual names to differ from the list. In this case, the existing zone name is retained as a non-standard name.
- The existing name of the zone is not included in the new list definition, and the list definition does not allow individual names to differ from the list. In this case, the existing zone name is removed and the zone name defaults to the first name in the new list definition.

For more information about list definitions, see [List Definitions](#) on page 2051.

Changing the Zone Boundary Offset

Use this procedure to redefine the offset of the zone boundary from its attached spaces.

The zone boundary is a boundary around a space attached to a zone. It helps to display the connections between spaces and zones. You can use it in addition to the zone connection line, or instead of it. For information on displaying and hiding the zone connection line and the zone boundary, see [Specifying the Layer, Color, and Linetype Properties of a Zone Style](#) on page 2074.

Zone boundary offset at 0 (left) and at an offset value (right)

If you define a zone boundary offset at 0, the boundary is drawn on top of the space base boundary. Depending on the draw order, it is possible that the zone boundary is invisible because it is underneath the space base boundary. To avoid this effect, define an offset greater than 0.

- 1 Select one or more zones, and double-click one of them.
- 2 Expand Dimensions.
- 3 For Zone boundary offset, enter the desired offset from the base boundary of the attached spaces.

TIP If you cannot see the zone boundary, the display component for the zone boundary may not be activated in the zone style. For more information, see [Specifying the Layer, Color, and Linetype Properties of a Zone Style](#) on page 2074.

Changing the Content Rules of a Zone

Use this procedure to redefine the allowed content for the zone as spaces only, zones only, or both types of object.

NOTE You can set additional content restrictions in the zone style. For more information, see [Restricting the Content of a Zone Based on the Zone Style](#) on page 2073.

- 1 Select one or more zones, and double-click one of them.
- 2 Expand Content.
- 3 Define the allowed content in the zone:

If you want to ...	Then...
allow spaces to be attached to the zone	select Yes for Can Contain Spaces.
allow zones to be attached to the zone	select Yes for Can Contain Zones.

Changing the Calculation Type of a Zone

Use this procedure to change the type of calculation (area, perimeter, or both) to be performed for spaces attached to a zone.

When you create zones from a zone template, the calculation type for each zone is predefined in the zone template. For more information, see [Zone Templates](#) on page 2079.

- 1 Select one or more zones, and double-click one of them.
- 2 Expand Calculation.
- 3 Specify the types of calculation to be performed for this zone:

If you want to ...	Then...
calculate the base area values of attached spaces	select Yes for Calculate Area.
calculate the base perimeter values of attached spaces	select Yes for Calculate Perimeter.

- 4 Click Close.

Changing Calculation Modifiers for a Zone

Use this procedure to add, remove, or sort calculation modifiers for a zone.

By default, a calculation modifier is applied only to the base area and base perimeter of spaces attached to a zone. To apply the modifier to the net, usable, and gross boundaries of an attached space, you need to create and apply a property set definition that contains properties for the calculated area and perimeter values of these 3 boundaries. For more information, see [Property Set Definitions](#) on page 2542

For information about creating calculation modifiers, see [Calculation Modifiers](#) on page 2088.

- 1 Select the zones you want to change, and double-click one of them.
- 2 Expand Basic, and expand General.
- 3 Click the setting for Calculation modifiers.

NOTE This setting can be edited for multiple zones only if these zones have the same modifiers attached in the same order.

- 4 Attach or detach calculation modifiers:

If you want to...

Then ...

attach a calculation modifier style

for Available, select the desired calculation modifier style, and click .

detach a calculation modifier style

for Attached, select the desired calculation modifier style, and click .

rearrange the order of attached calculation modifier styles

for Attached, select the calculation modifier style to move to a different position. Click  to move the calculation modifier style up in the list, or click  to move the calculation modifier style down in the list.

- 5 Click OK.

Ordering Zone Structures

Use this procedure to sort zones according to their hierarchy when you have a complex zone structure with many levels, and it has become difficult to recognize the hierarchy of the zones. To sort the zones according to their hierarchical positions, AutoCAD Architecture offers you an easy-to-use command.

Ordering zone structures

- 1 Select the top node of the zone structure you want to sort, right-click, and click Zone Layout.
- 2 Specify the vertical (column) and horizontal (row) distance between the entries in the zone structure, and press *ENTER*.

Creating Polylines from Zones

Use this procedure to create polylines from a zone, in cases such as the following:

- You want to export the floor plan to an application that can process only polylines.
- You need the space profile for other operations.

Creating polylines from zones

After converting spaces to polylines, you can convert the polylines back to spaces, as described in [Converting Polylines, Profiles, and Object Outlines to Spaces](#) on page 1963.

NOTE If the net, usable, and gross boundaries are offset from the base boundary, a polyline is created for each boundary.

- 1 Select the zone containing spaces you want to convert to polylines, right-click, and click Create Polyline.
- 2 Specify the source of the polylines:
 - To create polylines only from directly attached spaces, enter **D** (Directly Attached Spaces) on the command line.

- To create polylines from all attached spaces, regardless of whether they are attached directly or through subzones, press *ENTER*.

Polylines are created on top of the specified spaces. You can edit them as any other polyline.

TIP When polylines lie above spaces, it can be difficult to select the space without the polyline. Try one of the following:

- Press *CTRL*, and click the boundary. Then click until the space is highlighted.
 - If the space hatch is displayed, click the hatch.
 - Enter **qselect** on the command line and filter for spaces.
-

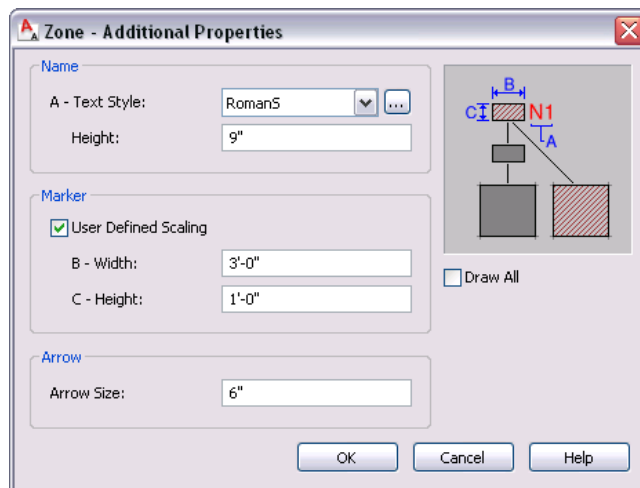

Specifying Additional Display Properties for a Zone

Use this procedure to specify the text style, zone marker size, and zone connection line arrow for a selected zone. You can also specify whether the zone hatch is used only for directly attached spaces or for those attached through subzones as well.

- 1 Double-click the zone.
- 2 On the Properties palette, click the Display tab.
- 3 Under the General category, for Display component, verify that **NONE** is selected.
- 4 For Display controlled by, select This object.

NOTE To apply your changes to all zones in the drawing, select Drawing default setting. To apply changes to all zones of this style, select Zone Style:<style name>. For more information on styles, see [Zone Styles](#) on page 2071.

- 5 For Display representation, verify that the desired display representation is selected.
- 6 If necessary, expand Object Display Properties ► Advanced.
- 7 Click  Additional properties.

- 8 Under Name, for Text Style, select a style for the zone name from the drop-down list, or click the worksheet button, and create a new text style, which will then be selectable from the list. For more information, see “Text Style Dialog Box” in AutoCAD Help.

9 For Height, enter the desired value.

10 Under Marker, specify whether you want to define the scaling for the zone marker:

If you want to display the marker at...	Then...
1/50 of the screen size	clear User Defined Scaling.
the scale you specify	select User Defined Scaling, and enter the desired values for Width and Height.

11 Under Arrow, enter the desired value for Arrow Size.

12 Specify which spaces will inherit the hatch of the zone:

If you want to...	Then...
use the zone hatch only for directly attached spaces	clear Draw All.
use the zone hatch for all directly attached spaces and all spaces attached through another zone	select Draw All.

13 Click OK.

You can also access these option through the zone's context menu, as follows:

1 Select the zone, right-click, and click Edit Object Display.

2 In the Object Display dialog, click the Display Properties tab.

The current display representation is displayed in bold.

3 Select the display representation where you want the changes to appear, and select Object

Override. If Object Override is already selected, click  at the upper-right corner of the tab.

4 In the Display Properties dialog, click the Other tab, and then specify these options as desired.

5 Click OK twice.

Attaching Hyperlinks, Notes, or Files to a Zone

Use this procedure to attach hyperlinks, text notes, or files to a zone.

1 Double-click the zone you want to attach information to.

2 Click the Extended Data tab.

3 To add a hyperlink, click the setting for Hyperlink, and specify the link.

For more information about adding hyperlinks, see "Add Hyperlinks to a Drawing" in AutoCAD Help.

4 Click the setting for Notes, and add a note. Then click OK.

5 Click the setting for Reference Documents.

6 Attach or detach reference files:

If you want to...	Then...
attach a reference file	click  , select a file, and click Open.

If you want to...	Then...
edit the description of a reference file	enter text for Description.
edit a reference file	double-click the reference file name to start its application.
detach a reference file	select the file name, and click  .

7 Click OK.

Zone Styles

The zone style can be used to control the display of the zone object, the zone and space connection lines, the zone boundary, and the zone hatch. If you add a hatch to a zone, the hatch is also displayed in spaces attached to the zone to indicate the relationship.

You can use zone styles to create zones with different display properties for construction spaces, rentable rooms, traffic spaces, or other space types. For example, you might draw and hatch all spaces in the construction zone, create the traffic zone in blue with a solid fill, and so on.

Living rooms and construction spaces with different styles

Properties in the zone style can also be used to set content restrictions for zones.

Zones are very useful for determining what is included or excluded when space evaluations are performed.

Creating a Zone Style

Use this procedure to create a zone style. You can start by using the default style or you can copy an existing style to use as your template. You then edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and expand Zone Styles.
- 3 Create a new zone style:

If you want to...	Then...
create a new style with default properties	right-click Zone Styles, and click New.

If you want to...	Then...
create a new style from an existing style	right-click the zone style you want to copy, and click Copy. Right-click, and click Paste.

4 Enter a name for the new zone style, and press *ENTER*.

5 Edit the style properties of your new zone style:

If you want to...	Then...
enter a description of the style	click the General tab, and enter a description.
attach a list definition to the style	see Attaching a List Definition to a Zone Style on page 2072
restrict the allowed content of the style	see Restricting the Content of a Zone Based on the Zone Style on page 2073.
add classifications to the style	see Specifying Classifications for a Zone Style on page 2073.
change the display of the zone	see Specifying the Display Properties of a Zone Style on page 2073.
add notes, files, or documents to the style	see Attaching Notes or Files to a Zone Style on page 2077

6 If you want to assign the style to a zone tool, drag the style from the Style Manager to a tool palette.

You can later rename the tool and specify other properties for it as described in [Creating a Zone Tool](#) on page 2060.

7 Click OK.

Attaching a List Definition to a Zone Style

Use this procedure to attach a list definition to a zone style, so that zones using that style are named consistently according to a user-defined list of names. List definitions can be created according to government or company standards or other systematics. For information about creating list definitions, see [List Definitions](#) on page 2051.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Zone Styles.
- 3 Select the zone style that you want to change.
- 4 Click the Design Rules tab.
- 5 For Zone Names, select a list definition from the drop-down list.

NOTE Only those list definitions that apply to zone names will appear here. For more information, see [Specifying the Application for a List Definition](#) on page 2052.

6 Click OK.

Restricting the Content of a Zone Based on the Zone Style

You can set content restrictions for zones based on the zone style. Content restrictions can help you to ensure that only valid zone structures are built.

- 1 Click Format menu ► Style Manager.
- 2 Expand Architectural Objects, and expand Zone Styles.
- 3 Select the zone style that you want to change.
- 4 Click the Design Rules tab.
- 5 For Exclusivity, select either or both of the following options:
 - **Space Exclusive:** Define that spaces can be attached only to one zone of the style. This would be useful for zones that represent real-world space compounds, like for example a zone style for apartments. In that case, you need to prevent that individual spaces can be attached to multiple zones of that style and be calculated more than once.
If you attach a space to a second zone of the same style, it is disconnected from the first zone.
 - **Zone Exclusive:** Define that zones of the style can only be attached to other zones of the same style. This would be useful for Building Systems applications where you want to generate HVAC and Lighting zones and want to ensure that an HVAC zone only can get attached to another HVAC zone, and a Lighting zone only to another Lighting zone.
If you try to attach a zone of the style to a zone with another style the connection is not created, and an error message is displayed on the command line.

IMPORTANT Zone content restrictions are observed in external references.

6 Click OK.

Specifying Classifications for a Zone Style

Use this procedure to specify classifications for any classification definition applied to a zone style.

For more information about creating and applying classification definitions, see [Classification Definitions](#) on page 2574.

- 1 Open a tool palette that has a zone tool.
- 2 Right-click a zone tool, and click Zone Styles.
- 3 Select the style that you want to change.
- 4 Click the Classifications tab.

By default, the classification for all classification definitions is Unspecified. If no classification definitions are listed, none are applied to zone styles.
- 5 For each classification definition, select the classification you want to apply to the current zone style.
- 6 Click OK.

Specifying the Display Properties of a Zone Style

You can change the display of zones and their attached spaces in the zone style.

Specifying the Layer, Color, and Linetype Properties of a Zone Style

You can specify these display properties for the following display components of a zone in the style:

Display components in plan views

Component	Description
Zone boundary	The boundary around any spaces attached to the zone
Hatch	Hatch component of the zone symbol and of any spaces connected to the zone. The zone hatch is drawn on top of the space hatch if both are visible.
Name	Zone label
Marker	Zone symbol
Zone Connection Line	Connecting line between the zone and any attached zones
Space Connection Line	Connecting line between the zone and any attached spaces

- 1 Open a tool palette that has a zone tool.
- 2 Right-click a zone tool, and click Zone Styles.
- 3 Select the zone style you want to change.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.
- 6 Click the Layer/Color/Linetype tab.
- 7 Select the zone component to change, and change the following settings:
 - Visibility
 - Layer
 - Color
 - Linetype/Lineweight/Linetype Scale
 - Plot Style
- 8 Click OK.

Specifying the Hatching of a Zone Style

Use this procedure to specify the hatch settings of a zone style. The specified hatch is applied to the zone symbol and to any spaces attached to the zone, allowing you to easily detect the structure in your drawing if you have many spaces and zones. The hatch is also important if you want to create a coding legend from the zone.

- 1 Open a tool palette that has a zone tool.
- 2 Right-click a zone tool, and click Zone Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

6 If necessary, click .

7 Click the Hatching tab.

8 Select a component, and click the setting for Pattern.

9 Select the hatching for the component:

If you want to...	Then...
select a hatching pattern that is available in the software	select Predefined for Type, and then select a pattern.
select a custom pattern	select Custom for Type, and then enter the name of the custom pattern. If necessary, click Browse, and navigate to the folder where the custom pattern file is located.
select single hatching	select User-defined for Type, and clear Double Hatch.
select double hatching	select User-defined for Type, and select Double Hatch.
select solid fill	select Solid Fill for Type.

10 Click OK.

11 Click Scale/Spacing, and enter a value that determines how the selected pattern is repeated.

12 Click Angle, and enter the angle for the selected pattern.

13 Click Orientation, and specify how the hatching is oriented:

If you want to...	Then...
orient the hatching to the object, regardless of the object rotation	select Object.
orient the hatching to the World Coordinate System	select Global.

14 Click OK twice.

Inheriting the Zone Hatch to Different Levels of Attached Spaces

Use this procedure to specify to which level of attached spaces the hatch of the zone should be inherited.

The zone hatch can either be inherited only to the directly attached spaces, or it can be inherited to all attached spaces, directly or indirectly through subzones.

Inheriting zone hatch to all attached spaces (top) or only to directly attached spaces (bottom)

- 1 Open a tool palette that has a zone tool.
- 2 Right-click a zone tool, and click Zone Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

6 If necessary, click  .

7 Click the Other tab.

8 Specify whether the hatch of the zone should be used only for directly attached spaces, or for all spaces:

If you want to...

Then...

use the zone hatch only for directly attached spaces

clear Draw All.

use the zone hatch for all directly attached spaces and all spaces attached through another zone

select Draw All.

9 Click OK.

Specifying Text Style, Marker Size, and Arrow of a Zone Style

Use this procedure to define the text style, zone marker size, and the zone connection line arrow of a zone.

- 1 Open a tool palette that has a zone tool.
- 2 Right-click a zone tool, and click Zone Styles.
- 3 Select the style you want to edit.
- 4 Click the Display Properties tab.
- 5 Select the display representation where you want the changes to appear, and select Style Override.

6 If necessary, click .

7 Click the Other tab.

8 Change the width and height of the zone marker by selecting User Defined Scaling and then entering a width and height.

To display the zone marker always in 1/50 of the screen size, clear User Defined Scaling.

9 Change the appearance of the zone name.

If you want to...

Then...

change the height of the zone name

enter a new height.

change the text style of the zone name

either select a text style from the list, or click the Browse button and create a new text style. For more information, see "Text Style Dialog Box" in AutoCAD Help.

10 Click OK twice.

Attaching Notes or Files to a Zone Style

Use this procedure to attach text notes and files to a zone style.

- 1 Open a tool palette that has a zone tool.
- 2 Right-click a zone tool, and click Zone Styles.
- 3 Select the style you want to edit.
- 4 Click the General tab.
- 5 To add a description to the zone style, enter it for Description.
- 6 Click Notes.
- 7 To add a note, click the Notes tab, and enter the note.
- 8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...

Then...

attach a reference file

click Add, select a file, and click Open.

If you want to...	Then...
edit the description of a reference file	select the file, and click Edit. Enter the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Close the application when you are done editing.
detach a reference file	select the file name, and click Delete.

9 Click OK twice.

Converting Area Group Styles to Zone Styles

If you open a drawing from a previous version of AutoCAD Architecture that has area group styles in it, the area group styles will be automatically converted to zone styles. The following table maps area group style properties to zone style properties:

Area group style property	Zone style property	Value/Default value
Name	Name	Existing value
Description	Description	Existing value
Keynote	Keynote	Existing value
Notes/Reference Docs	Notes/Reference Docs	Existing notes and attached documents
Property Sets	Property Sets	Area group property sets are converted to zone property sets and attached to the converted zone style
N/A	List Definition	Standard NOTE In previous versions of AutoCAD Architecture, list definitions were attached to zones or zone templates. They are now attached to the space style or the zone style.
Exclusivity		
N/A	Allow a space to only be attached to one zone of this style	Not selected
N/A	'Allow a zone of this style to only be attached to other zones of this style	Not selected

Area group style property	Zone style property	Value/Default value
Classifications	Classifications	Existing classification values. NOTE Area group classification definitions from legacy drawings are converted to zone classification definitions and applied to converted zone styles.
Display Representations		
Plan	Plan	Existing settings
Plan High Detail	Plan High Detail	Existing settings
Plan Low Detail	Plan Low Detail	Existing settings
N/A	Plan Presentation	Drawing Default
N/A	Plan Screened	Drawing Default

Zone Templates

A zone template is a structure definition for zones with multiple hierarchical levels. You define the zone template as a hierarchy with certain properties, and use it to create the zone structure in the drawing.

Zones according to DIN277

You use a zone template only to insert a zone structure. Later changes to the zone template are not copied to existing zones based on this template.

Similarly, when you change a zone structure that is based on a zone template, those changes do not affect the template.

You can create zone templates for structures you need frequently, and make them available through AutoCAD Architecture style drawings.

NOTE Area group templates from legacy drawings are automatically converted to zone templates when the drawings are opened in with the current version of the software. Area name definitions that were attached to an area group template will be disconnected from the zone template, as name definitions are now attached to the space style or the zone style rather than the zone template. For information about attaching list definitions to a zone style, see [Attaching a List Definition to a Zone Style](#) on page 2072.

Creating a Zone Template

Use this procedure to create a zone template. You can start by using the default template or you can copy an existing template and modify it.

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and expand Zone Templates.
- 3 Create a new zone template:

If you want to...	Then...
-------------------	---------

create a new template with default properties	right-click Zone Templates, and click New.
---	--

create a new template from an existing template	right-click the template you want to copy, and click Copy. Right-click, and click Paste.
---	--

- 4 Enter a name for the new zone template, and press *ENTER*.

- 5 Edit the style properties of your new zone template:

If you want to...	Then...
-------------------	---------

define the content of the zone template	see Building the Structure of a Zone Template on page 2080.
---	---

add notes or files to the zone template	see Attaching Notes and Files to a Zone Template on page 2082.
---	--

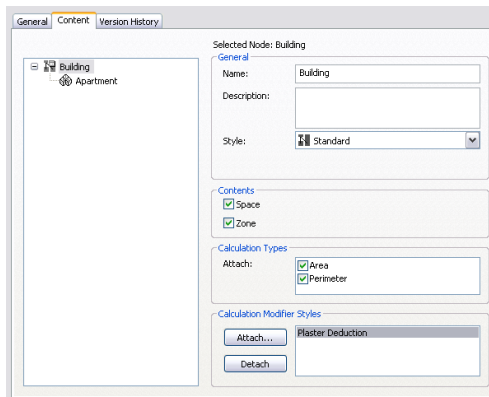

- 6 Click OK.

Building the Structure of a Zone Template

When you create a zone template, you set the following properties:

- structure of contained zones
- zone style (for each contained zone)
- zone content (for each contained zone)
- zone calculation type (for each contained zone)
- calculation modifier styles (for each contained zone)

For information about creating zones from a zone template, see [Creating Zone Structures from a Zone Template](#) on page 2059.

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and expand Zone Templates.
- 3 Select the template you want to edit.
- 4 Click the Content tab.

In the left pane of the Content tab, a tree structure displays the structure of the zone template with all zones and subzones. If you are creating a new zone template, only the top level zone node is present. All other subzones are yet to be inserted.

- 5 Add the desired subzones to your zone template.

If you want to...	Then...
add a subzone to the template	select the zone that will contain the subzone, right-click, and click New.
rename a zone	select the zone, right-click, and click Rename.
delete a zone	select the zone, right-click, and click Delete.

NOTE To rearrange zones within the structure, drag-and-drop them within the tree.

- 6 Select a zone.
- 7 Enter a description for the zone.
- 8 Select a style for the zone. For information about zone styles, see [Zone Styles](#) on page 2071.

TIP If you select a style that requires zone exclusivity, you will be able to add only subzones that are of the same style. If you try to attach a subzone of a different style, you will receive an error message. For information on setting exclusivity rules for zone styles, see [Restricting the Content of a Zone Based on the Zone Style](#) on page 2073.

- 9 Specify the types of objects that can be attached to the zone (spaces, zones, or both.)
- 10 Select the types of calculations performed for the zone in the evaluation of the floor plan.
For example, you might want to have a Carpet zone node to calculate how much carpet you need and Base board zone node to calculate how much baseboard you need. For the Carpet zone node, you would select Yes for Calculate area. For the Baseboard zone node, you would select Yes for Calculate perimeter.

You can select both calculation types if you want both values to appear in the evaluation.

- 11 Select one or more calculation modifiers to apply to the zone.

For example, if you have a Balconies zone node, you can attach a calculation modifier that reduces all calculated space values in this zone by 50 percent.

NOTE By default, a calculation modifier is applied only to the base area and base perimeter of spaces attached to the zone. To apply the modifier to the net, usable, and gross boundaries of spaces attached to a zone, you need to create and apply a property set definition that contains properties for the calculated area and perimeter values of these 3 boundaries.

Calculation modifiers are applied accumulatively. If you attach a 50 percent calculation modifier to a space directly, and then attach the space to a zone that also has a 50 percent calculation modifier, the resulting space value is 25 percent, because both calculation modifiers are applied.

Calculation modifiers are processed top-down, with the first style in the list processed first, the second style after that, and so on. Depending on your calculation formulas, you can receive different result values. To change the order of calculation modifiers, drag them to the correct positions within the list. For an example of how the order of calculation modifiers can affect the calculation results, see [Calculation Modifiers](#) on page 2088.

12 Click Attach.

13 In the Select a Space Calculation Modifier Style worksheet, select a calculation modifier to attach to the zone node, and click OK.

14 To detach a calculation modifier, select it, and click Detach.

15 Click OK.

Attaching Notes and Files to a Zone Template

Use this procedure to attach text notes and files to a zone template.

1 Click Format menu ► Style Manager.

2 Expand Documentation Objects, and expand Zone Templates.

3 Select the template for which you want to add a note or file.

4 Click the General tab.

5 To add a description to the zone template, enter the description for Description.

6 Click Notes.

7 To add a note, click the Notes tab, and enter the note.

8 Click the Reference Docs tab, and attach, edit, or detach a reference file:

If you want to...	Then...
attach a reference file	click Add, select a file, and click Open.
edit the description of a reference file	select the file, and click Edit. Edit the description, and click OK.
edit a reference file	double-click the reference file name to start its application. Close the application when you are done editing.
detach a reference file	select the file name, click Delete, and click OK.

9 Click OK twice.

Converting Area Group Templates to Zone Templates

If you open a drawing from a previous version of AutoCAD Architecture that has area group templates in it, the area group templates will be automatically converted to zone templates. The following table maps area group template properties to zone template properties:

Area group template property	Zone template property	Value/Default value
Name	Name	Existing value
Description	Description	Existing value
Notes/Reference Docs	Notes/Reference Docs	Existing notes and attached documents
List Definition	N/A	NOTE In previous versions of the software, name definitions could be attached to zone templates. Now, list definitions are attached to the space style or the zone style.
Style	Style	Area group styles from legacy drawings are automatically converted to zone styles and attached to the corresponding node in the zone template.
Content	Content	Existing content permissions. Area permissions are now space permissions, and area group permissions are zone permissions.
Calculation types	Calculation types	Existing values
Calculation Modifier Styles	Calculation Modifier Styles	Existing calculation modifiers

Working with Space Data

Spaces can have a number of different data types attached to them:

- Geometric data belonging to the space: This is data inherent to the space like its height or width. This data can be displayed in the Properties palette or used in schedule tables and space tags. For more information, see [Schedule Properties of Spaces](#) on page 2084.
- Modified and calculated data derived from the space: this is data derived from the geometric data by applying calculation modifier styles, boundary offset calculation formulas, or formula properties. For more information, see [Calculation Modifiers](#) on page 2088, [Working with Space Boundaries](#) on page 1973 and [Adding a Formula Property Definition to a Property Set Definition](#) on page 2547. Schedule properties exist for values created by calculation modifiers, boundary offsets, and formulas, so that they can be displayed in the Properties palette and used in a schedule table, too.
- Data generated by a geometric decomposition of the space area. For more information, see [Space Decomposition](#) on page 2093.

- Space surface properties: Data attached to the surfaces of a space. For more information, see [Editing Space Surface Properties](#) on page 2014.
- User-defined information sets: you can define any set of relevant property set data for spaces, like for example, floor finish, ceiling material etc. This data can be displayed in the Properties palette and used in schedule tables and space tags. For more information, see [Adding a Manual Property Definition to a Property Set Definition](#) on page 2556.

Schedule Properties of Spaces

There are a large number of schedule properties you can attach to a space. Property data is placed in a property set definition and attached to a space or space style. You can display it in the Properties palette or use it to create schedule tables. For information about how to create a property set definition containing schedule properties, see [Creating a Property Set Definition](#) on page 2554 and [Adding an Automatic Property Definition to a Property Set Definition](#) on page 2559.

The following schedule properties are available as automatic properties directly derived from a space:

Property	Description
Base Area	Area bounded by the base boundary
Base Area Minus Interferences	Area bounded by base boundary minus the area deducted by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Base Ceiling Area	Area bounded by the ceiling boundary. The ceiling boundary is always derived from the base boundary of the space. In an extruded 3D space, the base ceiling area is identical to the base area; in a 3D freeform space the base ceiling area can differ from the base area.
Base Perimeter	Perimeter of the base boundary
Base Perimeter Including Interferences	Perimeter of the base boundary including the length created by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Base Surface Area	The sum of surface areas on a space, calculated from the base volume of the space
Base Volume	Volume of the space as calculated from the base boundary
Calculated Area	Base area of a space after applying calculation modifiers. For more information, see Calculation Modifiers on page 2088.
Calculated Perimeter	Base perimeter of a space after applying calculation modifiers
Calculation Modifier	List of all calculation modifiers applied to the space
Calculation Plane 1 Area Calculation Plane 2 Area	Space area at the height of calculation cut planes 1 and 2. This property should be used for 3D freeform spaces only; in an extruded

Property	Description
	3D space the calculation cut plane area is identical at each cut plane. For more information, see Setting Calculation Cut Planes for 3D Freeform Spaces on page 2092.
Calculation Plane 1 Height Calculation Plane 2 Height	Height of calculation cut planes 1 and 2.
Calculation Plane 1 Perimeter Calculation Plane 2 Perimeter	Perimeter of calculation cut planes 1 and 2.
Ceiling Thickness	Thickness of the ceiling boundary. For more information, see Changing the Height of Extruded 3D Spaces on page 1992 and Changing the Height of 3D Freeform Spaces on page 1992.
Color	Color assigned to the space in the AutoCAD properties
Color - Text	Color of text
Description	Description added to the space
Description from Style	Description added to the space style
Documents	List of all documents attached to the space. For more information, see Attaching Hyperlinks, Notes, or Files to a Space on page 1972.
Documents from Style	List of all documents added to the space style. For more information, see Attaching Notes and Files to a Space Style on page 2049.
Drawing Fingerprint GUID	System value used in export to Building Systems applications
Floor Thickness	Thickness of the floor boundary. For more information, see Changing the Height of Extruded 3D Spaces on page 1992 and Changing the Height of 3D Freeform Spaces on page 1992.
Gross Area	Area bounded by the gross boundary
Gross Area Minus Interferences	Area bounded by gross boundary minus the area deducted by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Gross Calculated Area	Area bounded by the gross boundary after applying calculation modifiers
Gross Calculated Perimeter	Perimeter of the gross boundary after applying calculation modifiers
Gross Perimeter	Perimeter of the gross boundary

Property	Description
Gross Perimeter Including Interferences	Perimeter of the gross boundary including the length created by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Handle	Internal ID of space
Has Net, Usable, and Gross Boundaries	Legacy value from Autodesk Architectural Desktop 2006
Height	Ceiling height of the space.
Hyperlink	Lists all hyperlinks you have attached to the space. For more information, see Attaching Hyperlinks, Notes, or Files to a Space on page 1972.
Layer	Layer of the space
Length	Length of the space
Linetype	AutoCAD linetype of the space
Maximum Area/Length/Width	Maximum values for area, length, and width of spaces that have target dimensions defined in the space style. For more information, see Specifying Target Dimensions for the Space on page 2040.
Minimum Area/Length/Width	Minimum values for area, length, and width of spaces that have target dimensions defined in the space style. For more information, see Specifying Target Dimensions for the Space on page 2040.
Name	Name of the space
Net Area	Area bounded by the net boundary
Net Area Minus Interferences	Area bounded by net boundary minus the area deducted by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Net Calculated Area	Area bounded by the net boundary after applying calculation modifiers
Net Calculated Perimeter	Perimeter of the net boundary after applying calculation modifiers
Net Perimeter	Perimeter of the net boundary
Net Perimeter Including Interferences	Perimeter of the net boundary including the length created by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.

Property	Description
Net to Gross Offset	Offset of net boundary from gross boundary
Notes	Notes attached to the space
Notes from Style	Notes attached to the space style
Object ID	Internal ID
Object type	AEC object type. For spaces, this property is always set to SPACE.
Space Above Ceiling	Space above the ceiling boundary. For more information, see Changing the Height of Extruded 3D Spaces on page 1992 and Changing the Height of 3D Freeform Spaces on page 1992.
Style	The style of the space
Target Area/Length/Width	Target values for area, length, and width of spaces that have target dimensions defined in the space style. For more information, see Specifying Target Dimensions for the Space on page 2040.
Usable Area	Area bounded by the usable boundary
Usable Area Minus Interferences	Area bounded by usable boundary minus the area deducted by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Usable Calculated Area	Area bounded by the usable boundary after applying calculation modifiers
Usable Calculated Perimeter	Perimeter of the usable boundary after applying calculation modifiers
Usable Perimeter	Perimeter of the usable boundary
Usable Perimeter Including Interferences	Perimeter of the usable boundary including the length created by interference conditions. For more information, see Creating Interference Conditions for Spaces on page 1995.
Volume Above Ceiling	Volume of the space above the ceiling boundary. All volumes are calculated from the base volume.
Volume Below Floor	Volume of the space below the floor boundary.
Volume Overall	Overall volume of the space including ceiling and floor boundaries, and the volume above the ceiling and below the floor.
Wall Area	The area of the wall sides. Used for example in paint and plaster calculations.

Property	Description
Width	Width of the space

Calculation Modifiers

A calculation modifier is a formula that you can apply to a space to change the calculated results of its associated area or perimeter values. Calculation modifiers can also be applied to a zone to change the calculated results of all spaces attached to that zone. You might want to change calculated results for number of purposes; for example, to account for plaster deductions or the tiling in a bathroom.

By default, a calculation modifier is applied only to the base area and base perimeter of the space. To apply the modifier to the net, usable, and gross boundaries of a space, you need to create and apply a property set definition that contains properties for the calculated area and perimeter values of the those boundaries. For more information, see [Property Set Definitions](#) on page 2542.

Calculation modifiers work cumulatively. When you apply several different modifiers to a space or a zone, they are all applied. Therefore, it is important to define the order in which they are used.

Example: You have a space area of 25 square meters. You want to apply 2 different calculation modifiers to it. Calculation modifier A deducts a value of 0.3 square meters for a column. Calculation modifier B divides the space by 2 (in some international calculation schemes, this is used for calculating balconies).

- If you apply the plaster deduction first and the division second, you get the following result:
 Calculation Modifier A: $25 \text{ m}^2 - 0.3 \text{ m}^2 = 24.7 \text{ m}^2$
 Calculation Modifier B: $24.7 \text{ m}^2 / 2 = 12.35 \text{ m}^2$
- If you apply the division first and the plaster deduction second, you get the following result:
 Calculation Modifier B: $25 \text{ m}^2 / 2 = 12.5 \text{ m}^2$
 Calculation Modifier A: $12.5 \text{ m}^2 - 0.3 \text{ m}^2 = 12.2 \text{ m}^2$

You can set the order of calculation modifiers in the properties of the space. For information about ordering calculation modifiers, see [Adding and Removing Calculation Modifiers for Spaces](#) on page 2088.

Adding and Removing Calculation Modifiers for Spaces

Use this procedure to attach, detach, or sort calculation modifiers for spaces.

Calculation modifiers are values and formulas that can be applied to the area and perimeter values of a space to modify them. By default, a calculation modifier is applied only to the base area and base perimeter of a space. To apply the modifier to the net, usable, and gross boundaries of a space, you need to create and apply a property set definition that includes properties for these boundaries. For more information, see [Property Set Definitions](#) on page 2542

- 1 Select the spaces you want to attach a calculation modifier to, and double-click one of them.

NOTE This procedure can be applied to multiple spaces only when they all have the same modifiers attached in exactly the same order.

- 2 On the Properties palette, expand Basic, and expand General.
- 3 Click the setting for Calculation modifiers.

4 Attach or detach calculation modifiers:

If you want to...	Then ...
attach a calculation modifier	for Available, select the desired calculation modifier, and click  .
detach a calculation modifier	for Name, select the desired calculation modifier, and click  .
rearrange the order of attached calculation modifiers	for Name, select the calculation modifier you want to move to a different position. Click  to move the calculation modifier up in the list, or click  to move the calculation modifier down in the list.

NOTE Calculation modifiers are processed in the same top-down order in which they are listed on this worksheet.

5 Click OK.

Creating a Calculation Modifier Style

Use this procedure to create a calculation modifier style. You can start by using the default style or you can copy an existing style to use as your template. You then edit the style properties to customize the characteristics of the style.

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and expand Calculation Modifier Styles.
- 3 Create a new calculation modifier style:

If you want to...	Then...
create a new modifier style with default properties	right-click Calculation Modifier Styles, and click New.
create a new modifier style from an existing style	right-click the calculation modifier you want to copy, and click Copy. Right-click, and click Paste.

4 Enter a name for the new calculation modifier style, and press *ENTER*.

5 Edit the properties of your new calculation modifier style:

If you want to...	Then...
define the calculation type of the modifier style	see Specifying the Application for a Calculation Modifier Style on page 2090.
define the formula of the modifier style	see Defining the Formula for a Calculation Modifier on page 2090.

If you want to...	Then...
add notes, files, or documents to the modifier style	see Attaching Notes and Files to a Calculation Modifier Style on page 2091.

6 Click OK.

Specifying the Application for a Calculation Modifier Style

A space contains 2 values that can be affected by a calculation modifier: the area and the perimeter. You can choose to have a calculation modifier apply to either or both of these calculations.

For example you might want to set up a modifier that reduces the calculated base area by 50 percent. (This is obligatory for several space types in various international architectural standards.)

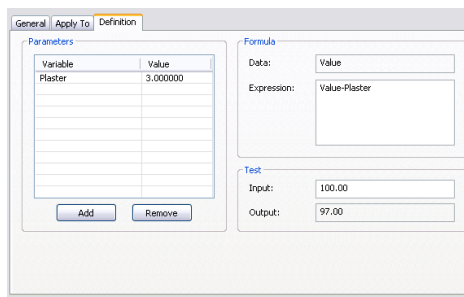

Or you might want a modifier that deducts length from the perimeter of a room for openings and stairs. This would be helpful in calculating the amount of baseboard material needed for this room.

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and expand Calculation Modifier Styles.
- 3 Select the modifier for which you want to set the calculation type.
- 4 Click the Apply To tab.
- 5 Select whether you want to apply the modifier to the (base) area or (base) perimeter of the space. You can also select both values here.
- 6 Click OK.

Defining the Formula for a Calculation Modifier

Use this procedure to define or edit the formula for a calculation modifier style.

Variable and formula for modifier

- 1 Click Format menu ► Style Manager.
- 2 Expand Documentation Objects, and expand Calculation Modifier Styles.
- 3 Select the modifier for which you want to define a formula.
- 4 Click the Definition tab.
- 5 Add a variable to the calculation modifier.

A variable consists of the variable name and its value. For example, to create a plaster deduction of 3 percent, click Add, and enter Plaster_Deduction for Variable and 0.97 for Value.

You should use a descriptive name as a variable name to add transparency to your formulas.

To set up formulas, you can also enter direct mathematical values.

The following characters and words are not allowed:

- Special characters such as ?()*- (You may, however use an underscore).
- Spaces
- Accent marks such as ä, ö, ü, ê, è, å
- Key words from Visual Basic®.

For information about Visual Basic key words, refer to the Visual Basic Reference.

One of the following values is displayed for Data depending on current selections on the Apply To tab:

- AreaValue (if Area is selected)
- PerimeterValue (if Perimeter is selected)
- Value (if both Area and Perimeter are selected)

You cannot edit this value; if you want to change it, click the Apply To tab and change the current selections there as desired.

6 For Expression, enter the formula for calculating the modifier.

You can enter direct mathematical values and operators, variables you have created, and Visual Basic key words, such as Mod, Exp, or Log.

For example, if you want to set up a plaster deduction of 3 percent, and you have defined a variable called Plaster_Deduction with a value of 0.97, enter $\text{AreaValue} * \text{Plaster_Deduction}$.

NOTE It is important to enter the variable names AreaValue and PerimeterValue exactly as they are displayed in the Data field. Alternative spellings such as "Area Value" or "perimetervalue" are not recognized.
